PREFACE

The principal purpose of the Commentary is to provide a basic volume of knowledge and facts relating to building construction as it pertains to the regulations set forth in the 2012 International Building Code. The person who is serious about effectively designing, constructing and regulating buildings and structures will find the Commentary to be a reliable data source and reference to almost all components of the built environment.

As a follow-up to the International Building Code, we offer a companion document, the International Building Code Commentary—Volume I. Volume I covers Chapters 1 through 15 of the 2012 International Building Code. The basic appeal of the Commentary is thus: it provides in a small package and at reasonable cost thorough coverage of many issues likely to be dealt with when using the International Building Code — and then supplements that coverage with historical and technical background. Reference lists, information sources and bibliographies are also included.

Throughout all of this, effort has been made to keep the vast quantity of material accessible and its method of presentation useful. With a comprehensive yet concise summary of each section, the Commentary provides a convenient reference for regulations applicable to the construction of buildings and structures. In the chapters that follow, discussions focus on the full meaning and implications of the code text. Guidelines suggest the most effective method of application, and the consequences of not adhering to the code text. Illustrations are provided to aid understanding; they do not necessarily illustrate the only methods of achieving code compliance.

The format of the Commentary includes the full text of each section, table and figure in the code, followed immediately by the commentary applicable to that text. At the time of printing, the Commentary reflects the most up-to-date text of the 2012 International Building Code. As stated in the preface to the International Building Code, the content of sections in the code which begin with a letter designation (i.e., Section [F]307.1) are maintained by another code development committee. Each section's narrative includes a statement of its objective and intent, and usually includes a discussion about why the requirement commands the conditions set forth. Code text and commentary text are easily distinguished from each other. All code text is shown as it appears in the International Building Code, and all commentary is indented below the code text and begins with the symbol $. Readers should note that the Commentary is to be used in conjunction with the International Building Code and not as a substitute for the code. The Commentary is advisory only; the code official alone possesses the authority and responsibility for interpreting the code.

Comments and recommendations are encouraged, for through your input, we can improve future editions. Please direct your comments to the Codes and Standards Development Department at the Chicago District Office.

The International Code Council would like to extend its thanks to the following individuals for their contributions to the technical content of this commentary:

Chris Marion     Gregory Cahanin
Jeff Tubbs       David Cooper
Rebecca Quinn    Dave Collins
Joann Surnar     Vickie Lovell
James Milke      John Valiulis
Richard Walke    Marcelo Hirschler
Dave Adams       Edward Keith
Zeno Martin      Phillip Samblanet
Jason Thompson

2012 INTERNATIONAL BUILDING CODE® COMMENTARY
**TABLE OF CONTENTS**

CHAPTER 1  SCOPE AND ADMINISTRATION ......................................................... 1-1 – 1-26

PART 1—SCOPE AND APPLICATION ................................................................. 1-1 – 1-5

PART 2—ADMINISTRATION AND ENFORCEMENT ........................................... 1-5 – 1-26

CHAPTER 2  DEFINITIONS ............................................................................. 2-1 – 2-106

CHAPTER 3  USE AND OCCUPANCY CLASSIFICATION ..................................... 3-1 – 3-42

CHAPTER 4  SPECIAL DETAILED REQUIREMENTS BASED ON USE AND OCCUPANCY ........ 4-1 – 4-138

CHAPTER 5  GENERAL BUILDING HEIGHTS AND AREAS ................................. 5-1 – 5-54

CHAPTER 6  TYPES OF CONSTRUCTION ......................................................... 6-1 – 6-18

CHAPTER 7  FIRE AND SMOKE PROTECTION FEATURES ............................. 7-1 – 7-198

CHAPTER 8  INTERIOR FINISHES ................................................................. 8-1 – 8-18

CHAPTER 9  FIRE PROTECTION SYSTEMS ..................................................... 9-1 – 9-128

CHAPTER 10  MEANS OF EGRESS ................................................................. 10-1 – 10-198

CHAPTER 11  ACCESSIBILITY ...................................................................... 11-1 – 11-66

CHAPTER 12  INTERIOR ENVIRONMENT ......................................................... 12-1 – 12-18

CHAPTER 13  ENERGY EFFICIENCY .............................................................. 13-1 – 13-2

CHAPTER 14  EXTERIOR WALLS ................................................................. 14-1 – 14-48

CHAPTER 15  ROOF ASSEMBLIES AND ROOFTOP STRUCTURES ..................... 15-1 – 15-40

INDEX ..................................................................................................... INDEX-1 – INDEX-38
Part 1—Scope and Application

Chapter 1: Scope and Administration

General Comments
This chapter contains provisions for the application, enforcement and administration of subsequent requirements of the code. In addition to establishing the scope of the code, Chapter 1 identifies which buildings and structures come under its purview. Section 101 addresses the scope of the code and references the other International Codes that are mentioned elsewhere in the code. Section 102 establishes the applicability of the code and addresses existing structures.

Section 103 establishes the department of building safety and the appointment of department personnel. Section 104 outlines the duties and authority of the building official with regard to permits, inspections and right of entry. It also establishes the authority of the building official to approve alternative materials, used materials and modifications. Section 105 states when permits are required and establishes the procedures for the review of applications and the issuance of permits. Section 106 provides requirements for posting live loads greater than 50 pounds per square foot (2394 Pa) (psf). Section 107 describes the information that must be included on the construction documents submitted with the application. Section 108 authorizes the building official to issue permits for temporary structures and uses. Section 109 establishes requirements for a fee schedule. Section 110 includes inspection duties of the building official or an inspection agency that has been approved by the building official. Provisions for the issuance of certificates of occupancy are detailed in Section 111. Section 112 gives the building official the authority to approve utility connections. Section 113 establishes the board of appeals and the criteria for making applications for appeal. Administrative provisions for violations are addressed in Section 114, including provisions for unlawful acts, violation notices, prosecution and penalties. Section 115 describes procedures for stop work orders. Section 116 establishes the criteria for unsafe structures and equipment and the procedures to be followed by the building official for abatement and for notification to the responsible party.

Each state's building code enabling legislation, which is grounded within the police power of the state, is the source of all authority to enact building codes. In terms of how it is used, police power is the power of the state to legislate for the general welfare of its citizens. This power enables passage of such laws as building codes. If the state legislature has limited this power in any way, the municipality may not exceed these limitations. While the municipality may not further delegate its police power (e.g., by delegating the burden of determining code compliance to the building owner, contractor or architect), it may turn over the administration of the building code to a municipal official, such as a building official, provided that sufficient criteria are given to establish clearly the basis for decisions as to whether or not a proposed building conforms to the code.

Chapter 1 is largely concerned with maintaining “due process of law” in enforcing the building performance criteria contained in the body of the code. Only through careful observation of the administrative provisions can the building official reasonably hope to demonstrate that “equal protection under the law” has been provided. While it is generally assumed that the administration and enforcement section of a code is geared toward a building official, this is not entirely true. The provisions also establish the rights and privileges of the design professional, contractor and building owner. The position of the building official is merely to review the proposed and completed work and to determine if the construction conforms to the code requirements. The design professional is responsible for the design of a safe structure. The contractor is responsible for constructing the structure in compliance with the plans.

During the course of construction, the building official reviews the activity to ascertain that the spirit and intent of the law are being met and that the safety, health and welfare of the public will be protected. As a public servant, the building official enforces the code in an unbiased, proper manner. Every individual is guaranteed equal enforcement of the provisions of the code. Furthermore, design professionals, contractors and building owners have the right of due process for any requirement in the code.

Purpose
A building code, as with any other code, is intended to be adopted as a legally enforceable document to safeguard health, safety, property and public welfare. A building code cannot be effective without adequate provisions for its administration and enforcement. The official charged with the administration and enforcement of building regulations has a great responsibility, and with this responsibility goes authority. No matter how detailed the building code may be, the building official must, to some extent, exercise his or her own judge-
SCOPE AND ADMINISTRATION

ment in determining code compliance. The building official has the responsibility to establish that the homes in which the citizens of the community reside and the buildings in which they work are designed and constructed to be structurally stable with adequate means of egress, light and ventilation and to provide a minimum acceptable level of protection to life and property from fire.

Chapter 1 contains two parts. Part 1, Scope and Application, contains all issues related to the scope and intent of the code, as well as the applicability of this code relative to other standards and laws that might also be applicable on a given building project, such as federal or state. Part 2, Administration and Enforcement, contains all issues related to the duties and powers of the building official, the issuance of permits and certificates of occupancy, and other related operational items.

SECTION 101
GENERAL

[A] 101.1 Title. These regulations shall be known as the Building Code of [NAME OF JURISDICTION], hereinafter referred to as "this code."

❖ The purpose of this section is to identify the adopted regulations by inserting the name of the adopting jurisdiction into the code.

[A] 101.2 Scope. The provisions of this code shall apply to the construction, alteration, relocation, enlargement, replacement, repair, equipment, use and occupancy, location, maintenance, removal and demolition of every building or structure or any appurtenances connected or attached to such buildings or structures.

Exception: Detached one- and two-family dwellings and multiple single-family dwellings (townhouses) not more than three stories above grade plane in height with a separate means of egress and their accessory structures shall comply with the International Residential Code.

❖ This section establishes when the regulations contained in the code must be followed, whether all or in part. Something must happen (construction of a new building, modification to an existing one or allowing an existing building or structure to become unsafe) for the code to be applicable. While such activity may not be as significant as a new building, a fence is considered a structure and, therefore, its erection is within the scope of the code. The building code is not a maintenance document requiring periodic inspections that will, in turn, result in an enforcement action, although periodic inspections are addressed by the International Fire Code® (IFC®).

The exception mandates that detached one- and two-family dwellings and townhouses that are not more than three stories above grade and have separate means of egress are to comply with the International Residential Code® (IRC®) and are not required to comply with this code. This applies to all such structures, whether or not there are lot lines separating them and also to their accessory structures, such as garages and pools. Such structures four stories or more in height are beyond the scope of the IRC and must comply with the provisions of the code and its referenced codes.

[A] 101.2.1 Appendices. Provisions in the appendices shall not apply unless specifically adopted.

❖ The provisions contained in Appendices A through K are not considered part of the code and are, therefore, not enforceable unless they are specifically included in the ordinance or other adopting law or regulation of the jurisdiction. See Section 1 of the sample legislation on page xxi of the code for where the appendices to be adopted are to be specified in the adoption ordinance.

[A] 101.3 Intent. The purpose of this code is to establish the minimum requirements to safeguard the public health, safety and general welfare through structural strength, means of egress facilities, stability, sanitation, adequate light and ventilation, energy conservation, and safety to life and property from fire and other hazards attributed to the built environment and to provide safety to fire fighters and emergency responders during emergency operations.

❖ The intent of the code is to set forth regulations that establish the minimum acceptable level to safeguard public health, safety and welfare and to provide protection for fire fighters and emergency responders in building emergencies. The intent becomes important in the application of such sections as Sections 102, 104.11 and 114 as well as any enforcement-oriented interpretive action or judgement. Like any code, the written text is subject to interpretation. Interpretations should not be affected by economics or the potential impact on any party. The only considerations should be protection of public health, safety and welfare and emergency responder safety.

[A] 101.4 Referenced codes. The other codes listed in Sections 101.4.1 through 101.4.6 and referenced elsewhere in this code shall be considered part of the requirements of this code to the prescribed extent of each such reference.

❖ The International Code Council® (ICC®) promulgates a complete set of codes to regulate the built environment. These codes are coordinated with each other so as to avoid conflicting provisions. When the code is adopted by a jurisdiction, the codes that regulate a building’s electrical, fuel gas, mechanical and plumbing systems are also included in the adoption and are considered a part of the code. The International Property Maintenance Code® (IPMC®) and the IFC are
also referenced and enable the building official to address unsafe conditions in existing structures. Various other sections of the code also specifically refer to these codes. Note that these codes are listed in Chapter 35 and further identified by the specific year of issue. Only that edition of the code is legally adopted and any future editions are not enforceable. The issuance of new editions of the International Codes® occurs concurrently and new editions of the referenced codes are adopted with each new edition of the code. Adoption is done in this manner so that there are not conflicting provisions in these codes.

[A] 101.4.1 Gas. The provisions of the International Fuel Gas Code® shall apply to the installation of gas piping from the point of delivery, gas appliances and related accessories as covered in this code. These requirements apply to gas piping systems extending from the point of delivery to the inlet connections of appliances and the installation and operation of residential and commercial gas appliances and related accessories.

The International Fuel Gas Code® (IFGC®) regulates gas piping and appliances and is adopted by reference from this section, as well as Section 2801.1, as the enforceable document for regulating gas systems. This section also establishes the scope of the IFGC as extending from the point of delivery to the inlet connections of each gas appliance. The "point of delivery" is defined in the IFGC as the outlet of the service meter, regulator or shutoff valve.

[A] 101.4.2 Mechanical. The provisions of the International Mechanical Code® shall apply to the installation, alterations, repairs and replacement of mechanical systems, including equipment, appliances, fixtures, fittings and/or appurtenances, including ventilating, heating, cooling, air-conditioning and refrigeration systems, incinerators and other energy-related systems.

The International Mechanical Code® (IMC®) regulates all aspects of a building's mechanical system, including ventilating, heating, cooling, air-conditioning and refrigeration systems, incinerators and other energy-related systems and is adopted by reference from this section, as well as Section 2801.1, as the enforceable document for regulating these systems.

[A] 101.4.3 Plumbing. The provisions of the International Plumbing Code® shall apply to the installation, alteration, repair and replacement of plumbing systems, including equipment, appliances, fixtures, fittings and appurtenances, and where connected to a water or sewage system and all aspects of a medical gas system. The provisions of the International Private Sewage Disposal Code® shall apply to private sewage disposal systems.

The International Plumbing Code® (IPC®) regulates the components of a building's plumbing system, including water supply and distribution piping; sanitary and storm drainage systems; the fixtures and appliances connected thereto; and medical gas and oxygen systems, and is adopted by reference from this section, as well as Section 2901.1, as the enforceable document for regulating these systems. The International Private Sewage Disposal Code® (IPSDC®) is also adopted as the enforceable document for regulating on-site sewage disposal systems.

[A] 101.4.4 Property maintenance. The provisions of the International Property Maintenance Code® shall apply to existing structures and premises; equipment and facilities; light, ventilation, space heating, sanitation; life and fire safety hazards; responsibilities of owners, operators and occupants; and occupancy of existing premises and structures.

The applicability of the code to existing structures is set forth in Section 101.2 and Chapter 34 and is generally limited to new work or changes in use that occur in these buildings. The IPMC, however, is specifically intended to apply to existing structures and their premises and provides a jurisdiction with an enforceable document for public health, safety and welfare when occupying all buildings, including those that were constructed prior to the adoption of the current building code.

[A] 101.4.5 Fire prevention. The provisions of the International Fire Code® shall apply to matters affecting or relating to structures, processes and premises from the hazard of fire and explosion arising from the storage, handling or use of structures, materials or devices; from conditions hazardous to life, property or public welfare in the occupancy of structures or premises; and from the construction, extension, repair, alteration or removal of fire suppression, automatic sprinkler systems and alarm systems or fire hazards in the structure or on the premises from occupancy or operation.

The IFC contains provisions for safeguarding structures and premises from the hazards of fire and explosion that result from: materials, substances and operations that may be present in a structure; circumstances that endanger life, property or public welfare; and the modification or removal of fire suppression and alarm systems. Many of the provisions contained in the code, especially in Chapters 9 and 10, also appear in the IFC. So that all International Codes® contain consistent provisions, only one development committee is responsible for considering proposed changes to such provisions and that committee is identified by a letter designation in brackets that appears at the beginning of affected sections. This is described more fully in the preface to the codes. The IFC also contains provisions that are specifically applicable to existing structures and uses and, like the IPMC, provides a jurisdiction with an enforceable document for public health, safety and welfare in all buildings.

The International Energy Conservation Code® (IECC®) contains provisions for the efficient use of energy in building construction by regulating the design of building envelopes for thermal resistance.
and low air leakage and the design and selection of mechanical systems for effective use of energy, and is adopted by reference in this section, as well as Section 1301.1.1, as the enforceable document for regulating these systems.

SECTION 102
APPLICABILITY

[A] 102.1 General. Where there is a conflict between a general requirement and a specific requirement, the specific requirement shall be applicable. Where, in any specific case, different sections of this code specify different materials, methods of construction or other requirements, the most restrictive shall govern.

In cases where the code establishes a specific requirement for a certain condition, that requirement is applicable even if it is less restrictive than a general requirement elsewhere in the code. For instance, specific requirements for certain uses and occupancies are located in Chapter 4 and take precedence over general requirements found in other chapters of the code. As an example, the requirements contained in Section 402.4 for means of egress in a covered mall building would govern over any differing requirements located in Chapter 10, whether the requirements in Section 402.4 are more or less restrictive.

The most restrictive requirement is to apply where there may be different requirements in the code for a specific issue.

[A] 102.2 Other laws. The provisions of this code shall not be deemed to nullify any provisions of local, state or federal law.

In some cases, other laws enacted by the jurisdiction or the state or federal government may be applicable to a condition that is also governed by a requirement in the code. In such circumstances, the requirements of the code are in addition to the other law that is still in effect, although the building official may not be responsible for its enforcement.

[A] 102.3 Application of references. References to chapter or section numbers, or to provisions not specifically identified by number, shall be construed to refer to such chapter, section or provision of this code.

In a situation where the code may make reference to a chapter or section number or to another code provision without specifically identifying its location in the code, assume that the referenced section, chapter or provision is in the code and not in a referenced code or standard.

[A] 102.4 Referenced codes and standards. The codes and standards referenced in this code shall be considered part of the requirements of this code to the prescribed extent of each such reference and as further regulated in Sections 102.4.1 and 102.4.2.

A referenced code, standard or portion thereof is an enforceable extension of the code as if the content of the standard were included in the body of the code. For example, Section 905.2 references NFPA 14 in its entirety for the installation of standpipe systems. In those cases when the code references only portions of a standard, the use and application of the referenced standard is limited to those portions that are specifically identified. For example, Section 412.4.6 refers to that aircraft hangars must be provided with fire suppression systems as required in NFPA 409. Section 412.4.6 cannot be construed to require compliance with NFPA 409 in its entirety. It is the intent of the code to be in harmony with the referenced standards. If conflicts occur because of scope or purpose, the code text governs.

[A] 102.4.1 Conflicts. Where conflicts occur between provisions of this code and referenced codes and standards, the provisions of this code shall apply.

The use of referenced codes and standards to cover certain aspects of various occupations and operations rather than write parallel or competing requirements into the code is a long-standing code development principle. Often, however, questions and potential conflicts in the use of referenced codes and standards can arise which can lead to inconsistent enforcement of the code. In the code, several sections illustrate this concern, such as Section [F] 415.6.4.

Section [F] 415.6.4 Dry cleaning plants. "The construction and installation of dry cleaning plants shall be in accordance with the requirements of this code, the International Mechanical Code, the International Plumbing Code and NFPA 32. Dry cleaning solvents and systems shall be classified in accordance with the International Fire Code."

Based on this text, NFPA 32, Standard for Dry Cleaning Plants, 2007 Edition, in Section 4.4.1.1 states, "General building and structure design and construction shall be in accordance with NFPA 5000, Building Construction and Safety Code, except as modified herein." Since the extent of the reference to NFPA 32 in Section 415.6.4 includes "...construction...", it has happened that designers construed this to mean that the requirements for building construction of dry cleaning plants will be required to follow NFPA 5000 instead on the IBC.

Another example is in the IMC, which references ANSI/ASHRAE 15 in Sections 1101.6 and 1108.1. ANSI/ASHRAE 15 then references NFPA 54 (ANSI Z23.1), National Fuel Gas Code. This could lead code users to interpret the mechanical code to mean that the National Fuel Gas Code is applicable to specific situations rather than the International Fuel Gas Code® (IFGC®).

[A] 102.4.2 Provisions in referenced codes and standards. Where the extent of the reference to a referenced code or standard includes subject matter that is within the scope of this code or the International Codes listed in Section 101.4, the provisions of this code or the International Codes listed in...
Section 101.4, as applicable, shall take precedence over the provisions in the referenced code or standard.

- Section 102.4.2 expands upon the provisions of proposed numbered Section 102.4.1 by making it clear that, even if a referenced standard contains requirements that parallel the code (or the other referenced International Codes) in the standards own duly referenced section(s), the provisions of the IBC (or the other referenced International Codes) will always take precedence. This proposed section does not intend to take the place of carefully scoped and referenced text for written standards for the International Codes but, rather, provides the policy underpinnings upon which sound code change proposals can be based.

[A] 102.5 Partial invalidity. In the event that any part or provision of this code is held to be illegal or void, this shall not have the effect of making void or illegal any of the other parts or provisions.

- Only invalid sections of the code (as established by the court of jurisdiction) can be set aside. This is essential to safeguard the application of the code text to situations when a provision is declared illegal or unconstitutional. This section preserves the legislative action that put the legal provisions in place.

[A] 102.6 Existing structures. The legal occupancy of any structure existing on the date of adoption of this code shall be permitted to continue without change, except as is specifically covered in this code, the International Property Maintenance Code or the International Fire Code, or as is deemed necessary by the building official for the general safety and welfare of the occupants and the public.

- Only invalid sections of the code (as established by the court of jurisdiction) can be set aside. This is essential to safeguard the application of the code text to situations when a provision is declared illegal or unconstitutional. This section preserves the legislative action that put the legal provisions in place.

PART 2—ADMINISTRATION AND ENFORCEMENT

SECTION 103
DEPARTMENT OF BUILDING SAFETY

[A] 103.1 Creation of enforcement agency. The Department of Building Safety is hereby created and the official in charge thereof shall be known as the building official.

- This section creates the building department and describes its composition (see Section 110 for a discussion of the inspection duties of the department). Appendix A contains qualifications for the employees of the building department involved in the enforcement of the code. A jurisdiction can establish the qualifications outlined in Appendix A for its employees by specifically referencing Appendix A in the adopting ordinance.

The executive official in charge of the building department is named the "building official" by this section. In actuality, the person who is in charge of the department may hold a different title, such as building commissioner, building inspector or construction official. For the purpose of the code, that person is referred to as the "building official."

[A] 103.2 Appointment. The building official shall be appointed by the chief appointing authority of the jurisdiction.

- This section establishes the building official as an appointed position of the jurisdiction.

[A] 103.3 Deputies. In accordance with the prescribed procedures of this jurisdiction and with the concurrence of the appointing authority, the building official shall have the authority to appoint a deputy building official, the related technical officers, inspectors, plan examiners and other employees. Such employees shall have powers as delegated by the building official. For the maintenance of existing properties, see the International Property Maintenance Code.

- This section provides the building official with the authority to appoint other individuals to assist with the administration and enforcement of the code. These individuals would have the authority and responsibility as designated by the building official. Such appointments, however, may be exercised only with the authorization of the chief appointing authority.

SECTION 104
DUTIES AND POWERS OF BUILDING OFFICIAL

[A] 104.1 General. The building official is hereby authorized and directed to enforce the provisions of this code. The building official shall have the authority to render interpretations of this code and to adopt policies and procedures in order to clarify the application of its provisions. Such interpretations, policies and procedures shall be in compliance with the intent and purpose of this code. Such policies and procedures shall not have the effect of waiving requirements specifically provided for in this code.

- The duty of the building official is to enforce the code, and he or she is the "authority having jurisdiction" for all matters relating to the code and its enforcement. It is the duty of the building official to interpret the code and to determine compliance. Code compliance will not always be easy to determine and will require judgement and expertise, particularly when enforcing the provisions of Sections 104.10 and 104.11. In exercising this authority, however, the building official cannot set aside or ignore any provision of the code.

[A] 104.2 Applications and permits. The building official shall receive applications, review construction documents and issue permits for the erection, and alteration, demolition and moving of buildings and structures, inspect the premises for which such permits have been issued and enforce compliance with the provisions of this code.

- The code enforcement process is normally initiated with an application for a permit. The building official is
responsible for processing applications and issuing permits for the construction or modification of buildings in accordance with this code.

[A] 104.3 Notices and orders. The building official shall issue all necessary notices or orders to ensure compliance with this code.

- An important element of code enforcement is the necessary advisement of deficiencies and corrections, which is accomplished through written notices and orders. The building official is required to issue orders to abate illegal or unsafe conditions. Section 116.3 contains additional information for these notices.

[A] 104.4 Inspections. The building official shall make all of the required inspections, or the building official shall have the authority to accept reports of inspection by approved agencies or individuals. Reports of such inspections shall be in writing and be certified by a responsible officer of such approved agency or by the responsible individual. The building official is authorized to engage such expert opinion as deemed necessary to report upon unusual technical issues that arise, subject to the approval of the appointing authority.

- The building official is required to make inspections as necessary to determine compliance with the code or to accept written reports of inspections by an approved agency. The inspection of the work in progress or accomplished is another significant element in determining code compliance. While a department does not have the resources to inspect every aspect of all work, the required inspections are those that are dictated by administrative rules and procedures based on many parameters, including available inspection resources. In order to expand the available resources for inspection purposes, the building official may approve an agency that, in his or her opinion, complies with the criteria set forth in Section 1703. When unusual, extraordinary or complex technical issues arise relative to building safety, the building official has the authority to seek the opinion and advice of experts. Since this usually involves the expenditure of funds, the approval of the jurisdiction's chief executive (or similar position) is required. A technical report from an expert requested by the building official can be used to assist in the approval process (also see Section 1704 for special inspection requirements).

[A] 104.5 Identification. The building official shall carry proper identification when inspecting structures or premises in the performance of duties under this code.

- This section requires the building official (including all authorized designees) to carry identification in the course of conducting the duties of the position. This removes any question as to the purpose and authority of the inspector.

[A] 104.6 Right of entry. Where it is necessary to make an inspection to enforce the provisions of this code, or where the building official has reasonable cause to believe that there exists in a structure or upon a premises a condition which is contrary to or in violation of this code which makes the structure or premises unsafe, dangerous or hazardous, the building official is authorized to enter the structure or premises at reasonable times to inspect or to perform the duties imposed by this code, provided that if such structure or premises be occupied that credentials be presented to the occupant and entry requested. If such structure or premises is unoccupied, the building official shall first make a reasonable effort to locate the owner or other person having charge or control of the structure or premises and request entry. If entry is refused, the building official shall have recourse to the remedies provided by law to secure entry.

- The first part of this section establishes the right of the building official to enter the premises in order to make the permit inspections required by Section 110.3. Permit application forms typically include a statement in the certification signed by the applicant (who is the owner or owner's agent) granting the building official the authority to enter areas covered by the permit in order to enforce code provisions related to the permit. The right to enter other structures or premises is more limited. First, to protect the right of privacy, the owner or occupant must grant the building official permission before an interior inspection of the property can be conducted. Permission is not required for inspections that can be accomplished from within the public right-of-way. Second, such access may be denied by the owner or occupant. Unless the inspector has reasonable cause to believe that a violation of the code exists, access may be unattainable. Third, building officials must present proper identification (see Section 104.5) and request admittance during reasonable hours—usually the normal business hours of the establishment—to be admitted. Fourth, inspections must be aimed at securing or determining compliance with the provisions and intent of the regulations that are specifically within the established scope of the building official's authority.

Searches to gather information for the purpose of enforcing the other codes, ordinances or regulations are considered unreasonable and are prohibited by the Fourth Amendment to the U.S. Constitution. "Reasonable cause" in the context of this section must be distinguished from "probable cause," which is required to gain access to property in criminal cases. The burden of proof establishing reasonable cause may vary among jurisdictions. Usually, an inspector must show that the property is subject to inspection under the provisions of the code; that the interests of the public health, safety and welfare outweigh the individual's right to maintain privacy; and that such an inspection is required solely to determine compliance with the provisions of the code.

Many jurisdictions do not recognize the concept of an administrative warrant and may require the building official to prove probable cause in order to gain access upon refusal. This burden of proof is usually more substantial, often requiring the building official to stipulate in advance why access is needed (usually access is restricted to gathering evidence for seeking
an indictment or making an arrest); what specific items or information is sought; its relevance to the case against the individual subject; how knowledge of the relevance of the information or items sought was obtained and how the evidence sought will be used. In all such cases, the right to privacy must always be weighed against the right of the building official to conduct an inspection to verify that public health, safety and welfare are not in jeopardy. Such important and complex constitutional issues should be discussed with the jurisdiction’s legal counsel. Jurisdictions should establish procedures for securing the necessary court orders when an inspection is deemed necessary following a refusal.

[A] 104.7 Department records. The building official shall keep official records of applications received, permits and certificates issued, fees collected, reports of inspections, and notices and orders issued. Such records shall be retained in the official records for the period required for retention of public records.

In keeping with the need for an efficiently conducted business practice, the building official must keep official records pertaining to permit applications, permits, fees collected, inspections, notices and orders issued. Such documentation provides a valuable resource of information if questions arise regarding the department’s actions with respect to a building. The code does not require that construction documents be kept after the project is complete. It requires that other documents be kept for the length of time mandated by a jurisdiction’s, or its state’s, laws or administrative rules for retaining public records.

[A] 104.8 Liability. The building official, member of the board of appeals or employee charged with the enforcement of this code, while acting for the jurisdiction in good faith and without malice in the discharge of the duties required by this code or other pertinent law or ordinance, shall not thereby be rendered liable personally and is hereby relieved from personal liability for any damage accruing to persons or property as a result of any act or by reason of an act or omission in the discharge of official duties. Any suit instituted against an officer or employee because of an act performed by that officer or employee in the lawful discharge of duties and under the provisions of this code shall be defended by legal representative of the jurisdiction until the final termination of the proceedings. The building official or any subordinate shall not be liable for cost in any action, suit or proceeding that is instituted in pursuance of the provisions of this code.

The building official, other department employees and members of the appeals board are not intended to be held liable for those actions performed in accordance with the code in a reasonable and lawful manner. The responsibility of the building official in this regard is subject to local, state and federal laws that may supersede this provision. This section further establishes that building officials (or subordinates) must not be liable for costs in any legal action instituted in response to the performance of lawful duties. These costs are to be borne by the state, county or municipality. The best way to be certain that the building official’s action is a “lawful duty” is always to cite the applicable code section on which the enforcement action is based.

[A] 104.9 Approved materials and equipment. Materials, equipment and devices approved by the building official shall be constructed and installed in accordance with such approval.

- The code is a compilation of criteria with which materials, equipment, devices and systems must comply to be suitable for a particular application. The building official has a duty to evaluate such materials, equipment, devices and systems for code compliance and, when compliance is determined, approve the same for use. The materials, equipment, devices and systems must be constructed and installed in compliance with, and all conditions and limitations considered as a basis for, that approval. For example, the manufacturer’s instructions and recommendations are to be followed if the approval of the material was based even in part on those instructions and recommendations. The approval authority given to the building official is a significant responsibility and is a key to code compliance. The approval process is first technical and then administrative and must be approached as such. For example, if data to determine code compliance are required, such data should be in the form of test reports or engineering analysis and not simply taken from a sales brochure.

[A] 104.9.1 Used materials and equipment. The use of used materials which meet the requirements of this code for new materials is permitted. Used equipment and devices shall not be reused unless approved by the building official.

- The code criteria for materials and equipment have changed over the years. Evaluation of testing and materials technology has permitted the development of new criteria that the old materials may not satisfy. As a result, used materials are required to be evaluated in the same manner as new materials. Used materials, equipment and devices must be equivalent to that required by the code if they are to be used again in a new installation.

[A] 104.10 Modifications. Wherever there are practical difficulties involved in carrying out the provisions of this code, the building official shall have the authority to grant modifications for individual cases, upon application of the owner or owner’s representative, provided the building official shall first find that special individual reason makes the strict letter of this code impractical and the modification is in compliance with the intent and purpose of this code and that such modification does not lessen health, accessibility, life and fire safety, or structural requirements. The details of action granting modifications shall be recorded and entered in the files of the department of building safety.

- The building official may amend or make exceptions to the code as needed where strict compliance is impractical. Only the building official has authority to
grant modifications. Consideration of a particular difficulty is to be based on the application of the owner and a demonstration that the intent of the code is accomplished. This section is not intended to permit setting aside or ignoring a code provision; rather, it is intended to provide acceptance of equivalent protection. Such modifications do not, however, extend to actions that are necessary to correct violations of the code. In other words, a code violation or the expense of correcting one cannot constitute a practical difficulty.

[A] 104.10.1 Flood hazard areas. The building official shall not grant modifications to any provision required in flood hazard areas as established by Section 1612.3 unless a determination has been made that:

1. A showing of good and sufficient cause that the unique characteristics of the size, configuration or topography of the site render the elevation standards of Section 1612 inappropriate.

2. A determination that failure to grant the variance would result in exceptional hardship by rendering the lot undevelopable.

3. A determination that the granting of a variance will not result in increased flood heights, additional threats to public safety, extraordinary public expense, cause fraud on or victimization of the public, or conflict with existing laws or ordinances.

4. A determination that the variance is the minimum necessary to afford relief, considering the flood hazard.

5. Submission to the applicant of written notice specifying the difference between the design flood elevation and the elevation to which the building is to be built, stating that the cost of flood insurance will be commensurate with the increased risk resulting from the reduced floor elevation, and stating that construction below the design flood elevation increases risks to life and property.

To be consistent with the requirements of the National Flood Insurance Program (NFIP), any modifications requested by an applicant that would reduce the requirements related to flood-resistant construction must be handled by the building official by granting a variance. The NFIP requires that such modifications be carefully considered and the procedures for that consideration are set forth in federal regulations [44 C.F.R. §60.6(a)].

[A] 104.11 Alternative materials, design and methods of construction and equipment. The provisions of this code are not intended to prevent the installation of any material or to prohibit any design or method of construction not specifically prescribed by this code, provided that any such alternative has been approved. An alternative material, design or method of construction shall be approved where the building official finds that the proposed design is satisfactory and complies with the intent of the provisions of this code, and that the material, method or work offered is, for the purpose intended, at least the equivalent of that prescribed in this code in quality, strength, effectiveness, fire resistance, durability and safety.

The code is not intended to inhibit innovative ideas or technological advances. A comprehensive regulatory document, such as a building code, cannot envision and then address all future innovations in the industry. As a result, a performance code must be applicable to and provide a basis for the approval of an increasing number of newly developed, innovative materials, systems and methods for which no code text or referenced standards yet exist. The fact that a material, product or method of construction is not addressed in the code is not an indication that such material, product or method is intended to be prohibited. The building official is expected to apply sound technical judgement in accepting materials, systems or methods that, while not anticipated by the drafters of the current code text, can be demonstrated to offer equivalent performance. By virtue of its text, the code regulates new and innovative construction practices while addressing the relative safety of building occupants. The building official is responsible for determining if a requested alternative provides the equivalent level of protection of public health, safety and welfare as required by the code.

[A] 104.11.1 Research reports. Supporting data, where necessary in the approval of materials or assemblies not specifically provided for in this code, shall consist of valid research reports from approved sources.

When an alternative material or method is proposed for construction, it is incumbent upon the building official to determine whether this alternative is, in fact, an equivalent to the methods prescribed by the code. Reports providing evidence of this equivalency are required to be supplied by an approved source, meaning a source that the building official finds to be reliable and accurate. The ICC Evaluation Service is an example of an agency that provides research reports for alternative materials and methods.

[A] 104.11.2 Tests. Whenever there is insufficient evidence of compliance with the provisions of this code, or evidence that a material or method does not conform to the requirements of this code, or in order to substantiate claims for alternative materials or methods, the building official shall have the authority to require tests as evidence of compliance to be made at no expense to the jurisdiction. Test methods shall be as specified in this code or by other recognized test standards. In the absence of recognized and accepted test methods, the building official shall approve the testing procedures. Tests shall be performed by an approved agency. Reports of such tests shall be retained by the building official for the period required for retention of public records.

To provide the basis on which the building official can make a decision regarding an alternative material or method, sufficient technical data, test reports and documentation must be provided for evaluation.
evidence satisfactory to the building official indicates that the alternative material or construction method is equivalent to that required by the code, he or she may approve it. Any such approval cannot have the effect of waiving any requirements of the code. The burden of proof of equivalence lies with the applicant who proposes the use of alternative materials or methods.

The building official must require the submission of any appropriate information and data to assist in the determination of equivalency. This information must be submitted before a permit can be issued. The type of information required includes test data in accordance with referenced standards, evidence of compliance with the referenced standard specifications and design calculations. A research report issued by an authoritative agency is particularly useful in providing the building official with the technical basis for evaluation and approval of new and innovative materials and methods of construction. The use of authoritative research reports can greatly assist the building official by reducing the time-consuming engineering analysis necessary to review these materials and methods. Failure to substantiate adequately a request for the use of an alternative is a valid reason for the building official to deny a request. Any tests submitted in support of an application must have been performed by an agency approved by the building official based on evidence that the agency has the technical expertise, test equipment and quality assurance to properly conduct and report the necessary testing. The test reports submitted to the building official must be retained in accordance with the requirements of Section 104.7.

SECTION 105
PERMITS

[A] 105.1 Required. Any owner or authorized agent who intends to construct, enlarge, alter, repair, move, demolish, or change the occupancy of a building or structure, or to erect, install, enlarge, alter, repair, remove, convert or replace any electrical, gas, mechanical or plumbing system, the installation of which is regulated by this code, or to cause any such work to be done, shall first make application to the building official and obtain the required permit.

In some instances, such as large buildings or industrial facilities, the repair, replacement or alteration of electrical, gas, mechanical or plumbing systems occurs on a frequent basis, and this section allows the building official to issue an annual permit for this work. This relieves both the building department and the owners of such facilities from the burden of filing and processing individual applications for this activity, however, there are restrictions on who is entitled to these permits. They can be issued only for work on a previously approved installation and only to an individual or corporation that employs persons specifically qualified in the trade for which the permit is issued. If tradespeople who perform the work involved are required to be licensed in the jurisdiction, then only those persons would be permitted to perform the work. If trade licensing is not required, then the building official needs to review and approve the qualifications of the persons who will be performing the work. The annual permit can apply only to the individual property that is owned or operated by the applicant.

[A] 105.1.2 Annual permit records. The person to whom an annual permit is issued shall keep a detailed record of alterations made under such annual permit. The building official shall have access to such records at all times or such records shall be filed with the building official as designated.

The work performed in accordance with an annual permit must be inspected by the building official, so it is necessary to know the location of such work and when it was performed. This can be accomplished by having records of the work available to the building official either at the premises or in the official's office, as determined by the official.

[A] 105.2 Work exempt from permit. Exemptions from permit requirements of this code shall not be deemed to grant authorization for any work to be done in any manner in violation of the provisions of this code or any other laws or ordi-
nances of this jurisdiction. **Permits** shall not be required for the following:

**Building:**

1. One-story detached accessory structures used as tool and storage sheds, playhouses and similar uses, provided the floor area is not greater than 120 square feet (11 m²).
2. Fences not over 7 feet (2134 mm) high.
3. Oil derricks.
4. Retaining walls that are not over 4 feet (1219 mm) in height measured from the bottom of the footing to the top of the wall, unless supporting a surcharge or impounding Class I, II or IIIA liquids.
5. Water tanks supported directly on grade if the capacity is not greater than 5,000 gallons (18 925 L) and the ratio of height to diameter or width is not greater than 2:1.
6. Sidewalks and driveways not more than 30 inches (762 mm) above adjacent grade, and not over any basement or story below and are not part of an accessible route.
7. Painting, papering, tiling, carpeting, cabinets, counter tops and similar finish work.
8. Temporary motion picture, television and theater stage sets and scenery.
9. Prefabricated swimming pools accessory to a Group R-3 occupancy that are less than 24 inches (610 mm) deep, are not greater than 5,000 gallons (18 925 L) and are installed entirely above ground.
10. Shade cloth structures constructed for nursery or agricultural purposes, not including service systems.
11. Swings and other playground equipment accessory to detached one- and two-family dwellings.
12. Window awnings in Group R-3 and U occupancies, supported by an exterior wall that do not project more than 54 inches (1372 mm) from the exterior wall and do not require additional support.
13. Nonfixed and movable fixtures, cases, racks, counters and partitions not over 5 feet 9 inches (1753 mm) in height.

**Electrical:**

**Repairs and maintenance:** Minor repair work, including the replacement of lamps or the connection of approved portable electrical equipment to approved permanently installed receptacles.

**Radio and television transmitting stations:** The provisions of this code shall not apply to electrical equipment used for radio and television transmissions, but do apply to equipment and wiring for a power supply and the installations of towers and antennas.

**Temporary testing systems:** A permit shall not be required for the installation of any temporary system required for the testing or servicing of electrical equipment or apparatus.

**Gas:**

1. Portable heating appliance.
2. Replacement of any minor part that does not alter approval of equipment or make such equipment unsafe.

**Mechanical:**

1. Portable heating appliance.
2. Portable ventilation equipment.
3. Portable cooling unit.
4. Steam, hot or chilled water piping within any heating or cooling equipment regulated by this code.
5. Replacement of any part that does not alter its approval or make it unsafe.
6. Portable evaporative cooler.
7. Self-contained refrigeration system containing 10 pounds (5 kg) or less of refrigerant and actuated by motors of 1 horsepower (746 W) or less.

**Plumbing:**

1. The stopping of leaks in drains, water, soil, waste or vent pipe, provided, however, that if any concealed trap, drain pipe, water, soil, waste or vent pipe becomes defective and it becomes necessary to remove and replace the same with new material, such work shall be considered as new work and a permit shall be obtained and inspection made as provided in this code.
2. The clearing of stoppages or the repairing of leaks in pipes, valves or fixtures and the removal and reinstallation of water closets, provided such repairs do not involve or require the replacement or rearrangement of valves, pipes or fixtures.

❖ Section 105.1 essentially requires a permit for any activity involving work on a building and its systems and other structures. This section lists those activities that are permitted to take place without first obtaining a permit from the building department. Note that in some cases, such as Items 9, 10, 11 and 12, the work is exempt only for certain occupancies. It is further the intent of the code that even though work may be exempted for permit purposes, it must still comply with the code and the owner is responsible for proper and safe construction for all work being done. Work exempted by the codes adopted by reference in Section 101.4 is also included here.

[A] **105.2.1 Emergency repairs.** Where equipment replacements and repairs must be performed in an emergency situation, the permit application shall be submitted within the next working business day to the building official.

❖ This section recognizes that in some cases, emergency replacement and repair work must be done as quickly as possible, so it is not practical to take the...
necessary time to apply for and obtain approval. A permit for the work must be obtained the next day that the building department is open for business. Any work performed before the permit is issued must be done in accordance with the code and corrected if not approved by the building official.

[A] 105.2.2 Repairs. Application or notice to the building official is not required for ordinary repairs to structures, replacement of lamps or the connection of approved portable electrical equipment to approved permanently installed receptacles. Such repairs shall not include the cutting away of any wall, partition or portion thereof, the removal or cutting of any structural beam or load-bearing support, or the removal or change of any required means of egress, or rearrangement of parts of a structure affecting the egress requirements; nor shall ordinary repairs include addition to, alteration of, replacement or relocation of any standpipe, water supply, sewer, drainage, drain leader, gas, soil, waste, vent or similar piping, electric wiring or mechanical or other work affecting public health or general safety.

This section distinguishes between what might be termed by some as repairs but are in fact alterations, wherein the code is to be applicable, and ordinary repairs, which are maintenance activities that do not require a permit.

[A] 105.2.3 Public service agencies. A permit shall not be required for the installation, alteration or repair of generation, transmission, distribution or metering or other related equipment that is under the ownership and control of public service agencies by established right.

Utilities that supply electricity, gas, water, telephone, television cable, etc., do not require permits for work involving the transmission lines and metering equipment that they own and control; that is, to their point of delivery. Utilities are typically regulated by other laws that give them specific rights and authority in this area. Any equipment or appliances installed or serviced by such agencies that are not owned by them and under their full control are not exempt from a permit.

[A] 105.3 Application for permit. To obtain a permit, the applicant shall first file an application therefor in writing on a form furnished by the department of building safety for that purpose. Such application shall:

1. Identify and describe the work to be covered by the permit for which application is made.
2. Describe the land on which the proposed work is to be done by legal description, street address or similar description that will readily identify and definitely locate the proposed building or work.
3. Indicate the use and occupancy for which the proposed work is intended.
4. Be accompanied by construction documents and other information as required in Section 107.
5. State the valuation of the proposed work.

6. Be signed by the applicant, or the applicant’s authorized agent.

7. Give such other data and information as required by the building official.

This section requires that a written application for a permit be filed on forms provided by the building department and details the information required on the application. Permit forms will typically have sufficient space to write a very brief description of the work to be accomplished, which is sufficient for only small jobs. For larger projects, the description will be augmented by construction documents as indicated in Item 4. As required by Section 105.1, the applicant must be the owner of the property or an authorized agent of the owner, such as an engineer, architect, contractor, tenant or other. The applicant must sign the application, and permit forms typically include a statement that if the applicant is not the owner, he or she has permission from the owner to make the application.

[A] 105.3.1 Action on application. The building official shall examine or cause to be examined applications for permits and amendments thereto within a reasonable time after filing. If the application or the construction documents do not conform to the requirements of pertinent laws, the building official shall reject such application in writing, stating the reasons therefor. If the building official is satisfied that the proposed work conforms to the requirements of this code and laws and ordinances applicable thereto, the building official shall issue a permit therefor as soon as practicable.

This section requires the building official to act with reasonable speed on a permit application. In some instances, this time period is set by state or local law. The building official must refuse to issue a permit when the application and accompanying documents do not conform to the code. In order to ensure effective communication and due process of law, the reasons for denial of an application for a permit are required to be in writing. Once the building official determines that the work described conforms with the code and other applicable laws, the permit must be issued upon payment of the fees required by Section 109.

[A] 105.3.2 Time limitation of application. An application for a permit for any proposed work shall be deemed to have been abandoned 180 days after the date of filing, unless such application has been pursued in good faith or a permit has been issued; except that the building official is authorized to grant one or more extensions of time for additional periods not exceeding 90 days each. The extension shall be requested in writing and justifiable cause demonstrated.

Typically, an application for a permit is submitted and goes through a review process that ends with the issuance of a permit. If a permit has not been issued 180 days after the date of filing, however, the application is considered abandoned, unless the applicant
was diligent in efforts to obtain the permit. The building official has the authority to extend this time limitation (in increments of 90 days), provided there is reasonable cause. This would cover delays beyond the applicant’s control, such as prerequisite permits or approvals from other authorities within the jurisdiction or state. The intent of this section is to limit the time between the review process and the issuance of a permit.

[A] 105.4 Validity of permit. The issuance or granting of a permit shall not be construed to be a permit for, or an approval of, any violation of any of the provisions of this code or of any other ordinance of the jurisdiction. Permits presuming to give authority to violate or cancel the provisions of this code or other ordinances of the jurisdiction shall not be valid. The issuance of a permit based on construction documents and other data shall not prevent the building official from requiring the correction of errors in the construction documents and other data. The building official is also authorized to prevent occupancy or use of a structure where in violation of this code or of any other ordinances of this jurisdiction.

- This section states the fundamental premise that the permit is only a license to proceed with the work. It is not a license to violate, cancel or set aside any provisions of the code. This is significant because it means that despite any errors or oversights in the approval process, the permit applicant, not the building official, is responsible for code compliance. Also, the permit can be suspended or revoked in accordance with Section 105.6.

[A] 105.5 Expiration. Every permit issued shall become invalid unless the work on the site authorized by such permit is commenced within 180 days after its issuance, or if the work authorized on the site by such permit is suspended or abandoned for a period of 180 days after the time the work is commenced. The building official is authorized to grant, in writing, one or more extensions of time, for periods not more than 180 days each. The extension shall be requested in writing and justifiable cause demonstrated.

- The permit becomes invalid under two distinct situations—both based on a 180-day period. The first situation is when no work was initiated 180 days from issuance of a permit. The second situation is when the authorized work has stopped for 180 days. The person who was issued the permit should be notified, in writing, that the permit is invalid and what steps must be taken to reinstate it and restart the work. The building official has the authority to extend this time limitation (in increments of 180 days), provided the extension is requested in writing and there is reasonable cause, which typically includes events beyond the permit holder’s control.

[A] 105.6 Suspension or revocation. The building official is authorized to suspend or revoke a permit issued under the provisions of this code wherever the permit is issued in error or on the basis of incorrect, inaccurate or incomplete information, or in violation of any ordinance or regulation or any of the provisions of this code.

- A permit is a license to proceed with the work. The building official, however, can suspend or revoke permits shown to be based, all or in part, on any false statement or misrepresentation of fact. A permit can also be suspended or revoked if it was issued in error, such as an omitted prerequisite approval or code violation indicated on the construction documents. An applicant may subsequently apply for a reinstatement of the permit with the appropriate corrections or modifications made to the application and construction documents.

[A] 105.7 Placement of permit. The building permit or copy shall be kept on the site of the work until the completion of the project.

- The permit, or copy thereof, is to be kept on the job site until the work is complete and made available to the building official or representative to conveniently make required entries thereon.

SECTION 106
FLOOR AND ROOF DESIGN LOADS

[A] 106.1 Live loads posted. Where the live loads for which each floor or portion thereof of a commercial or industrial building is or has been designed to exceed 50 psf (2.40 kN/m²), such design live loads shall be conspicuously posted by the owner in that part of each story in which they apply, using durable signs. It shall be unlawful to remove or deface such notices.

- This section requires that live loads be posted for most occupancies, since many of the live loads specified in Table 1607.1 exceed 50 psf (2.40 kN/m²). Where part of the floor is designed for 50 psf (2.40 kN/m²) or less and part for more than 50 psf (2.40 kN/m²), the live loads are required to be posted for those portions more than 50 psf (2.40 kN/m²). The code requires that the posting be done in the part where it applies. For example, an assembly area such as a restaurant would need to have the live load posted in the dining room.

This live load posting gives the building department easy access to the information for field verification. It also serves as a notice of the loading restriction that is stated in Section 106.3.

[A] 106.2 Issuance of certificate of occupancy. A certificate of occupancy required by Section 111 shall not be issued until the floor load signs, required by Section 106.1, have been installed.

- The design live load signs required by Section 106.1 need to be in place prior to the occupancy of the building for reference purposes. They serve as a record of the structural design loads for future reference, particularly when a change in occupancy is contemplated.
[A] 106.3 Restrictions on loading. It shall be unlawful to place, or cause or permit to be placed, on any floor or roof of a building, structure or portion thereof, a load greater than is permitted by this code.

- The loads that this section is referring to are the various structural loads specified in Chapter 16. For example, Table 1607.1 includes the minimum live loads for building design. Unless the building is designed for higher loads than specified in Table 1607.1, those values are not to be exceeded. Note that the loads in Table 1607.1 are minimum live loads. A building is permitted to be designed for higher loads, in which case the higher loads would be the limit of the actual applied loads.

SECTION 107 SUBMITTAL DOCUMENTS

[A] 107.1 General. Submittal documents consisting of construction documents, statement of special inspections, geotechnical report and other data shall be submitted in two or more sets with each permit application. The construction documents shall be prepared by a registered design professional required by the statutes of the jurisdiction in which the project is to be constructed. Where special conditions exist, the building official is authorized to require additional construction documents to be prepared by a registered design professional.

Exception: The building official is authorized to waive the submission of construction documents and other data not required to be prepared by a registered design professional if it is found that the nature of the work applied for is such that review of construction documents is not necessary to obtain compliance with this code.

- This section establishes the requirement to provide the building official with construction drawings, specifications and other documents that describe the structure or system for which a permit is sought (see Section 202 for a complete definition). It also describes the information that must be included in the documents, which must prepare them and procedures for approving them.

A detailed description of the work for which an application is made must be submitted. When the work can be briefly described on the application form and the services of a registered design professional are not required, the building official may utilize judgment in determining the need for detailed documents. An example of work that may not involve the submission of detailed construction documents is the replacement of an existing 60-amp electrical service with a 200-amp service. Other sections of the code also contain specific requirements for construction documents, such as Sections 1603, 1901.4, 2101.3 and 3103.2. These provisions are intended to reflect the minimum scope of information needed to determine code compliance. Although this section specifies that "one or more" sets of construction documents be submitted, note that Section 106.3.1 requires one set of approved documents to be retained by the building official and one set to be returned to the applicant, essentially requiring at least two sets of construction documents. The building official should establish a consistent policy of the number of sets required by the jurisdiction and make this information readily available to applicants.

This section also requires the building official to determine that any state professional registration laws be complied with as they apply to the preparation of construction documents.

[A] 107.2 Construction documents. Construction documents shall be in accordance with Sections 107.2.1 through 107.2.5.

- This section provides instructions regarding the form and content of construction documents.

[A] 107.2.1 Information on construction documents. Construction documents shall be dimensioned and drawn upon suitable material. Electronic media documents are permitted to be submitted when approved by the building official. Construction documents shall be of sufficient clarity to indicate the location, nature and extent of the work proposed and show in detail that it will conform to the provisions of this code and relevant laws, ordinances, rules and regulations, as determined by the building official.

- The construction documents are required to be of a quality and detail such that the building official can determine that the work conforms to the code and other applicable laws and regulations. General statements on the documents, such as "all work must comply with the International Building Code," are not an acceptable substitute for showing the required information. The following subsections and sections in other chapters indicated in the commentary to Sections 107.2.2 through 107.2.5 specify the detailed information that must be shown on the submitted documents. When specifically allowed by the building official, documents can be submitted in electronic form.

[A] 107.2.2 Fire protection system shop drawings. Shop drawings for the fire protection system(s) shall be submitted to indicate conformance to this code and the construction documents and shall be approved prior to the start of system installation. Shop drawings shall contain all information as required by the referenced installation standards in Chapter 9.

- Since the fire protection contractor(s) may not have been selected at the time a permit is issued for construction of a building, detailed shop drawings for fire protection systems are not available. Because they provide the information necessary to determine code compliance, as specified in the appropriate referenced standard in Chapter 9, they must be submitted and approved by the building official before the contractor can begin installing the system. For example, the professional responsible for the design of an automatic sprinkler system should determine that the water supply is adequate, but will not be able to prepare a final set of hydraulic calculations if the specific
materials and pipe sizes, lengths and arrangements have not been identified. Once the installing contractor is selected, specific hydraulic calculations can be prepared. Factors, such as classification of the hazard, amount of water supply available and the density or concentration to be achieved by the system, are to be included with the submission of the shop drawings. Specific data sheets identifying sprinklers, pipe dimensions, power requirements for smoke detectors, etc., should also be included with the submission.

[A] 107.2.3 Means of egress. The construction documents shall show in sufficient detail the location, construction, size and character of all portions of the means of egress including the path of the exit discharge to the public way in compliance with the provisions of this code. In other than occupancies in Groups R-2, R-3, and I-1, the construction documents shall designate the number of occupants to be accommodated on every floor, and in all rooms and spaces.

- The complete means of egress system is required to be indicated on the plans to permit the building official to initiate a review and identify pertinent code requirements for each component. Additionally, requiring such information to be reflected in the construction documents requires the designer not only to become familiar with the code, but also to be aware of egress principles, concepts and purposes. The need to ensure that the means of egress leads to a public way also is a consideration during the plan review. Such an evaluation cannot be made without the inclusion of a site plan, as required by Section 107.2.5.

Information essential for determining the required capacity of the egress components (see Section 1005) and the number of egress components required from a space (see Sections 1014.1 and 1018.1) must be provided. The designer must be aware of the occupancy of a space and properly identify that information, along with its resultant occupant load, on the construction documents. In occupancies in Groups I-1, R-2 and R-3, the occupant load can be readily determined with little difference in the number so that the designation of the occupant load on the construction documents is not required.

The exit discharge path to the public way must also be shown on the construction documents. The exit discharge path to the public way is an important component of the means of egress system for all buildings or structures. The exit discharge path needs to be delineated on the submitted and approved plans to ensure the path is reviewed for compliance with the provisions of the code. This will also provide an historical reference once the building is occupied to ensure the exit discharge path is maintained as intended for the life of the building or structure unless modifications are approved.

[A] 107.2.4 Exterior wall envelope. Construction documents for all buildings shall describe the exterior wall envelope in sufficient detail to determine compliance with this code. The construction documents shall provide details of the exterior wall envelope as required, including flashing, intersections with dissimilar materials, corners, end details, control joints, intersections at roof, eaves or parapets, means of drainage, water-resistive membrane and details around openings.

The construction documents shall include manufacturer's installation instructions that provide supporting documentation that the proposed penetration and opening details described in the construction documents maintain the weather resistance of the exterior wall envelope. The supporting documentation shall fully describe the exterior wall system which was tested, where applicable, as well as the test procedure used.

- This section specifically identifies details of exterior wall construction that are critical to the weather resistance of the wall and requires those details to be provided on the construction documents. Where the weather resistance of the exterior wall assembly is based on tests, the submitted documentation is to describe the details of the wall envelope and the test procedure that was used. This provides the building official with the information necessary to determine code compliance.

[A] 107.2.3 Site plan. The construction documents submitted with the application for permit shall be accompanied by a site plan showing to scale the size and location of new construction and existing structures on the site, distances from lot lines, the established street grades and the proposed finished grades and, as applicable, flood hazard areas, floodways, and design flood elevations; and it shall be drawn in accordance with an accurate boundary line survey. In the case of demolition, the site plan shall show construction to be demolished and the location and size of existing structures and construction that are to remain on the site or plot. The building official is authorized to waive or modify the requirement for a site plan when the application for permit is for alteration or repair or when otherwise warranted.

- Certain code requirements are dependent on the structure's location on the lot (see Sections 506.2, 507, 705, 1025 and 1206) and the topography of the site (see Sections 1104, 1107.7.4 and 1804.3). As a result, a scaled site plan containing the data listed in this section is required to permit review for compliance. The building official can waive the requirement for a site plan when it is not required to determine code compliance, such as work involving only interior alterations or repairs.

[A] 107.2.5.1 Design flood elevations. Where design flood elevations are not specified, they shall be established in accordance with Section 1612.3.1.

- A large percentage of areas that are mapped as special flood hazard areas by the NFIP do not have either flood elevations or floodway designations (floodways are areas along riverine bodies of water that convey the bulk of floodwaters). Section 1612.3 gives the authority to the code official to require use of data which may be obtained from other sources, or to require the applicant to develop flood hazard data.
[A] 107.3 Examination of documents. The building official shall examine or cause to be examined the accompanying submittal documents and shall ascertain by such examinations whether the construction indicated and described is in accordance with the requirements of this code and other pertinent laws or ordinances.

- The requirements of this section are related to those found in Section 105.3.1 regarding the action of the building official in response to a permit application. The building official can delegate review of the construction documents to subordinates as provided for in Section 103.3.

[A] 107.3.1 Approval of construction documents. When the building official issues a permit, the construction documents shall be approved, in writing or by stamp, as "Reviewed for Code Compliance." One set of construction documents so reviewed shall be retained by the building official. The other set shall be returned to the applicant, shall be kept at the site of work and shall be open to inspection by the building official or a duly authorized representative.

- The building official must stamp or otherwise endorse as "Reviewed for Code Compliance" the construction documents on which the permit is based. One set of approved construction documents must be kept on the construction site to serve as the basis for all subsequent inspections. To avoid confusion, the construction documents on the site must be the documents that were approved and stamped. This is because inspections are to be performed with regard to the approved documents, not the code itself. Additionally, the contractor cannot determine compliance with the approved construction documents unless they are readily available. If the approved construction documents are not available, the inspection should be postponed and work on the project halted.

[A] 107.3.2 Previous approvals. This code shall not require changes in the construction documents, construction or designated occupancy of a structure for which a lawful permit has been heretofore issued or otherwise lawfully authorized, and the construction of which has been pursued in good faith within 180 days after the effective date of this code and has not been abandoned.

- If a permit is issued and construction proceeds at a normal pace and a new edition of the code is adopted by the legislative body, requiring that the building be constructed to conform to the new code is unreasonable. This section provides for the continuity of permits issued under previous codes, as long as such permits are being "actively prosecuted" subsequent to the effective date of the ordinance adopting this edition of the code.

[A] 107.3.3 Phased approval. The building official is authorized to issue a permit for the construction of foundations or any other part of a building or structure before the construction documents for the whole building or structure have been submitted, provided that adequate information and detailed statements have been filed complying with pertinent requirements of this code. The holder of such permit for the foundation or other parts of a building or structure shall proceed at the holder's own risk with the building operation and without assurance that a permit for the entire structure will be granted.

- The building official has the authority to issue a partial permit to allow for the practice of "fast tracking" a job. Any construction under a partial permit is "at the holder's own risk" and "without assurance that a permit for the entire structure will be granted." The building official is under no obligation to accept work or issue a complete permit in violation of the code, ordinances or statutes simply because a partial permit had been issued. Fast tracking puts an unusual administrative and technical burden on the building official. The purpose is to proceed with construction while the design continues for other aspects of the work. Coordinating and correlating the code aspects into the project in phases requires attention to detail and project tracking so that all code issues are addressed. The coordination of these submittals is the responsibility of the registered design professional in responsible charge described in Section 107.3.4.

[A] 107.3.4 Design professional in responsible charge. When it is required that documents be prepared by a registered design professional, the building official shall be authorized to require the owner to engage and designate on the building permit application a registered design professional who shall act as the registered design professional in responsible charge. If the circumstances require, the owner shall designate a substitute registered design professional in responsible charge who shall perform the duties required of the original registered design professional in responsible charge. The building official shall be notified in writing by the owner if the registered design professional in responsible charge is changed or is unable to continue to perform the duties.

The registered design professional in responsible charge shall be responsible for reviewing and coordinating submittal documents prepared by others, including phased and deferred submittal items, for compatibility with the design of the building.

- At the time of permit application and at various intervals during a project, the code requires detailed technical information to be submitted to the building official. This will vary depending on the complexity of the project, but typically includes the construction documents with supporting information, applications utilizing the phased approval procedure in Section 107.3.3 and reports from engineers, inspectors and testing agencies required in Chapter 17. Since these documents and reports are prepared by numerous individuals, firms and agencies, it is necessary to have a single person charged with responsibility for coordinating their submittal to the building official. This person is the point of contact for the building official for all information relating to the project. Otherwise, the building official could waste time and effort attempting to locate the source of accurate information when trying to resolve an issue such as a dis-
crepancy in plans submitted by different designers. The requirement that the owner engage a person to act as the design professional in responsible charge is applicable to projects where the construction documents are required by law to be prepared by a registered design professional (see Section 107.1) and when required by the building official. The person employed by the owner to act as the design professional in responsible charge must be identified on the permit application, but the owner can change the designated person at any time during the course of the review process or work, provided the building official is so notified in writing.

[A] 107.3.4.1 Deferred submittals. For the purposes of this section, deferred submittals are defined as those portions of the design that are not submitted at the time of the application and that are to be submitted to the building official within a specified period.

Deferral of any submittal items shall have the prior approval of the building official. The registered design professional in responsible charge shall list the deferred submittals on the construction documents for review by the building official.

Documents for deferred submittal items shall be submitted to the registered design professional in responsible charge who shall review them and forward them to the building official with a notation indicating that the deferred submittal documents have been reviewed and found to be in general conformance to the design of the building. The deferred submittal items shall not be installed until the deferred submittal documents have been approved by the building official.

Often, especially on larger projects, details of certain building parts are not available at the time of permit issuance because they have not yet been designed; for example, exterior cladding, prefabricated items such as trusses and stairs and the components of fire protection systems (see Section 107.2.2). The design professional in responsible charge must identify on the construction documents the items to be included in any deferred submittals. Documents required for the approval of deferred items must be reviewed by the design professional in responsible charge for compatibility with the design of the building, forwarded to the building official with a notation that this is the case and approved by the building official before installation of the items. Sufficient time must be allowed for the approval process. Note that deferred submittals differ from the phased permits described in Section 107.3.3 in that they occur after the permit for the building is issued and are not for work covered by separate permits.

[A] 107.4 Amended construction documents. Work shall be installed in accordance with the approved construction documents, and any changes made during construction that are not in compliance with the approved construction documents shall be resubmitted for approval as an amended set of construction documents.

Any amendments to the approved construction documents must be filed before constructing the amended item. In the broadest sense, amendments include all addenda, change orders, revised drawings and marked-up shop drawings. Building officials should maintain a policy that all amendments be submitted for review. Otherwise, a significant amendment may not be submitted because of misinterpretation, resulting in an activity that is not approved and that causes a needless delay in obtaining approval of the finished work.

[A] 107.5 Retention of construction documents. One set of approved construction documents shall be retained by the building official for a period of not less than 180 days from date of completion of the permitted work, or as required by state or local laws.

A set of the approved construction documents must be kept by the building official as may be required by state or local laws, but for a period of no less than 180 days after the work is complete. Questions regarding an item shown on the approved documents may arise in the period immediately following completion of the work and the documents should be available for review. See Section 104.7 for requirements to retain other records that are generated as a result of the work.

SECTION 108
TEMPORARY STRUCTURES AND USES

[A] 108.1 General. The building official is authorized to issue a permit for temporary structures and temporary uses. Such permits shall be limited as to time of service, but shall not be permitted for more than 180 days. The building official is authorized to grant extensions for demonstrated cause.

In the course of construction or other activities, structures that have a limited service life are often necessary. This section contains the administrative provisions that permit such temporary structures without full compliance with the code requirements for permanently occupied structures. This section should not be confused with the scope of Section 3103, which regulates temporary structures larger than 120 square feet (11 m²) in area.

This section allows the building official to issue permits for temporary structures or uses. The applicant must specify the time period desired for the temporary structure or use, but the approval period cannot exceed 180 days. Structures or uses that are temporary but are anticipated to be in existence for more than 180 days are required to conform to code requirements for permanent structures and uses. The section also authorizes the building official to grant
extensions to this time period if the applicant can provide a valid reason for the extension, which typically includes circumstances beyond the applicant’s control. This provision is not intended to be used to circumvent the 180-day limitation.

[A] 108.2 Conformance. Temporary structures and uses shall conform to the structural strength, fire safety, means of egress, accessibility, light, ventilation and sanitary requirements of this code as necessary to ensure public health, safety and general welfare.

- This section prescribes those categories of the code that must be complied with, despite the fact that the structure will be removed or the use discontinued some time in the future. These criteria are essential for measuring the safety of any structure or use, temporary or permanent; therefore, the application of these criteria to a temporary structure cannot be waived.

“Structural strength” refers to the ability of the temporary structure to resist anticipated live, environmental and dead loads (see Chapter 16). It also applies to anticipated live and dead loads imposed by a temporary use in an existing structure.

“Fire safety” provisions are those required by Chapters 7, 8 and 9 invoked by virtue of the structure’s size, use or location on the property.

“Means of egress” refers to full compliance with Chapter 10.

“Accessibility” refers to full compliance with Chapter 11 for making buildings accessible to physically disabled persons, a requirement that is repeated in Section 1103.1.

“Light, ventilation and sanitary” requirements are those imposed by Chapter 12 of the code or applicable sections of the IPC or IMC.

[A] 108.3 Temporary power. The building official is authorized to give permission to temporarily supply and use power in part of an electric installation before such installation has been fully completed and the final certificate of completion has been issued. The part covered by the temporary certificate shall comply with the requirements specified for temporary lighting, heat or power in NFPA 70.

- Commonly, the electrical service on most construction sites is installed and energized long before all of the wiring is completed. This procedure allows the power supply to be increased as construction demands; however, temporary permission is not intended to waive the requirements set forth in NFPA 70. Construction power from the permanent wiring of the building does not require the installation of temporary ground-fault circuit-interrupter (GFCI) protection or the assured equipment grounding program, because the building wiring installed as required by the code should be as safe for use during construction as it would be for use after completion of the building.

[A] 108.4 Termination of approval. The building official is authorized to terminate such permit for a temporary structure or use and to order the temporary structure or use to be discontinued.

- This section provides the building official with the necessary authority to terminate the permit for a temporary structure or use. The building official can order that a temporary structure be removed or a temporary use be discontinued if conditions of the permit have been violated or the structure or use poses an imminent hazard to the public, in which case the provisions of Section 116 become applicable. This text is important because it allows the building official to act quickly when time is of the essence in order to protect public health, safety and welfare.

SECTION 109
FEES

[A] 109.1 Payment of fees. A permit shall not be valid until the fees prescribed by law have been paid, nor shall an amendment to a permit be released until the additional fee, if any, has been paid.

- The code anticipates that jurisdictions will establish their own fee schedules. It is the intent that the fees collected by the department for building permit issuance, plan review and inspection be adequate to cover the costs to the department in these areas. If the department has additional duties, then its budget will need to be supplemented from the general fund. This section requires that all fees be paid prior to permit issuance or release of an amendment to a permit. Since department operations are intended to be supported by fees paid by the user of department activities, it is important that these fees are received before incurring any expense. This philosophy has resulted in some departments having fees paid prior to the performance of two areas of work: plan review and inspection.

[A] 109.2 Schedule of permit fees. On buildings, structures, electrical, gas, mechanical, and plumbing systems or alterations requiring a permit, a fee for each permit shall be paid as required, in accordance with the schedule as established by the applicable governing authority.

- The jurisdiction inserts its desired fee schedule at this location. The fees are established by law, such as in an ordinance adopting the code (see page xv of the code for a sample), a separate ordinance or legally promulgated regulation, as required by state or local law. Fee schedules are often based on a valuation of the work to be performed. This concept is based on the proposition that the valuation of a project is related to the amount of work to be expended in plan review, inspections and administering the permit, plus an excess to cover the department overhead.

To assist jurisdictions in establishing some uniformity in fees, building evaluation data are published periodically in ICC’s Building Safety Journal.

[A] 109.3 Building permit valuations. The applicant for a permit shall provide an estimated permit value at time of
APPLICATION

Permit valuations shall include total value of work, including materials and labor, for which the permit is being issued, such as electrical, gas, mechanical, plumbing equipment and permanent systems. If, in the opinion of the building official, the valuation is underestimated on the application, the permit shall be denied, unless the applicant can show detailed estimates to meet the approval of the building official. Final building permit valuation shall be set by the building official.

As indicated in Section 109.2, jurisdictions usually base their fees on the value of the work being performed. This section, therefore, requires the applicant to provide this figure, which is to include the total value of the work, including materials and labor, for which the permit is sought. If the building official believes that the value provided by the applicant is underestimated, the permit is to be denied unless the applicant can substantiate the value by providing detailed estimates of the work to the satisfaction of the building official. For the construction of new buildings, the building valuation data referred to in Section 109.2 can be used by the building official as a yardstick against which to compare the applicant’s estimate.

[A] 109.4 Work commencing before permit issuance. Any person who commences any work on a building, structure, electrical, gas, mechanical or plumbing system before obtaining the necessary permits shall be subject to a fee established by the building official that shall be in addition to the required permit fees.

The building official will incur certain costs (i.e., inspection time and administrative) when investigating and citing a person who has commenced work without having obtained a permit. The building official is, therefore, entitled to recover these costs by establishing a fee, in addition to that collected when the required permit is issued, to be imposed on the responsible party. Note that this is not a penalty, as described in Section 114.4, for which the person can also be liable.

[A] 109.5 Related fees. The payment of the fee for the construction, alteration, removal or demolition for work done in connection to or concurrently with the work authorized by a building permit shall not relieve the applicant or holder of the permit from the payment of other fees that are prescribed by law.

The fees for a building permit may be in addition to other fees required by the jurisdiction or others for related items, such as sewer connections, water service taps, driveways and signs. It cannot be construed that the building permit fee includes these other items.

[A] 109.6 Refunds. The building official is authorized to establish a refund policy.

This section allows for a refund of fees, which may be full or partial, typically resulting from the revocation, abandonment or discontinuance of a building project for which a permit has been issued and fees have been collected. The refund of fees should be related to the cost of enforcement services not provided because of the termination of the project. The building official, when authorizing a fee refund, is authorizing the disbursement of public funds; therefore, the request for a refund must be in writing and for good cause.

SECTION 110
INSPECTIONS

[A] 110.1 General. Construction or work for which a permit is required shall be subject to inspection by the building official and such construction or work shall remain accessible and exposed for inspection purposes until approved. Approval as a result of an inspection shall not be construed to be an approval of a violation of the provisions of this code or of other ordinances of the jurisdiction. Inspections presuming to give authority to violate or cancel the provisions of this code or of other ordinances of the jurisdiction shall not be valid. It shall be the duty of the permit applicant to cause the work to remain accessible and exposed for inspection purposes. Neither the building official nor the jurisdiction shall be liable for expense entailed in the removal or replacement of any material required to allow inspection.

The inspection function is one of the more important aspects of building department operations. This section authorizes the building official to inspect the work for which a permit has been issued and requires that the work to be inspected remain accessible to the building official until inspected and approved. Any expense incurred in removing or replacing material that conceals an item to be inspected is not the responsibility of the building official or the jurisdiction. As with the issuance of permits (see Section 105.4), approval as a result of an inspection is not a license to violate the code and an approval in violation of the code does not relieve the applicant from complying with the code and is not valid.

[A] 110.2 Preliminary inspection. Before issuing a permit, the building official is authorized to examine or cause to be examined buildings, structures and sites for which an application has been filed.

The building official is granted authority to inspect the site before permit issuance. This may be necessary to verify existing conditions that impact the plan review and permit approval. This section provides the building official with the right-of-entry authority that otherwise does not occur until after the permit is issued (see Section 104.6).

[A] 110.3 Required inspections. The building official, upon notification, shall make the inspections set forth in Sections 110.3.1 through 110.3.10.

The building official is required to verify that the building is constructed in accordance with the approved
construction documents. It is the responsibility of the permit holder to notify the building official when the item is ready for inspection. The inspections that are necessary to provide such verification are listed in the following sections, with the caveat in Section 110.3.8 that inspections in addition to those listed here may be required depending on the work involved.

[A] 110.3.1 Footing and foundation inspection. Footing and foundation inspections shall be made after excavations for footings are complete and any required reinforcing steel is in place. For concrete foundations, any required forms shall be in place prior to inspection. Materials for the foundation shall be on the job, except where concrete is ready mixed in accordance with ASTM C 94, the concrete need not be on the job.

- It is necessary for the building official to inspect the soil upon which the footing or foundation is to be placed. This inspection also includes any reinforcing steel, concrete forms and materials to be used in the foundation, except for ready-mixed concrete that is prepared off site.

[A] 110.3.2 Concrete slab and under-floor inspection. Concrete slab and under-floor inspections shall be made after in-slab or under-floor reinforcing steel and building service equipment, conduit, piping accessories and other ancillary equipment items are in place, but before any concrete is placed or floor sheathing installed, including the subfloor.

- The building official must be able to inspect the soil and any required under-slab drainage, waterproofing or dampproofing material, as well as reinforcing steel, conduit, piping and other service equipment embedded in or installed below a slab prior to placing the concrete. Similarly, items installed below a floor system other than concrete must be inspected before they are concealed by the floor sheathing or subfloor.

[A] 110.3.3 Lowest floor elevation. In flood hazard areas, upon placement of the lowest floor, including the basement, and prior to further vertical construction, the elevation certification required in Section 1612.5 shall be submitted to the building official.

- Where a structure is located in a flood hazard area, as established in Section 1612.5, the building official must be provided with certification that either the lowest floor elevation (for structures located in flood hazard areas not subject to high-velocity wave action) or the elevation of the lowest horizontal structural member (for structures located in flood hazard areas subject to high-velocity wave action) is in compliance with Section 1612. This certification must be submitted prior to any construction proceeding above this level.

[A] 110.3.4 Frame inspection. Framing inspections shall be made after the roof deck or sheathing, all framing, fireblocking and bracing are in place and pipes, chimneys and vents to be concealed are complete and the rough electrical, plumbing, heating wires, pipes and ducts are approved.

- This section requires that the building official be able to inspect the framing members, such as studs, joists, rafters and girders and other items, such as vents and chimneys, that will be concealed by wall construction. Rough electrical work, plumbing, heating wires, pipes and ducts must have already been approved in accordance with the applicable codes prior to this inspection.

[A] 110.3.5 Lath and gypsum board inspection. Lath and gypsum board inspections shall be made after lathing and gypsum board, interior and exterior, is in place, but before any plastering is applied or gypsum board joints and fasteners are taped and finished.

  Exception: Gypsum board that is not part of a fire-resistance-rated assembly or a shear assembly.

- In order to verify that lath and gypsum board is properly attached to framing members, it is necessary for the building official to be able to conduct an inspection before the plaster or joint finish material is applied. This is required only for gypsum board that is part of either a fire-resistant assembly or a shear wall.

[A] 110.3.6 Fire- and smoke-resistant penetrations. Protection of joints and penetrations in fire-resistance-rated assemblies, smoke barriers and smoke partitions shall not be concealed from view until inspected and approved.

- The building official must have an opportunity to inspect joint protection required by Section 714 and penetration protection required by Section 713 for fire-resistance-rated assemblies, smoke barriers, and smoke partitions before they become concealed from view.

[A] 110.3.7 Energy efficiency inspections. Inspections shall be made to determine compliance with Chapter 13 and shall include, but not be limited to, inspections for: envelope insulation R- and U-values, fenestration U-value, duct system R-value, and HVAC and water-heating equipment efficiency.

- Items installed in a building that are required by the IECC to comply with certain criteria, such as insulation material, windows, HVAC and water-heating equipment, must be inspected and approved.

[A] 110.3.8 Other inspections. In addition to the inspections specified in Sections 110.3.1 through 110.3.7, the building official is authorized to make or require other inspections of any construction work to ascertain compliance with the provisions of this code and other laws that are enforced by the department of building safety.

- Any item regulated by the code is subject to inspection by the building official to determine compliance with the applicable code provision, and no list can include all items in a given building. This section, therefore, gives the building official the authority to inspect any regulated items.
[A] 110.3.9 Special inspections. For special inspections, see Chapter 17.

- Special inspections are to be provided by the owner for the types of work required in Section 1704. The building official is to approve special inspectors and verify that the required special inspections have been conducted. See the commentary to Section 1704 for a complete discussion of this topic.

[A] 110.3.10 Final inspection. The final inspection shall be made after all work required by the building permit is completed.

- Upon completion of the work for which the permit has been issued and before issuance of the certificate of occupancy required by Section 111.1, a final inspection is to be made. All violations of the approved construction documents and permit are to be noted and the holder of the permit is to be notified of the discrepancies.

[A] 110.3.10.1 Flood hazard documentation. If located in a flood hazard area, documentation of the elevation of the lowest floor as required in Section 1612.5 shall be submitted to the building official prior to the final inspection.

- The lowest floor inspection called for in Section 109.3.3 of the code requires submission of documentation of elevations upon placement of the lowest floor and prior to further vertical construction. The purpose for submission at that time is to confirm compliance at a point during construction when insufficient elevation can be corrected most readily. This proposal would require submission of elevation information when construction is completed. Work that is performed subsequent to the placement of the lowest floor may alter the reference level that is deemed the lowest floor. Building owners must provide this "as-built" documentation when they obtain federal flood insurance policies from the NFIP. Documentation of the "as-built" lowest floor elevations is required to be obtained and maintained by communities that participate in the NFIP. A building for which the community does not have this documentation is, by federal regulation, considered to be in violation of the minimum NFIP requirements (see definition of "violation" in 44 C.F.R. §59.2).

[A] 110.4 Inspection agencies. The building official is authorized to accept reports of approved inspection agencies, provided such agencies satisfy the requirements as to qualifications and reliability.

- As an alternative to the building official conducting the inspection, he or she is permitted to accept inspections of and reports by approved inspection agencies. Appropriate criteria on which to base approval of inspection agencies can be found in Section 1703.

[A] 110.5 Inspection requests. It shall be the duty of the holder of the building permit or their duly authorized agent to notify the building official when work is ready for inspection. It shall be the duty of the permit holder to provide access to and means for inspections of such work that are required by this code.

- It is the responsibility of the permit holder or other authorized person, such as the contractor performing the work, to arrange for the required inspections when completed work is ready and to allow for sufficient time for the building official to schedule a visit to the site to prevent work from being concealed prior to being inspected. Access to the work to be inspected must be provided, including any special means such as a ladder.

[A] 110.6 Approval required. Work shall not be done beyond the point indicated in each successive inspection without first obtaining the approval of the building official. The building official, upon notification, shall make the requested inspections and shall either indicate the portion of the construction that is satisfactory as completed, or notify the permit holder or his or her agent wherein the same fails to comply with this code. Any portions that do not comply shall be corrected and such portion shall not be covered or concealed until authorized by the building official.

- This section establishes that work cannot progress beyond the point of a required inspection without the building official's approval. Upon making the inspection, the building official must either approve the completed work or notify the permit holder or other responsible party of that which does not comply with the code. Approvals and notices of noncompliance must be in writing, as required by Section 104.4, to avoid any misunderstanding as to what is required. Any item not approved cannot be concealed until it has been corrected and approved by the building official.

SECTION 111
CERTIFICATE OF OCCUPANCY

[A] 111.1 Use and occupancy. No building or structure shall be used or occupied, and no change in the existing occupancy classification of a building or structure or portion thereof shall be made, until the building official has issued a certificate of occupancy therefor as provided herein. Issuance of a certificate of occupancy shall not be construed as an approval of a violation of the provisions of this code or of other ordinances of the jurisdiction.

Exception: Certificates of occupancy are not required for work exempt from permits under Section 105.2.

- This section establishes that a new building or structure cannot be occupied until a certificate of occupancy is issued by the building official, which reflects the conclusion of the work allowed by the building permit. Also, no change in occupancy of an existing building is permitted without first obtaining a certificate of occupancy for the new use.

The tool that the building official uses to control the uses and occupancies of various buildings and structures within the jurisdiction is the certificate of occupancy. It is unlawful to use or occupy a building or
structure unless a certificate of occupancy has been issued. Its issuance does not relieve the building owner from the responsibility for correcting any code violation that may exist.

The exception simply states that when work is not under the monitor of the building department, there is no need to deal with a certificate of occupancy.

[A] 111.2 Certificate issued. After the building official inspects the building or structure and finds no violations of the provisions of this code or other laws that are enforced by the department of building safety, the building official shall issue a certificate of occupancy that contains the following:

1. The building permit number.
2. The address of the structure.
3. The name and address of the owner.
4. A description of that portion of the structure for which the certificate is issued.
5. A statement that the described portion of the structure has been inspected for compliance with the requirements of this code for the occupancy and division of occupancy and the use for which the proposed occupancy is classified.
6. The name of the building official.
7. The edition of the code under which the permit was issued.
8. The use and occupancy, in accordance with the provisions of Chapter 3.
9. The type of construction as defined in Chapter 6.
10. The design occupant load.
11. If an automatic sprinkler system is provided, whether the sprinkler system is required.
12. Any special stipulations and conditions of the building permit.

The building official is required to issue a certificate of occupancy after a successful final inspection has been completed and all deficiencies and violations have been resolved. This section lists the information that must be included on the certificate. This information is useful to both the building official and the owner because it indicates the criteria under which the structure was evaluated and approved at the time the certificate was issued. This is important when applying Chapter 34 to existing buildings.

[A] 111.3 Temporary occupancy. The building official is authorized to issue a temporary certificate of occupancy before the completion of the entire work covered by the permit, provided that such portion or portions shall be occupied safely. The building official shall set a time period during which the temporary certificate of occupancy is valid.

The building official is permitted to issue a temporary certificate of occupancy for all or a portion of a building prior to the completion of all work. Such certification is to be issued only when the building or portion in question can be safely occupied prior to full completion. The certification is intended to acknowledge that some building features may not be completed even though the building is safe for occupancy, or that a portion of the building can be safely occupied while work continues in another area. This provision precludes the occupancy of a building or structure that does not contain all of the required fire protection systems and means of egress. Temporary certificates should be issued only when incidental construction remains, such as site work and interior work that is not regulated by the code and exterior decoration not necessary to the integrity of the building envelope. The building official should view the issuance of a temporary certificate of occupancy as substantial an act as the issuance of the final certificate. Indeed, the issuance of a temporary certificate of occupancy offers a greater potential for conflict because once the building or structure is occupied, it is very difficult to remove the occupants through legal means. The certificate must specify the time period for which it is valid.

[A] 111.4 Revocation. The building official is authorized to, in writing, suspend or revoke a certificate of occupancy or completion issued under the provisions of this code wherever the certificate is issued in error, or on the basis of incorrect information supplied, or where it is determined that the building or structure or portion thereof is in violation of any ordinance or regulation or any of the provisions of this code.

The building official is authorized to, in writing, suspend or revoke a certificate of occupancy or completion issued under the provisions of this code wherever the certificate is issued in error, or on the basis of incorrect information supplied, or where it is determined that the building or structure or portion thereof is in violation of any ordinance, regulation or any of the provisions of this code.

This section is needed to give the building official the authority to revoke a certificate of occupancy for the reasons indicated in the code text. The building official may also suspend the certificate of occupancy until all of the code violations are corrected.

SECTION 112
SERVICE UTILITIES

[A] 112.1 Connection of service utilities. No person shall make connections from a utility, source of energy, fuel or power to any building or system that is regulated by this code for which a permit is required, until released by the building official.

This section establishes the authority of the building official to approve utility connections to a building for items such as water, sewer, electricity, gas and steam, and to require their disconnection when hazardous conditions or emergencies exist.

The approval of the building official is required before a connection can be made from a utility to a building system that is regulated by the code, includ-
being those referenced in Section 101.4. This includes utilities supplying water, sewer, electricity, gas and steam services. For the protection of building occupants, including workers, such systems must have had final inspection approvals, except as allowed by Section 112.2 for temporary connections.

[A] 112.2 Temporary connection. The building official shall have the authority to authorize the temporary connection of the building or system to the utility source of energy, fuel or power.

- The building official is permitted to issue temporary authorization to make connections to the public utility system prior to the completion of all work. This acknowledges that, because of seasonal limitations, time constraints or the need for testing or partial operation of equipment, some building systems may be safely connected even though the building is not suitable for final occupancy. The temporary connection and utilization of connected equipment should be approved when the requesting permit holder has demonstrated to the building official's satisfaction that public health, safety and welfare will not be endangered.

[A] 112.3 Authority to disconnect service utilities. The building official shall have the authority to authorize disconnection of utility service to the building, structure or system regulated by this code and the referenced codes and standards set forth in Section 101.4 in case of emergency where necessary to eliminate an immediate hazard to life or property or when such utility connection has been made without the approval required by Section 112.1 or 112.2. The building official shall notify the serving utility, and wherever possible the owner and occupant of the building, structure or service system of the decision to disconnect prior to taking such action. If not notified prior to disconnecting, the owner or occupant of the building, structure or service system shall be notified in writing, as soon as practical thereafter.

- Disconnection of one or more of a building’s utility services is the most radical method of hazard abatement available to the building official and should be reserved for cases in which all other lesser remedies have proven ineffective. Such an action must be preceded by written notice to the utility and the owner and occupants of the building. Disconnection must be accomplished within the time frame established by the building official in the notice. When the hazard to the public health, safety or welfare is so imminent as to mandate immediate disconnection, the building official has the authority and even the obligation to cause disconnection without notice. In such cases, the owner or occupants must be given written notice as soon as possible.

SECTION 113
BOARD OF APPEALS

[A] 113.1 General. In order to hear and decide appeals of orders, decisions or determinations made by the building official relative to the application and interpretation of this code, there shall be and is hereby created a board of appeals. The board of appeals shall be appointed by the applicable governing authority and shall hold office at its pleasure. The board shall adopt rules of procedure for conducting its business.

- This section provides an aggrieved party with a material interest in the decision of the building official a process to appeal such a decision before a board of appeals. This provides a forum, other than the court of jurisdiction, in which to review the building official's actions.

Section 113 literally allows any person to appeal a decision of the building official. In practice, this section has been interpreted to permit appeals only by those aggrieved parties with a material or definitive interest in the decision of the building official. An aggrieved party may not appeal a code requirement per se. The intent of the appeal process is not to waive or set aside a code requirement; rather, it is intended to provide a means of reviewing a building official's decision on an interpretation or application of the code or to review the equivalency of protection to the code requirements. The members of the appeals board are appointed by the "governing body" of the jurisdiction, typically a council or administrator, such as a mayor or city manager, and remain members until removed from office. The board must establish procedures for electing a chairperson, scheduling and conducting meetings and administration. Note that Appendix B contains complete, detailed requirements for creating an appeals board, including number of members, qualifications and administrative procedures. Jurisdictions desiring to utilize these requirements must include Appendix B in their adopting ordinance.

[A] 113.2 Limitations on authority. An application for appeal shall be based on a claim that the true intent of this code or the rules legally adopted thereunder have been incorrectly interpreted, the provisions of this code do not fully apply or an equally good or better form of construction is proposed. The board shall have no authority to waive requirements of this code.

- This section establishes the grounds for an appeal, which claims that the building official has misinterpreted or misapplied a code provision. The board is not allowed to set aside any of the technical requirements of the code; however, it is allowed to consider alternative methods of compliance with the technical requirements (see Section 104.11).

[A] 113.3 Qualifications. The board of appeals shall consist of members who are qualified by experience and training to pass on matters pertaining to building construction and are not employees of the jurisdiction.

- It is important that the decisions of the appeals board are based purely on the technical merits involved in an appeal. It is not the place for policy or political deliberations. The members of the appeals board are, therefore, expected to have experience in build-
ing construction matters. Appendix B provides more
detailed qualifications for appeals board members
and can be adopted by jurisdictions desiring that level
of expertise.

SECTION 114
VIOLATIONS

[A] 114.1 Unlawful acts. It shall be unlawful for any person,
firm or corporation to erect, construct, alter, extend, repair,
moving, remove or demolish or occupy any building, structure or
equipment regulated by this code, or cause same to be done,
in conflict with or in violation of any of the provisions of this
code.

- Violations of the code are prohibited and form the
  basis for all citations and correction notices.

[A] 114.2 Notice of violation. The building official is au-
thorized to serve a notice of violation or order on the person
responsible for the erection, construction, alteration, exten-
sion, repair, moving, removal, demolition or occupancy of a
building or structure in violation of the provisions of this
code, or in violation of a permit or certificate issued under the
provisions of this code. Such order shall direct the discontinu-
ance of the illegal action or condition and the abatement of
the violation.

- The building official is required to notify the person
  responsible for the erection or use of a building found
  to be in violation of the code. The section that is alleg-
  edly being violated must be cited so that the respon-
sible party can respond to the notice.

[A] 114.3 Prosecution of violation. If the notice of violation
is not complied with promptly, the building official is au-
thorized to request the legal counsel of the jurisdiction to insti-
tute the appropriate proceeding at law or in equity to restrain,
correct or abate such violation, or to require the removal or
termination of the unlawful occupancy of the building or
structure in violation of the provisions of this code or of the
order or direction made pursuant thereto.

- The building official must pursue, through the use of
  legal counsel of the jurisdiction, legal means to cor-
  rect the violation. This is not optional.

  Any extensions of time, so that the violations may
  be corrected voluntarily, must be for a reasonable
  and valid cause or the building official may be subject
to criticism for "arbitrary and capricious" actions. In
general, it is better to have a standard time limitation
for correction of violations. Departures from this stan-
dard must be for a clear and reasonable purpose,
usually stated in writing by the violator.

[A] 114.4 Violation penalties. Any person who violates a
provision of this code or fails to comply with any of the
requirements thereof or who erects, constructs, alters or
repairs a building or structure in violation of the approved
construction documents or directive of the building official,
or of a permit or certificate issued under the provisions of this
code, shall be subject to penalties as prescribed by law.

- Penalties for violating provisions of the code are typi-
cally contained in state law, particularly if the code is
adopted at that level, and the building department
must follow those procedures. If there is no such pro-
cedure already in effect, one must be established
with the aid of legal counsel.

SECTION 115
STOP WORK ORDER

[A] 115.1 Authority. Whenever the building official finds
any work regulated by this code being performed in a manner
either contrary to the provisions of this code or dangerous or
unsafe, the building official is authorized to issue a stop work
order.

- Whenever the building official finds any work regu-
lated by this code being performed in a manner either
contrary to the provisions of this code or dangerous or
unsafe, the building official is authorized to issue a
stop work order.

  This section provides for the suspension of work for
which a permit was issued, pending the removal or
correction of a severe violation or unsafe condition
identified by the building official.

  Normally, correction notices, issued in accordance
with Section 110.6, are used to inform the permit
holder of code violations. Stop work orders are issued
when enforcement can be accomplished no other
way or when a dangerous condition exists.

[A] 115.2 Issuance. The stop work order shall be in writing
and shall be given to the owner of the property involved, or to
the owner's agent, or to the person doing the work. Upon issu-
ance of a stop work order, the cited work shall immediately
cease. The stop work order shall state the reason for the order,
and the conditions under which the cited work will be permit-
ted to resume.

- Upon receipt of a violation notice from the building
  official, all construction activities identified in the
  notice must immediately cease, except as expressly
  permitted to correct the violation.

[A] 115.3 Unlawful continuance. Any person who shall con-
tinue any work after having been served with a stop work
order, except such work as that person is directed to perform
to remove a violation or unsafe condition, shall be subject to
penalties as prescribed by law.

- This section states that the work in violation must ter-
minate and that all other work, except that which is
necessary to correct the violation or unsafe condition,
must cease as well. As determined by the municipal-
ity or state, a penalty may be assessed for failure to
comply with this section.
SECTION 116
UNSAFE STRUCTURES AND EQUIPMENT

[A] 116.1 Conditions. Structures or existing equipment that are or hereafter become unsafe, insanitary or deficient because of inadequate means of egress facilities, inadequate light and ventilation, or which constitute a fire hazard, or are otherwise dangerous to human life or the public welfare, or that involve illegal or improper occupancy or inadequate maintenance, shall be deemed an unsafe condition. Unsafe structures shall be taken down and removed or made safe, as the building official deems necessary and as provided for in this section. A vacant structure that is not secured against entry shall be deemed unsafe.

- This section describes the responsibility of the building official to investigate reports of unsafe structures and equipment and provides criteria for such determination.

Unsafe structures are defined as buildings or structures that are insanitary; deficient in light and ventilation or adequate egress facilities; constitute a fire hazard or are otherwise dangerous to human life.

This section establishes that unsafe buildings can result from illegal or improper occupancies. For example, prima facie evidence of an unsafe structure is an unsecured (open at door or window) vacant building. All unsafe buildings must either be demolished or made safe and secure as deemed appropriate by the building official.

[A] 116.2 Record. The building official shall cause a report to be filed on an unsafe condition. The report shall state the occupancy of the structure and the nature of the unsafe condition.

- The building official must file a report on each investigation of unsafe conditions, stating the occupancy of the structure and the nature of the unsafe condition. This report provides the basis for the notice described in Section 116.3.

[A] 116.3 Notice. If an unsafe condition is found, the building official shall serve on the owner, agent or person in control of the structure, a written notice that describes the condition deemed unsafe and specifies the required repairs or improvements to be made to abate the unsafe condition, or that requires the unsafe structure to be demolished within a stipulated time. Such notice shall require the person thus notified to declare immediately to the building official acceptance or rejection of the terms of the order.

- The building official must file a report on each investigation of unsafe conditions, stating the occupancy of the structure and the nature of the unsafe condition. This report provides the basis for the notice described in Section 116.3.

[A] 116.4 Method of service. Such notice shall be deemed properly served if a copy thereof is (a) delivered to the owner personally; (b) sent by certified or registered mail addressed to the owner at the last known address with the return receipt requested; or (c) delivered in any other manner as prescribed by local law. If the certified or registered letter is returned showing that the letter was not delivered, a copy thereof shall be posted in a conspicuous place in or about the structure affected by such notice. Service of such notice in the foregoing manner upon the owner's agent or upon the person responsible for the structure shall constitute service of notice upon the owner.

- The notice must be delivered personally to the owner. If the owner or agent cannot be located, additional procedures are established, including posting the unsafe notice on the premises in question. Such action may be considered the equivalent of personal notice; however, it may or may not be deemed by the courts as representing a "good faith" effort to notify. In addition to complying with this section, therefore, public notice through the use of newspapers and other postings in a prominent location at the government center should be used.

[A] 116.5 Restoration. The structure or equipment determined to be unsafe by the building official is permitted to be restored to a safe condition. To the extent that repairs, alterations or additions are made or a change of occupancy occurs during the restoration of the structure, such repairs, alterations, additions or change of occupancy shall comply with the requirements of Section 105.2.2 and Chapter 34.

- This section provides that unsafe structures may be restored to a safe condition. This means that the cause of the unsafe structure notice can be abated without the structure being required to comply fully with the provisions for new construction. Any work done to eliminate the unsafe condition, as well as any change in occupancy that may occur, must comply with the code.

Bibliography

The following resource materials are referenced in this chapter or are relevant to the subject matter addressed in this chapter.

Chapter 2: Definitions

General Comments

Nearly all terms defined in the code are listed and defined in Chapter 2. While many terms are used primarily in one chapter or another, the vast majority of terms are used outside of their chapter of primary significance. An example would be the term "fire barrier." The requirements for the construction of a fire barrier are found in Section 708, but fire barriers are required to provide fire-resistive separations by such diverse Sections as 508.4 for separated mixed occupancies, and 1022 for the enclosure of interior exit stairways.

There are some terms which have definitions that are specifically limited to the use of the term in a specific chapter or section of the code. This chapter specifically states where this is the case. There are other terms that have more than one definition. For example, "basement" is defined for general application, but is also defined differently for application of flood plain hazard regulation in Section 1612.

This chapter only provides a reference to definitions which, in Chapter 19, are amended versions of definitions in a referenced standard.

Purpose

Codes, by their very nature, are technical documents. As such, literally every word, term and punctuation mark can add to or change the meaning of the intended result. This is even more so with a performance-based code where the desired result often takes on more importance than the specific words. Furthermore, the code, with its broad scope of applicability, includes terms inherent in a variety of construction disciplines. These terms often have multiple meanings depending on the context or discipline being used at the time. For these reasons, it is necessary to maintain a consensus on the specific meaning of terms contained in the code. Chapter 2 performs this function by stating clearly what specific terms mean for the purpose of the code.

SECTION 201
GENERAL

This section contains language and provisions that are supplemental to the use of Chapter 2. It gives guidance to the use of the defined words relevant to tense, gender and plurality. Finally, this section provides direction on how to apply terms that are not defined in the code.

201.1 Scope. Unless otherwise expressly stated, the following words and terms shall, for the purposes of this code, have the meanings shown in this chapter.

The use of words and terms in the code is governed by the provisions of this section. This includes code-defined terms as well as those terms that are not.

201.2 Interchangeability. Words used in the present tense include the future; words stated in the masculine gender include the feminine and neuter; the singular number includes the plural and the plural, the singular.

While the definitions contained in Chapter 2 are to be taken literally, gender and tense are interchangeable.

201.3 Terms defined in other codes. Where terms are not defined in this code and are defined in the International Energy Conservation Code, International Fuel Gas Code, International Fire Code, International Mechanical Code or International Plumbing Code, such terms shall have the meanings ascribed to them as in those codes.

Definitions that are applicable in other International Codes® (I-Codes®) are applicable everywhere the term is used in the code. Definitions of terms can help in the understanding and application of code requirements.

201.4 Terms not defined. Where terms are not defined through the methods authorized by this section, such terms shall have ordinarily accepted meanings such as the context implies.

Words or terms not defined within the I-Code series are intended to be applied based on their "ordinarily accepted meanings." The intent of this statement is that a dictionary definition may suffice, provided it is in context. Often times, construction terms used throughout the code are not specifically defined in the code or even in a dictionary. In such a case, the definitions contained in the referenced standards (see Chapter 35) and published textbooks on the subject in question are good resources.
DEFINITIONS

SECTION 202
DEFINITIONS

24-HOUR CARE. The actual time that a person is an occupant within a facility for the purpose of receiving care. It shall not include a facility that is open for 24 hours and is capable of providing care to someone visiting the facility during any segment of the 24 hours.

- 24-hour care is used to differentiate groups and levels of protection between institutional facilities that typically house patients for more than a day, such as hospitals, detoxification facilities, foster care and nursing homes, and other care facilities that keep patients for only part of a day, such as day cares, clinics, day surgery centers and outpatient facilities. To better understand how these concepts work together, see the definitions for "Ambulatory care center," "Custodial care," "Personal care," "Medical care" and "Incapable of self-preservation." Facilities that have patients/residents/customers that typically stay for 24 hours or more are 24-hour care facilities. However, a facility such as a day care, that operates on a 24-hour basis, would not be considered a 24-hour care facility if the clients did not stay 24 hours, but instead were in and out of the facility similar to one that closed for the night.

AAC MASONRY. Masonry made of autoclaved aerated concrete (AAC) units, manufactured without internal reinforcement and bonded together using thin- or thick-bed mortar.

- This definition establishes that the requirements of Chapter 21 apply to masonry units manufactured from autoclaved aerated concrete (AAC). AAC masonry units are low-density cementitious products first introduced into the 2005 edition of the Building Requirements Code for Masonry Structures (TMS 402/ACI 530/ASCE 5) and Specifications for Masonry Structures (TMS 602/ACI 530.1/ASCE 6), although its use has been prevalent in other countries for several decades. Besides being a relatively lightweight product, AAC is also considered to provide good thermal and acoustic insulation. AAC masonry units are bonded together using a thin-bed polymer mortar specifically manufactured for use with AAC masonry.

ACCESSIBLE. A site, building, facility or portion thereof that complies with Chapter 11.

- This definition identifies the fundamental concept of Chapter 11. Accessibility is deemed to be accomplished if a building, site or facility complies with the applicable provisions of the code and ICC A117.1. It is not the intent of the code to accommodate fully every type and range of disability, as it would not be feasible to do so. The extent to which the code requires accessible features in the various occupancies covered by Chapter 11 (scoping) and the characteristics those features are required to meet through reference to ICC A117.1 (technical requirements) establish that which the code considers accessible.

ACCESSIBLE MEANS OF EGRESS. A continuous and unobstructed way of egress travel from any accessible point in a building or facility to a public way.

- Accessible means of egress requirements are needed to provide those persons with physical disabilities or mobility impairments a means of egress to exit the building. Because of physical limitations, some occupants may need assistance to exit a building. See Section 1007 for requirements establishing areas where people can safely wait for assisted rescue. Chapter 4 of the IFC also includes requirements in the fire safety and evacuation plans for specific planning to address occupants who may need assistance in evacuation during emergencies. In addition, Chapter 9 of the code includes requirements for emergency evacuation notification for persons with hearing and vision disabilities.

The accessible means of egress requirements may not be the same route as that required for ingress into the building (see Sections 1104 and 1105). For example, a two-story building requires one accessible route to connect all accessible spaces within the building. The accessible route to the second level is typically by an elevator. During a fire emergency, persons with mobility impairments on the second level would be moving to the exit stairways for assisted rescue, not back to the way they came onto the level, via the elevator.

ACCESSIBLE ROUTE. A continuous, unobstructed path that complies with Chapter 11.

- An accessible route enables a person with a disability to approach and utilize a facility's accessible fixtures and features. While there are a variety of mobility devices, the design and construction of an accessible route is based predominantly on provisions necessary for accessibility to a person using a wheelchair. There are typically more physical barriers in the built environment to people with a mobility impairment than in any other category of disability. An accessible route must also be safe and usable by people with other disabilities and, therefore, requirements are set forth in consideration of those needs. For example, there are restrictions on objects that protrude into an accessible route in consideration of a person with a visual impairment. Accessible routes are required for both ingress and egress (see Sections 1007 and 1104).

ACCESSIBLE UNIT. A dwelling unit or sleeping unit that complies with this code and the provisions for Accessible units in ICC A117.1.

- There are three levels of accessibility described in the code pertaining to dwelling units: Accessible units (always spelled with a capital "A"), Type A units and Type B units. Accessible units are required to be constructed as fully accessible, meaning all required features are present at first occupancy. Unlike Type A and Type B units, Accessible units have no features left as adaptable. Accessible units provide a "higher"
level of accessibility than Type A and Type B units and are mandated in all Group I occupancies (as a percentage), in Group R-1 occupancies (per Table 1107.6.1.1), in most Group R-2 congregate living (per Table 1107.6.1.1) and in Group R-4 (at least one unit). The technical criteria for Accessible dwelling units are identified in Section 1002 of the 2003 and 2009 ICC A117.1, whereas in the 1998 ICC A117.1, they were spread throughout Chapters 1 through 9. Also see the commentary for the definitions of "Dwelling unit" and "Sleeping unit" and to Section 1107.2.

**ACREDITATION BODY.** An approved, third-party organization that is independent of the grading and inspection agencies, and the lumber mills, and that initially accredits and subsequently monitors, on a continuing basis, the competency and performance of a grading or inspection agency related to carrying out specific tasks.

- The process of determining the grade of lumber not only includes the actual method of applying the grade stamp to the product, but also the certification of the grading agency and its methods of quality control, its rules and the work of its agents. For example, an independent third-party quality control program meeting the accreditation requirements of the American Lumber Standard Committee, Inc. (ALS/C) or an equivalent process is required for all softwood lumber that is to be graded for use in construction in the United States.

**ADDITON.** An extension or increase in floor area or height of a building or structure.

- This term is used to describe the condition when the floor area or height of an existing building or structure is increased (see Chapter 34). This term is only applicable to existing buildings, never new ones. This would include additional floor area that is added within an existing building, such as adding a new mezzanine.

**ADHERED MASONRY VENEER.** Veneer secured and supported through the adhesion of an approved bonding material applied to an approved backing.

- This type of masonry veneer relies on the backing surface for both vertical and lateral load resistance. The components of adhered masonry veneer construction generally include the masonry veneer, the adhering material and the backing to which the veneer is attached. It should be noted that the term "approve" means components are subject to approval by the building official or the authority having jurisdiction, in accordance with Section 104.

**ADOBE CONSTRUCTION.** Construction in which the exterior load-bearing and non-load-bearing walls and partitions are of unfired clay masonry units, and floors, roofs and interior framing are wholly or partly of wood or other approved materials.

Adobe, stabilized. Unfired clay masonry units to which admixtures, such as emulsified asphalt, are added during the manufacturing process to limit the units' water absorption so as to increase their durability.

Adobe, unstabilized. Unfired clay masonry units that do not meet the definition of "Adobe, stabilized."

- Adobe masonry was popular in the southwest United States due to the availability of soil for units, the frequent exposure to intense sunlight to dry the units, the thermal mass provided by the completed adobe structure and the low cost of this form of construction. This form of construction has relatively low strength, a lack of formalized design procedures and labor-intensive manufacture of units and construction of the building; thus, it has not been used as much in recent years.

Two types of adobe masonry, stabilized and unstabilized, are briefly described. Prescriptive design requirements for adobe masonry are contained in Section 2109.3.

In stabilized adobe, admixtures are used to produce more durable units (see Section 2109.3.2).

Unstabilized adobe does not contain stabilizers in the soil and is, therefore, not as durable as stabilized adobe (see Section 2109.3.1).

**[F] AEROSOL.** A product that is dispensed from an aerosol container by a propellant. Aerosol products shall be classified by means of the calculation of their chemical heats of combustion and shall be designated Level 1, Level 2 or Level 3.

- Level 1 aerosol products. Those with a total chemical heat of combustion that is less than or equal to 8,600 British thermal units per pound (Btu/lb) (20 kJ/g).

- Level 2 aerosol products. Those with a total chemical heat of combustion that is greater than 8,600 Btu/lb (20 kJ/g), but less than or equal to 13,000 Btu/lb (30 kJ/g).

- Level 3 aerosol products. Those with a total chemical heat of combustion that is greater than 13,000 Btu/lb (30 kJ/g).

- The intent of the code is to regulate those aerosols that contain a flammable propellant, such as butane, isobutane or propane. An aerosol product such as whipped cream is a water-based material with a non-flammable propellant (nitrous oxide) and would, therefore, not be regulated as a hazardous material. The contents of the aerosol container may be dispensed in the form of a mist spray, foam, gel or aerated powder.

Because of the wide range of flammability of aerosol products, a classification system was established to determine the required level of fire protection. Categories are defined according to the aerosol's chemical heat of combustion expressed in Btu per pound (Btu/lb). Aerosol category classifications of Levels 1, 2 and 3 are used to avoid confusion with flammable liquid classifications.

Examples of Level 1 aerosol products are shaving gel, whipped cream and air fresheners. Level 1 aerosols are not regulated as a hazardous material and...
are essentially exempt from the requirements of Sections 307 and 414. Examples of Level 2 aerosols include some hair sprays and insect repellents. Level 3 aerosols include carburetor cleaner and other petroleum-based aerosols.

While aerosols are defined as hazardous materials, note that they are not listed in Table 307.1(1) or 307.1(2) as having a maximum allowable quantity per control area. As stated in Exception 11 to Section 307.1, a building or structure used for aerosol storage is classified as Group S-1, provided the requirements of the IFC are satisfied; therefore, the Group H classification is not utilized since the design must satisfy the IFC in order to be in compliance.

[F] AEROSOL CONTAINER. A metal can or a glass or plastic bottle designed to dispense an aerosol. Metal cans shall be limited to a maximum size of 33.8 fluid ounces (1000 ml). Glass or plastic bottles shall be limited to a maximum size of 4 fluid ounces (118 ml).

- All design criteria for the aerosol container, including the maximum size and minimum strength, are set by the U.S. Department of Transportation (DOT) 49 CFR. These container regulations are essential for safe transportation of aerosol products.

AGGREGATE. In roofing, crushed stone, crushed slag or water-worn gravel used for surfacing for roof coverings.

- Aggregate is gravel, stone or slag used as a roof surfacing to provide a walking surface and protection to the roof covering. An aggregate typically is not used as a ballast material based on its small size.

AGRICULTURAL BUILDING. A structure designed and constructed to house farm implements, hay, grain, poultry, livestock or other horticultural products. This structure shall not be a place of human habitation or a place of employment where agricultural products are processed, treated or packaged, nor shall it be a place used by the public.

- This definition is needed for the proper application of the utility and miscellaneous occupancy group and Appendix C provisions. The use of the building is quite restricted such that buildings that include habitable or public spaces are not agricultural buildings by definition.

AIR-INFLATED STRUCTURE. A structure that uses air-pressurized membrane beams, arches or other elements to enclose space. Occupants of such a structure do not occupy the pressurized area used to support the structure.

- This type of membrane structure is characterized by multiple layers arranged such that air-pressurized membrane beams, arches or similar elements are formed. These elements are pressurized with air and form the membrane structure. Note that the occupants of the structure are not subjected to the pressurized areas, because the pressurization is in the structural elements, not within the space used by the occupants.

AIR-SUPPORTED STRUCTURE. A structure wherein the shape of the structure is attained by air pressure and occupants of the structure are within the elevated pressure area. Air-supported structures are of two basic types:

**Double skin.** Similar to a single skin, but with an attached liner that is separated from the outer skin and provides an airspace which serves for insulation, acoustic, aesthetic or similar purposes.

**Single skin.** Where there is only the single outer skin and the air pressure is directly against that skin.

- An air-supported structure identifies those membrane structures that are completely pressurized for the purposes of supporting the membrane covering. Most “domed” sports arenas use air pressure within the structure to support the membrane covering. The membrane covering can consist of one layer or multiple layers; thus, air-supported structures are classified as either “single skin” or “double skin.”

A double-skin, air-supported structure contains multiple layers of membrane sheathing. The membranes are usually separated by enough distance to allow for pressurized air or other materials to be inserted between the layers. The pressurized air or other materials usually serve to increase the insulating and acoustical properties.

A single-skin, air-supported structure consists of just one membrane covering that is directly supported by the interior pressurized air. No other membranes are provided for insulating or acoustical purposes. If the membrane covering consists of several laminated plies, such an arrangement is still considered a single-skin, air-supported structure.

AISLE. An unenclosed exit access component that defines and provides a path of egress travel.

- Aisles and aisle accessways are both utilized as part of the means of egress in facilities where tables, seats, displays or other furniture may limit the path of travel. The aisle accessways lead to the main aisles that lead to the exits from the space and building (see Figure 202.1(1)). While both may result in a confined path of travel, an aisle is an unenclosed component, while a corridor would be an enclosed component of the means of egress (see Sections 1017 and 1028 for requirements for aisles).

AISLE ACCESSWAY. That portion of an exit access that leads to an aisle.

- As illustrated in Figure 202.1(1), an aisle accessway is intended for one-way travel or limited two-way travel. The space between tables, seats, displays or other furniture (i.e., aisle accessway) utilized for means of egress will lead to a main aisle (see Sections 1017 and 1028 for requirements for aisle accessways).

[F] ALARM NOTIFICATION APPLIANCE. A fire alarm system component such as a bell, horn, speaker, light or text display that provides audible, tactile or visible outputs, or any combination thereof.

- The code requires that fire alarm systems be equipped with approved alarm notification appliances.
so that in an emergency, the fire alarm system will notify the occupants of the need for evacuation or implementation of the fire emergency plan. Alarm notification devices required by the code are of two general types: visible and audible. Except for emergency voice/alarms communication systems, once the fire alarm system has been activated, all visible and audible communication alarms are required to activate. Emergency voice/alarms communication systems are special signaling systems that are activated selectively in response to specific emergency conditions but have the capability to be activated throughout the building if necessary.

[F] ALARM SIGNAL. A signal indicating an emergency requiring immediate action, such as a signal indicative of fire.

- This is a general term for all types of supervisory and trouble signals. An example would be a supervisory (tamper) switch on a sprinkler control valve. It could also be the response to a specific device that is not part of the alarm notification system but that causes a specific function such as a smoke detector for elevator recall. The activation of the device does not necessarily indicate that there is a fire; however, the level of protection may have been compromised (see the definition of "Fire alarm signal").

[F] ALARM VERIFICATION FEATURE. A feature of automatic fire detection and alarm systems to reduce unwanted alarms wherein smoke detectors report alarm conditions for a minimum period of time, or confirm alarm conditions within a given time period, after being automatically reset, in order to be accepted as a valid alarm-initiation signal.

- False fire (evacuation) alarms are a nuisance. For this reason the code specifies that alarms activated by smoke detectors are not to be sounded until the alarm signal is verified by cross-zoned detectors in a single protected area or by system features that will retard the alarm until the signal is determined to be valid. Valid alarm initiation signals can be determined by detectors that report alarm conditions for a minimum period of time or that, after being reset, continue to report an alarm condition. The alarm verification feature may not retard signal activation for a period of more than 60 seconds and must not apply to alarm-initiating devices other than smoke detectors (which may be connected to the same circuit). Alarm verification is not the same as presignal features that delay an alarm signal for more than 1 minute and that are allowed only where specifically permitted by the authority having jurisdiction.

ALLOWABLE STRESS DESIGN. A method of proportioning structural members, such that elastically computed stresses produced in the members by nominal loads do not exceed specified allowable stresses (also called "working stress design").

- This definition describes the allowable stress design (ASD) method, which is one of the design approaches recognized under the code in Section 1604.1. In this approach, the computed stresses determined from the unfactored, or "nominal loads" (see the definition for "Nominal loads") cannot exceed allowable stresses, which provide a factor of safety. The material chapters of the code specify either the allowable stresses for a given material or, in some cases, provide allowable capacities of specific assemblies, such as the wood structural panel shear wall capacities specified in Chapter 23.

[A] ALTERATION. Any construction or renovation to an existing structure other than repair or addition.

- The code utilizes this term to reflect construction operations intended for an existing building (see Chapter 34), but not within the scope of an addition or repair (see the definitions of "Addition" and "Repair").

ALTERNATING TREAD DEVICE. A device that has a series of steps between 50 and 70 degrees (0.87 and 1.22 rad) from horizontal, usually attached to a center support rail in an alternating manner so that the user does not have both feet on the same level at the same time.

- An alternating tread device is commonly used in areas that would otherwise be provided with a ladder where there is not adequate space for a full stairway. Where these devices are permitted is specifically listed in the code (i.e., Section 1015.3). The device is
used extensively in industrial facilities for worker access to platforms or equipment. Requirements are found with stairways in Section 1009.

**AMBULATORY CARE FACILITY.** Buildings or portions thereof used to provide medical, surgical, psychiatric, nursing or similar care on a less than 24-hour basis to individuals who are rendered *incapable of self-preservation* by the services provided.

- The code provides different requirements for outpatient clinics, ambulatory care facilities and hospitals. Ambulatory care facilities, while still classified as a Group B occupancy, have additional standards above those of an outpatient clinic because its patients are temporarily unable to respond to emergencies due to treatment processes (see commentary, Section 422). Ambulatory care facilities include day surgery centers and similar facilities where patients may receive fairly intensive treatment, but do not stay at the facility more than a few hours. If patients are receiving 24-hour care, such facilities would be defined as hospitals.

**ANCHOR.** Metal rod, wire or strap that secures *masonry* to its structural support.

- Masonry anchors are fasteners connecting two components. Figure 202.1(2) shows examples of anchor bolts that can be used in masonry. Figure 202.1(3) shows some uses of anchor bolts to connect wood floors and masonry walls.

  Anchors are often used to connect masonry walls to adjoining walls, floors, roofs or the foundation below. Requirements for strength and durability of metal anchors are given in the provisions that are referenced in Section 2103.14.
ANCHOR BUILDING. An exterior perimeter building of a group other than H having direct access to a covered or open mall building but having required means of egress independent of the mall.

- A key to understanding what distinguishes an anchor building from a tenant space is that anchor buildings are typically retail establishments (Group M), although this may not always be the case. The anchor building is typically some facility that, by its nature, draws a considerable number of people. The tenants in the adjoining covered or open mall building then seek to capitalize on this traffic generated by the anchor building. The scale or size of the building is not a primary factor in determining whether it is an anchor building; rather, its function is such that it draws people to the site in sufficient numbers so that other facilities can benefit from being located in the same facility [see Figure 202.1(4)].

Generally, the anchor building will have its own identity and there is a high probability that it will have separate management and its own hours of operation. This will necessitate a means of egress that does not rely on the mall being available for its patrons to enter or leave. Similarly, the means of egress from the covered or open mall building cannot rely on the anchor building being open and available for patrons to exit through; hence, egress facilities for the anchor building must be independent of those for the covered or open mall building. An anchor building is a separate building from the covered or open mall building and must comply with the provisions of the code for its own identity, except as modified by Section 402 (see Sections 402.4 and 402.4.2.2.1).

ANCHORED MASONRY VENEER. Veneer secured with approved mechanical fasteners to an approved backing.

- This type of masonry veneer is generally supported from below and anchored to the sheathing, studs or other structural portion of the wall. Veneers provide little, if any, strength to the wall and are, therefore, considered to be nonstructural. Anchored masonry veneer is unique in that it is usually supported from below by a footing, lintels or shelf angles. Anchored masonry veneer must not, however, support loads other than its own dead loads, wind loads and seismic loads resulting from the dead load of the wall.

ANNULAR SPACE. The opening around the penetrating item.

- The annular space is the space created between the outer surface of a penetrating item and the construction penetrated. If left unfilled, the space can provide a means of free passage for smoke, fire and products of combustion [see Figure 202.1(5) for an example of an annular space]. Sections 714.3.1, 714.3.2,
DEFINITIONS

714.4.1.1 and 714.4.1.2 contain the requirements for protection of annular spaces. Tested and listed through-penetration firestop systems (see Sections 714.3.1.2 and 714.4.1.1.2), which are commonly used to seal these annular spaces, generally specify maximum and minimum allowable annular spaces, neither of which must be exceeded in order to ensure that the intended fire-resistance rating is achieved. The minimum and maximum annular space for a penetrating item is frequently not equal, as penetrating items are often located eccentrically in the hole (i.e., not perfectly centered).

[A] APPROVED AGENCY. An established and recognized agency regularly engaged in conducting tests or furnishing inspection services, when such agency has been approved.

- In order to identify the basic criteria or understand what agencies are being referred to in Section 1703, there is a need to define the term “approved agency.” The word “approved” means “acceptable to the building official” (see the definition of “Approved”). The basis for the building official’s approval of any agency for a particular activity may include, but is not necessarily limited to, the capacity and capability of the agency to perform the work in accordance with Section 1705 and other applicable sections. This is typically done through a review of the résumés and references of the agency and its personnel.

APPROVED FABRICATOR. An established and qualified person, firm or corporation approved by the building official pursuant to Chapter 17 of this code.

- An approved fabricator is one who has received approval to perform work without a code-required special inspection. The approval is based upon review of the fabricator’s written procedural and quality-control manuals, and periodic auditing of fabrication practices by an approved special inspection agency.

APPROVED SOURCE. An independent person, firm or corporation, approved by the building official, who is competent and experienced in the application of engineering principles to materials, methods or systems analyses.

- The building official sometimes needs to rely on evaluation reports, analyses or other types of reports that purport to validate the use of a material, system or method as complying with the code. This definition establishes that the building official needs to rely on independent, competent individuals or agencies as the source of these reports.

ARCHITECTURAL TERRA COTTA. Plain or ornamental hard-burned modified clay units, larger in size than brick, with glazed or unglazed ceramic finish.

- Architectural terra cotta refers to fired clay units with architectural shape and fired glazed coating. While rarely used today in new construction, repairs to terra cotta in existing building construction are not uncommon. These clay masonry units are usually produced for custom-made, anchored, ornamental veneers.

AREA (for masonry).

Cross cross-sectional. The area delineated by the out-to-out specified dimensions of masonry in the plane under consideration.

Net cross-sectional. The area of masonry units, grout and mortar crossed by the plane under consideration based on out-to-out specified dimensions.

- Various areas are used for structural calculations in Chapter 21. It is important to use the appropriate areas required by the code, since they may give dramatically different results.

[F] ANNUNCIATOR. A unit containing one or more indicator lamps, alphanumeric displays or other equivalent means in which each indication provides status information about a circuit, condition or location.

- This refers to the panel that displays the status of the monitored fire protection systems and devices. It is not the fire alarm control unit; however, the control panel may include an annunciator.

[A] APPROVED. Acceptable to the building official or authority having jurisdiction.

- As related to the process of acceptance of building installations, including materials, equipment and construction systems, this definition identifies where the ultimate authority rests. Whenever this term is used, it intends that only the enforcing authority can accept a specific installation or component as complying with the code. For the International Building Code, the building official is identified as the person responsible for administering its provisions.
The gross cross-sectional area of the masonry is the specified masonry width (thickness) multiplied by the specified length, as illustrated in Figure 202.1(6). While subtraction of core areas of the masonry unit is not required, the space between wythes must be discounted in noncomposite walls. Empirical compressive stress design is based on the gross cross-sectional area of the masonry.

The net cross-sectional area encompasses the area of units, grout and mortar contained within the plane under consideration. For ungrouted masonry, this area is sometimes equal to the bedded area, or more often to the minimum specified area of the face shells. For grouted masonry, this also includes that area of cores, cells or spaces filled with grout.

AREA, BUILDING. The area included within surrounding exterior walls (or exterior walls and fire walls) exclusive of vent shafts and courts. Areas of the building not provided with surrounding walls shall be included in the building area if such areas are included within the horizontal projection of the roof or floor above.

Allowable building areas (as established by the provisions of Chapter 5 and Table 503) are a function of the potential fire hazard and the level of fire endurance of the building's structural elements, as defined by the types of construction in Chapter 6. A building area is the "footprint" of the building; that is, the area measured within the perimeter formed by the inside surface of the exterior walls. This excludes spaces that are inside this perimeter and open to the outside atmosphere at the top, such as open shafts and courts (see Section 1206). When a portion of the building has no exterior walls, the area regulated by Chapter 5 is defined by the projection of the roof or floor above [see Figure 202.1(7)]. The roof overhang on portions of a building where there are exterior enclosure walls does not add to the building area because the area is defined by exterior walls.

AREA OF REFUGE. An area where persons unable to use stairways can remain temporarily to await instructions or assistance during emergency evacuation.

- The area of refuge is a temporary waiting area used during emergency evacuations for persons who are unable to exit the building using the stairways. The fire safety plans (in accordance with IFC Section 404) include the locations of areas of refuge so that the fire department will know where people may be waiting for rescue assistance. See Section 1007 for where areas of refuge are required at stairways and elevators. Areas of refuge have requirements for separa-

---

**Figure 202.1(7)**
BUILDING AREA—PROJECTED

**Figure 202.1(6)**
GROSS CROSS-SECTIONAL AREA FOR SINGLE WYTHE WALL UNDER LOAD
DEFINITIONS

...tion, size, signage, instructional information and two-way communication systems.

AREA WAY. A subsurface space adjacent to a building open at the top or protected at the top by a grating or guard.

- Areaways are often constructed to provide access to below-grade building services, including transformers, ventilation shafts and pipe tunnels.

ASSEMBLY SEATING, MULTILEVEL. See "Multilevel assembly seating."

- This is primarily known as "multilevel assembly seating" and is addressed in the commentary under that term.

ATRIUM. An opening connecting two or more stories other than enclosed stairways, elevators, hoistways, escalators, plumbing, electrical, air-conditioning or other equipment, which is closed at the top and not defined as a mall. Stories, as used in this definition, do not include balconies within assembly groups or mezzanines that comply with Section 505.

- The definition identifies that an atrium is a floor opening or a series of floor openings that connects the environments of adjacent stories. The definition of "Atrium" excludes enclosed stairways, elevators, hoistways and other similar openings in order to clarify that those elements would not fall under the purview as to what is considered an atrium, and therefore, the associated requirements found in Section 404 would not apply. What this does not preclude is the inclusion of elevators and open stairways within atriums. Such elements would need to be entirely within the atrium to meet the separation requirements found in Section 404.6. Building features, such as stairways, elevators, hoistways, escalators, plumbing, electrical, air conditioning or other equipment openings, are required to be enclosed in fire-resistance-rated shafts in accordance with Sections 712 and 713. Atriums are specified in Section 712.1.6 to address openings in horizontal assemblies. An atrium is not defined by size or use. A series of floor openings that are enclosed with exterior walls, yet open at the roof, would be considered a court and would be exempt from the requirements of Section 404. Balconies associated with assembly occupancies and mezzanines are not considered individual stories that would contribute to the classification of a space as an atrium.

ATTIC. The space between the ceiling beams of the top story and the roof rafters.

- The definition of "Attic" identifies the specific portion of a building or structure for the purpose of determining the applicability of requirements that are specific to attics, such as ventilation (see Section 1203) and draftstopping (see Section 718). Additionally, the code has access requirements (see Section 1209) and uniformly distributed live load requirements (see Table 1607.1) for attics. An attic is considered the space or area located immediately below the roof sheathing within the roof framing system of a building. Pitched roof systems, such as gabled, hip, saw-toothed or curved roofs, all create spaces between the roof sheathing and ceiling membrane, which are considered attics.

[F] AUDIBLE ALARM NOTIFICATION APPLIANCE. A notification appliance that alerts by the sense of hearing.

- Audible alarms that are part of a fire alarm system must be loud enough to be heard in every occupied space of a building. Section 907.5.2.1.1 prescribes the minimum sound pressure level for all audible alarm notification appliances depending on the occupancy of the building and the function of the space.

AUTOCLAVED AERATED CONCRETE (AAC). Low density cementitious product of calcium silicate hydrates, whose material specifications are defined in ASTM C 1386.

- Autoclaved aerated concrete (AAC) is a relatively lightweight concrete product which is manufactured in panels that can be cut into smaller blocks to use as masonry units. The referenced material standard establishes the minimum compressive strength based on the class of the AAC. The definition of "AAC masonry" given above establishes that requirements in Chapter 21 apply to masonry units that consist of AAC.

[F] AUTOMATIC. As applied to fire protection devices, a device or system providing an emergency function without the necessity for human intervention and activated as a result of a predetermined temperature rise, rate of temperature rise or combustion products.

- This term, when used in conjunction with fire protection systems or devices, means that the system or device will perform its intended function without a person being present or performing any task in its control or operation. The device or system has the inherent capability to detect a developing fire condition and perform some predetermined function. Automatic devices and systems operate completely without human presence or intervention.

[F] AUTOMATIC FIRE-EXTINGUISHING SYSTEM. An approved system of devices and equipment which automatically detects a fire and discharges an approved fire-extinguishing agent onto or in the area of a fire.

- This term is the generic name for all types of automatic fire-extinguishing systems, including the most common type—the automatic sprinkler system. See Section 904 for requirements for particular alternative automatic fire-extinguishing systems, such as wet-chemical, dry-chemical, foam, carbon dioxide, Halon and clean-agent systems.

[F] AUTOMATIC SMOKE DETECTION SYSTEM. A fire alarm system that has initiation devices that utilize smoke detectors for protection of an area such as a room or space with detectors to provide early warning of fire.

- Chapter 9 provides requirements for various automatic protection systems including: "automatic fire
detected by heat from a fire and discharges water over the fire area.

An automatic sprinkler system is one type of automatic fire-extinguishing system. Automatic sprinkler systems are the most common, and their life safety attributes are widely recognized. The code specifies three types of automatic sprinkler systems: one installed in accordance with NFPA 13, one in accordance with NFPA 13R and the other in accordance with NFPA 13D. To be considered for most code design alternatives, a building’s automatic sprinkler system must be installed throughout in accordance with NFPA 13 (see Section 903.3.1.1).

In a fire, sprinklers automatically open and discharge water onto the fire in a spray pattern that is designed to contain or extinguish the fire. Originally, automatic sprinkler systems were developed just for the protection of buildings and their contents. Because of the development and improvements in sprinkler head response time and water distribution, however, automatic sprinkler systems are now also considered a life safety system. Proper operation of an automatic sprinkler system requires careful selection of the sprinkler heads so that water in sufficient quantity at adequate pressure and properly distributed will be available to suppress the fire. Note that the context of the use of the term "fire area" in the last sentence of the definition is to refer to the area in which the fire is occurring, not in the context of the defined term "fire area."

There are many different types of automatic sprinkler systems—wet pipe, dry pipe, preaction, anti-freeze and various combinations. Sprinklers can be pendant, upright or sidewall and can be designed for standard or extended coverage. Additional information can be found in NFPA 13.

[F] AVERAGE AMBIENT SOUND LEVEL. The root mean square, A-weighted sound pressure level measured over a 24-hour period, or the time any person is present, whichever time period is less.

The ambient noise that can be expected depends on the occupancy of the building. To attract the attention of the occupants, the audible alarm devices must be heard above the ambient noise in the space. For this reason, the alarm devices must have minimum sound pressure levels above the average ambient sound level. Section 907.5.2.1.1 prescribes the minimum sound pressure levels for the audible alarm notification appliances for all occupancy conditions.

Although it is possible to measure the ambient sound within an occupied space, the alarm notification devices are usually designed and installed before buildings are occupied, thus it is typically a careful analysis of the types of uses within a space that will determine the average ambient sound level. If, after the building is occupied, the alarm notification devices are below expected audibility, a field measurement may be necessary to determine whether or not the design assumptions are correct.

AWNING. An architectural projection that provides weather protection, identity or decoration and is partially or wholly supported by the building to which it is attached. An awning is comprised of a lightweight frame structure over which a covering is attached.

Similar to a canopy, an awning typically provides weather protection, signage or decoration. Its distinguishing characteristic is the lightweight frame structure. It is also supported, at least in part, by the building from which it projects. See Section 3105 for general requirements and Section 3202 for encroachment requirements. This definition helps to clarify the applicability of roof loads in Section 1607.12.4. Also see the definitions for "Retractable awning," "Canopy" and "Marquee."

BACKING. The wall or surface to which the veneer is secured.

The backing is the portion of a structure that provides support for the exterior veneer. The backing also typically resists lateral and transverse loads imposed by the veneer and may be load bearing or nonload bearing.

[F] BALED COTTON. A natural seed fiber wrapped in and secured with industry accepted materials, usually consisting of burlap, woven polypropylene, polyethylene or cotton or sheet polyethylene, and secured with steel, synthetic or wire bands or wire; also includes linters (lint removed from the cottonseed) and motes (residual materials from the ginning process).

This definition of standard "Baled cotton" is being included only to distinguish it from "Baled cotton, densely packed" (see the commentary to the definition of "Baled cotton, densely packed"). The Joint Cotton Industry Bale Packaging Committee (JCIIBC) represents all parts of the cotton industry and sets standards and specifications for packaging of cotton bales that include bale density. The JCIIBC specifications for baling of cotton require that all cotton bales be secured with fixed-length wire bands, polyester plastic strapping or cold-rolled, high-tensile steel strapping and then covered in fully coated woven polyolefin, polyethylene film or burlap.
DEFINITIONS

[F] BALED COTTON, DENSELY PACKED. Cotton made into banded bales with a packing density of at least 22 pounds per cubic foot (360 kg/m³), and dimensions complying with the following: a length of 55 inches (1397 mm), a width of 21 inches (533.4 mm) and a height of 27.6 to 35.4 inches (701 to 899 mm).

v Currently, over 99 percent of all U.S. cotton is pressed and stored as densely packed baled cotton, with bales meeting the weight and dimension requirements of ISO 8115. One reason that the cotton industry has chosen to use such bales is because they are very difficult to ignite, which allows the industry to transport them without being labeled as "flammable solids" or "dangerous goods" by the national or international transport authorities. It is intended that this definition be used to distinguish such bales from other combustible fibers.

In order to counteract some erroneous information regarding the combustibility characteristics of densely packed cotton bales, flammability research was conducted on baled cotton. The research demonstrated that densely packed baled cotton meeting the size and weight requirements of ISO 8115 is not a hazardous material. In view of that data, the U.S. Department of Transportation (U.S. Coast Guard), the United Nations (UN) and the International Maritime Organization (IMO) have all removed the listing of baled cotton from the list of hazardous materials and from the list of flammable solids, provided the cotton bales are the densely packed type that meet the standard noted above. The research conclusions were:

1. Standard cotton fiber "passed" the Department of Transportation's spontaneous combustion test: the cotton did not exceed the oven temperature and was not classified as self-heating.

2. Cotton, as densely packed baled cotton, did not cause sustained smoldering propagation: an electric heater placed within the bales was unable to cause sustained smoldering propagation, because of the lack of oxygen inside the densely packed bale.

3. Cotton, as densely packed baled cotton, was exposed to ignition from a cigarette and a match and performed very well: no propagating combustion with either.

4. Cotton, as densely packed baled cotton, was exposed to ignition from the gas burner source in ASTM E 1590 (also known as California Technical Bulletin 129) of 12 L/min of propane gas for 180 seconds and passed all the criteria, including mass loss of less than 1.36 kg (3 pounds), heat release rate less than 100 kW and total heat release of less than 25 MJ in the first 10 minutes of the test.

BALLOAST. In roofing, ballast comes in the form of large stones or paver systems or light-weight interlocking paver systems and is used to provide uplift resistance for roofing systems that are not adhered or mechanically attached to the roof deck.

v Ballast is a material, usually stone or concrete, that is used specifically to provide uplift resistance for roof coverings that are not otherwise attached to the structure.

[F] BARRICADE. A structure that consists of a combination of walls, floor and roof, which is designed to withstand the rapid release of energy in an explosion and which is fully confined, partially vented or fully vented; or other effective method of shielding from explosive materials by a natural or artificial barrier.

Artificial barricade. An artificial mound or revetment a minimum thickness of 3 feet (914 mm).

Natural barricade. Natural features of the ground, such as hills, or timber of sufficient density that the surrounding exposures that require protection cannot be seen from the magazine or building containing explosives when the trees are bare of leaves.

v Barricade means effectively screening a building containing explosives by means of natural or artificial barrier from a magazine, another building, a railway or a highway. When suitable natural features do not exist to protect adjacent people and structures from flying debris and blast effects if an explosion in a magazine occurs, an artificial barrier must be constructed. For further information, see Chapter 56 of the IFC.

BASE FLOOD. The flood having a 1-percent chance of being equaled or exceeded in any given year.

v This term is used to define the land area along a body of water that is subject to flooding and within which flood-resistant design and construction requirements are applied. Typically, an authority, such as FEMA or a state or local jurisdiction, prepares flood hazard maps. In doing so, the base flood is derived by applying hydrologic models or by examining regional or local flood history to determine the 1-percent annual chance event, also referred to as the "100-year flood." The 1-percent annual chance event has been the standard used to regulate flood hazard areas for more than 40 years.

BASE FLOOD ELEVATION. The elevation of the base flood, including wave height, relative to the National Geodetic Vertical Datum (NGVD), North American Vertical Datum (NAVD) or other datum specified on the Flood Insurance Rate Map (FIRM).

v The base flood elevation is the height to which floodwaters are predicted to rise during passage or occurrence of the base flood. It is determined using commonly accepted computer models that estimate hydrologic and hydraulic conditions to determine the 1-percent annual chance (base) flood. Along rivers and streams, statistical methods and computer models may be used to estimate runoff and to develop flood elevations. The models take into consideration watershed characteristics, and the shape and nature
DEFINITIONS

of the flood plain, including natural ground contours and the presence of buildings, bridges and culverts. Along coastal areas, base flood elevations may be developed using models that take into account offshore bathymetry, historical storms and typical wind patterns. In many coastal areas, the base flood elevation includes wave heights.

**BASEMENT** (for flood loads). The portion of a building having its floor subgrade (below ground level) on all sides. This definition of “Basement” is limited in application to the provisions of Section 1612.

- ASCE 24 specifies that lowest floors, including the floors of basements that are below grade on all sides, must be elevated to or above the elevations required by ASCE 24, which vary based on the occupancy category and flood zone. Buildings that are specifically designed to be dry floodproofed in accordance with ASCE 24 may have their lowest floors (including basements) below the design flood elevation. In terms of National Flood Insurance Program (NFIP) flood insurance, buildings with basements (below grade on all sides) are subject to higher premium rates.

**BASEMENT.** A story that is not a story above grade plane (see “Story above grade plane”). This definition of “Basement” does not apply to the provisions of Section 1612 for flood loads.

- Unlike previous editions of the I-Codes® where a story would be defined as a basement if any portion of the story was below grade, a basement is now defined as a story that has its floor surface below the adjoining ground level and that does not qualify as a story above grade plane (see the commentary to the definition of “Story above grade plane”). Figure 202.2(1) illustrates the application of the definition of “Story above grade plane.” Since a basement is not a story above grade, it does not contribute to the height of the building for the purpose of applying the allowable building height in stories from Table 503. This definition of “Basement” applies to all sections of the code except for flood loads.

Basements in buildings that are located in flood hazard areas and subject to flood loads are defined differently than this general definition of basement [see the definition of “Basement (for flood loads)”].

**BEARING WALL STRUCTURE.** A building or other structure in which vertical loads from floors and roofs are primarily supported by walls.

- This definition describes the structure types that are covered under Section 1615.4.

**BED JOINT.** The horizontal layer of mortar on which a masonry unit is laid.

- This is a horizontal mortar joint [see Figure 202.2(2)] that separates a course of masonry units from the ones above and supports the weight of the masonry. Unlike the head or collar joint, it is easily closed when the masonry unit is placed. For a masonry unit in the typical (stretcher) orientation, the bed joint faces are the top and bottom, while the bed surface of the masonry unit is the underside. A special type of bed joint is the base-course joint or starting joint placed over foundations (Section 2104.1.2 references TMS 602/ACI 530.1/ASCE 6 for requirements for thicknesses, placement and permitted tolerances for bed joints).

**BLEACHERS.** Tiered seating supported on a dedicated structural system and two or more rows high and is not a building element (see “Grandstands”).

- Bleachers, folding and telescopic seating, and grandstands are essentially unique forms of tiered seating that are supported on a dedicated structural system. All types are addressed in ICC 300, Standard on Bleachers, Folding and Telescopic Seating and Grandstands, the safety standard for these types of seating arrangements (see Section 1028.1.1). Bleachers often do not have backrests. The travel path across the bleachers is not restricted to designated rows, aisles and aisle accessways. Without backrests, occupants can traverse from row to row without traveling to the designated egress aisles (see Section 1028.1.1). "Building element" is a defined term that is primarily used in conjunction with the structural elements regulated in Table

---

Figure 202.2(1) STOY ABOVE GRADE

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.
DEFINITIONS

601. Bleachers have a separate structural system and
are not considered a building element of the building or
structure in which they are located. An individual bench
seat directly attached to a floor system is not a bleacher.
The terms "bleacher" and "grandstand" are basically
interchangeable. There is no cutoff in size or number of
seats that separates bleachers and grandstands.

BOARDING HOUSE. A building arranged or used for lodg-
ing for compensation, with or without meals, and not occu-
pied as a single-family unit.

- A boarding house is a structure housing lodgers or
boarders in which the occupants are provided lodging
or meals and lodging for a fee. The individual rooms
used for lodging usually do not contain all of the per-
manent living provisions of a dwelling unit (e.g., per-
manent cooking facilities). Most often, the term
"boarding house" describes a facility that is primarily
for transient occupants; however, these facilities
might also be used for nontransient purposes.
Depending on the extent of transiency, a boarding
house could be classified as Group R-1 when an
occupant typically stays for not more than 30 days or
Group R-2 when the length of stay is greater than 30
days [see Section 310 and Figure 202.2(3)].

[F] BOILING POINT. The temperature at which the vapor
pressure of a liquid equals the atmospheric pressure of 14.7
pounds per square inch (psia) (101 kPa) or 760 mm of mer-
cury. Where an accurate boiling point is unavailable for the
material in question, or for mixtures which do not have a con-
stant boiling point, for the purposes of this classification, the
20-percent evaporated point of a distillation performed in
accordance with ASTM D 86 shall be used as the boiling
point of the liquid.

- The boiling point of a liquid is significant in determin-
ing the appropriate division for Class I flammable liq-
uids. Temperatures above the established boiling
point for a given liquid would result in the atmospher-
ical pressure not longer being able to keep the liquid in a
liquid state. Liquids with low boiling points present a
greater fire hazard because of the increased vapor
pressure at normal ambient temperatures.

BOND BEAM. A horizontal grouted element within
masonry in which reinforcement is embedded.

- Bond beams permit horizontal reinforcement to be
placed in masonry. For hollow masonry unit walls,
special units can either be manufactured or the webs
and end shells can be reduced by saw cutting to
allow horizontal reinforcing bars to be placed in the
wall.

BRACED WALL LINE. A series of braced wall panels in a
single story that meets the requirements of Section 2308.3 or
2308.12.4.

- A braced wall line consists of conventionally framed
braced wall panels that provide lateral support for
buildings constructed in accordance with the pre-
scriptive conventional construction provisions of Sec-
tion 2308.

BRACED WALL PANEL. A section of wall braced in
accordance with Section 2308.9.3 or 2308.12.4.

- A braced wall panel is a segment of a braced wall
line. Braced wall panels are discussed in Section
2308.9.3. Braced wall panels are similar to shear
walls but are designed by prescriptive rules rather
than engineered like shear walls.

BRICK.

- Brick is composed of masonry units that are generally
prismatic (rectangular) in shape.

Calcium silicate (sand lime brick). A pressed and subse-
quently autoclaved unit that consists of sand and lime,
with or without the inclusion of other materials.

- This solid brick unit is made principally from high-sil-
ica sand and lime.

Clay or shale. A solid or hollow masonry unit of clay or
shale, usually formed into a rectangular prism, then burned
or fired in a kiln; brick is a ceramic product.

- These masonry units are manufactured from surface
clay, shale or fire clay. Different manufacturing pro-
cesses and physical properties are associated with
each material. Surface clays are found in sedimen-

\[F\] BOILING POINT. The temperature at which the vapor
pressure of a liquid equals the atmospheric pressure of 14.7
pounds per square inch (psia) (101 kPa) or 760 mm of mer-
cury. Where an accurate boiling point is unavailable for the
material in question, or for mixtures which do not have a con-
stant boiling point, for the purposes of this classification, the
20-percent evaporated point of a distillation performed in
accordance with ASTM D 86 shall be used as the boiling
point of the liquid.

- The boiling point of a liquid is significant in determin-
ing the appropriate division for Class I flammable liq-
uids. Temperatures above the established boiling
point for a given liquid would result in the atmospher-
ical pressure not longer being able to keep the liquid in a
liquid state. Liquids with low boiling points present a
greater fire hazard because of the increased vapor
pressure at normal ambient temperatures.

BOND BEAM. A horizontal grouted element within
masonry in which reinforcement is embedded.

- Bond beams permit horizontal reinforcement to be
placed in masonry. For hollow masonry unit walls,
special units can either be manufactured or the webs
and end shells can be reduced by saw cutting to
allow horizontal reinforcing bars to be placed in the
wall.

BRACED WALL LINE. A series of braced wall panels in a
single story that meets the requirements of Section 2308.3 or
2308.12.4.

- A braced wall line consists of conventionally framed
braced wall panels that provide lateral support for
buildings constructed in accordance with the pre-
scriptive conventional construction provisions of Sec-
tion 2308.

BRACED WALL PANEL. A section of wall braced in
accordance with Section 2308.9.3 or 2308.12.4.

- A braced wall panel is a segment of a braced wall
line. Braced wall panels are discussed in Section
2308.9.3. Braced wall panels are similar to shear
walls but are designed by prescriptive rules rather
than engineered like shear walls.

BRICK.

- Brick is composed of masonry units that are generally
prismatic (rectangular) in shape.

Calcium silicate (sand lime brick). A pressed and subse-
quently autoclaved unit that consists of sand and lime,
with or without the inclusion of other materials.

- This solid brick unit is made principally from high-sil-
ica sand and lime.

Clay or shale. A solid or hollow masonry unit of clay or
shale, usually formed into a rectangular prism, then burned
or fired in a kiln; brick is a ceramic product.

- These masonry units are manufactured from surface
clay, shale or fire clay. Different manufacturing pro-
cesses and physical properties are associated with
each material. Surface clays are found in sedimen-

\[F\] BOILING POINT. The temperature at which the vapor
pressure of a liquid equals the atmospheric pressure of 14.7
pounds per square inch (psia) (101 kPa) or 760 mm of mer-
cury. Where an accurate boiling point is unavailable for the
material in question, or for mixtures which do not have a con-
stant boiling point, for the purposes of this classification, the
20-percent evaporated point of a distillation performed in
accordance with ASTM D 86 shall be used as the boiling
point of the liquid.

- The boiling point of a liquid is significant in determin-
ing the appropriate division for Class I flammable liq-
uids. Temperatures above the established boiling
point for a given liquid would result in the atmospher-
ical pressure not longer being able to keep the liquid in a
liquid state. Liquids with low boiling points present a
greater fire hazard because of the increased vapor
pressure at normal ambient temperatures.
tary layers near the surface. Shales are clays subjected to geologic pressure, resulting in a solid state similar to slate. Fire clays are mined from deeper layers, resulting in more uniform properties. These units are formed into the desired shape by extrusion, molding or pressing. They are then fired in a kiln to increase their strength and durability.

**Concrete.** A concrete masonry unit made from Portland cement, water, and suitable aggregates, with or without the inclusion of other materials.

- Concrete brick units are made from a zero-slump mix of Portland cement (and possibly other cementitious materials), aggregates, water and admixtures. These units are solid or have a shallow depression called a "frog." Slump brick, for example, is a decorative concrete brick with bulged sides resulting from the consistency of the mix and the manufacturing process.

**[A] BUILDING.** Any structure used or intended for supporting or sheltering any use or occupancy.

- The code uses this term to identify those structures that provide shelter for a function or activity. See the definition for "Area, building" for situations when a single structure may be two or more "Buildings" created by fire walls.

**BUILDING AREA.** See "Area, building."

- Building area is defined under "Area, building" and is addressed in the commentary under that term. It is most commonly used in the code as "building area" or "building height and area."

**BUILDING ELEMENT.** A fundamental component of building construction, listed in Table 601, which may or may not be of fire-resistance-rated construction and is constructed of materials based on the building type of construction.

- Building elements include primary structural members, secondary structural members, exterior walls and interior partitions. The fire-resistance ratings of the elements are found in Tables 601 and 602.

**BUILDING HEIGHT.** See "Height, building."

- Building height is defined under "Height, building" and is addressed in the commentary under that term. It is most commonly used in the code as "building height" or "building height and area."

**BUILDING LINE.** The line established by law, beyond which a building shall not extend, except as specifically provided by law.

- This term defines the limitations or boundaries for construction of a building. This line is typically established by a zoning statute or rights-of-way dedication and is not specified in the code.

---

**Figure 202.2(3)**

**GROUP R-2—BOARDING HOUSE (OCCUPANTS PRIMARILY NONTRANSIENT)**
DEFINITIONS

[A] BUILDING OFFICIAL. The officer or other designated authority charged with the administration and enforcement of this code, or a duly authorized representative.

- The statutory power to enforce the code is normally vested in a building department of a state, county or municipality that has a designated enforcement officer termed the "building official" (see Section 103.1).

BUILT-UP ROOF COVERING. Two or more layers of felt cemented together and surfaced with a cap sheet, mineral aggregate, smooth coating or similar surfacing material.

- Because of their low melting points and self-healing characteristics, built-up roofs are typically constructed of coal tar membranes that are commonly installed on lower slopes and dead-level roofs.

CABLE-RESTRAINED, AIR-SUPPORTED STRUCTURE. A structure in which the uplift is resisted by cables or webbings which are anchored to either foundations or dead men. Reinforcing cable or webbing is attached by various methods to the membrane or is an integral part of the membrane. This is not a cable-supported structure.

- This definition establishes a variation of the air-supported membrane structure. A single-skin or double-skin membrane is still pressurized by interior air, but does not have the strength or tearing resistance against the internal air pressure. A "fishnet" system of cable wires is placed over the exterior surface of the membrane or is integrally woven into the membrane material. The "fishnet" system is then tied to exterior walls of the building or other structural supports to resist the internal air pressure.

CANOPY. A permanent structure or architectural projection of rigid construction over which a covering is attached that provides weather protection, identity or decoration. A canopy is permitted to be structurally independent or supported by attachment to a building on one or more sides.

- A canopy can be either an architectural projection from a building, or it can be an independent structure. An example of the former is typically found covering an entrance walkway in front of a hotel or apartment building, or perhaps a fancy restaurant (see the figures in Chapter 31). An example of the latter is a canopy built over fuel pumps at a gasoline station. This definition distinguishes a canopy from an awning, which consists of a lightweight frame that is supported by the building or other structures. In doing so, the definition clarifies the applicability of roof loads in Section 1607.12.4 (see Section 3105 for general requirements and Section 3202 for encroachment requirements).

[F] CARBON DIOXIDE EXTINGUISHING SYSTEMS. A system supplying carbon dioxide (CO₂) from a pressurized vessel through fixed pipes and nozzles. The system includes a manual- or automatic-actuating mechanism.

- Carbon dioxide (CO₂) extinguishing systems are useful in extinguishing fires in specific hazards or equipment in occupancies where an inert electrically nonconductive medium is essential or desirable and where cleanup of other extinguishing agents, such as dry-chemical residue, presents a problem. The system works by displacing the oxygen in an enclosed area by flooding the space with CO₂. To effectively flood the enclosure, automatic door and window closers and control dampers for the mechanical ventilation system must be installed.

These types of gaseous extinguishing systems have some inherent disadvantages that should be considered before selection. Because the oxygen is being displaced, occupants should not be in the space for a period after discharge, depending on the concentration of CO₂ to be achieved. Additionally, the discharge rate can result in a rapid increase in pressure within the space where the system is discharged. Where water is not a desired means of suppression, CO₂ and other gaseous suppression systems can be very effective. NFPA 12 contains minimum requirements for the design, installation, testing, inspection, approval, operation and maintenance of carbon dioxide extinguishing systems.

CARE SUITE. A group of treatment rooms, care recipient sleeping rooms and their associated support rooms or spaces and circulation space within Group I-2 occupancies where staff are in attendance for supervision of all care recipients within the suite, and the suite is in compliance with the requirements of Section 407.4.3.

- Care suites are designed to allow for a group of rooms to function as a unit in the treatment and care of patients. Suites allow staff to have clear and unobstructed supervision of patients/care recipients in specific treatment and sleeping rooms through the elimination of corridor width or rating requirements. The term is not intended to apply to day rooms or business sections of the hospital. This term is only applicable to suites of patient rooms in Group I-2 occupancies, and should not be confused with similar layouts in other parts of the hospital or within other occupancies that may referred to as a "suite." Care suites are to meet the requirements of Section 407.

CAST STONE. A building stone manufactured from Portland cement concrete precast and used as a trim, veneer or facing on or in buildings or structures.

- Cast stone is a simulated stone precast from Portland cement concrete. This material is typically used for veneer, but can also be used in other applications.

[F] CEILING LIMIT. The maximum concentration of an airborne contaminant to which one may be exposed. The ceiling limits utilized are those published in DOL 29 CFR Part 1910,1000. The ceiling Recommended Exposure Limit (REL-C) concentrations published by the U.S. National Institute for Occupational Safety and Health (NIOSH), Threshold Limit Value—Ceiling (TLV-C) concentrations published by the American Conference of Governmental Industrial Hygen-
ists (ACGIH). Ceiling Work place Environmental Exposure Level (WEL-Ceiling) Guides published by the American Industrial Hygiene Association (AIHA), and other approved, consistent measures are allowed as surrogates for hazardous substances not listed in DOL 29 CFR Part 1910.1000.

- This term is used in Section 908.3 and indicates the threshold at which a gas detection system is required for highly toxic and toxic materials. It represents the maximum level of exposure for employees or occupants to hazardous air contaminants during any part of a normal workday. DOL 29 CFR Part 1910.1000 provides acceptable ceiling limits of contamination for various substances.

**CEILING RADIATION DAMPER.** A listed device installed in a ceiling membrane of a fire-resistance-rated floor/ceiling or roof/ceiling assembly to limit automatically the radiative heat transfer through an air inlet/outlet opening.

- See the commentary to the definition of "Damper."

**CELL (Group I-3 occupancy).** A room within a housing unit in a detention or correctional facility used to confine inmates or prisoners.

- This term defines a large intentional void within a masonry unit. Grout and reinforcing steel are often placed in cells to form reinforced masonry.

**CELL (masonry).** A void space having a gross cross-sectional area greater than 1\(\frac{1}{2}\) square inches (967 mm\(^2\)).

- Cells are the smallest unit in the portion of a Group I-3 prison or jail for the housing of inmates. In contrast to other occupancies, many of the provisions in Section 408 refer to cells. Requirements for Group I-3 occupancies in other chapters may refer to cells that are parts of housing units as "sleeping units."

**CELL TIER.** Levels of cells vertically stacked above one another within a housing unit.

- A tier is one level of cells. There can be multiple tiers within a single housing unit as well as more than one cell tier within a story [see the commentary for "Cell (Group I-3 occupancy)"].

**CEMENT PLASTER.** A mixture of portland or blended cement, Portland cement or blended cement and hydrated lime, masonry cement or plastic cement and aggregate and other approved materials as specified in this code.

- Cement plaster (often referred to as "stucco") is a cementitious-based plaster material with excellent water-resistant properties. It is the only type of plaster that is permitted by the code to be used as an exterior wall covering and as a base coat and finish coat. Cement plaster can also be used as an interior finish wall covering, but is required by the code to be used in all interior wet areas such as toilet rooms, showers, saunas, steam rooms, indoor swimming pools or any other area that will be exposed to excessive amounts of moisture or humidity for prolonged periods of time.

**CERAMIC FIBER BLANKET.** A mineral wool insulation material made of alumina-silica fibers and weighing 4 to 10 pounds per cubic foot (pcf) (64 to 160 kg/m\(^3\)).

- This form of insulation is used in conjunction with the provisions of Section 722.2.1.3.1, where joints in precast walls must be insulated (protected) in order to maintain the fire-resistance integrity of the precast wall panel (see Code Figure 722.2.1.3.1).

**CERTIFICATE OF COMPLIANCE.** A certificate stating that materials and products meet specified standards or that work was done in compliance with approved construction documents.

- A certificate of compliance is a document issued by a supplier of materials and products that certifies they meet the specified requirements.

[**M**] **CHIMNEY.** A primarily vertical enclosure containing one or more passageways for conveying flue gases to the outside atmosphere.

- The International Fuel Gas Code\(^*\) (IFGC\(^*\)) and the International Mechanical Code\(^*\) (IMC\(^*\)) address the installation of chimneys and venting systems that are required to convey products of combustion from fuel-burning appliances to the atmosphere. A chimney is a primarily vertical enclosure containing one or more flues. The code regulates the construction of masonry chimneys in Section 2113. Chimneys differ from metal vents in the materials from which they are constructed and the type of appliance they are designed to serve. Chimneys can vent much hotter flue gases than metal vents.

**CHIMNEY TYPES.**

- Provisions for several types of chimneys are contained in Chapter 21, as described below. The construction of the chimney is affected by the type of appliance and the temperature of the flue gases that are generated.

  **High-heat appliance type.** An approved chimney for removing the products of combustion from fuel-burning, high-heat appliances producing combustion gases in excess of 2000°F (1093°C) measured at the appliance flue outlet (see Section 2113.11.3).

- High-heat chimneys are used in industrial applications, such as incinerators, kilns and blast furnaces. Section 2113.11.3 contains requirements for the construction and installation of chimneys for high-heat appliances.

  **Low-heat appliance type.** An approved chimney for removing the products of combustion from fuel-burning, low-heat appliances producing combustion gases not in excess of 1000°F (538°C) under normal operating condi-
DEFINITIONS

tions, but capable of producing combustion gases of 1400°F (760°C) during intermittent forces firing for periods up to 1 hour. Temperatures shall be measured at the appliance flue outlet.

- Most domestic fuel-burning appliances are low-heat appliances. Low-heat appliances include solid fuel-burning appliances, such as room heaters and wood stoves. Section 2113 contains requirements for the construction and installation of chimneys for low-heat appliances.

**Masonry type.** A field-constructed chimney of solid masonry units or stones.

- Masonry chimneys can have one or more flues and are field constructed of masonry units, stone, concrete and fired-clay materials. Masonry chimneys can stand alone or be part of a masonry fireplace. Section 2113 contains requirements for the construction and installation of masonry chimneys.

Most masonry chimneys require a chimney liner that is resistant to heat and the corrosive action of the products of combustion. Chimney liners are generally made of fired-clay tile, refractory brick, poured-in-place refractory materials or stainless steel.

**Medium-heat appliance type.** An approved chimney for removing the products of combustion from fuel-burning, medium-heat appliances producing combustion gases not exceeding 2000°F (1093°C) measured at the appliance flue outlet (see Section 2113.11.2).

- Some examples of medium-heat appliances are annealing furnaces, galvanizing furnaces, pulp dryers and charcoal furnaces. Section 2113.11.2 contains requirements for the construction and installation of chimneys for medium-heat appliances.

**Circulation Path.** An exterior or interior way of passage from one place to another for pedestrians.

- Examples of circulation paths include sidewalks, walkways, corridors, aisles, courtyards, ramps, stairways and landings. While a stairway is never part of an accessible route, it can be part of a general circulation path for ambulatory persons.

[F] **CLEAN AGENT.** Electrically nonconducting, volatile or gaseous fire extinguishant that does not leave a residue upon vaporization.

- The two categories of clean agents are halocarbon compounds and inert gas agents. Halocarbon compounds include bromine, carbon, chloride, fluorine, hydrogen and iodine. Halocarbon compounds suppress the fire through a combination of breaking the chemical chain reaction of the fire, reducing the ambient oxygen supporting the fire and reducing the ambient temperature of the fire origin to reduce the propagation of fire. The clean agents that are inert gas agents contain primary components consisting of helium, neon or argon, or a combination of all three. Inert gases work by reducing the oxygen concentra-

CLEANOUT. An opening to the bottom of a grout space of sufficient size and spacing to allow the removal of debris.

- These openings allow debris to be removed from a space to be grouted. The code references TMS 402/ACI 530/ASCE 5 and TMS 602/ACI 530.1/ASCE 6, which includes specifications for minimum construction requirements for masonry, including the minimum size and maximum spacing of cleanouts for grouted masonry.

**CLINIC, OUTPATIENT.** Buildings or portions thereof used to provide medical care on less than a 24-hour basis to persons who are not rendered incapable of self-preservation by the services provided.

- Outpatient clinics generally consist of doctors' offices where various medical services can be provided. These clinics typically function during normal business hours (i.e., less than 24 hours) and, unlike ambulatory care facilities, the patients are generally ambulatory and capable of self-preservation. This definition clarifies the difference between ambulatory surgery centers (ambulatory care facilities) and the typical doctor’s office. In many cities, outpatient clinics are open at all hours to be available to people who work a variety of shifts. The term “urgent care” is often used to describe such facilities. An outpatient facility that is open 24/7 may still be classified as a Group B occupancy, provided all patients are outpatients and individual patients are not treated for periods in excess of 24 hours. The latter would describe a Group I-2 hospital (see the commentaries to Sections 407 and 423).

[F] **CLOSED SYSTEM.** The use of a solid or liquid hazardous material involving a closed vessel or system that remains closed during normal operations where vapors emitted by the product are not liberated outside of the vessel or system and the product is not exposed to the atmosphere during normal operations; and all uses of compressed gases. Examples of closed systems for solids and liquids include product conveyed through a piping system into a closed vessel, system or piece of equipment.

- The difference between a closed system and an open system is whether the hazardous material involved in the process is exposed to the atmosphere. While not specific in the definition, certain gases are also allowed in closed systems, as indicated in Tables 307.7(1) and 307.7(2). Materials in closed or open systems are assumed to be "in use" as opposed to "in storage." Gases are always assumed to be in closed systems, since they would be immediately dispersed in an open system if exposed to the atmosphere without some means of containment (see the definition of "Open system").

**COLLAR JOINT.** Vertical longitudinal space between wythes of masonry or between masonry wythe and backup
construction that is permitted to be filled with mortar or grout.

- A collar joint is a filled space between masonry wythes [see Figure 202.2(2)]. Care is necessary for proper construction of collar joints, particularly where solid filling is required.

**COLLECTOR.** A horizontal diaphragm element parallel and in line with the applied force that collects and transfers diaphragm shear forces to the vertical elements of the lateral-force-resisting system and/or distributes forces within the diaphragm.

- The collector is an element of the diaphragm that transfers the diaphragm shear from the point of application into the adjoining vertical lateral force-resisting elements, usually the shear walls. See also Section 11.2 of ASCE 7, which defines a collector as, "A diaphragm or shear wall boundary element parallel to the applied load that collects and transfers diaphragm shear forces to the vertical force-resisting elements or distributes forces within the diaphragm or shear wall."

**COMBINATION FIRE/SMOKE DAMPER.** A listed device installed in ducts and air transfer openings designed to close automatically upon the detection of heat and resist the passage of flame and smoke. The device is installed to operate automatically, controlled by a smoke detection system, and where required, is capable of being positioned from a fire command center.

- A combination damper is used when the code requires not only a fire damper but also a smoke damper designed to limit the passage of smoke from one side of fire-resistance-rated construction to the other. Fire and smoke dampers are required at duct penetrations of shafts in accordance with Section 717.5.3. Both fire and smoke dampers are required at duct and air transfer openings in fire walls utilized as horizontal exits in accordance with Section 717.5.1.1. Both shall (subject to exceptions listed) also be required at duct penetrations of fire barrier walls utilized as horizontal exits in accordance with Section 717.5.2. Both shall (subject to exceptions listed) also be required at duct penetrations of fire partitions utilized as corridor partitions in accordance with Section 717.5.4.1.

The combination fire/smoke damper must be actuated automatically by a smoke detection system. Where the damper is part of a smoke control system in Section 909, it shall also be controlled from the fire command center.

**F** COMBUSTIBLE DUST. Finely divided solid material that is 420 microns or less in diameter and which, when dispersed in air in the proper proportions, could be ignited by a flame, spark or other source of ignition. Combustible dust will pass through a U.S. No. 40 standard sieve.

- Combustible dusts are combustible solids in a finely divided state that are suspended in the air. An explosion hazard exists when the concentration of the combustible dust is within the explosive limits and exposed to an ignition source of sufficient energy and duration to initiate self-sustained combustion. A review of the occupancy classification for Group H-2 in Section 307.4 indicates that combustible dusts are classified in that occupancy group. The intent of that section is that when combustible dust is determined by an engineering analysis to meet the definition parameter that, in a given occupancy, it is dispersed in air in the proper proportions so as to be ignitable by an ignition source, then the deflagration hazard is sufficient to classify the occupancy in Group H-2. Combustible dust, as a material, that does not rise to that defined level of hazard in a particular building would not cause the building or portion thereof housing the hazard to be classified in Group H-2, but rather in the occupancy group that is most appropriate for the particular operation.

The original tabular MAQ per control area for combustible dust included in the legacy building and fire codes was deleted because of its questionable value given the complexities of dust explosion hazards. In the 2012 edition of the code, a row for combustible dust has been added to Table 307.1(1) along with a new Note q. The note reinforces the fact that determining a theoretical MAQ of combustible dust and the potential for a dust explosion requires a thorough evaluation and technical report based on the provisions of Section 414.1.3. Such determination is complex and requires evaluation far beyond the simple 1 pound per 1,000 cubic feet (16 g/m³) MAQ previously used by the legacy codes. Critical factors, such as particle size, material density, humidity and oxygen concentration, play a major role in the evaluation of the dust hazard and are much too complex to be simply addressed.

**F** COMBUSTIBLE FIBERS. Readily ignitable and free-burning materials in a fibrous or shredded form, such as cocoa fiber, cloth, cotton, excelsior, hay, hemp, henequen, isle, jute, kapok, oakum, rags, sisal, Spanish moss, straw, tow, wastepaper, certain synthetic fibers or other like materials. This definition does not include densely packed baled cotton.

- Operations involving combustible fibers are typically associated with paper milling, recycling, cloth manufacturing, carpet and textile mills and agricultural operations, among others. The primary hazards associated with such operations involve the abundance of materials and their ready ignitability. Many organic fibers are prone to spontaneous ignition if improperly dried and kept in areas without sufficient ventilation. Densely packed baled cotton is a special type of combustible fiber that, based on its weight
and dimension requirements, is not easily ignitable and is not a hazardous material.

[F] COMBUSTIBLE LIQUID. A liquid having a closed cup flash point at or above 100°F (38°C). Combustible liquids shall be subdivided as follows:

Class II. Liquids having a closed cup flash point at or above 100°F (38°C) and below 140°F (60°C).

Class IIIA. Liquids having a closed cup flash point at or above 140°F (60°C) and below 200°F (93°C).

Class IIIB. Liquids having a closed cup flash point at or above 200°F (93°C).

The category of combustible liquids does not include compressed gases or cryogenic fluids.

❖ Combustible liquids differ from flammable liquids in that the closed cup flash point of all combustible liquids is at or above 100°F (38°C) (see the definition of "flash point"). There are three categories of combustible liquids. The range of their closed cup flash point dictates the class of combustible liquid. The flash point range of 100°F (38°C) to 140°F (60°C) for Class II liquids is based on a possible indoor ambient temperature exceeding 100°F (38°C). Only a moderate degree of heating would be required to bring the liquid to its flash point in this type of condition. Class III liquids, which have flash points higher than 140°F (38°C), would require a significant heat source besides ambient temperature conditions to reach their flash point (see the definition of "Flammable liquid"). Class IIIA has a closed cup flash point range of 140°F (93°C). Class IIIB has a closed cup flash point at or above 200°F (93°C). Combustible liquids are primarily considered Group H-2 materials except for Class II and IIIA liquids that are considered Group H-3 when used or stored in normally closed containers or systems pressurized at less than 15 psig (103.4 kPa). Motor oil is a typical example of a Class IIIB combustible liquid. Note that Class IIIB liquids are not regulated to be classified as Group H per Table 307.1(1). While cryogenic fluids and compressed gases may be combustible, they are to be regulated separately from combustible liquids.

COMMON PATH OF EGRESS TRAVEL. That portion of exit access which the occupants are required to traverse before two separate and distinct paths of egress travel to two exits are available. Paths that merge are common paths of travel. Common paths of egress travel shall be included within the permitted travel distance.

❖ The common path of egress travel is a concept used to refine travel distance criteria. A common path of travel is the route an occupant will travel where the only way in is also the only way out, similar to a dead-end corridor or single exit suite. The length of a common path of egress travel is limited so that the means of egress path of travel provides a choice before the occupant has traveled an excessive distance (see Section 1014.3). This reduces the possibility that, although the exits are remote from one another, a single fire condition will render both paths unavailable.

COMMON USE. Interior or exterior circulation paths, rooms, spaces or elements that are not for public use and are made available for the shared use of two or more people.

❖ Some buildings include areas that are restricted to employees only or where public access is limited. Common-use spaces may be part of employee work areas but do not include public-use spaces. Any space that is shared by two or more persons, such as copy areas, break rooms, toilet rooms or circulation paths, are common use areas. A grade school classroom would be another example of a common use space (see also the commentary for the definition of "Public-use areas" and "Employee work area").

[F] COMPRRESSED GAS. A material, or mixture of materials, that:

1. Is a gas at 68°F (20°C) or less at 14.7 pounds per square inch atmosphere (psia) (101 kPa) of pressure; and

2. Has a boiling point of 68°F (20°C) or less at 14.7 psia (101 kPa) which is either liquefied, nonliquefied or in solution, except those gases which have no other health- or physical-hazard properties are not considered to be compressed until the pressure in the packaging exceeds 41 psia (282 kPa) at 68°F (20°C).

The states of a compressed gas are categorized as follows:

1. Nonliquefied compressed gases are gases, other than those in solution, which are in a packaging under the charged pressure and are entirely gaseous at a temperature of 68°F (20°C).

2. Liquefied compressed gases are gases that, in a packaging under the charged pressure, are partially liquid at a temperature of 68°F (20°C).

3. Compressed gases in solution are nonliquefied gases that are dissolved in a solvent.

4. Compressed gas mixtures consist of a mixture of two or more compressed gases contained in a packaging, the hazard properties of which are represented by the properties of the mixture as a whole.

❖ This term refers to all types of gases that are under pressure at normal room or outdoor temperatures inside their containers, including, but not limited to, flammable, nonflammable, highly toxic, toxic, cryogenic and liquefied gases. The vapor pressure limitations provide the distinction between a liquid and a gas. Gases are materials that boil at a temperature of 68°F (20°C) or less at a pressure of 14.7 psia (101.3 kPa). Liquefied and nonliquefied compressed gases are determined by the state of the gas at a tempera-
ture of 68°F (20°C). Nonliquefied gases are entirely
gaseous, while liquefied gases are partially liquid.

**COMPRESSIVE STRENGTH OF MASONRY.** Maximum
compressive force resisted per unit of net cross-sessional
area of masonry, determined by the testing of masonry
prisms

- The specified compressive strength of masonry, $f'_{cm}$
is used for the engineered design of masonry (allow-
able stress design of Section 2107 and strength
design of Section 2108). The average compressive
strength of masonry, determined by the prism test
method or the unit strength method (see Section
2105.2), must equal or exceed the specified compres-
sive strength.

**CONCRETE.**

- **Carbonate aggregate.** Concrete made with aggregates
consisting mainly of calcium or magnesium carbonate,
such as limestone or dolomite, and containing 40 percent
or less quartz, chert or flint.

- Concrete made with this type of aggregate is listed in
Tables 721.1(1) (items 1, 2, 3, 4, 5, 6 and 7) and
721.1(2) (item 4) with prescriptive details regarding
concrete fire-resistance ratings. This type of aggregate
is also indicated for concrete assemblies that require calculations to
determine the fire-resistance rating in accordance with Section 722.2 (i.e., Table
722.2.1.1).

- **Cellular.** A lightweight insulating concrete made by
mixing a preformed foam with Portland cement slurry
and having a dry unit weight of approximately 30 pcf (480 kg/
m³).

- Concrete made with this type of aggregate is listed in
Table 721.1(3) (items 9 and 19) with prescriptive
details regarding concrete fire-resistance ratings.
This type of aggregate is also indicated for concrete
assemblies that require calculations to determine the
fire-resistance rating in accordance with Section
722.2.1 (i.e., Table 722.2.1.2(1), Note a).

- **Lightweight aggregate.** Concrete made with aggregates
of expanded clay, shale, slag or sintered fly ash or
any natural lightweight aggregate meeting ASTM C 330
and possessing equivalent fire-resistance properties and
weighting 85 to 115 pcf (1360 to 1840 kg/m³).

- Concrete made with this type of aggregate is listed in
Tables 721.1(1) (items 1, 2, 3, 4, 5, 6 and 7), 721.1(2)
(item 4) and 721.1(3) (item 4) with prescriptive details
regarding concrete fire-resistance ratings. This type of aggregate is also indicated for concrete
assemblies that require calculations to determine the
fire-resistance rating in accordance with Section
722.2.1 (i.e., Table 722.2.1.1) (also see Section 702.1).

- **Perlite.** A lightweight insulating concrete having a dry
unit weight of approximately 30 pcf (480 kg/m³) made
with perlite concrete aggregate. Perlite aggregate is
produced from a volcanic rock which, when heated, expands
to form a glass-like material of cellular structure.

- Concrete made with this type of aggregate is listed in
Tables 721.1(1) (item 1), 721.1(2) (item 1) and
721.1(3) (items 7, 16, 17, 18, 19 and 20) with pre-
scriptive details regarding concrete fire-resistance
ratings. This type of aggregate is also indicated for concrete
assemblies that require calculations to determine the fire-resistance rating in accordance
with Section 722.2.1 (i.e., Section 722.2.1.1.2).

- **Sand-lightweight.** Concrete made with a combination of expanded clay, shale, slag, slate, sintered fly ash, or any
natural lightweight aggregate meeting ASTM C 330 and
possessing equivalent fire-resistance properties and natu-
ral sand. Its unit weight is generally between 105 and 120
pcf (1680 and 1920 kg/m³).

- Concrete made with this type of aggregate is listed in
Tables 721.1(1) (items 1, 2, 3, 4, 5, 6 and 7), 721.1(2)
(item 4) and 721.1(3) (item 3) with prescriptive details
regarding concrete fire-resistance ratings. This type of aggregate is also indicated for concrete
assemblies that require calculations to determine the fire-
resistance rating in accordance with Section 722.2.1
(i.e., Table 722.2.1.1) (also see Section 702.1).

- **Siliceous aggregate.** Concrete made with normal-weight
aggregates consisting mainly of silica or compounds other
than calcium or magnesium carbonate, which contains
more than 40-percent quartz, chert or flint.

- Concrete made with this type of aggregate is listed in
Tables 721.1(1) (items 1, 2, 4, 5, 6 and 7), 721.1(2)
(items 3 and 4) and 721.1(3) (item 1) with prescrip-
tive details regarding concrete fire-resistance ratings.
This type of aggregate is also indicated for concrete
assemblies that require calculations to determine the
fire-resistance rating in accordance with Section
722.2.1 (i.e., Table 722.2.1.1).

- ** Vermiculite.** A light weight insulating concrete made
with vermiculite concrete aggregate which is laminated
micaceous material produced by expanding the ore at high
temperatures. When added to a Portland cement slurry
the resulting concrete has a dry unit weight of approximately
30 pcf (480 kg/m³).

- Concrete made with this type of aggregate is listed in
Tables 721.1(1) (item 1), 721.1(2) (item 1) and
720.1(3) (item 15) with prescriptive details regarding
concrete fire-resistance ratings. This type of aggregate
is also indicated for concrete assemblies that require calculations to determine the fire-resistance rating in accordance with Section 722.2.1 (i.e., Table
722.2.1.2(1), Note a).
CONGREGATE LIVING FACILITIES. A building or part thereof that contains sleeping units where residents share bathroom and/or kitchen facilities.

- Congregate living facilities are those pertaining to group housing (i.e., dormitories, fraternities, convents) that combine individual sleeping quarters with communal facilities for food, care, sanitation and recreation. The number of occupants in the facility determines the appropriate occupancy classification.

There are two thresholds: 10 and 16. A congregate living facility with 16 or fewer nontransient residents falls in the R-3 classification—for above 16 nontransient residents the classification is R-2. For transient residents, if there are 10 or fewer in the facility, it is also in the R-3 classification. If over 10 transient residents, it is an R-1 occupancy.

[F] CONSTANTLY ATTENDED LOCATION. A designated location at a facility staffed by trained personnel on a continuous basis where alarm or supervisory signals are monitored and facilities are provided for notification of the fire department or other emergency services.

- These locations are intended to receive trouble, supervisory and fire alarm signals transmitted by the fire protection equipment installed within a protected facility. It is the intent of Chapter 9 to have both an approved location and personnel who are acceptable to the code official responsible for actions taken when the fire protection system requires attention. The term "constantly attended" implies 24-hour surveillance of the system, at the designated location.

[A] CONSTRUCTION DOCUMENTS. Written, graphic and pictorial documents prepared or assembled for describing the design, location and physical characteristics of the elements of a project necessary for obtaining a building permit.

- To determine whether or not proposed construction is in compliance with code requirements, it is necessary that sufficient information be submitted to the building official for review. This typically consists of the drawings (such as floor plans, elevations, sections and details), specifications and product information describing the proposed work.

CONSTRUCTION TYPES. See Section 602.

Type I. See Section 602.2.
Type II. See Section 602.2.
Type III. See Section 602.3.
Type IV. See Section 602.4.
Type V. See Section 602.5.

- Construction types are "defined" by the materials and fire-resistance rating of the construction as specified by the provisions in Chapter 6.

[F] CONTINUOUS GAS DETECTION SYSTEM. A gas detection system where the analytical instrument is maintained in continuous operation and sampling is performed without interruption. Analysis is allowed to be performed on a cyclical basis at intervals not to exceed 30 minutes.

- This term refers to a system that is capable of constantly monitoring the presence of highly toxic or toxic compressed gases at or below the permissible exposure limit (PEL) for the gas. A continuous gas detection system will provide notification of a leak or rupture in a compressed gas cylinder or tank in a storage or use condition.

[F] CONTROL AREA. Spaces within a building where quantities of hazardous materials not exceeding the maximum allowable quantities per control area are stored, dispensed, used or handled. See also the definition of "Outdoor control area" in the International Fire Code.

- Control areas provide an alternative method for the use and storage of hazardous materials without classifying the building or structure as a high-hazard occupancy (Group H). This concept is based on regulating the allowable quantities of hazardous materials per control area, rather than per building area, by giving credit for further compartmentation through the use of fire barriers and horizontal assemblies having a minimum fire-resistance rating of not less than 1 hour. The maximum quantities of hazardous materials within a given control area cannot exceed the amounts for a given material listed in either Table 307.1(1) or 307.1(2) (see commentary, Section 414.2). Control areas are not limited to within buildings. A storage area that is exposed to the elements (wind, rain, snow, etc.) also cannot exceed the MAQ.

CONTROLLED LOW-STRENGTH MATERIAL. A self-compacte, cementitious material used primarily as a backfill in place of compacted fill.

- The definition provided is from ACI 229R. This type of material is known by many "local" names (e.g., flowable fill) and is commonly used in lieu of a compacted backfill. Requirements for its use under the code are outlined in Section 1804.6.

CONVENTIONAL LIGHT-FRAME CONSTRUCTION. A type of construction whose primary structural elements are formed by a system of repetitive wood-framing members. See Section 2308 for conventional light-frame construction provisions.

- Conventional light-frame construction is one of the three methods for designing wood buildings or structures that are recognized in Chapter 23. Section 2308 provides prescriptive provisions and specifications for this method. Since it is a prescriptive approach, conventional construction is necessarily limited in applicability (see Section 2308.2).

CORNICE. A projecting horizontal molded element located at or near the top of an architectural feature.

- This definition facilitates the applicability of roof loads that are listed in Table 1607.1.
CORRIDOR. An enclosed exit access component that defines and provides a path of egress travel.

- Corridors are regulated in the code because they serve as principal elements of travel in many means of egress systems within buildings. Typically, corridors have walls that extend from the floor to the ceiling. They need not extend above the ceiling or have doors in their openings unless a fire-resistance rating is required (see Section 1018).

While both aisles and corridors may result in a confined path of travel, an aisle is an unenclosed component, while a corridor would be an enclosed component of the means of egress. The enclosed character of the corridor restricts the sensory perception of the user. A fire located on the other side of the corridor wall, for example, may not be as readily seen, heard or smelled by the occupants traveling through the egress corridor. The code does not specifically state what is considered "enclosed" when corridors are not fire-resistance rated. When an egress path is bounded by partial-height walls, such as work-station partitions in an office, issues would be if the walls provided a confined path of travel and limited fire recognition in adjacent spaces by restricting line of sight, hearing and smell.

CORROSION RESISTANCE. The ability of a material to withstand deterioration of its surface or its properties when exposed to its environment.

- There are different environments that contain different types of materials to which building construction materials are exposed. "Corrosion resistance" is not an absolute term; it is relative to the building material and where it is being used. For instance, certain types of plastic polymers might resist corrosion when used in an exterior environment, but might not be resistant to corrosion from certain chemical gases that could be present in a laboratory.

[F] CORROSIVE. A chemical that causes visible destruction of, or irreversible alterations in, living tissue by chemical action at the point of contact. A chemical shall be considered corrosive if, when tested on the intact skin of albino rabbits by the method described in DOTn 49 CFR, Part 173.137, such chemical destroys or changes irreversibly the structure of the tissue at the point of contact following an exposure period of 4 hours. This term does not refer to action on inanimate surfaces.

- This definition is derived from DOL 29 CFR, Part 1910.1200. While corrosive materials do not present a fire, explosion or reactivity hazard, they do pose a handling and storage problem. Corrosive materials, therefore, are primarily considered a health hazard and are classified as Group H-4 material. Many corrosive chemicals are also strong oxidizing agents that require classification as a multiple hazard in accordance with Section 307.8.

COURT. An open, uncovered space, unobstructed to the sky, bounded on three or more sides by exterior building walls or other enclosing devices.

- Though not specifically identified in the definition, the provisions in the code for courts (see Section 1206) are only applicable to those areas created by the arrangement of exterior walls and used to provide natural light or ventilation (see Section 1206.1 and the definition of "Yard." See also the definition of "Egress court" for courts that are utilized for exit discharge.)

COVERED MALL BUILDING. A single building enclosing a number of tenants and occupants, such as retail stores, drinking and dining establishments, entertainment and amusement facilities, passenger transportation terminals, offices and other similar uses wherein two or more tenants have a main entrance into one or more malls. Anchor buildings shall not be considered as a part of the covered mall building. The term "covered mall building" shall include open mall buildings as defined below.

- The covered mall building is the entire area of the building (area of mall plus gross leasable area), excluding the anchor buildings. Passenger transportation terminals frequently are developed as wide concourses with small shops along the sides. For this reason, passenger transportation facilities are included. Transportation facilities used for freight or other purposes are not to be considered a covered mall building [see Figure 202.1(4)]. The term "covered mall building" also includes open mall buildings. Unless noted otherwise, open mall buildings shall comply with all the provisions for a covered mall building.

Mall. A roofed or covered common pedestrian area within a covered mall building that serves as access for two or more tenants and not to exceed three levels that are open to each other. The term "mall" shall include open malls as defined below.

- The mall is an interior, climate-controlled pedestrian way that is open to the tenant spaces within the mall building and typically connects to the anchor buildings. The term "mall" shall also include open mall. Unless noted otherwise, open malls must comply with all the provisions for malls.

Open mall. An unroofed common pedestrian way serving a number of tenants not exceeding three levels. Circulation at levels above grade shall be permitted to include open exterior balconies leading to exits discharging at grade.

- The open mall is an uncovered common pedestrian walk that is open to the sky above and to tenant spaces within the open mall building and typically connects to the anchor buildings. The size of the openings to the sky is in accordance with Section
DEFINITIONS

402.4.3. Unless noted otherwise, open malls must comply with all the provisions for malls.

Open mall building. Several structures housing a number of tenants, such as retail stores, drinking and dining establishments, entertainment and amusement facilities, offices, and other similar uses, wherein two or more tenants have a main entrance into one or more open malls. Anchor buildings are not considered as a part of the open mall building.

- The open mall building includes all of the buildings housing a number of tenants wherein two or more tenants have a main entrance into one or more open malls. Because the open mall is characterized by there not being a roof connecting one side of the pedestrian mall to the other, the covered mall "building" may actually be a collection of separate buildings which all rely on a shared pedestrian concourse for egress. Similar to the covered mall building, the open mall "building" does not include the anchor buildings. Unless noted otherwise, open mall buildings have to comply with all the provisions for covered mall buildings.

CRIPPLE WALL. A framed stud wall extending from the top of the foundation to the underside of floor framing for the lowest occupied floor level.

- Cripple walls are built on the top of footings or foundation walls. They can typically be found along the top of stepped foundation walls where the grade adjoining the structure changes height. Cripple walls must be properly braced to resist lateral forces. They are often treated the same as a first-story wall. Provisions for the bracing of cripple walls are located in Section 2308.9.4.

[F] CRYOGENIC FLUID. A liquid having a boiling point lower than \(-150^\circ\text{F}\) \((-101^\circ\text{C})\) at 14.7 pounds per square inch atmosphere (psia) (an absolute pressure of 101 kPa).

- Cryogenic fluids present a hazard because they are extremely cold. Should a spill occur, their extremely cold temperature affects other compounds exposed to the spilled cryogenic fluid. Cryogenic fluids may be flammable or nonflammable; however, nonflammable cryogenics may possess properties that cause them to support combustion or react severely with other materials. The code is only intended to classify flammable or oxidizing cryogenic fluids as a hazardous material.

CUSTODIAL CARE. Assistance with day-to-day living tasks; such as assistance with cooking, taking medication, bathing, using toilet facilities and other tasks of daily living. Custodial care include occupants who evacuate at a slower rate and/or who have mental and psychiatric complications.

- Persons who need custodial care may evacuate at a slower rate, but they are capable of self-preservation. See the commentary to Section 308, Group I-1, and Section 310, Group R-4.

CARE facilities encompass a full spectrum of acuity and support services and span a wide range of occupancy types including Groups E, I and R. There are three types of care defined in the codes: personal, custodial and medical. On the lower end of the care spectrum (i.e., personal care), occupants are supervised but do not need custodial or medical care. Where occupants may be elderly or impaired (i.e., custodial care), they may need occasional daily living assistance such as cooking and cleaning. While occupants may take longer to evacuate than average, they are capable of self-preservation. On the opposite end of the care spectrum, occupants may be completely bedridden and dependent on medical gases and emergency power to maintain life (i.e., medical care). The level of care provided describes the condition and capabilities of an occupant which then indicates appropriate standards for protection systems, both active and passive. See also the definitions for "24-hour care," "Ambulatory care facility," "Detoxification facility," "Foster care facility," "Nursing home," "Hospitals and psychiatric hospitals," "Medical care," "Personal care services" and "Incapable of self-preservation."

DALLE GLASS. A decorative composite glazing material made of individual pieces of glass that are embedded in a cast matrix of concrete or epoxy.

- Dalle glass is a form of "stained" or "decorative" glass, and is more commonly known as "faceted" glass. Dalle glass is an outdated term and is rarely used. It can be prefabricated in panels that are set into framed openings, or it can be constructed in place, similar to the way a mason would construct a single wythe masonry wall. The actual glazing can be heavy pieces of flat or textured glass, irregular-shaped chunks of glass, glass shapes or translucent minerals cut to form geometric patterns or artistic scenes. Knowing that Dalle glass or faceted glass is a type of decorative glass is necessary because decorative glass is not required to be safety glazed in hazardous locations as required in Section 2406.4 (see Sections 2406.4.1, 2406.4.2 and 2406.4.3 for specific exceptions).

DAMPER. See "Ceiling radiation damper," "Combination fire/smoke damper," "Fire damper" and "Smoke damper."

- Fire dampers are used primarily in heating, ventilating and air-conditioning (HVAC) duct systems that pass through fire-resistance-rated walls or floors. Dampers may also be installed in rated walls independent of HVAC duct systems. Dampers are provided to maintain the fire-resistance rating of the penetrated assembly. Fire dampers are regulated by UL 555, ceiling dampers by UL 555C and smoke dampers by UL 555S.

DANGEROUS. Any building, structure or portion thereof that meets any of the conditions described below shall be deemed dangerous:

1. The building or structure has collapsed, has partially collapsed, has moved off its foundation or lacks the necessary support of the ground.
2. There exists a significant risk of collapse, detachment or dislodgment of any portion, member, appurtenance or ornamentation of the building or structure under service loads.

- This definition describes two conditions that are considered to be dangerous in buildings in regards to support, loading and the ability of the structure to resist loads. Its purpose is to clarify the building official's authority under Section 3401.5.

**[F] DAY BOX.** A portable magazine designed to hold explosive materials constructed in accordance with the requirements for a Type 3 magazine as defined and classified in Chapter 56 of the International Fire Code.

- A day box is an explosive magazine that is listed in Note e of Table 307.1(1). Where used, a day box will allow an increase in the MAQs of hazardous materials.

**DEAD LOAD.** The weight of materials of construction incorporated into the building, including but not limited to walls, floors, roofs, ceilings, stairways, built-in partitions, finishes, cladding and other similarly incorporated architectural and structural items, and the weight of fixed service equipment, such as cranes, plumbing stacks and risers, electrical feeders, heating, ventilating and air-conditioning systems and automatic sprinkler systems.

- The definition of "dead loads" identifies the type of items that must be accounted for (also see Section 1607.12.3.1 for inclusion of items on landscaped roofs). This definition is necessary to distinguish dead loads from other loads, and for use in load combinations, as specified by Section 1605. Dead loads are considered permanent in the load combinations. The nominal dead load is to be determined in accordance with Section 1606.

The weights of service equipment, such as plumbing stacks and risers; heating, ventilating and air-conditioning (HVAC) equipment; elevators and elevator machinery; fire protection systems and similar fixed equipment are to be included in the dead load. For the most part, tracking the weights of each utility system is not practical and the structural design is therefore based on a dead load allowance for these items. At times the actual weight of equipment to be installed is unknown during the design phase of a building because the supplier of the equipment has not yet to be determined. The structural design must often proceed based on an estimated equipment dead load. For additional comments on dead load estimates, see the commentary to Section 1606.2.

**DECORATIVE GLASS.** A carved, leaded or Dalle glass or glazing material whose purpose is decorative or artistic, not functional; whose coloring, texture or other design qualities or components cannot be removed without destroying the glazing material and whose surface, or assembly into which it is incorporated, is divided into segments.

- This definition is needed to understand and properly apply exceptions to the requirements for safety glazing. Decorative glass is excluded at specific hazardous locations, and thus is not required to be safety glazing (see Sections 2406.4.1, 2406.4.2 and 2406.4.3).

**[F] DECORATIVE MATERIALS.** All materials applied over the building interior finish for decorative, acoustical or other effect (such as curtains, draperies, fabrics, streamers and surface coverings), and all other materials utilized for decorative effect (such as batting, cloth, cotton, hay, stalks, straw, vines, leaves, trees, moss and similar items), including foam plastics and materials containing foam plastics. Decorative materials do not include floor coverings, ordinary window shades, interior finish and materials 0.025 inch (0.64 mm) or less in thickness applied directly to and adhering tightly to a substrate.

- The significance of this definition is to provide information as to what is not regulated as decorative materials in the application of code requirements. While any dictionary would define floor coverings, window shades and wall paper as being "decorative" in a building interior, they are not considered decorative materials for the flame-resistance testing to which the code requirements are intended to apply.

**DEEP FOUNDATION.** A deep foundation is a foundation element that does not satisfy the definition of a shallow foundation.

- Chapter 18 identifies two major classifications for foundations; either shallow or deep. This definition clarifies that foundations not meeting the definition of "Shallow foundation" are, by default, considered to be deep foundations.

**[F] DEFLAGRATION.** An exothermic reaction, such as the extremely rapid oxidation of a flammable dust or vapor in air, in which the reaction progresses through the unburned material at a rate less than the velocity of sound. A deflagration can have an explosive effect.

- Materials that present a deflagration hazard usually burn very rapidly with the release of energy from a chemical reaction in the form of intense heat. Confined deflagration hazards under pressure can result in an explosion. Most hazardous materials that pose a severe deflagration hazard are classified as Group H-2 in accordance with Section 307.4 (see the definition of "Detonation").

**[F] DELUGE SYSTEM.** A sprinkler system employing open sprinklers attached to a piping system connected to a water supply through a valve that is opened by the operation of a detection system installed in the same areas as the sprinklers. When this valve opens, water flows into the piping system and discharges from all sprinklers attached thereto.

- A deluge system applies large quantities of water or foam throughout the protected area by means of a system of open sprinklers. In a fire, the system is activated by a fire detection system that makes it possible to apply water to a fire more quickly and to cover a larger area than with a conventional automatic
sprinkler system, which depends on sprinklers being activated individually as the fire spreads. As the definition indicates, the sprinklers are open. There is no fusible link so when water is admitted into the system by the fire detection system, it flows through the piping and is immediately discharged through the sprinkler heads.

Deluge systems are particularly beneficial in hazardous areas where the fuel loads (combustible contents) are of such a nature that fire may grow with exceptional rapidity and possibly flash ahead of the operations of conventional automatic sprinklers.

**DEFINITIONS**

**DESIGN DISPLACEMENT.** See Section 1905.1.1.

- This definition is a modification of ACI 318 text and is therefore located in Section 1905.

**DESIGN EARTHQUAKE GROUND MOTION.** The earthquake ground motion that buildings and structures are specifically proportioned to resist in Section 1613.

- A structure must be designed for the level of ground motion corresponding to the design earthquake. This is determined in Section 1613.3.4 as two-thirds of the maximum earthquake ground motions with adjustments to account for the site's soil profile.

**DESIGN FLOOD.** The flood associated with the greater of the following two areas:

1. Area with a flood plain subject to a 1-percent or greater chance of flooding in any year; or
2. Area designated as a flood hazard area on a community’s flood hazard map, or otherwise legally designated.

- The design flood is either the base flood or another flood based on other criteria. A state or local jurisdiction may choose to prepare and adopt flood hazard maps that show flood hazard areas that are not on maps prepared by FEMA. These may be areas that FEMA did not study or areas that were studied with different criteria. For example, as a general rule, FEMA is concerned primarily with flooding sources that have a drainage area of 1 square mile (2.590 km²) or more. For another example, some communities elect to prepare flood hazard maps based on the assumption that the upland watershed is built out to existing zoning, often called “ultimate development” and sometimes the “flood of record” is the basis for regulation.

**DESIGN FLOOD ELEVATION.** The elevation of the “design flood,” including wave height, relative to the datum specified on the community’s legally designated flood hazard map. In areas designated as Zone AO, the design flood elevation shall be the elevation of the highest existing grade of the building’s perimeter plus the depth number (in feet) specified on the flood hazard map. In areas designated as Zone AO where a depth number is not specified on the map, the depth number shall be taken as being equal to 2 feet (610 mm).

- The design flood elevation is the height to which floodwaters are predicted to rise during passage or occurrence of the design flood. Unless a community has adopted another flood hazard map or otherwise designated the design flood, the design flood elevation is the base flood elevation shown on the Flood Insurance Rate Maps (FIRM). The datum specified on the flood hazard map is important because it may differ from the datum used locally for other purposes.

Some flood hazard maps have areas denoted as AO Zones, identifying areas subject to sheet flow flooding, shallow flooding or ponding. Specific instruction for these zones is provided in the code because the maps specify a flood depth above grade rather than a height above datum.

FEMA refers to some areas subject to shallow flooding as AH Zones. AH Zones have specified base flood elevations and they are treated the same as the other A Zones with base flood elevations.

**DESIGN PROFESSIONAL, REGISTERED.** See “Registered design professional.”

**DESIGN PROFESSIONAL IN RESPONSIBLE CHARGE, REGISTERED.** See “Registered design professional in responsible charge.”

- The code uses two terms when requiring action by a design professional: “registered design professional” and “registered design professional in responsible charge.” See the commentary under those definitions.

**DESIGN STRENGTH.** The product of the nominal strength and a resistance factor (or strength reduction factor).

- This definition is needed to apply the strength design requirements in the code. The design strength is the nominal strength multiplied by a resistance or strength reduction factor that is less than one. The design strength and corresponding strength reduction factors are specified in the applicable material chapter of the code or a standard that is referenced therein.

**DESIGNATED SEISMIC SYSTEM.** Those nonstructural components that require design in accordance with Chapter 13 of ASCE 7 and for which the component importance factor, Iₚ, is greater than 1 in accordance with Section 13.1.3 of ASCE 7.

- Designated seismic systems are those architectural, electrical and mechanical components and systems in the referenced ASCE 7 provisions that are assigned a component importance factor of 1.5. The importance factor is an indication that, compared with nonstructural components with the typical factor of
1.0, there is a higher level of importance placed on the system so that it will remain operational during and after an earthquake. This definition is important in correctly applying the provisions for special inspection and testing for designated seismic systems.

**[F] DETACHED BUILDING.** A separate single-story building, without a basement or crawl space, used for the storage or use of hazardous materials and located an approved distance from all structures.

- The term is used to define the type of structure the code recognizes for the use and storage of hazardous materials in excess of the MAQ. While the definition addresses all hazardous materials, a detached storage building is only required for Group H-1, H-2 and H-3 structures as indicated in Sections 415.5.2 and 415.6, and Table 415.5.2. The location of the structure may be regulated by Section 415.5.1 based on the characteristics of the materials contained in the building.

**DETAILED PLAIN CONCRETE STRUCTURAL WALL.** See Section 1905.1.1.

- This definition is a modification of ACI 318 text and is therefore located in Section 1905.

**DETECTABLE WARNING.** A standardized surface feature built in or applied to walking surfaces or other elements to warn visually impaired persons of hazards on a circulation path.

- A detectable warning is a change in texture that is detectable by a person with a vision impairment. Technical specifications for a detectable warning surface are set forth in ICC A117.1. Detectable warnings are only required for transit platform edges so that users can be confident of the warning that is intended to be communicated and not be confused by multiple, different surfaces intended to convey the same warning (see commentary, Section 1109.10).

**[F] DETECTOR, HEAT.** A fire detector that senses heat—either abnormally high temperature or rate of rise, or both.

- In a fire, heat is released that causes the temperature in a room or space to increase. Automatic fire detectors that sense abnormally high temperature or rate of temperature rise are known as heat detectors. These include fixed temperature detectors, rate compensation detectors and rate-of-rise detectors. The code requires all automatic fire detectors to be smoke detectors, except that heat detectors tested and approved in accordance with NFPA 72 may be used as an alternative to smoke detectors in rooms and spaces where, during normal operation, products of combustion are present in sufficient quantity to activate a smoke detector.

**[F] DETONATION.** An exothermic reaction characterized by the presence of a shock wave in the material which establishes and maintains the reaction. The reaction zone progresses through the material at a rate greater than the velocity of sound. The principal heating mechanism is one of shock compression. Detonations have an explosive effect.

- Detonations are distinguished from deflagrations (which are produced by explosive gases, dusts, vapors and mists) by the speed with which they propagate a blast effect. Detonations occur much faster than deflagrations, since they propagate a combustion zone at a velocity greater than the speed of sound. Deflagrations propagate a combustion zone at a velocity less than the speed of sound. The speed of sound is approximately 1,100 feet per second (336 m/s) at sea level. Both detonations and deflagrations may produce explosive results when they occur in a confined space. Materials that are considered a detonation hazard are classified as Group H-1 materials in accordance with Section 307.3.

**DETOXIFICATION FACILITIES.** Facilities that provide treatment for substance abuse, serving care recipients who are incapable of self-preservation or who are harmful to themselves or others.

- Persons in detoxification facilities may be physically incapable of self-preservation, or they may be confined within an area of a building for care or security purposes. See the commentary to Sections 308 and 407, Group 1-2.

Care facilities encompass a full spectrum of acuity and support services and span a wide range of occupancy types including Groups B, E, I and R. The level of care provided describes the condition and capabilities of an occupant which then indicates appropriate standards for protection systems, both passive and active. See also the definitions for “24-hour care,” “Ambulatory care facility,” “Group home,” “Hospitals and psychiatric hospitals,” “Incapable of self-preservation,” “Medical care,” “Nursing home” and “Personal care services.”

**DIAPHRAGM.** A horizontal or sloped system acting to transmit lateral forces to the vertical-resisting elements. When the term “diaphragm” is used, it shall include horizontal bracing systems.

- Floor and roof diaphragms act to transfer the lateral forces, such as wind or seismic loads, to the vertical-resisting elements (e.g., shear walls, braced frames, moment frames, etc.) supporting them at their perimeter or intermittent locations.

**Diaphragm, blocked.** In light-frame construction, a diaphragm in which all sheathing edges not occurring on a framing member are supported on and fastened to blocking.

- Unblocked diaphragms can resist low and moderate in-plane shear forces. Diaphragm sheathing may be applied with the long dimension of the sheathing either perpendicular or parallel to the main framing members. When there is no blocking under the edge of the sheathing that is not supported by the main framing member, the diaphragm is considered to be unblocked. Tables in Chapter 23 provide different val-
DEFINITIONS

ues for stapled structural sheathing when it is blocked and when it is not blocked. The ANSI/AF&PA Special Design Provisions for Wind and Seismic (SDPWS) contains separate tables for nailed diaphragms that are blocked and unblocked.

Diaphragm boundary. In light-frame construction, a location where shear is transferred into or out of the diaphragm sheathing. Transfer is either to a boundary element or to another force-resisting element.

Diaphragm boundary is typically the connection between the floor or roof sheathing and the band board surrounding the diaphragm.

Diaphragm chord. A diaphragm boundary element perpendicular to the applied load that is assumed to take axial stresses due to the diaphragm moment.

A diaphragm acts as a deep horizontal beam. The chords of the beam are the elements at the boundary of the diaphragm that are perpendicular to the direction of the applied load.

Diaphragm flexible. A diaphragm is flexible for the purpose of distribution of story shear and torsional moment where so indicated in Section 12.3.1 of ASCE 7.

Because analysis requirements in Section 1604.4 depend on the type of diaphragm, it is necessary to distinguish a rigid diaphragm from a flexible diaphragm. A flexible diaphragm deforms more than a rigid diaphragm when subjected to the same load. Where the diaphragm is determined to be flexible, the effect of diaphragm rigidity on the distribution of lateral forces is negligible and it need not be considered in the structural analysis. Load distribution from a flexible diaphragm to vertical supporting elements need not include torsional effects and is usually based on the tributary area associated with those elements.

This definition facilitates the classification of the diaphragm. While these diaphragm definitions apply to lateral loads in general, this definition makes a direct reference to the ASCE 7 earthquake provision that addresses the classification of diaphragms. That provision prescribes diaphragm construction that can be assumed to be flexible without the need of a substantiating calculation. Similarly, it prescribes diaphragm construction that can be assumed to be rigid.

Diaphragm, rigid. A diaphragm is rigid for the purpose of distribution of story shear and torsional moment when the lateral deformation of the diaphragm is less than or equal to two times the average story drift.

This definition facilitates the classification of a diaphragm. A rigid diaphragm deforms less than a flexible diaphragm when subjected to the same load. Load distribution from a rigid diaphragm is based on the stiffness of the vertical-resisting elements. Because they act as rigid bodies, torsion is also a consideration (see Section 1604.4 for analysis requirements).

Diaphragm, unblocked. A diaphragm that has edge nailing at supporting members only. Blocking between supporting structural members at panel edges is not included. Diaphragm panels are field nailed to supporting members.

Diaphragm boundary is typically the connection between the floor or roof sheathing and the band board surrounding the diaphragm.

Unblocked diaphragms can resist low and moderate shear forces. Diaphragm sheathing may be applied with the long dimension of the sheathing either perpendicular or parallel to the main framing members. When the edge of the sheathing is not supported by the main framing member, the diaphragm is considered to be unblocked. Various tables in Chapter 23 provide different values for structural sheathing when it is blocked and when it is not blocked.

DIMENSIONS.

Different dimensions are used to designate sizes of masonry units and masonry elements. The terms denote the common meanings of various types of dimensions used in Chapter 21.

Nominal. The specified dimension plus an allowance for the joints with which the units are to be laid. Nominal dimensions are usually stated in whole numbers. Thickness is given first, followed by height and then length.

The nominal dimensions of a masonry unit are the specified dimensions, plus the specified thickness of one mortar joint. Nominal dimensions are used for architectural layout of masonry structures. Figure 202.4(1) shows nominal dimensions for a specific concrete masonry unit.

Specified. Dimensions specified for the manufacture or construction of a unit, joint element.

The specified dimensions are prescribed in the construction documents. Figure 202.4(1) shows specified and nominal dimensions for a concrete masonry unit.

[F] DISPENSING. The pouring or transferring of any material from a container, tank or similar vessel, whereby vapors, dusts, fumes, mists or gases are liberated to the atmosphere.

This term refers to a specific operation whereby the act of transferring a material occurs and that has a hazard associated with the liberation of the material in the forms listed in the definition. It is not "handling" and should not be confused with that term (see the definitions of "Closed system" and "Handling").

DOOR, BALANCED. A door equipped with double-pivoted hardware so designed as to cause a semicounter balanced swing action when opening.

Balanced doors are commonly used to decrease the force necessary to open the door or to reduce the length of the door swing. Balanced doors typically reduce the clear opening width more than normally hinged doors [see Figure 202.4(2) and Section 1008.1.10.2].

DORMITORY. A space in a building where group sleeping accommodations are provided in one room, or in a series of closely associated rooms, for persons not members of the
same family group, under joint occupancy and single management, as in college dormitories or fraternity houses.

- Dormitories typically consist of a large room serving as a community sleeping room and many smaller rooms grouped together and serving as private or semiprivate sleeping rooms (sleeping units). A typical setting for dormitories is on college campuses; however, sleeping areas of a fire station and similar lodging facilities for occupants not of the same family group are also considered dormitories. Dormitories most often are not the permanent residence of the occupants. They are typically occupied only for a designated period of time, such as a school year. Though limited, the period of occupancy is usually more than 30 days, which provides the occupant with a familiarity of the structure such that the occupancy is not considered transient. A dormitory is classified as Group R-2 (see Section 310.4).

Structures containing a dormitory often have a cafeteria or central eating area and common recreational areas. When such conditions exist, the structure must comply with the mixed occupancy provisions of the code (see Section 508 and Figure 202.4(3)).

**DRAFTSTOP.** A material, device or construction installed to restrict the movement of air within open spaces of concealed areas of building components such as crawl spaces, floor/ceiling assemblies, roof/ceiling assemblies and attics.

- Draftstopping is required in concealed combustible spaces to limit the movement of air, smoke and other products of combustion. Draftstopping materials are permitted to be combustible based on the rationale that a large and thick enough combustible material will act as a hindrance against the free movement of air, of flame/fire and of the products of combustion [see Figures 202.4(4) and 202.4(5) for typical draftstopping applications (also see Section 718)]. Although the term “draftstopping” would seem to imply that its primary purpose is to hinder the circulation of air within the space, its intended purpose is to stop the movement of fire and products of combustion, as evidenced by the fact that draftstopping can be omitted in some cases when appropriate automatic fire sprinkler pro-tection is installed (see Sections 718.3.2, 718.3.3, 718.4.2 and 718.4.3).

**DRAG STRUT.** See “Collector.”

- The term “drag strut” is another term for “collector.”

2012 INTERNATIONAL BUILDING CODE® COMMENTARY
2-29
DEFINITIONS

Figure 202.4(3)
GROUP R-2—DORMITORY
(OCCUPANTS PRIMARILY NONTRANSIENT)

Figure 202.4(4)
EXAMPLE OF DRAFTSTOPPING
**DEFINITIONS**

**DRILLED SHAFT.** A drilled shaft is a cast-in-place deep foundation element constructed by drilling a hole (with or without permanent casing) into soil or rock and filling it with fluid concrete.

- This definition clarifies a term that refers to a specific type of deep foundation element (see the requirements of Section 1810.3.9.5).

- **Socketed drilled shaft.** A socketed drilled shaft is a drilled shaft with a permanent pipe or tube casing that extends down to bedrock and an uncased socket drilled into the bedrock.

- This definition clarifies a term that refers to a specific type of deep foundation element (see the requirements of Sections 1810.3.9.6 and 1810.4.9).

**[F] DRY-CHEMICAL EXTINGUISHING AGENT.** A powder composed of small particles, usually of sodium bicarbonate, potassium bicarbonate, urea-potassium-based bicarbonate, potassium chloride or monoammonium phosphate, with added particulate material supplemented by special treatment to provide resistance to packing, resistance to moisture absorption (caking) and the proper flow capabilities.

- A dry-chemical system extinguishes a fire by placing a chemical barrier between the fire and oxygen, which acts to smother a fire. This system is best known for protecting commercial ranges, commercial fryers and exhaust hoods. Wet-chemical extinguishing systems, however, are more commonly used for new installations in commercial cooking equipment.

The type of dry chemical to be used in the extinguishing system is a function of the hazard expected. The type of dry chemical used in a system must not be changed, unless it has been proven changeable by a testing laboratory; is recommended by the manufacturer of the equipment and is acceptable to the fire code official for the hazard expected. Additional guidance on the use of various dry-chemical agents can be found in NFPA 17, which gives minimum requirements for the design, installation, testing, inspection, approval, operation and maintenance of dry-chemical extinguishing systems.

**DRY FLOODPROOFING.** A combination of design modifications that results in a building or structure, including the attendant utility and sanitary facilities, being water tight with walls substantially impermeable to the passage of water and with structural components having the capacity to resist loads as identified in ASCE 7.

- All residential buildings and most nonresidential buildings in flood hazard areas are elevated so that the lowest floors (including basements) are at or above the design flood elevation. Under certain circumstances, nonresidential buildings (and nonresidential portions of mixed-use buildings) may be designed and constructed to incorporate dry floodproofing modifications that are designed to keep out water, and to withstand hydrostatic and hydrodynamic loads.

---

2012 INTERNATIONAL BUILDING CODE® COMMENTARY 2-31
DEFINITIONS

DURATION OF LOAD. The period of continuous application of a given load, or the aggregate of periods of intermittent applications of the same load.

- An understanding of duration of load is necessary since the allowable design stresses for wood members and fasteners must be modified by a duration of load factor that is a function of the length of time that the wood member must resist an applied load. See Section 4.3 of the AF&PA National Design Specification for Wood Construction (NDS) for discussion of the load duration factor for wood structures. Note that it can be applied in the basic allowable stress load combinations of Section 1605.3.1.1 even though traditional allowable stress increases are not permitted.

DWELLING. A building that contains one or two dwelling units used, intended or designed to be used, rented, leased, let or hired out to be occupied for living purposes.

- Dwellings are buildings intended to serve as residences for one or two families. Dwellings can be owner occupied or rented. The term “dwelling,” which refers to the building itself, is defined to distinguish it from the term “dwelling unit,” which is a single living unit within a building. It is important to recognize that the code is not intended to regulate detached one- and two-family dwellings and townhouses that are regulated by the International Residential Code® (IRC®) (see Section 101.2). See also the definition for “Townhouse.”

DWELLING UNIT. A single unit providing complete, independent living facilities for one or more persons, including permanent provisions for living, sleeping, eating, cooking and sanitation.

- A dwelling unit, as stated, is a residential unit that contains all of the necessary facilities for independent living. This provides a single, independent unit that serves a single family or single group of individuals. This terminology is used throughout the code for the determination of the application of various provisions. A dwelling unit is also distinguished from a sleeping unit which does not have all of the features of a dwelling unit and must comply with a different set of requirements (see the definition for “Sleeping unit”). A building containing one or more dwelling units is a “dwelling” (see the definitions for “ Dwelling” and “ Townhouse”). A building containing three or more dwelling units is regulated as a Group R-2 occupancy. The most common term used for such a building is an apartment house or condominium. To be considered a Group R-3 occupancy, the structure must have one or two dwelling units, or be subdivided by fire walls between every unit or every two units.

DWELLING UNIT OR SLEEPING UNIT, MULTI-STORY. See definition for “Multi-story unit.”

- In the application of Chapter 11, dwelling and sleeping units that have more than one story are subject to distinct provisions. See the commentary to “Multi-story unit.”

EGRESS COURT. A court or yard which provides access to a public way for one or more exits.

- The egress court requirements address situations where the exit discharge portion of the means of egress passes through confined areas near the building and therefore faces a hazard not normally found in the exit discharge (see Section 1027.4).

[F] ELEVATOR GROUP. A grouping of elevators in a building located adjacent or directly across from one another that responds to common hall call buttons.

- This definition clarifies the application of the emergency voice/alarm communication system requirements in Section 907.5.2.2 as to the locations, called “paging zones,” where system speakers are required (see commentary, Section 907.5.2.2).

[F] EMERGENCY ALARM SYSTEM. A system to provide indication and warning of emergency situations involving hazardous materials.

- Because of the potentially volatile nature of hazardous materials, an emergency alarm system is required outside of interior building rooms or areas containing hazardous materials in excess of the MAQs permitted in Tables 307.1(1) and 307.1(2). The intent of the emergency alarm, upon actuation by an alarm-initiating device, is to alert the occupants to an emergency condition involving hazardous materials. The initiation of the emergency alarm can be by manual or automatic means depending on the hazard and the specific requirements for the type of hazard (see Section 908).

[F] EMERGENCY CONTROL STATION. An approved location on the premises where signals from emergency equipment are received and which is staffed by trained personnel.

- This definition identifies the room or area located in the hazardous production materials (HPM) facility that is utilized for the purpose of receiving various alarms and signals. The smoke detectors located in the building’s recirculation ventilation ducts, the gas-monitoring/detection system and the telephone/fireprotective signaling systems located outside of HPM storage rooms are all required to be connected to the emergency control station. The location of the emergency control station must be approved by the building official. An approved location should be based on personnel being able to adequately monitor the necessary alarms and signals and on the fire department being able to gain access quickly when responding to emergency situations. Additionally, the room must be occupied by persons who are trained to respond to the various alarms and signals in the appropriate fashion.

2-32 2012 INTERNATIONAL BUILDING CODE® COMMENTARY
EMERGENCY ESCAPE AND RESCUE OPENING. An operable window, door or other similar device that provides for a means of escape and access for rescue in the event of an emergency.

- These are commonly windows that are sized and located such that they can be used to exit a building directly from a basement or bedroom during an emergency condition. The openings are also used by emergency personnel to rescue the occupants in a building (see Section 1029). They are never considered to be exit or exit access components for purposes of meeting minimum number of exit requirements.

[F] EMERGENCY VOICE/ALARM COMMUNICATIONS. Dedicated manual or automatic facilities for originating and distributing voice instructions, as well as alert and evacuation signals pertaining to a fire emergency, to the occupants of a building.

- An emergency voice/alarm communication system is a special feature of fire alarm systems in buildings with special evacuation considerations, such as a high-rise building or a large assembly space. Emergency voice/ alarm communication systems automatically communicate a fire emergency message to all occupants of a building on a general or selective basis. Such systems also enable the fire service to manually transmit voice instructions to the building occupants about a fire emergency condition and the action to be taken for evacuation or movement to another area of the building. Although most systems use prerecorded messages, some now use computer synthesized voices to communicate messages that allow customized messages unique to the facility.

EMPLOYEE WORK AREA. All or any portion of a space used only by employees and only for work. Corridors, toilet rooms, kitchenettes and break rooms are not employee work areas.

- An employee work area is different in an office versus on a factory line. An employee work area may expand past the station or desk where an employee performs his or her job. An employee work area could include common use spaces, but not public use spaces. Depending on the duties of the employee, it may also include copy areas, stock rooms, filing areas, an assembly line, etc. (see also the commentary for the definitions of "Common use" and "Public-use areas").

Note that not all employee-only areas are considered part of employee work areas (i.e., bathrooms, corridors, breakrooms).

ENTRANCE, PUBLIC. See "Public entrance."

ENTRANCE, RESTRICTED. See "Restricted entrance."

ENTRANCE, SERVICE. See "Service entrance."

- The requirements of Chapter 11 vary by the type of entrance being considered. See the commentary for "Public entrance," "Restricted entrance" and "Service entrance."

EQUIPMENT PLATFORM. An unoccupied, elevated platform used exclusively for mechanical systems or industrial process equipment, including the associated elevated walkways, stairs, alternating tread devices and ladders necessary to access the platform (see Section 505.3).

- A distinction is made between equipment platforms and mezzanines by way of this definition. Equipment platforms, covered in Section 505.3, are unoccupied and used exclusively for housing equipment and providing access thereto, and are not subject to the requirements for mezzanines. Their purpose could also be to allow access for maintenance, repair or modification of elevated or very large equipment. Equipment platforms allow efficient use of high bay areas by locating infrequently accessed equipment or processes overhead without the occupant load or increasing the hazard to occupants in the room. Elevated floor areas that do not meet this definition would be subject to the requirements for mezzanines.

ESSENTIAL FACILITIES. Buildings and other structures that are intended to remain operational in the event of extreme environmental loading from flood, wind, snow or earthquakes.

- This definition is needed to facilitate identification of Risk Category IV buildings under Section 1604.5. This is critical in determining the design earthquake, flood, snow and wind load criteria that apply to the facility.

[F] EXHAUSTED ENCLOSURE. An appliance or piece of equipment that consists of a top, a back and two sides providing a means of local exhaust for capturing gases, fumes, vapors and mists. Such enclosures include laboratory hoods, exhaust fume hoods and similar appliances and equipment used to locally retain and exhaust the gases, fumes, vapors and mists that could be released. Rooms or areas provided with general ventilation, in themselves, are not exhausted enclosures.

- Exhausted enclosures, such as laboratory hoods or exhaust fume hoods, are utilized to contain hazardous fumes and vapors. The use of an approved exhausted enclosure may allow an increase in the MAQ per control area of a given hazardous material. Exhausted enclosures are typically utilized when highly toxic or toxic compressed gases are involved. The exhausted enclosures are required to be of non-combustible construction, have specific ventilation criteria and be protected by an approved fire-extinguishing system.

EXISTING CONSTRUCTION. Any buildings and structures for which the start of construction commenced before the effective date of the community’s first flood plain management code, ordinance or standard. "Existing construction" is also referred to as "existing structures."

- For the NFIP, buildings and structures are considered to be "existing" if construction started before the local jurisdiction adopted its first regulation governing development in flood hazard areas. This distinction is important because new construction, for which the
DEFINITIONS

start of construction is after the date of the first regulation, is to be in full compliance with the regulation, including all subsequent alterations, improvements, repairs and additions. The distinction between existing construction and new construction also affects the rates used by the NFIP for flood insurance premiums. When work is proposed for existing construction or structures, the building official is required to examine costs of that work and determine if it is a "substantial improvement" as defined later in this section. If the work is a substantial improvement (or repair of substantial damage, as defined in this section), then the entire existing structure is to be brought into compliance with the flood-resistant provisions of the code.

EXISTING STRUCTURE (For Section 1612.2). See "Existing construction."

- This definition clarifies which buildings and structures would be considered as existing for the application of Chapter 34. More specifically, they are defined as buildings that were previously built and have valid permits. Buildings without permits would not be legally considered existing as far as receiving any of the exceptions afforded to buildings undergoing repairs and alterations and full compliance with the code for new buildings would be required. For the application of flood hazard area requirements, an existing structure is defined as "Existing construction."

EXISTING STRUCTURE (For Chapter 34). A structure erected prior to the date of adoption of the appropriate code, or one for which a legal building permit has been issued.

- See the commentary for the definition of "Existing construction."

EXIT. That portion of a means of egress system between the exit access and the exit discharge or public way. Exit components include exterior exit doors at the level of exit discharge, interior exit stairways, interior exit ramps, exit passageways, exterior exit stairways and exterior exit ramps and horizontal exits.

- Exits are the critical element of the means of egress system that the building occupants travel through to reach the exterior at the level of exit discharge. Exit stairways and ramps from upper and lower stories must be separated from adjacent areas with fire-resistance-rated construction. The fire-resistance-rated construction serves as a barrier between the fire and the means of egress and protects the occupants while they travel through the exit. Separation by fire-resistance-rated construction is not required, however, where the exit leads directly to the exterior at the level of exit discharge (e.g., exterior door at grade). Figure 202.5(1) illustrates three different types of exits: interior exit stairway, exterior exit stairway and exterior exit door.

A horizontal exit, while not discharging to the outside, does discharge to another building or refuge area. The door to the refuge area is through a fire wall or fire barrier (see the definition for "Exit, horizontal" and Section 1025).

EXIT ACCESS. That portion of a means of egress system that leads from any occupied portion of a building or structure to an exit.

- The exit access portion of the means of egress consists of all floor areas that lead from usable spaces within the building to the exit or exits serving that floor area. Crawl spaces and concealed attic and roof spaces are not considered to be part of the exit.
access. As shown in Figure 202.5(2), the exit access begins at the furthest points within each room or space and ends at the entrance to the exit.

EXIT ACCESS DOORWAY. A door or access point along the path of egress travel from an occupied room, area, or space where the path of egress enters an intervening room, corridor, exit access stair or exit access ramp.

- Exit access doorways are used to design many critical aspects of the means of egress including arrangement, number, separation, opening protection and exit sign placement. The term "doorway" has traditionally been limited to those situations where an actual opening, either with or without a door, is present. With "access point," the term "exit access doorway" is inclusive of specific points in the means of egress, which may not include a "door," such as when an unenclosed exit access stairway is used in the egress path.

EXIT ACCESS RAMP. An interior ramp that is not a required interior exit ramp.

- Unenclosed ramps may serve as part of the route for exit access when floor levels have changes in elevation. For the limited situations where exit access ramps can be used between stories, see Section 1010.2. Exit access elements are included in the travel distance requirements unless specifically exempted (i.e., open parking garages, outdoor facilities) (see Section 1016.3.1).

EXIT ACCESS STAIRWAY. An interior stairway that is not a required interior exit stairway.

- Unenclosed steps and stairways may serve as part of the route for exit access when floor levels have changes in elevation. For the limited situations where exit access stairways can be used between stories, see Section 1009.3. Exit access elements are included in the travel distance requirements unless specifically exempted (i.e., open parking garages, outdoor facilities) (see Section 1016.3.1).

EXIT DISCHARGE. That portion of a means of egress system between the termination of an exit and a public way.

- The exit discharge will typically begin when the building occupants reach the exterior at or very near grade level. It provides occupants with a path of travel away from the building. All components between the building and the public way are considered to be the exit discharge, regardless of the distance. In areas of sloping terrain, it is possible to have steps or stairs in the exit discharge leading to the public way. The exit discharge is part of the means of egress and, therefore, its components are subject to the requirements of the code [see Figures 202.5(1) and 202.5(3) and Section 1027].
DEFINITIONS

EXIT DISCHARGE, LEVEL OF. The story at the point at which an exit terminates and an exit discharge begins.

- The term is intended to describe the story where the transition from exit to exit discharge occurs. At this level, the occupant needs only to move in a substantially horizontal path to move along exit discharge [see Figure 202.5(4)]. Since the level is a volume rather than a horizontal plane, exterior exit steps may be part of the exit discharge when they provide access to the level that is closest to grade.

EXIT HARDWARE, FIRE. See “Fire exit hardware.”

- Fire exit hardware is a specific type of exit hardware. See the commentary for “Fire exit hardware.”

EXIT, HORIZONTAL. A path of egress travel from one building to an area in another building on approximately the same level, or a path of egress travel through or around a wall or partition to an area on approximately the same level in the same building, which affords safety from fire and smoke from the area of incidence and areas communicating therewith.

- This term refers to a fire-resistance-rated wall that subdivides a structure into multiple compartments and provides an effective barrier to protect occupants from a fire condition within one of the compartments. After occupants pass through a horizontal exit, they must be provided not only with sufficient space to gather but also with access to another exit, such as an exterior door or exit stairway, through which they can exit the building. Figure 202.5(5) depicts the exits serving a single building that is subdivided with a fire-resistance-rated wall (see Section 1025).

EXIT PASSAGeway. An exit component that is separated from other interior spaces of a building or structure by fire-resistance-rated construction and opening protectives, and provides for a protected path of egress travel in a horizontal direction to an exit or to the exit discharge.

- This term refers to a horizontal portion of the means of egress that serves as an exit element. Since an exit passageway is considered an exit element, it must be protected and separated as required by the code for exits (see Section 1023). Exit passageways between a vertical exit enclosure and an exterior exit door are typically found on the level of exit discharge to provide a protected path from a centrally located exit stairway to the exit discharge. In taller buildings that reduce floor sizes as they move up (sometimes called a wedding cake building), exit passageways may be utilized at “transfer floors” as stairway locations shift to move the vertical shafts in as the floor size decreases. Exit passageways that lead to an exterior exit door are commonly used in malls to satisfy the travel distance in buildings having a large floor area.

EXPANDED VINYL WALL COVERING. Wall covering consisting of a woven textile backing, an expanded vinyl base coat layer and a nonexpanded vinyl skin coat. The expanded base coat layer is a homogeneous vinyl layer that contains a
blowing agent. During processing, the blowing agent decomposes, causing this layer to expand by forming closed cells. The total thickness of the wall covering is approximately 0.055 inch to 0.070 inch (1.4 mm to 1.78 mm).

- Expanded vinyl wall coverings are manufactured with a textile backing, an expanded vinyl base coat layer consisting of closed cells and a vinyl skin coat. Expanded vinyl wall coverings are subject to the requirements of Section 803.7.

**[F] EXPLOSION.** An effect produced by the sudden violent expansion of gases, which may be accompanied by a shock wave or disruption, or both, of enclosing materials or structures. An explosion could result from any of the following:

1. Chemical changes such as rapid oxidation, deflagration or detonation, decomposition of molecules and runaway polymerization (usually detonations).
2. Physical changes such as pressure tank ruptures.
3. Atomic changes (nuclear fission or fusion).

- Materials that pose a threat of explosion are classified as Group H-1 when present in quantities exceeding the MAQ in Table 307.1(1), and are required to be kept in a detached storage building meeting the requirements of Section 415.6 of the code and Chapter 56 of the IFC.

**[F] EXPLOSIVE.** A chemical compound, mixture or device, the primary or common purpose of which is to function by explosion. The term includes, but is not limited to, dynamite, black powder, pellet powder, initiating explosives, detonators, safety fuses, squibs, detonating cord, igniter cord, igniters and display fireworks, 1.3G.

The term "explosive" includes any material determined to be within the scope of USC Title 18: Chapter 40 and also includes any material classified as an explosive other than consumer fireworks, 1.4G by the hazardous materials regulations of DOTn 49 CFR Parts 100-185.

**High explosive.** Explosive material, such as dynamite, which can be caused to detonate by means of a No. 8 test blasting cap when unconfined.

**Low explosive.** Explosive material that will burn or deflagrate when ignited. It is characterized by a rate of reaction that is less than the speed of sound. Examples of low explosives include, but are not limited to, black powder; safety fuse; igniters; igniter cord; fuse lighters; fireworks, 1.3G and propellants, 1.3C.

**Mass-detonating explosives.** Division 1.1, 1.2 and 1.5 explosives alone or in combination, or loaded into various types of ammunition or containers, most of which can be expected to explode virtually instantaneously when a small portion is subjected to fire, severe concussion, impact, the impulse of an initiating agent or the effect of a considerable discharge of energy from without. Materials that react in this manner represent a mass explosion hazard. Such an explosive will normally cause severe structural damage to adjacent objects. Explosive propagation could occur immediately to other items of ammunition and explosives stored sufficiently close to and not adequately protected from the initially exploding pile with a time interval short enough so that two or more quantities must be considered as one for quantity-distance purposes.

**UN/DOTn Class 1 explosives.** The former classification system used by DOTn included the terms "high" and "low" explosives as defined herein. The following terms further define explosives under the current system applied by DOTn for all explosive materials defined as hazard Class 1 materials. Compatibility group letters are used in concert with the division to specify further limitations on each division noted (i.e., the letter G identifies the material as a pyrotechnic substance or article containing a pyrotechnic substance and similar materials).

**Division 1.1.** Explosives that have a mass explosion hazard. A mass explosion is one which affects almost the entire load instantaneously.

**Division 1.2.** Explosives that have a projection hazard but not a mass explosion hazard.

**Division 1.3.** Explosives that have a fire hazard and either a minor blast hazard or a minor projection hazard or both, but not a mass explosion hazard.
DEFINITIONS

Division 1.4. Explosives that pose a minor explosion hazard. The explosive effects are largely confined to the package and no projection of fragments of appreciable size or range is to be expected. An external fire must not cause virtually instantaneous explosion of almost the entire contents of the package.

Division 1.5. Very insensitive explosives. This division is comprised of substances that have a mass explosion hazard, but that are so insensitive there is very little probability of initiation or of transition from burning to detonation under normal conditions of transport.

Division 1.6. Extremely insensitive articles which do not have a mass explosion hazard. This division is comprised of articles that contain only extremely insensitive detonating substances and which demonstrate a negligible probability of accidental initiation or propagation.

 Explosives either detonate or deflagrate when initiated by either heat, shock or electric current. While these materials are normally designed and intended to be initiated by detonators under controlled conditions, heat, shock and electric current from uncontrolled sources may initiate these materials to produce an explosion. DOTn classifies explosives in six classes according to the degree of hazard posed by the material. The most dangerous of these materials is capable of almost simultaneous detonation of all of the material in a single load or store. The least-sensitive explosives produce blasts limited to the packages in which they are transported. This definition of explosives includes materials such as detonators, blasting agents and water gels; examples of these materials are listed in DOTn 27 CFR, Part 55.23.

Explosive materials are subdivided into high, low, mass-detonating and UN/DOTn Class 1 explosives. High explosives and mass-detonating explosives are typically classified as Group H-1 and present a detonation hazard. Low explosives more commonly are classified as Group H-2, as they tend to deflagrate or burn upon ignition. Mass-detonating devices present a greater threat to adjacent objects and structures. The IFC, therefore, contains provisions in the form of Table 5605.3 to deal with the separation distances for mass explosion hazards.

The definitions cited in this section are consistent with DOTn 49 CFR, Part 173.50. The hazards of this group of materials vary with the nature of the material, with some explosives being very sensitive and others less sensitive. Some explosives detonate, others deflagrate and the hazards of others are limited to intense burning. The classification system was designed to correlate with the system of classification developed under recommendations of the UN, wherein all explosive materials are placed into a hazard class of Class 1. This class is further divided into six divisions: Divisions 1.1 through 1.6.

EXTERIOR INSULATION AND FINISH SYSTEMS (EIFS). EIFS are nonstructural, nonload-bearing, exterior wall cladding systems that consist of an insulation board attached either adhesively or mechanically, or both, to the substrate; an integrally reinforced base coat and a textured protective finish coat.

 An exterior insulation and finish system (EIFS) is an exterior cladding that is specifically addressed in Section 1408. A definition is necessary in order to ensure the proper application of these requirements.

EXTERIOR INSULATION AND FINISH SYSTEMS (EIFS) WITH DRAINAGE. An EIFS that incorporates a means of drainage applied over a water-resistive barrier.

 Although EIFS and EIFS with drainage are somewhat similar, the presence of the water-resistive barrier makes it necessary to treat this material differently in code regulations.

EXTERIOR SURFACES. Weather-exposed surfaces.

 Exterior surfaces are the vertical and horizontal surfaces located on the outside of a building or structure and are subject to weather conditions, such as wind, changes in temperature, humidity, moisture and dampness. The commentary for the definition of "Weather-exposed surfaces" allows for specific exceptions to areas on the exterior of a building or structure that will not be exposed to direct contact with water, such as rain, sleet and frozen or melting snow.

EXTERIOR WALL. A wall, bearing or nonbearing, that is used as an enclosing wall for a building, other than a fire wall, and that has a slope of 60 degrees (1.05 rad) or greater with the horizontal plane.

 A wall is defined as an exterior element that encloses a structure and that has a slope equal to or greater than 60 degrees (1.05 rad) from the horizontal plane. Exterior enclosing elements with slopes less than this are generally subjected to more severe weather exposure than vertical surfaces and thus may experience a greater amount of water intrusion. These sloped surfaces, which may include elements such as inset window sills, sloped parapets and other architectural elements, should be designed to resist water penetration in a manner similar to a roof.

EXTERIOR WALL COVERING. A material or assembly of materials applied on the exterior side of exterior walls for the purpose of providing a weather-resisting barrier, insulation or for aesthetics, including but not limited to, veneers, siding, exterior insulation and finish systems, architectural trim and embellishments such as cornices, soffits, facias, gutters and leaders.

 Materials such as wood, masonry, metal, concrete, structural glass and plastics are used for exterior wall coverings. It should be noted that exterior wall coverings that are combustible are to meet the requirements for combustible materials found in Section 1406.2.

EXTERIOR WALL ENVELOPE. A system or assembly of exterior wall components, including exterior wall finish materials, that provides protection of the building structural
members, including framing and sheathing materials, and conditioned interior space, from the detrimental effects of the exterior environment.

- This definition is needed for the understanding and proper application of the weather protection requirements in Section 1403.2.

**F RATING.** The time period that the through-penetration firestop system limits the spread of fire through the penetration when tested in accordance with ASTM E 814 or UL 1479.

- See the definition of "Through-penetration firestop system." The F rating is determined not only from a fire endurance test, but also includes a test for mechanical integrity of the through-penetration seal after fire exposure, known as the "hose stream test." The F rating indicates that the firestop system is capable of stopping the fire, flame and hot gases from passing through the assembly at the penetration.

**FABRIC PARTITION.** A partition consisting of a finished surface made of fabric, without a continuous rigid backing, that is directly attached to a framing system in which the vertical framing members are spaced greater than 4 feet (1219 mm) on center.

- This definition identifies which assemblies are considered fabric partitions for the purpose of applying the specific load criteria that is given in Section 1607.14.1. They are typically for uses such as office furniture panel systems, for open floor plans in offices and similar occupancies.

**FABRICATED ITEM.** Structural, load-bearing or lateral load-resisting assemblies consisting of materials assembled prior to installation in a building or structure, or subjected to operations such as heat treatment, thermal cutting, cold working or reforming after manufacture and prior to installation in a building or structure. Materials produced in accordance with standard specifications referenced by this code, such as rolled structural steel shapes, steel reinforcing bars, masonry units and wood structural panels, or in accordance with a referenced standard which provides requirements for quality control done under the supervisions of a third-party quality control agency, shall not be considered "fabricated items."

- The term "fabricated item" can easily be misinterpreted to encompass a number of items for which the code does not intend special inspections; therefore, the term is defined to clarify the intent of the code (see Section 1704). Common construction items are often fabricated under standards that are referenced in the code and many of these provide for quality assurance by third-party supervision. Since special inspections are analogous to such quality assurance programs, in these cases it is not warranted to also require special inspections.

**[F] FABRICATION AREA.** An area within a semiconductor fabrication facility and related research and development areas in which there are processes using hazardous production materials. Such areas are allowed to include ancillary rooms or areas such as dressing rooms and offices that are directly related to the fabrication area processes.

- This definition describes the basic component of an HPM facility. The code uses this definition to provide certain material limitations on both a quantity and density basis, and to require enclosure of the fabrication areas with fire barrier assemblies. The fabrication area of an HPM facility is the area where hazardous materials are actively handled and processed. The fabrication area includes accessory rooms and spaces, such as work stations and employee dressing rooms.

**FACILITY.** All or any portion of buildings, structures, site improvements, elements and pedestrian or vehicular routes located on a site.

- This term is intentionally broad and includes all portions within a site and all aspects of that site that contain features required to be accessible. This includes parking areas, exterior walkways leading to accessible features, recreational facilities, such as playgrounds and picnic areas, as well as any structures on the site (see also the commentary to the definition of "Site").

**FACTORED LOAD.** The product of a nominal load and a load factor.

- This definition explains the term "factored loads" so that the loads to be applied in strength design are clear. Factored loads are determined for strength design for load and resistance factor design (LRFD) by multiplying nominal load (see the definition of "Nominal loads") by a load factor, as in the load combinations of Section 1605.2. While this definition is clear for most loading, the exception would be the wind load, W, and earthquake load, E, both of which are computed directly at a strength level without the need for applying a load factor. This is evidenced by a load factor of 1.0 applied to earthquake and wind loads in the strength load combinations of Section 1605.2.

**FIBER-CEMENT SIDING.** A manufactured, fiber-reinforcing product made with an inorganic hydraulic or calcium silicate binder formed by chemical reaction and reinforced with discrete organic or inorganic nonasbestos fibers, or both. Additives that enhance manufacturing or product performance are permitted. Fiber-cement siding products have either smooth or textured faces and are intended for exterior wall and related applications.

- Fiber-cement siding is also a material used for weather-resistant siding. It is manufactured from fiber-reinforced cement, and the code permits its use as either panel siding or horizontal lap siding.
DEFINITIONS

FIBER-REINFORCED POLYMER. If a polymeric composite material consisting of reinforcement fibers, such as glass, impregnated with a fiber-binding polymer which is then molded and hardened. Fiber-reinforced polymers are permitted to contain cores laminated between fiber-reinforced polymer facings.

- Fiber-reinforced polymer is used in building construction for purposes such as light-transmitting sheet panels, structural forms for concrete, sandwich panel construction and the replication of historic building ornamentation. The purpose of this definition is to describe the composition of this material in order to properly identify the element that is to comply with Section 2612.

FIBERBOARD. A fibrous, homogeneous panel made from lignocellulosic fibers (usually wood or cane) and having a density of less than 31 pounds per cubic foot (pcf) (497 kg/m³) but more than 10 pcf (160 kg/m³).

- Fiberboard is used primarily as an insulating board and for decorative purposes, but may also be used as wall or roof sheathing. The cellulosic components of fiberboard are broken down into ﬁbers and molded to create the bond between the ﬁbers. Other ingredients may be added during processing to provide or improve certain properties, such as strength and water resistance, in addition to surface ﬁnishes for decorative products. Fiberboard is used in all locations where panels are desirable, including wall sheathing, insulation of walls and roofs, roof decking, doors and interior finish.

FIELD NAILING. See "Nailing, field."

- See the commentary for "Nailing, field."

[F] FIRE ALARM BOX, MANUAL. See "Manual fire alarm box."

- This is primarily known as a "manual fire alarm box" and is addressed in the commentary for that term.

[F] FIRE ALARM CONTROL UNIT. A system component that receives inputs from automatic and manual fire alarm devices and may be capable of supplying power to detection devices and transponders or off-premises transmitters. The control unit may be capable of providing a transfer of power to the notification appliances and transfer of condition to relays or devices.

- The fire alarm control unit (panel) acts as a point where all signals initiated within the protected building are received before the signal is transmitted to a constantly attended location. As the name implies, it also contains controls to test and manually activate or silence systems.

[F] FIRE ALARM SIGNAL. A signal initiated by a fire alarm-initiating device such as a manual fire alarm box, automatic fire detector, waterflow switch or other device whose activation is indicative of the presence of a fire or fire signature.

- This signal is transmitted to a fire alarm control unit as a warning that requires immediate action. The personnel at the constantly attended location are trained to immediately respond to a fire alarm signal, which indicates the presence of a fire. A fire alarm signal assumes an actual fire has been detected (see the definition of "Alarm signal"). The fire alarm signal is not the signal used to notify the occupants of an emergency condition. Such an action would involve the audible alarm, visual alarm or emergency voice/ alarm notification appliances.

[F] FIRE ALARM SYSTEM. A system or portion of a combination system consisting of components and circuits arranged to monitor and announce the status of fire alarm or supervisory signal-initiating devices and to initiate the appropriate response to those signals.

- Fire alarm systems are installed in buildings to limit fire casualties and property losses by notifying the occupants of the building, the local fire department or both of an emergency condition. The alarm notification appliances associated with fire alarm systems are intended to be evacuation alarms. All fire alarm systems must be designed and installed to comply with NFPA 72. The term is among the most generic used in the code. It does not necessarily imply an automatic or manual system nor does it identify what type of notification, if any, should be provided. The definition only indicates that an appropriate response must be provided but does not indicate what that response must be. The appropriate responses are identified within the respective sections of Section 907.

FIRE AREA. The aggregate floor area enclosed and bounded by fire walls, fire barriers, exterior walls or horizontal assemblies of a building. Areas of the building not provided with surrounding walls shall be included in the fire area if such areas are included within the horizontal projection of the roof or floor next above.

- This term is used to describe a specific and controlled area within a building that may consist of a portion of the floor area within a single story, one entire story or the combined floor area of several stories, depending on how these areas are enclosed and separated from other floor areas. Where a fire barrier with a fire-resistance rating in accordance with Section 707.3.10 divides the floor area of a one-story building, the floor area on each side of the wall would constitute a separate fire area. If a horizontal assembly separating the two stories in a two-story building is fire-resistance rated in accordance with Section 711.3, each story would be a separate fire area. In cases where mezzanines are present, the floor area of the mezzanine is included in the fire area calculations, even though the area of the mezzanine does not contribute to the building area calculations. See the commentary to Sections 707.3.10 and 711.3 for further information.

Note that fire walls are one way of creating fire areas but are typically used to create separate buildings.
FIRE BARRIER. A fire-resistance-rated wall assembly of materials designed to restrict the spread of fire in which continuity is maintained.

- The term represents wall assemblies with a fire-resistance rating that are constructed in accordance with Section 707. Even though the definition applies to walls, horizontal assemblies also can be fire barriers. See the definition of "Horizontal assembly" and the requirements in Section 711 that would apply to floor and roof assemblies designed to restrict the spread of fire. See Figure 202.6(1) for examples of fire barriers and Figure 202.8(3) for examples of horizontal assemblies.

![Diagram of Fire Barrier]

[F] FIRE COMMAND CENTER. The principal attended or unattended location where the status of detection, alarm communications and control systems is displayed, and from which the systems can be manually controlled.

- Fire command centers are communication centers where dedicated manual and automatic facilities are located for the origination, control and transmission of information and instruction pertaining to a fire emergency to the occupants (including fire department personnel) of the building. Fire command centers must provide facilities for the control and display of the status of all fire protection (detection, signaling, etc.) systems. These stations must be located in secure areas as approved by the authority having jurisdiction. Often this is a location near the primary building entrance. Fire command centers also may be combined with other building operations and security facilities when permitted by the authority having jurisdiction; however, operating controls for use by the fire department must be clearly marked.

FIRE DAMPER. A listed device installed in ducts and air transfer openings designed to close automatically upon detection of heat and resist the passage of flame. Fire dampers are classified for use in either static systems that will automatically shut down in the event of a fire, or in dynamic systems that continue to operate during a fire. A dynamic fire damper is tested and rated for closure under elevated temperature airflow.

- See the definition of "Damper."

[F] FIRE DETECTOR, AUTOMATIC. A device designed to detect the presence of a fire signature and to initiate action.

- Automatic fire detectors include all approved devices designed to detect the presence of a fire and automatically initiate emergency action. These include smoke-sensing fire detectors, heat-sensing fire detectors, flame-sensing fire detectors, gas-sensing fire detectors and other fire detectors that operate on other principles as approved by the fire code official. Automatic fire detectors must be selected based on the type and size of fire to be detected and the response required. The automatic fire detector sends a signal to a processing unit to initiate some predeter- mined action. The processing unit may be internal to the device as is the case with single-station smoke detectors or it may be an external unit as in the case of a fire alarm control unit. Automatic fire detectors must be approved, installed and tested to comply with the code and NFPA 72.

FIRE DOOR. The door component of a fire door assembly.

- A fire door is the primary component of a fire door assembly. The fire protection rating assigned to a tested fire door is only valid if the door is installed in a labeled frame with appropriate hardware. Installation requirements are contained in the referenced standard, NFPA 80. Door ratings are expressed in minutes or hours. Field modification of doors are primarily limited to the mounting of listed hardware.

FIRE DOOR ASSEMBLY. Any combination of a fire door, frame, hardware and other accessories that together provide a specific degree of fire protection to the opening.

- Fire door assemblies, (door, frame and hardware) are required to be tested using the appropriate standard and then installed in accordance with NFPA 80. Side-hinged doors, hardware and frames are often manufactured separately with manufacturers' and listing agencies defining acceptable combinations of assembly components that have been tested together.

FIRE DOOR ASSEMBLY, FLOOR. See "Floor fire door assembly."

- This category of fire door assembly is referred to in the code as a "floor fire door assembly." Commentary is provided with that definition.

FIRE EXIT HARDWARE. Panic hardware that is listed for use on fire door assemblies.

- Where a door that is required to be of fire-resistance-rated construction also has panic hardware, the hardware is required to be listed for use on the fire door. Thus, fire door hardware has been tested to function
DEFINITIONS

properly when exposed to the effects of a fire (see the definition for "Panic hardware" and Section 1008.1.10).

[F] FIRE LANE. A road or other passageway developed to allow the passage of fire apparatus. A fire lane is not necessarily intended for vehicular traffic other than fire apparatus.

- The term "fire lane" is synonymous with the term "fire apparatus access road," both being a road that provides access from a fire station to a building, or portion thereof. However, it should be noted that the driving surface is not necessarily the same as that provided for a public road. The driving surface must be a surface that can be shown to adequately support the load of anticipated emergency vehicles.

FIRE PARTITION. A vertical assembly of materials designed to restrict the spread of fire in which openings are protected.

- Fire partitions are used as wall assemblies to separate adjacent tenant spaces in covered and open mall buildings, to separate dwelling units, to separate sleeping rooms, to enclose corridors and to enclose elevator lobbies. Section 708 establishes the construction requirements for fire partitions. The fire-resistance ratings, continuity requirements and opening protective requirements for fire partitions are usually less restrictive than those for fire barriers.

FIRE PROTECTION RATING. The period of time that an opening protective will maintain the ability to confine a fire as determined by tests prescribed in Section 715. Ratings are stated in hours or minutes.

- The term "fire protection rating" applies to the fire performance of an opening protective, such as a fire door, which is determined through tests performed in accordance with NFPA 252 or UL 10C.

[F] FIRE PROTECTION SYSTEM. Approved devices, equipment and systems or combinations of systems used to detect a fire, activate an alarm, extinguish or control a fire, control or manage smoke and products of a fire or any combination thereof.

- A fire protection system is any approved device or equipment used singly or in combination, either manually or automatically, and that is intended to detect a fire, notify the building occupants of a fire or suppress the fire. Fire protection systems include fire suppression systems, standpipe systems, fire alarm systems, fire detection systems, smoke control systems and smoke vents. All fire protection systems must be approved by the fire code official and tested in accordance with the referenced standards and Section 901.6.

FIRE-RATED GLAZING. Glazing with either a fire protection rating or a fire-resistance rating.

- Fire-rated glazing can be of two types—fire-resistance rating or fire protection rating. Fire-resistance-rated glazing is tested to ASTM E 119 or UL 263 and may be used in walls and is not considered as an opening. Fire-protection-rated glazing is tested to NFPA 257 or UL 9 and is usually in doors or limited size window openings in fire barriers and fire partitions.

FIRE RESISTANCE. That property of materials or their assemblies that prevents or retards the passage of excessive heat, hot gases or flames under conditions of use.

- All materials offer some degree of fire resistance. A sheet of plywood has a low level of fire resistance as compared to a concrete block, which has a higher level of fire resistance. The fire resistance of a material or an assembly is evaluated by testing performed in accordance with ASTM E 119. Tested materials will be assigned a fire-resistance rating consistent with the demonstrated performance.

FIRE-RESISTANCE RATING. The period of time a building element, component or assembly maintains the ability to confine a fire, continues to perform a given structural function, or both, as determined by the tests, or the methods based on tests, prescribed in Section 703.

- This refers to the period of time a building element, component or assembly maintains the ability to confine a fire, continues to perform a given structural function, or both, as determined by tests or the methods based on tests prescribed in Section 703.

The fire-resistance rating is developed using standardized test methods (e.g., ASTM E 119). Assemblies rated under these tests are deemed to be able to perform their function for a specified period of time under specific fire conditions (standard time-temperature curve).

The fire-resistance rating is not intended to be a prediction of the actual length of time that an assembly will perform its intended function under actual fire conditions. Although the time-temperature curves of standardized fire test methods are usually selected to approximate at least some real-life fire conditions, the very wide range of actual fire conditions makes the listed fire-resistance rating more of a nominal, comparative index than a predictor of fire-resistance time in any given fire incident.

FIRE-RESISTANT JOINT SYSTEM. An assemblage of specific materials or products that are designed, tested and fire-resistance rated in accordance with either ASTM E 1966 or UL 2079 to resist for a prescribed period of time the passage of fire through joints made in or between fire-resistance-rated assemblies.

- In order to maintain the fire-resistant integrity of fire-resistance-rated assemblies, joints that occur within an assembly or between adjacent assemblies must be protected through an installation that has been tested in accordance with ASTM E 1966 or UL 2079. Some common examples of applications where a fire-resistant joint system would be required are expansion joints in fire-resistance-rated floors or walls and the junction between fire-resistance-rated floors and walls [see Figure 202.6(2) for examples].
The regular joints that occur within a uniform assembly are most often tested as part of fire testing (e.g., in accordance with ASTM E 119) for that entire assembly. The required details for these joints are specified in the listings for the underlying assembly. These joints do not need additional testing in accordance with ASTM E 1966 or UL 2079. An example of such joints is the joints between individual sheets of gypsum board in a gypsum-sheathed stud wall. Consequently, other than the joints covering or filling the gaps within an assembly, the need for ASTM E 1966 or UL 2079 tested joint systems is usually for the joints between dissimilar assemblies or adjacent assemblies.

[F] FIRE SAFETY FUNCTIONS. Building and fire control functions that are intended to increase the level of life safety for occupants or to control the spread of harmful effects of fire.

- In many cases automatic fire detectors are installed even in buildings not required to have a fire alarm system. These fire detectors perform specific functions such as releasing door hold-open devices, activating elevator recall, smoke damper activation or air distribution system shutdown (see Section 907.3).

FIRE SEPARATION DISTANCE. The distance measured from the building face to one of the following:

1. The closest interior lot line.
2. To the centerline of a street, an alley or public way; or
3. To an imaginary line between two buildings on the property.

The distance shall be measured at right angles from the face of the wall.

- Fire separation distance is the distance from the exterior wall of the building to one of the following property locations, measured perpendicular to the exterior wall face: an interior lot line [see Figure 202.6(3)], the centerline of a street or public way [see Figure 202.6(4)] or an imaginary line between two buildings on the same property [see Figure 202.6(5)]. The imaginary line can be located anywhere between the two buildings; it is the designer’s choice, but once established, the location of the line applies to both buildings and cannot be revised.
DEFINITIONS

The distance can vary with irregular-shaped lots and buildings, as shown in Figures 202.6(3) and 202.6(4). When applying the exterior wall requirements of Table 602, the required exterior wall fire-resistance rating might vary along a building side; for example, where the lot line is not parallel to the exterior wall.

**FIRE WALL.** A fire-resistance-rated wall having protected openings, which restricts the spread of fire and extends continuously from the foundation to or through the roof, with sufficient structural stability under fire conditions to allow collapse of construction on either side without collapse of the wall.

- Fire walls must meet the construction requirements in Section 706. The requirements for fire walls are much more restrictive than fire barriers or fire partitions. The material constituting the fire wall must be non-combustible in all construction types except Type V. The vertical and horizontal continuity requirements are much more restrictive as are the opening protectives. A fire wall, unlike the fire barrier and fire partition, must be constructed so it will remain in place if
the construction on either side of it collapses. However, the fire wall is not required to remain in place if construction on both sides of it collapses (i.e., the fire wall is not required to be a free-standing cantilever wall). Fire walls are used to divide a structure into separate buildings (see the definition of "Areas, building"). To be considered separate buildings, the division must be vertical. The code applies the term "fire wall" to vertically constructed assemblies only and not to horizontal assemblies.

**FIRE WINDOW ASSEMBLY.** A window constructed and glazed to give protection against the passage of fire.

- Fire windows are "opening protectives" and contain glazing (see Section 716.6). They are required to be tested in accordance with NFPA 257 or UL 9 and are then to be installed in accordance with NFPA 80.

**FIREBLOCKING.** Building materials, or materials approved for use as fireblocking, installed to resist the free passage of flame to other areas of the building through concealed spaces.

- Fireblocking is required to hinder the concealed spread of flame, heat and other products of combustion within hollow spaces inside of walls or floor/ceiling assemblies. This is done by periodically subdividing that space, as indicated in Section 718.2, using construction materials that have some resistance to fire and by sealing the openings around penetrations through those materials.

Some fireblocking materials are permitted to be combustible based on the rationale that a substantial combustible material will provide a barrier adequate to perform the intended function (also see Section 718).

**FIREPLACE.** A hearth and fire chamber or similar prepared place in which a fire may be made and which is built in conjunction with a chimney.

- Requirements for masonry fireplaces are contained in Section 2111. Note that a chimney must be provided, as that is the means of conveying the products of combustion to the exterior of the building.

**FIREPLACE THROAT.** The opening between the top of the firebox and the smoke chamber.

- This definition is necessary for proper understanding of the code criteria for location and minimum cross-sectional area. This criterion is based on many years of successful performance and is needed to provide proper construction requirements (see Section 2111.7).

**FIRESTOP, MEMBRANE Penetration.** See "Membrane penetration firestop."

- This is one category of firestop. See the commentary for the definition of "Membrane penetration firestop."

**FIRESTOP, PENETRATION.** See "Penetration firestop."

- This term is typically used as "penetration firestop." See the commentary for the definition of the term.

**FIRESTOP SYSTEM, THROUGH PENETRATION.** See "Through penetration firestop system."

- This is one category of firestop system. See the commentary for the definition of "Through-penetration firestop system."

2012 INTERNATIONAL BUILDING CODE® COMMENTARY 2-45
DEFINITIONS

[F] FIREWORKS. Any composition or device for the purpose of producing a visible or audible effect for entertainment purposes by combustion, deflagration or detonation that meets the definition of 1.4G fireworks or 1.3G fireworks as set forth herein.

Fireworks, 1.3G. Large fireworks devices, which are explosive materials, intended for use in fireworks displays and designed to produce audible or visible effects by combustion, deflagration or detonation. Such 1.3G fireworks include, but are not limited to, firecrackers containing more than 130 milligrams (2 grains) of explosive composition, aerial shells containing more than 40 grams of pyrotechnic composition, and other display pieces which exceed the limits for classification as 1.4G fireworks. Such 1.3G fireworks are also described as fireworks, UN0335 by the DOTn.

Fireworks, 1.4G. Small fireworks devices containing restricted amounts of pyrotechnic composition designed primarily to produce visible or audible effects by combustion. Such 1.4G fireworks which comply with the construction, chemical composition and labeling regulations of the DOTn for fireworks, UN0336, and the U.S. Consumer Product Safety Commission (CPSC) as set forth in CPSC 16 CFR: Parts 1500 and 1507, are not explosive materials for the purpose of this code.

❖ Any device containing an explosive material that produces an audible or visible effect through combustion, deflagration, detonation or explosion is considered a firework. Fireworks are divided into two categories, 1.4G and 1.3G, based on the amount of pyrotechnic composition present.

The definitions of "Fireworks, 1.3G" and "Fireworks, 1.4G" are derived from the DOTn 49 CFR classification system for transporting explosives, and from NFPA 1124. The amount of pyrotechnic composition is the distinguishing factor between the two types of fireworks (see the commentary to the definition of "Pyrotechnic composition"). Fireworks that contain a limited amount of pyrotechnic composition are classified as 1.4G fireworks. 1.4G fireworks represent a physical hazard (Group H-3), while display fireworks represent a detonation hazard (Group H-1).

The requirements for storage, display and labeling depend on the correct application of the definition of "Fireworks, 1.4G." This definition reflects the construction, chemical composition and labeling requirements of the U.S. Consumer Product Safety Commission (CPSC) found in 16 CFR, Parts 1500 and 1507. Also, 1.4G fireworks are not considered to be explosives in accordance with the provisions of Chapter 56 of the IFC.

FIXED BASE OPERATOR (FBO). A commercial business granted the right by the airport sponsor to operate on an airport and provide aeronautical services, such as fueling, hangaring, tie-down and parking, aircraft rental, aircraft maintenance and flight instruction.

❖ Fixed base operator (FBO) is a term of the aviation industry used to describe a firm that is permanently based at an airport and provides a variety of aircraft services. It is used in conjunction with Section 412.4.6 in the context of determining the appropriate level of fire suppression required in various aircraft hangars at an airport (see commentary, Section 412.4.6).

FIXED SEATING. Furniture or fixture designed and installed for the use of sitting and secured in place including bench-type seats and seats with or without backs or arm rests.

❖ Fixed seating is secured to the floor or is a part of a seating system. Some of the varieties are: bench seating such as in bleachers, which can come with or without back rests; theater seating with arms for each viewer and seats that flip up; lecture halls with individual seats with tablet arms that are fixed or retractable; pew-type seating in courtrooms or places of religious worship; or booths in a restaurant. To allow appropriate egress from these spaces, the occupant load tables allow for the individual seats to be counted to determine occupant load for the space. Space between the seats (i.e., aisle accessways) and aisles leading to the exits for these types of seating is addressed in Section 1028. Given their unique issues, bleachers, folding and telescopic seating and grandstands are referenced in ICC 300 in Section 1028.1.1.

FLAME SPREAD. The propagation of flame over a surface.

❖ The rate at which flames travel along the surface of a combustible finish material directly impacts the speed with which a fire spreads within a room or space, and is, therefore, regulated by Chapter 8.

FLAME SPREAD INDEX. A comparative measure, expressed as a dimensionless number, derived from visual measurements of the spread of flame versus time for a material tested in accordance with ASTM E 84 or UL 723.

❖ The ASTM E 84 and UL 723 test methods render measurements of surface flame spread (and smoke density) in comparison with test results obtained by using select red oak as a control material. Red oak is used as a control material for furnace calibration because it is a fairly uniform grade of lumber that is readily available nationally, is uniform in thickness and moisture content, and generally gives consistent and reproducible results. The results of this test simply provide a relative understanding of flame spread potential. The flame spread index is sometimes abbreviated as FSI.

[F] FLAMMABLE GAS. A material that is a gas at 68°F (20°C) or less at 14.7 pounds per square inch atmosphere (psia) (101 kPa) of pressure [a material that has a boiling point of 68°F (20°C) or less at 14.7 psia (101 kPa)] which:

1. Is ignitable at 14.7 psia (101 kPa) when in a mixture of 13 percent or less by volume with air; or
2. Has a flammable range at 14.7 psia (101 kPa) with air of at least 12 percent, regardless of the lower limit.
The limits specified shall be determined at 14.7 psi (101 kPa) of pressure and a temperature of 68°F (20°C) in accordance with ASTM E 681.

- This term essentially refers to any type of compressed gas that burns in normal concentrations of oxygen in the air (see the definition of "Compressed gas"). The definition is consistent with the provisions of ASTM E 681.

[F] FLAMMABLE LIQUEFIED GAS. A liquefied compressed gas which, under a charged pressure, is partially liquid at a temperature of 68°F (20°C) and which is flammable.

- This term essentially refers to any type of liquefied compressed gas that burns in normal concentrations of oxygen in the air (see the definition of "Compressed gas").

[F] FLAMMABLE LIQUID. A liquid having a closed cup flash point below 100°F (38°C). Flammable liquids are further categorized into a group known as Class I liquids. The Class I category is subdivided as follows:

Class IA. Liquids having a flash point below 73°F (23°C) and a boiling point below 100°F (38°C).

Class IB. Liquids having a flash point below 73°F (23°C) and a boiling point at or above 100°F (38°C).

Class IC. Liquids having a flash point at or above 73°F (23°C) and below 100°F (38°C). The category of flammable liquids does not include compressed gases or cryogenic fluids.

- While all flammable liquids have a closed cup flash point less than 100°F (38°C), the further classification of the Class I liquids is dependent on the boiling point (see the definition of "Boiling point"). The 100°F (38°C) flash point limitation for flammable liquids assumes possible indoor ambient temperature conditions of 100°F (38°C).

[F] FLAMMABLE MATERIAL. A material capable of being readily ignited from common sources of heat or at a temperature of 600°F (316°C) or less.

- Many standardized tests, such as those contained in ASTM E 136 and NFPA 701, have been developed to assess the flammability and fire hazards of materials. Both of these test standards include objective criteria for evaluating the combustibility of different materials; however, great care must be taken in conducting and evaluating the results of such tests.

[F] FLAMMABLE SOLID. A solid, other than a blasting agent or explosive, that is capable of causing fire through friction, absorption or moisture, spontaneous chemical change, or retained heat from manufacturing or processing, or which has an ignition temperature below 212°F (100°C) or which burns so vigorously and persistently when ignited as to create a serious hazard. A chemical shall be considered a flammable solid as determined in accordance with the test method of CPSC 16 CFR; Part 1500.44, if it ignites and burns with a self-sustained flame at a rate greater than 0.1 inch (2.5 mm) per second along its major axis.

- Flammable solids are combustible materials that ignite easily and burn rapidly. Solids that may cause a fire due to friction are considered flammable solids as well as metal powders that can be readily ignited. Examples of flammable solids include nitrocellulose and combustible metals, such as magnesium and titanium. For further discussion of this material definition, see the commentary to it in Chapter 2 of the International Fire Code and Commentary.

[F] FLAMMABLE VAPORS OR FUMES. The concentration of flammable constituents in air that exceed 25 percent of their lower flammable limit (LFL).

- Vapors or fumes are considered to be flammable when they exceed 25 percent of their LFL. The LFL of a given vapor in air is the concentration at which flame propagation could occur in the presence of an ignition source (see the definition of "Lower flammable limit").

[F] FLASH POINT. The minimum temperature in degrees Fahrenheit at which a liquid will give off sufficient vapors to form an ignitable mixture with air near the surface or in the container, but will not sustain combustion. The flash point of a liquid shall be determined by appropriate test procedure and apparatus as specified in ASTM D 56, ASTM D 93 or ASTM D 3278.

- The flash point is the characteristic used in the classification of flammable and combustible liquids. The Tag Closed Tester (ASTM D 56), the Pensky-Martens Closed Cup Tester (ASTM D 93) and the Small Scale Closed-Cup Apparatus (ASTM D 3278) are the referenced test procedures for determining the flash points of liquids. The applicability of the respective test method is dependent on the viscosity of the test liquid and the expected flash point.

FLIGHT. A continuous run of rectangular treads, winders or combination thereof from one landing to another.

- Two points of clarification for stairways have been addressed by the definition of "Flight." First, a flight is made up of the treads and risers that occur between landings. Therefore, a stairway connecting two stories that includes an intermediate landing consists of two flights. Secondly, the inclusion of winders within a stairway does not create multiple flights. Winders are simply treads within a flight and are often combined with rectangular treads within the same flight.

FLOOD or FLOODING. A general and temporary condition of partial or complete inundation of normally dry land from:

1. The overflow of inland or tidal waters.
DEFINITIONS

2. The unusual and rapid accumulation or runoff of surface waters from any source.

- The term "flood" is broadly defined because the condition may occur near all types and sizes of bodies of water. Along streams and riverine areas, flooding results from the accumulation of rainfall runoff that drains from upland watersheds. Along coasts and the shorelines of large lakes, flooding is caused by wind-driven surges and waves that push water onshore, often augmented by tidal influences.

FLOOD DAMAGE-RESISTANT MATERIALS. Any construction material capable of withstanding direct and prolonged contact with floodwaters without sustaining any damage that requires more than cosmetic repair.

- A building or structure located within a flood hazard area will have certain structural and nonstructural elements below the design flood elevation, even when the lowest floor is elevated to be compliant with the requirements of Section 1612. To minimize damage and facilitate cleanup, the materials composing those elements are to be resistant to damage by floodwater. In flood hazard areas subject to high-velocity wave action (commonly called "V zones"), walls that are designed to break away during the design flood may be wetted during floods of lesser magnitude. When flood damage-resistant materials are used, the owners are not faced with significant repairs. In riverine and inland coastal flood hazard areas (commonly called "A zones"), enclosures may be allowed if designed and constructed with openings that allow floodwater to enter and exit without causing structural damage. To minimize costs and facilitate cleanup, materials used for those enclosures are to resist flood damage. Prolonged contact is generally considered to be partial or total inundation for at least 72 hours (or 12 hours in coastal areas). In some instances, materials that are not flood damage-resistant materials, such as wiring for fire alarms and emergency lighting, are allowed below the flood elevation, if specifically required to address life safety and electrical code requirements for building access and storage areas.

For further guidance, refer to FEMA FIA-TB #2, Flood Damage-resistant Materials Requirements for Buildings Located in Special Flood Hazard Areas.

FLOOD, DESIGN. See "Design flood."

- This is one of a collection of flood hazard-related terms. It is typically used as "flood design." See the commentary for the definition of "Design flood."

FLOOD ELEVATION, DESIGN. See "Design flood elevation."

- This is one of a collection of flood hazard-related terms. It is typically used as "design flood elevation." See the commentary for the definition of "Design flood elevation."

FLOOD HAZARD AREA. The greater of the following two areas:

1. The area within a flood plain subject to a 1-percent or greater chance of flooding in any year.

2. The area designated as a flood hazard area on a community's flood hazard map, or otherwise legally designated.

- FEMA prepares (FIRMs) that delineate the land area that is subject to inundation by the 1-percent annual chance flood. Some states and local jurisdictions develop and adopt maps of flood hazard areas that are more extensive than the areas shown on FEMA's maps. For the purpose of the code, the flood hazard area within which the requirements are to be applied is the greater of the two delineated areas.

FLOOD HAZARD AREAS, SPECIAL. See "Special flood hazard areas."

- This is one of a collection of flood hazard-related terms. It is typically used as "Special flood hazard areas." See the commentary under that definition.

FLOOD HAZARD AREA SUBJECT TO HIGH-VELOCITY WAVE ACTION. Area within the flood hazard area that is subject to high-velocity wave action, and shown on a Flood Insurance Rate Map (FIRM) or other flood hazard map as Zone V, VO, VE or V1-30.

- Some coastal and lake shorelines experience flooding that includes wind-driven waves. Flood hazard areas that are anticipated to have high-velocity wave action, which changes anticipated flood loads, are specifically designated on FEMA's flood hazard area maps and commonly are referred to as "V Zones." In these areas, wave heights are predicted to be greater than or equal to 3 feet (914 mm) or the wave runup elevations are predicted to reach 3 feet (914 mm) or more above grade.

FLOOD INSURANCE RATE MAP (FIRM). An official map of a community on which the Federal Emergency Management Agency (FEMA) has delineated both the special flood hazard areas and the risk premium zones applicable to the community.

- The FIRM shows the flood hazard areas along bodies of water where some level of assessment or study by FEMA has determined that there is a risk of flooding. In addition to showing the extent of flood hazard areas, base flood elevations are shown where studies using detailed methods were conducted and floodways may be delineated. Users are cautioned that FIRMs may not show all bodies of water or all areas prone to flooding, including areas with local drainage problems.

FLOOD INSURANCE STUDY. The official report provided by the Federal Emergency Management Agency containing the Flood Insurance Rate Map (FIRM), the Flood
Boundary and Floodway Map (FBFM), the water surface elevation of the base flood and supporting technical data.

- A Flood Insurance Study is prepared for each local jurisdiction for which FEMA has evaluated flood hazards. The report summarizes the information that describes and supports the flood hazard area maps, including narratives of records of past floods, descriptions of the methodologies used and (if applicable) floodway data tables with additional information for waterways for which floodways have been designated.

FLOODWAY. The channel of the river, creek or other watercourse and the adjacent land areas that must be reserved in order to discharge the base flood without cumulatively increasing the water surface elevation more than a designated height.

- FEMA delineates floodways along most rivers and streams that are studied using detailed methods. The floodway is the area that is to be kept clear of encroachments, such as fill and buildings, in order to allow a base flood to pass without increasing the water surface more than a designated height. The designated height is found by referencing the floodway data table in the Flood Insurance Study. In general, floodways have faster flow velocities and deeper water than in adjacent floodway fringe areas.

FLOOR AREA, GROSS. The floor area within the inside perimeter of the exterior walls of the building under consideration, exclusive of vent shafts and courts, without deduction for corridors, stairways, closets, the thickness of interior walls, columns or other features. The floor area of a building, or portion thereof, not provided with surrounding exterior walls shall be the usable area under the horizontal projection of the roof or floor above. The gross floor area shall not include shafts with no openings or interior courts.

- Gross floor area is that area measured within the perimeter formed by the inside surface of the exterior walls. The area of all occupiable and nonoccupiable spaces, including mechanical and elevator shafts, toilet rooms, closets and mechanical equipment rooms, are included in the gross floor area. This area could also include any covered porches, carpots or other exterior space intended to be used as part of the building’s occupiable space. This gross and net floor area is primarily used for the determination of occupant load in accordance with Table 1004.1.2.

FLOOR AREA, NET. The actual occupied area not including unoccupied accessory areas such as corridors, stairways, toilet rooms, mechanical rooms and closets.

- This area is intended to be only the room areas that are used for specific occupancy purposes and does not include circulation areas, such as corridors or stairways, and service and utility spaces, such as toilet rooms and mechanical and electrical equipment rooms. Net floor area is typically measured between inside faces of walls within a room. Floor area, net and gross, is utilized in Table 1004.1.2 to determine occupant load for a space.

FLOOR FIRE DOOR ASSEMBLY. A combination of a fire door, a frame, hardware and other accessories installed in a horizontal plane, which together provide a specific degree of fire protection to a through-opening in a fire-resistance-rated floor (see Section 711.8).

- Floor fire door assemblies are required to be tested in accordance with NFPA 288 and are used to protect openings in fire-resistance-rated floors. They are one alternative for protecting a floor opening, such as an access opening to mechanical equipment. See the commentary to Section 711.8 for additional information on floor fire door assemblies.

[F] FOAM-EXTINGUISHING SYSTEM. A special system discharging a foam made from concentrates, either mechanically or chemically, over the area to be protected.

- Foam-extinguishing systems must be of an approved type and installed and tested to comply with NFPA 11, 11A and 16. All foams are intended to exclude oxygen from the fire, cool the area of the fire and insulate adjoining surfaces from heat caused by fires. Foam systems are commonly used to extinguish flammable or combustible liquid fires (see commentary, Section 904.7). While water applied by an automatic sprinkler system can only act horizontally upon the surface that it reaches, foam-extinguishing agents have the ability to act vertically in addition to horizontally; and, unlike gaseous extinguishing agents, foam does not dissipate rapidly where there is no confined space. Thus, foam systems are also used where there is a need to fill a nonconfined space with extinguishing material as in the case of certain industrial applications.

FOAM PLASTIC INSULATION. A plastic that is intentionally expanded by the use of a foaming agent to produce a reduced-density plastic containing voids consisting of open or closed cells distributed throughout the plastic for thermal insulating or acoustical purposes and that has a density less than 20 pounds per cubic foot (pcf) (320 kg/m³).

- Foam plastic insulation is plastic that is imbedded with gas.

FOLDING AND TELESCOPIC SEATING. Tiered seating having an overall shape and size that is capable of being reduced for purposes of moving or storing and is not a building element.

- Bleachers, folding and telescopic seating and grandstands are essentially unique forms of tiered seating that are supported on a dedicated structural system. All types are addressed in ICC 300, the safety standard for these types of seating arrangements. Folding and telescopic seating is commonly used in gymnasiums and sports arenas where the seating can be configured in a variety of ways for various types of events. "Building element" is a defined term that is primarily used in conjunction with the structural elements regulated in Table 601. While telescopic seating may be attached to a wall, the system when pulled out or folded includes its main support system. Such seating is not considered a building element of
DEFINITIONS

the building or structure in which it is located (see Section 1028.1.1).

FOOD COURT. A public seating area located in the mall that serves adjacent food preparation tenant spaces.

- Typical mall building layouts include a central gathering area for food and drink consumption. These areas are usually located in the mall itself and chairs are provided for the public's use to consume the food and drink. This public area is usually surrounded by numerous tenant spaces where food is prepared and sold over the counter. A separate design occupant load is required to be calculated in accordance with Section 402.8.2.4.

FOSTER CARE FACILITIES. Facilities that provide care to more than five children, 2 1/2 years of age or less.

- Foster care facilities are group homes where children live, not day care facilities. By being under 2 1/2 years of age, children are assumed not capable of self-preservation, thus there is a need for higher levels of active and passive protection in the building (see the commentary to Group I-2 in Section 308.4). Group homes with children over 2 1/2 years of age would be classified as Group R-4 or I-1, depending on the number of children housed in the facility. The "more than five children" is intended to clarify that a foster care family would not be considered a Group I-2 facility. See also the definitions for "24-hour care," "Custodial care," "Group home," "personal care" and "Incapable of self-preservation."

FOUNDATION PIER. An isolated vertical foundation member whose horizontal dimension measured at right angles to its thickness does not exceed three times its thickness and whose height is equal to or less than four times its thickness.

- This definition is intended specifically for masonry construction. Masonry foundation piers are similar to masonry columns, except that they are shorter and do not need to comply with the prescriptive reinforcement detailing requirements for masonry columns.

FRAME STRUCTURE. A building or other structure in which vertical loads from floors and roofs are primarily supported by columns.

- This definition describes the structure types that are covered under Section 1615.3.

[F] GAS CABINET. A fully enclosed, ventilated noncombustible enclosure used to provide an isolated environment for compressed gas cylinders in storage or use. Doors and access ports for exchanging cylinders and accessing pressure-regulating controls are allowed to be included.

- Gas cabinets are used to provide adequate control for escaping gas in the event of a leaking cylinder of compressed gases. Gas cabinets are commonly used when dealing with highly toxic and toxic compressed gases. Sections 5003.8.6 and 6004.1.2 of the IFC provide additional construction and ventilation requirements for gas cabinets.

[F] GAS ROOM. A separately ventilated, fully enclosed room in which only compressed gases and associated equipment and supplies are stored or used.

- Gas rooms are used exclusively for the storage or use of hazardous gases in excess of the MAQs permitted by Tables 307.1(1) and 307.1(2). Gas rooms are commonly used as an alternative storage area for HPM gases in a Group H-5 facility.

[F] GASEOUS HYDROGEN SYSTEM. An assembly of piping, devices and apparatus designed to generate, store, contain, distribute or transport a nontoxic, gaseous hydrogen-containing mixture having at least 95-percent hydrogen gas by volume and not more than 1-percent oxygen by volume. Gaseous hydrogen systems consist of items such as compressed gas containers, reactors and appurtenances, including pressure regulators, pressure relief devices, manifolds, pumps, compressors and interconnecting piping and tubing and controls.

- This term includes the source of hydrogen and all piping and devices between the source and the equipment being used. The gas in a hydrogen system is above the upper flammable limit (UFL) and is therefore "too rich" to burn. Any leakage, however, can quickly create conditions that will be explosive under ambient conditions.

GLASS FIBERBOARD. Fibrous glass roof insulation consisting of inorganic glass fibers formed into rigid boards using a binder. The board has a top surface faced with asphalt and kraft reinforced with glass fiber.

- Depending on the type and location of insulation in walls, floors and roofs, the insulation may impact the fire-resistance rating (see Sections 703.2 and 721.1). Glass fiber insulation is specifically listed in Table 722.6.2(5).

GLUED BUILT-UP MEMBER. A structural element, the section of which is composed of built-up lumber, wood structural panels or wood structural panels in combination with lumber, all parts bonded together with structural adhesives.

- Typically, these built-up beam and column sections consist of one or more webs with glued-lumber flanges and stiffeners. They are custom-designed structural elements that require the application of ASD or LRFD standards.

GRADE FLOOR OPENING. A window or other opening located such that the sill height of the opening is not more than 44 inches (1118 mm) above or below the finished ground level adjacent to the opening.

- Openings used for emergency escape or rescue are clearly easier to use the closer they are to grade. This definition specifies that the maximum sill height above the exterior adjacent grade must be no more than 44 inches (1118 mm) for an opening to qualify as a grade floor opening (see Section 1029.2).

GRADE (LUMBER). The classification of lumber in regard to strength and utility in accordance with American Softwood
Lumber Standard DOC PS 20 and the grading rules of an approved lumber rules-writing agency.

- The grade identifies how capable a particular piece of lumber is to resist applied loads. The mark is applied to solid sawn pieces of wood and includes the species, grade and whether it was finished (surfaced) green or dry. The species and grade designation on the grade mark, when used in conjunction with the design value in the NDS, provides all the information necessary to determine what load the piece of lumber is capable of holding. The ALSC provides facsimile sheets for agencies accredited to grade lumber. Although rare, fake grade stamps can be found in the marketplace.

**GRADE PLANE.** A reference plane representing the average of finished ground level adjoining the building at **exterior walls**. Where the finished ground level slopes away from the **exterior walls**, the reference plane shall be established by the lowest points within the area between the building and the **lot line** or, where the **lot line** is more than 6 feet (1829 mm) from the building, between the building and a point 6 feet (1829 mm) from the building.

- This term is used in the definitions of "Basement" and "Story above grade plane." It is critical in determining the height of a building and the number of stories, which are regulated by Chapter 5. Since the finished ground surface adjacent to the building may vary (depending on site conditions), the mean average taken at various points around the building constitutes the grade plane. One method of determining the grade plane elevation is illustrated in Figure 202.7(1), where the ground slopes uniformly along the length of each exterior wall.

Where a site has a more complex slope, a more detailed calculation that takes into account the various segments of the perimeter walls must be taken. Figure 202.7(2) shows an example of a complex finished grade. A full calculation will show the grade plane to be an elevation of 498.64 feet (151,986 mm). If a calculation is done based on just the four extreme corners, grade plane would be thought to be 495.5 feet (151,029 mm), an error of over 3 feet (914 mm).

Situations may arise where the ground adjacent to the building slopes away from the building because of site or landscaping considerations. In this case, the lowest finished ground level at any point between the building's exterior wall and a point 6 feet (1829 mm) from the building (or the lot line, if closer than 6 feet [1829 mm]) comes under consideration. These points are used to determine the elevation of the grade plane as illustrated in Figures 202.7(3) and 202.7(4).

In the context of the code, the term "grade" means the finished ground level at the exterior walls. While the grade plane is a hypothetical horizontal plane derived as indicated above, the grade is that which actually exists or is intended to exist at the completion of site work. The only situation where the grade plane and the grade are identical is when the site is perfectly level for a distance of 6 feet (1829 mm) from all exterior walls.

**Figure 202.7(1)**
**DETERMINATION OF GRADE PLANE ELEVATION WHERE GRADE SLOPES UNIFORMLY ALONG THE ENTIRE LENGTH OF THE EXTERIOR WALLS**

For SI: 1 foot = 304.8 mm.
DEFINITIONS

A = (490 + 500)/2 = 495
B = (500 + 500)/2 = 500
C = (500 + 490)/2 = 495
D = (490 + 490)/2 = 490
E = (490 + 500)/2 = 495
F = (500 + 503)/2 = 501.5
G = (502 + 500)/2 = 501
H = (500 + 490)/2 = 495
J = (504 + 500)/2 = 502
K = (506 + 500)/2 = 503
L = (490 + 490)/2 = 490

TOTAL PERIMETER = 490 + 495 + 495 + 490 + 500 + 501.5 + 501 + 495 + 502 + 503 + 506 + 490 = 4980

For SI: 1 foot = 304.8 mm.

Figure 202.7(2)
DETERMINATION OF GRADE PLANE ELEVATIONS WHERE GRADE AND EXTERIOR WALLS ARE IRREGULAR

6'-0"

OR LOT LINE, WHICHEVER IS LESS

THE GRADE ELEVATION THAT IS USED IN DETERMINING THE GRADE PLANE ELEVATION IS 487.5'.

ELEVATION: 490.0'

ELEVATION: 487.5'

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

Figure 202.7(3)
DETERMINATION OF GRADE PLANE WHERE GRADE SLOPES AWAY FROM THE EXTERIOR WALL
GRADE PLANE, STORY ABOVE. See “Story above grade plane.”

- Building heights are limited to a number of stories above grade plane in Chapter 5. See additional commentary for the definitions of “Grade plane,” “Story,” “Story above grade plane” and “Basement.”

GRANDSTAND. Tiered seating supported on a dedicated structural system and two or more rows high and is not a building element (see “Bleachers”).

- Bleachers, folding and telescopic seating and grandstands is essentially unique forms of tiered seating that is supported on a dedicated structural system. All types are addressed in the safety standard for these types of seating arrangements, ICC 300. Grandstands can be found at a county fair ground, along a parade route or within indoor facilities. Examples are sports arenas and public auditoriums, as well as places of religious worship and gallery-type lecture halls. "Building element" is a defined term that is primarily used in conjunction with the structural elements regulated in Table 601. Grandstands have a separate structural system. Individual bench seats directly attached to a floor system are not a grandstand. The terms “bleacher” and “grandstand” are basically interchangeable. There is no cutoff in size or number of seats that separates bleachers and grandstands (see Section 1028.1.1).

GROSS LEASABLE AREA. The total floor area designed for tenant occupancy and exclusive use. The area of tenant occupancy is measured from the centerlines of joint partitions to the outside of the tenant walls. All tenant areas, including areas used for storage, shall be included in calculating gross leasable area.

- The gross leasable area represents the aggregate area available in a covered or open mall building for tenant occupancy. It does not include the area of the mall, unless portions of it are leased for the purposes of setting up separate tenant spaces (kiosks). The area is used to determine the design occupant load in accordance with Section 402.8.2.1.

GROUP HOME. A facility for social rehabilitation, substance abuse or mental health problems that contains a group housing arrangement that provides custodial care but does not provide acute care.

- The term "group home" is listed under Group I-1 and R-4 occupancies. By using the defined term "custodial care" this clarifies that residents in these types of facilities are capable of self-preservation. The number of occupants would differentiate which occupancy classification is applicable to the facility. Residents live in a supervised living arrangement. Facilities can be for persons with developmental, emotional, mental or physical difficulties or for persons recovering from drugs or alcohol abuse. The intent of these facilities is

---

**Figure 202.7(4)**

**DETERMINATION OF GRADE PLANE ELEVATION WHERE GRADE DOES NOT SLOPE UNIFORMLY ALONG THE LENGTH OF THE EXTERIOR WALLS**

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.
DEFINITIONS

to promote recovery, community integration and improved quality of life. While there may be security restrictions, occupants are not restrained (see Section 308, Group I-3 for restrained conditions). The focus is to increase an individual's capacity to be successful in living, working, learning and social environments to the best of their ability. See also the commentary for "24-hour care," "Foster care facility," "Personal care," "Custodial care," "Nursing home" and "Incapable of self-preservation."

GUARD. A building component or a system of building components located at or near the open sides of elevated walking surfaces that minimizes the possibility of a fall from the walking surface to a lower level.

- Guards are sometimes mistakenly referred to as "guardrails." In actuality, the guard consists of the entire vertical portion of the barrier, not just the top rail (see commentary for "Handrail" and Section 1013). The purpose of guards is to minimize the potential for falls at dropoffs adjacent to walking surfaces. Loading requirements for guards are located in Section 1607.8.

GYPSUM BOARD. Gypsum wallboard, gypsum sheathing, gypsum base for gypsum veneer plaster, exterior gypsum soffit board, predecorated gypsum board or water-resistant gypsum backing board complying with the standards listed in Tables 2506.2, 2507.2 and Chapter 35.

- Gypsum board is the most commonly used material for interior wall covering. Gypsum board is also used for exterior sheathing, plaster lath and ceiling covering. Because it is installed in sheet form, it is less labor intensive and generally considered more cost effective than other wall and ceiling materials, such as plaster. Gypsum board requires a minimal amount of finishing and will readily accept paint, wallpaper, vinyl fabric, special textured paint and similar surface finish materials.

Gypsum board will be subject to severe failure when placed in direct contact with water or continuous moisture. For this reason, the code does not allow gypsum board to be used in wet areas unless it is provided with a finish material impervious to moisture.

GYPSUM PLASTER. A mixture of calcined gypsum or calcined gypsum and lime and aggregate and other approved materials as specified in this code.

- Gypsum plaster is available in several forms and is designed for a variety of applications, including those where fire protection of building components, construction of fire-resistance-rated assemblies within the building or control of sound transmission is needed. Gypsum plaster can be applied using a two- or three-coat method, depending upon the backing or lathing system.

Gypsum plaster provides a hard, smooth finish surface that will readily receive most decorative finishes, such as paint, vinyl wall fabric, wallpaper and textured paint. Various aggregates can be added to the plaster composition to achieve different surface textures, from a smooth troweled to a heavily textured finish.

However, the code does not permit the use of gypsum plaster at exterior locations or at wet areas on the interior of the building.

GYPSUM VENEER PLASTER. Gypsum plaster applied to an approved base in one or more coats normally not exceeding 1/4 inch (6.4 mm) in total thickness.

- Gypsum veneer plaster is specifically designed for use as a one-coat veneer plaster finish surface. Gypsum veneer plaster must be applied over a solid base such as gypsum board lath, gypsum base for veneer plaster, concrete or concrete unit masonry. Although gypsum veneer plaster is designed to be applied in one coat, it can be applied in two coats, as long as the maximum thickness does not exceed 1/4 inch (6.4 mm).

Gypsum veneer plaster provides a hard, smooth finish surface, much like three-coat gypsum plaster, that will readily receive a variety of decorative finishes. Like gypsum plaster, the code does not permit the use of gypsum veneer plaster at exterior locations or at wet areas on the interior of the building.

HABITABLE SPACE. A space in a building for living, sleeping, eating or cooking. Bathrooms, toilet rooms, closets, halls, storage or utility spaces and similar areas are not considered habitable spaces.

- These spaces are normally considered inhabited in the course of residential living and provide the four basic characteristics associated with it: living, sleeping, eating and cooking. All habitable spaces are considered occupiable spaces, though other occupiable spaces, such as halls or utility rooms, are not considered habitable (see the definition of "Occupiable space").

[F] HALOGENATED EXTINGUISHING SYSTEM. A fire-extinguishing system using one or more atoms of an element from the halogen chemical series: fluorine, chlorine, bromine and iodine.

- Halon is a colorless, odorless gas that inhibits the chemical reaction of fire. Halon extinguishing systems are useful in occupancies such as computer rooms where an electrically nonconductive medium is essential or desirable and where cleanup of other extinguishing agents presents a problem. The Halon extinguishing system must be of an approved type and installed and tested to comply with NFPA 12A.

Halon extinguishing agents have been identified as a source of emissions resulting in the depletion of the stratospheric ozone layer. For this reason, production of new supplies of Halon has been phased out. Alternative gaseous extinguishing agents, such as clean agents, have been developed as alternatives to Halon.
[F] HANDLING. The deliberate transport by any means to a point of storage or use.

- The term “handling” pertains to the transporting or movement of hazardous materials within a building. Handling presents a level of hazard that is of a lesser degree than that of use or dispensing operations but greater than storage. Material is handled only when it is transported from one point to another; it is the act of conveyance. The definition provides the means to determine proper controls necessary to provide safety in the transport mode. Specific handling requirements for various hazardous materials are contained in the IFC.

HANDRAIL. A horizontal or sloping rail intended for grasping by the hand for support or guidance.

- Handrails are provided along walking surfaces that lead from one elevation to another, such as ramps, and stairways. Handrails may be any shape in cross section provided that they can be gripped by hand for support and guidance and for checking possible falls on the adjacent walking surface. In addition to being necessary in normal day-to-day use, handrails are especially needed in times of emergency when the pace of egress travel is hurried and the probability for occupant instability while traveling along the sloped or stepped walking surface is greater. Handrails, by themselves, are not intended to be used in place of guards to limit falls at drop-offs. Where guards and handrails are used together, the handrail is a separate element typically attached to the inside surface of the guard. The top guard cannot be used as a required handrail, except within dwelling units where the height is restricted to that of a handrail (see Section 1012). See the commentary for “Guard.” For loading on handrails, see Section 1607.8.

HARDBOARD. A fibrous-felted, homogeneous panel made from lignocellulosic fibers consolidated under heat and pressure in a hot press to a density not less than 31 pcf (497 kg/m²).

- Hardboard is used for various interior applications, as well as siding applications. Other ingredients may be added during processing to provide or improve properties, such as strength, water resistance and general utility.

[F] HAZARDOUS MATERIALS. Those chemicals or substances that are physical hazards or health hazards as classified in Section 307 and the International Fire Code, whether the materials are in usable or waste condition.

- The term “hazardous materials” refers to those materials that present either a physical or health hazard. A specific listing of hazardous materials is indicated in Sections 307.3, 307.4, 307.5 and 307.6. An occupancy containing greater than the MAQ per control area of these materials as indicated in Table 307.1(1) or 307.1(2) is classified in one of the four high-hazard occupancy classifications.

[F] HAZARDOUS PRODUCTION MATERIAL (HPM). A solid, liquid or gas associated with semiconductor manufacturing that has a degree-of-hazard rating in health, flammability or instability of Class 3 or 4 as ranked by NFPA 704 and which is used directly in research, laboratory or production processes which have as their end product materials that are not hazardous.

- This definition identifies those specific materials that can be contained within an HPM facility. The restriction in the definition for only hazardous materials with a Class 3 or 4 rating is not intended to exclude materials that are less hazardous, but to clarify that materials of the indicated higher ranking are still permitted in an HPM facility without classifying the building as Group H. NFPA 704 is referenced in order to establish the degree of hazard ratings for all materials as related to health, flammability and instability risks.

HEAD JOINT. Vertical mortar joint placed between masonry units within the wythe at the time the masonry units are laid.

- Vertically oriented joints between masonry units are head joints [see Figure 202.2(2)].

[F] HEALTH HAZARD. A classification of a chemical for which there is statistically significant evidence that acute or chronic health effects are capable of occurring in exposed persons. The term “health hazard” includes chemicals that are toxic or highly toxic, and corrosive.

- Materials that present risks to people from handling or exposure are considered health hazards. Examples of these types of materials are indicated in Section 307.6. Buildings and structures containing materials that present a health hazard in excess of the MAQ would be classified as Group H-4. Materials that present a health hazard may also present a physical hazard (see the definition of “Physical hazard”) and must comply with the requirements of the code applicable to both hazards.

HEAT DETECTOR. See “Detector, heat.”

- Heat detector is defined under “Detector, heat” and is addressed in the commentary for that term.

HEIGHT, BUILDING. The vertical distance from grade plane to the average height of the highest roof surface.

- This definition establishes the two points of measurement that determine the height of a building. This measurement is used to determine compliance with the building height limitations of Section 503.1 and Table 503, which limits building height both in terms of the number of stories and the number of feet between the two points of measurement.

The lower point of measurement is the grade plane (see the definition of “Grade plane”). The upper point of measurement is the roof surface of the building, with consideration given to sloped roofs (such as a hip or gable roof). In the case of sloped roofs, the average height would be used as the upper point of measurement, rather than the eave line or the ridge.
line. The average height of the roof is the mid-height between the roof eave and the roof ridge, regardless of the shape of the roof.

This definition also indicates that building height is measured to the highest roof surface. In the case of a building with multiple roof levels, the highest of the various roof levels must be used to determine the building height. If the highest of the various roof levels is a sloped roof, then the average height of that sloped roof must be used. The average height of multiple roof levels is not to be used to determine the building height. Where structures are divided into multiple buildings by fire walls, building height is determinable for each building separately.

The distance that a building extends above ground also determines the relative hazards of that building. Simply stated, a taller building presents relatively greater safety hazards than a shorter building for several reasons, including fire service access and time for occupant egress. The code specifically defines how building height is measured to enable various code requirements, such as type of construction and fire suppression, to be consistent with those relative hazards [see Figure 202.8(1) for the computation of building height in terms of feet and stories].

The term "height" is also used frequently in the code for other limitations related to, and sometimes not related to, "building height." For example, Section 1509 limits the height of a penthouse above the top of the roof. Since a "Penthouse" is defined as a structure that is built above the roof of a building, it is above the point to which "Building height" is measured. Therefore a penthouse would not affect the measurement of building height and can be located above the maximum allowed roof height provided it complies with the limitations of Section 1509. Other provisions such as Sections 1013 and 1406 specify requirements based on height, but such height is usually measured from a location other than grade plane and is not intended to be building height.

**HELICAL PILE.** Manufactured steel deep foundation element consisting of a central shaft and one or more helical bearing plates. A helical pile is installed by rotating it into the ground. Each helical bearing plate is formed into a screw thread with a uniform defined pitch.

- This definition clarifies a term that refers to a specific type of deep foundation element (see the design requirements in Section 1810.3.1.5).

---

**Figure 202.8(1) BUILDING HEIGHT**

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.
HELIPAD. A structural surface that is used for the landing, taking off, taxying and parking of helicopters.

- This definition provides a specific term that refers to the portion of a structure that is subject to the helicopter live loads in Section 1607.8.

HELIPORT. An area of land or water or a structural surface that is used, or intended for the use, for the landing and taking off of helicopters, and any appurtenant areas that are used, or intended for use, for heliport buildings or other heliport facilities.

- A heliport includes not only the immediate landing and take-off pad, but also all other adjacent service areas. The fueling, maintenance, repairs or storage of helicopters may be done within or outside of a building or structure. These outside areas or enclosed spaces are considered as part of the heliport.

HELISTOP. The same as “heliport,” except that no fueling, defueling, maintenance, repairs or storage of helicopters is permitted.

- A helistop, by definition, is limited only to the immediate landing and take-off pad. Examples of helistops would be the pad located on top of a hospital for the unloading of emergency room patients, a pad for discharging commuters outside of an office building or the pad used to load and unload tourists at a sightseeing attraction.

HIGH-PRESSURE DECORATIVE EXTERIOR GRADE COMPACT LAMINATE (HPL). Panels consisting of layers of cellulose fibrous material impregnated with thermosetting resins and bonded together by a high-pressure process to form a homogeneous nonporous core suitable for exterior use.

- HPL is an exterior finish material. While in common use in Europe, HPL is finding expanded use elsewhere. The definition is based on the International Standard EN 428. Section 1409 specifies the requirements and uses for HPL.

HIGH-PRESSURE DECORATIVE EXTERIOR GRADE COMPACT LAMINATE (HPL) SYSTEM. An exterior wall covering fabricated using HPL in a specific assembly including joints, seams, attachments, substrate, framing and other details as appropriate to a particular design.

- HPL systems are intended for exterior application for buildings. The definition is based on the International Standard EN 428. Section 1409 specifies the requirements and uses for HPL systems.

HIGH-RISE BUILDING. A building with an occupied floor located more than 75 feet (22.860 mm) above the lowest level of fire department vehicle access.

- Determining what qualifies as a high-rise building is a fairly unique measurement of height and is not based on the definition of “Building height.” The critical measurement is from the lowest ground location where a fire department will be able to set its fire-fighting equipment to a floor level of occupied floors (including any occupied roofs) as shown in Figure 202.8(2). It is not a measurement from grade plane to top of the building. The basis of the measurement is analyzing the capability of fighting a fire and rescuing occupants from the outside the building. Once past a height of 75 feet (22.860 mm) above ground level, ground-based fire fighting will not be sufficient. High-rise buildings must comply with the requirements of Section 403.

[F] HIGHLY TOXIC. A material which produces a lethal dose or lethal concentration that falls within any of the following categories:

1. A chemical that has a median lethal dose (LD₅₀) of 50 milligrams or less per kilogram of body weight when administered orally to albino rats weighing between 200 and 300 grams each.
DEFINITIONS

2. A chemical that has a median lethal dose (LD_{50}) of 200 milligrams or less per kilogram of body weight when administered by continuous contact for 24 hours (or less if death occurs within 24 hours) with the bare skin of albino rabbits weighing between 2 and 3 kilograms each.

3. A chemical that has a median lethal concentration (LC_{50}) in air of 200 parts per million by volume or less of gas or vapor, or 2 milligrams per liter or less of mist, fume or dust, when administered by continuous inhalation for 1 hour (or less if death occurs within 1 hour) to albino rats weighing between 200 and 300 grams each.

Mixtures of these materials with ordinary materials, such as water, might not warrant classification as highly toxic. While this system is basically simple in application, any hazard evaluation that is required for the precise categorization of this type of material shall be performed by experienced, technically competent persons.

The definition is derived from DOL 29 CFR, Part 1910.1200. These materials are considered dangerous to humans when either inhaled, absorbed or injected through the skin or ingested orally. Highly toxic materials present a health hazard and are subsequently listed as Group H-4 in Section 307.6. Examples of highly toxic materials include gases such as arsine, fluorine and hydrogen cyanide, liquid acrylic acid and calcium cyanide in solid form.

Mixtures of these materials with ordinary materials, such as water, might not warrant a highly toxic classification. While this system is basically simple in application, any hazard evaluation that is required for the precise categorization of this type of material is to be performed by experienced, technically competent persons. For further discussion of this material definition, see the commentary to it in Chapter 2 of the International Fire Code and Commentary.

HISTORIC BUILDINGS. Buildings that are listed in or eligible for listing in the National Register of Historic Places, or designated as historic under an appropriate state or local law (see Sections 3409 and 3411.9).

The code provides a subjective exception for compliance in Sections 3409 and 3411.9 to registered historic buildings that are receiving improvements or undergoing changes of any kind. To be a historic building it needs to be designated as such through a federal, state or local law. In addition, there are buildings that have been reviewed for eligibility to be listed as a national historic building. Those listed as eligible for national listing also are considered historic for the purposes of the code. Buildings that are within a historic district are not necessarily, themselves, historic buildings. The determination of their designation as historic would depend on the specifics of the listing of the historic area.

HORIZONTAL ASSEMBLY. A fire-resistance-rated floor or roof assembly of materials designed to restrict the spread of fire in which continuity is maintained.

A horizontal assembly is a component for completing compartmentation. Horizontal assemblies have all openings and penetrations protected equal to the rating for the fire-resistance-rated floor or roof assembly [see Figure 202.8(3)].

HORIZONTAL EXIT. See "Exit, horizontal."

Horizontal exit is defined under "Exit, horizontal" and is addressed in the commentary for that term.

HOSPITALS AND PSYCHIATRIC HOSPITALS. Facilities that provide care or treatment for the medical, psychiatric, obstetrical, or surgical treatment of care recipients that are incapable of self-preservation.

Persons in hospital facilities may be physically incapable of self-preservation or at least extremely limited

---

Figure 202.8(3)
EXAMPLES OF HORIZONTAL ASSEMBLIES
in their ability to evacuate. In psychiatric hospitals, they may be confined within an area of a building for care or security purposes. In consideration of an occupant's health, as well as safety, hospitals and nursing homes at least partially rely on defend-in-place strategies. See the commentary for Sections 308 and 407, Group I-2.

Care facilities encompass a full spectrum of acuity and support services and span a wide range of occupancy types including Groups B, E, I and R. The level of care provided describes the condition and capabilities of an occupant, which then indicates appropriate standards for protection systems, both passive and active. See also the definitions for "24-hour care," "Care suites," "Custodial care," "Detoxification facilities," "Medical care," "Nursing homes" and "Incapsulate of self-preservation."

**HOUSING UNIT.** A dormitory or a group of cells with a common dayroom in Group I-3.

- A housing unit is a key delineation of space within a Group I-3 occupancy. Often inmates are restricted to their housing unit and not allowed to move freely outside of the unit. A housing unit can include more than one tier of cells. Because a housing unit is often designed as a multiple-level area with a shared day room, it will typically share a common atmosphere (see Section 408.5 for the protection of vertical openings). See also the commentary for "Cell" and "Cell tier."

**[F] HPM FLAMMABLE LIQUID.** An HPM liquid that is defined as either a Class I flammable liquid or a Class II or Class IIIA combustible liquid.

- This definition clarifies that an HPM liquid is essentially all classes of flammable or combustible liquids except Class IIIB combustible liquids, which have a flash point at or above 200°F (93°C). Class IIIB liquids, therefore, are not considered a hazardous production material.

**[F] HPM ROOM.** A room used in conjunction with or serving a Group H-5 occupancy, where HPM is stored or used and which is classified as a Group H-2, H-3 or H-4 occupancy.

- An HPM room in a Group H-5 facility is utilized for the storage and use of hazardous production materials in excess of the MAQs permitted in Table 307.1(1) or 307.1(2). The rooms are, therefore, considered a Group H-2, H-3 or H-4 occupancy depending on the type of hazardous material.

**HURRICANE-PRONE REGIONS.** Areas vulnerable to hurricanes defined as:

1. The U.S. Atlantic Ocean and Gulf of Mexico coasts where the ultimate design wind speed, $V_{10}$, for Risk Category buildings is greater than 115 mph (51.4 m/s);
2. Hawaii, Puerto Rico, Guam, Virgin Islands and American Samoa.

- This definition identifies the areas where hurricane-force winds are expected.

**[F] HYDROGEN CUTOFF ROOM.** A room or space that is intended exclusively to house a gaseous hydrogen system.

- This term refers to an enclosed space used exclusively for a gaseous hydrogen system that requires construction and protection that are unique to the hazards associated with this use. The room itself may be considered as an incidental accessory occupancy or a Group H occupancy, depending upon the amount of hydrogen in such rooms. The definition itself should not be interpreted to prevent hydrogen piping systems from serving distributed hydrogen-using equipment and appliances located elsewhere on site or in the building. However, the amount of hydrogen within such piping needs to be evaluated with respect to the MAQs in Table 307.1(1).

**ICE-SENSITIVE STRUCTURE.** A structure for which the effect of an atmospheric ice load governs the design of a structure or portion thereof. This includes, but is not limited to, lattice structures, guyed masts, overhead lines, light suspension and cable-stayed bridges, aerial cable systems (e.g., for ski lifts or logging operations), amusement rides, open catwalks and platforms, flagpoles and signs.

- This definition describes the type of structures that must consider atmospheric ice loading (see Section 1614).

**[F] IMMEDIATELY DANGEROUS TO LIFE AND HEALTH (IDLH).** The concentration of air-borne contaminants which poses a threat of death, immediate or delayed permanent adverse health effects, or effects that could prevent escape from such an environment. This contaminant concentration level is established by the National Institute of Occupational Safety and Health (NIOSH) based on both toxicity and flammability. It generally is expressed in parts per million by volume (ppmv/v) or milligrams per cubic meter (mg/m³). If adequate data do not exist for precise establishment of IDLH concentrations, an independent certified industrial hygienist, industrial toxicologist, appropriate regulatory agency or other source approved by the building official shall make such determination.

- The definition of "Immediately dangerous to life and health (IDLH)" is the minimum concentration of an air-borne contaminant, such as a highly toxic compressed gas, that a person could be exposed to before the risk of permanent adverse side effects. IDLH is important in determining the design of treatment systems for highly toxic or toxic compressed gases.

**IMPACT LOAD.** The load resulting from moving machinery, elevators, craneways, vehicles and other similar forces.
DEFINITIONS

and kinetic loads, pressure and possible surcharge from fixed or moving loads.

- This definition identifies the scope of the type of loading addressed in Section 1607.9. The effect of impact loads on a structure can be significantly higher than the weight of the impacting elements because of their movement or vibration.

INCAPABLE OF SELF-PRESERVATION. Persons because of age, physical limitations, mental limitations, chemical dependency, or medical treatment who cannot respond as an individual to an emergency situation.

- Patients/residents of nursing homes and hospitals may be in situations where they are unable to self-evacuate due to a variety of physical limitations (e.g., medication, operation, injury, connection to medical equipment).

Care facilities encompass a full spectrum of acuity and support services and span a wide range of occupancy types including Groups E, I and R. There are three types of care defined in the codes: personal, custodial and medical. The level of care provided describes the condition and capabilities of an occupant which then indicates appropriate standards for protection systems, both active and passive. See also the definitions for “24-hour care,” “Custodial care,” “Detoxification facilities,” “Foster care facility,” “Group home,” “Hospitals and psychiatric hospitals,” “Medical care,” “Nursing home” and “Personal care services.”

[F] INCOMPATIBLE MATERIALS. Materials that, when mixed, have the potential to react in a manner that generates heat, fumes, gases or byproducts which are hazardous to life or property.

- These materials, whether in storage or in use, constitute a dangerous chemical combination. Determination of which chemicals in combination present a hazard is a difficult situation for the building official. Material Safety Data Sheets (MSDS) alone may not provide all of the necessary information. When in doubt, the building official should seek additional information from the manufacturer of the chemicals involved, the building owner or from experts who are knowledgeable in industrial hygiene or chemistry.

[F] INERT GAS. A gas that is capable of reacting with other materials only under abnormal conditions such as high temperatures, pressures and similar extrinsic physical forces. Within the context of the code, inert gases do not exhibit either physical or health hazard properties as defined (other than acting as a simple asphyxiant) or hazard properties other than those of a compressed gas. Some of the more common inert gases include argon, helium, krypton, neon, nitrogen and xenon.

- Inert gases do not react readily with other materials under normal temperature and pressure (NTP), but it is possible for a reaction to occur. For example, even nitrogen combines with some of the more active metals such as lithium and magnesium to form nitrides, and at high temperatures it will also combine with oxygen and other elements. The formation of compounds utilizing inert gases is also possible. Xenon combines with fluorine to form various fluorides, and with oxygen to form oxides. The compounds formed are crystalline solids. As indicated in Table 307.1(1), there are no MAQs specified for inert gases. As such, inert gases are not regulated by the code as hazardous materials with respect to a potential Group H occupancy classification.

[F] INITIATING DEVICE. A system component that originates transmission of a change-of-state condition, such as in a smoke detector, manual fire alarm box or supervisory switch.

- All fire protection systems consist of devices, which upon use or actuation, will initiate the intended operation. A manual fire alarm box, for example, upon actuation will transmit a fire alarm signal. In the case of a single-station device, the initiating device and the notification appliance are one in the same.

INSPECTION CERTIFICATE. An identification applied on a product by an approved agency containing the name of the manufacturer, the function and performance characteristics, and the name and identification of an approved agency that indicates that the product or material has been inspected and evaluated by an approved agency (see Section 1703.5 and “Label,” “Manufacturer’s designation” and “Mark”).

- An inspection certificate is an identification applied to a product indicating that the individual product has been inspected by a third-party agency. The identification should include three items:

1. The name of the manufacturer;
2. The function and performance characteristics of the product; and
3. The name of the approved agency completing the inspection and evaluation for the product.

Note that the requirements for a label (see definition of "Label") differ from those of an inspection certificate. A label is issued by a third-party inspection agency that performs periodic inspections, while an inspection certificate is issued for the product at the time of inspection. The issuance of inspection certificates is an ongoing process.

INTENDED TO BE OCCUPIED AS A RESIDENCE. This refers to a dwelling unit or sleeping unit that can or will be used all or part of the time as the occupant’s place of abode.

- A unit that is a person’s home, rather than a unit used for a more transient nature, is a place of abode. Fair housing regulations do not include a 30-day criteria for transient/nontransient, similar to what has been traditionally used by the building codes (see the commentary to Section 1107 for additional information); therefore, beach homes, timeshares and extended-stay hotels may be included.

INTERIOR EXIT RAMP. An exit component that serves to meet one or more means of egress design requirements, such as required number of exits or exit access travel distance, and
provides for a protected path of egress travel to the exit discharge or public way.

- To qualify as an interior exit ramp, the ramp must be enclosed with a fire-rated enclosure in order to provide a protected path between the exit access and exit discharge. This enclosure must extend directly to the exterior at grade; extend through an exit passageway to grade; or comply with one of the allowances for exit discharge through a lobby, vestibule or horizontal exit. Travel distance is measured to the entrance to the enclosure for the interior exit ramp. Ramps that are utilized by occupants for evacuation, but do not meet the provisions for exits, are considered exit access elements (see "Exit access ramp"). For exterior exit ramp requirements, see Section 1026.

**INTERIOR EXIT STAIRWAY.** An exit component that serves to meet one or more means of egress design requirements, such as required number of exits or exit access travel distance, and provides for a protected path of egress travel to the exit discharge or public way.

- To qualify as an interior exit stairway, the stairway must be enclosed with a fire-rated enclosure in order to provide a protected path between the exit access and exit discharge. This enclosure must extend directly to the exterior at grade; extend through an exit passageway to grade; or comply with one of the allowances for exit discharge through a lobby, vestibule or horizontal exit. Travel distance is measured to the entrance to the enclosure for the interior exit stairway. Stairways that are utilized by occupants for evacuation, but do not meet the provisions for exits, are considered exit access elements (see "Exit access stairway"). For exterior exit stairway requirements, see Section 1026.

**INTERIOR FINISH.** Interior finish includes interior wall and ceiling finish and interior floor finish.

- This is a general term that addresses all exposed surfaces, which includes walls, ceilings and floors. Interior finish material is exposed to the interior space enclosed by these building elements.

**INTERIOR FLOOR FINISH.** The exposed floor surfaces of buildings including coverings applied over a finished floor or stair, including risers.

- This definition clarifies which part of the interior finish is considered the floor. Floors are treated differently than walls and ceilings as they pose a minimal fire hazard in comparison to that potentially created by the interior finish on walls and ceilings (see commentary, Section 804). Materials that are installed above the structural floor element and exposed to the room or space are considered floor finish materials. Such materials are, therefore, subject to the requirements of Section 804. This section also restricts the combustibility and ability to propagate a fire based upon radiant exposure levels.

**INTERIOR FLOOR-WALL BASE.** Interior floor finish trim used to provide a functional or decorative border at the intersection of walls and floors.

- This definition, which addresses interior floor-wall base trim materials, provides an understanding and clarification of these types of products versus other interior trim materials. In many cases, floor-covering material is just seamlessly turned up or used at the intersection of the floor and the wall, thus becoming the floor-wall base trim. Because of their location at the floor line, floor-wall base materials are not likely to be involved in a fire until the floor covering is also involved, usually at room flashover (see also commentary, Section 806.6).

**INTERIOR SURFACES.** Surfaces other than weather exposed surfaces.

- Interior surfaces are all surfaces, exposed and unexposed to view, on the inside of a building or structure that are not subject to damage or failure of their intended purpose because of the effects of uncontrollable weather conditions, such as rain, sleet, snow and wind. Interior surfaces are generally exposed to mechanically controlled climatic conditions through air-conditioning, heating and humidity control. Because of these controls, interior surfaces require far less restrictions than exterior surfaces; therefore, the quantities and types of materials and finishes permitted for use on interior surfaces are greatly increased.

**INTERIOR WALL AND CEILING FINISH.** The exposed interior surfaces of buildings, including but not limited to: fixed or movable walls and partitions; toilet room privacy partitions; columns; ceilings; and interior wainscoting, paneling or other finish applied structurally or for decoration, acoustical correction, surface insulation, structural fire resistance or similar purposes, but not including trim.

- A material that is applied to ceilings as well as walls, columns, partitions (including the privacy partitions in bathrooms that could pose a significant threat in larger bathrooms if unrated) and other vertical interior surfaces whether fixed or movable. The application of this material may be for structural, decorative, acoustical, structural fire resistance and other similar reasons. Trim, such as baseboard, door or window casing, is not considered interior wall and ceiling finish. Interior wall and ceiling finish is regulated by Section 803.

**INTERLAYMENT.** A layer of felt or nonbituminous saturated felt not less than 18 inches (457 mm) wide, shingled between each course of a wood-shake roof covering.

- According to Section 1507.9.5, interlayment is required to comply with ASTM D 226, Type I, which is commonly referred to as No. 15 asphalt felt.

**INTUMESCENT FIRE-RESISTANT COATINGS.** Thin film liquid mixture applied to substrates by brush, roller, spray or trowel which expands into a protective foamed layer.
DEFINITIONS

to provide fire-resistant protection of the substrates when exposed to flame or intense heat.

- Section 1705.14 requires special inspections for intumescent fire-resistant coatings in accordance with AWCI 12-B, based on the fire-resistance design. Because AWCI 12-B does not define or describe these materials, this definition facilitates correct application of the special inspections.

JOINT. The opening in or between adjacent assemblies that is created due to building tolerances, or is designed to allow independent movement of the building in any plane caused by thermal, seismic, wind or any other loading.

- This term defines the void created when two assemblies meet and an open space occurs between the assemblies [see Figure 202.8(2) for examples of building joints].

[A] JURISDICTION. The governmental unit that has adopted this code under legislative authority.

- The governmental unit adopting the code has the legal authority to do so under state statutes.

L RATING. The air leakage rating of a through penetration firestop system or a fire-resistant joint system when tested in accordance with UL 1479 or UL 2079, respectively.

- The term "L rating" is a companion rating similar to F and T ratings. The term is already widely used in the industry. Air leakage for breaches of smoke barriers can be limited by adherence to the requirements in Sections 714.5 and 715.6. Only through penetrations and joints in smoke barriers are required to meet the limits on air leakage.

[A] LABEL. An application identified on a product by the manufacturer that contains the name of the manufacturer, the function and performance characteristics of the product or material, and the name and identification of an approved agency and that indicates that the representative sample of the product or material has been tested and evaluated by an approved agency (see Section 1703.5 and "Inspection certificate," "Manufacturer's designation" and "Mark").

- A label provides verification of testing and inspection of materials, products or assemblies (see commentary Section 1703.5). See also the commentary for definitions of "Listed," "Mark," "Labeled" and "Manufacturer's designation."

[A] LABELED. Equipment, materials or products to which has been affixed a label, seal, symbol or other identifying mark of a nationally recognized testing laboratory, inspection agency or other organization concerned with product evaluation that maintains periodic inspection of the production of the above-labeled items and whose labeling indicates either that the equipment, material or product meets identified standards or has been tested and found suitable for a specified purpose.

- The term is an adjective applied to equipment, materials and products that has been tested or otherwise determined to meet the intended purpose or meet a standard. The label is that of a laboratory or other agency qualified to do the evaluations (see commentary, Section 1703.5). See also the commentary for definitions of "Listed," "Mark," "Label" and "Manufacturer's designation."

LEVEL OF EXIT DISCHARGE. See "Exit discharge, level of."

- Level of exit discharge is defined under "exit discharge, level of" and is addressed in the commentary for that term.

LIGHT-DIFFUSING SYSTEM. Construction consisting in whole or in part of lenses, panels, grids or baffles made with light-transmitting plastics positioned below independently mounted electrical light sources, skylights or light-transmitting plastic roof panels. Lenses, panels, grids and baffles that are part of an electrical fixture shall not be considered a light-diffusing system.

- Heat-resistant plastics, such as polystyrene and urea, are frequently used for light diffusion.

LIGHT-FRAME CONSTRUCTION. A type of construction whose vertical and horizontal structural elements are primarily formed by a system of repetitive wood or cold-formed steel framing members.

- The code uses the term "light frame" to distinguish this unique type of framing system from other structural systems. The structural integrity of light-frame construction is dependent upon numerous connections or frequent bracing. Other framing systems or terms commonly used in the building industry that are considered as light-frame construction include: "stick built," "platform frame," "western frame" and "balloon frame." Section 2211 pertains to light-frame cold-formed steel construction. Section 2308 defines a specific subclass of light-frame construction called "conventional light-frame construction," which is limited to wood materials.

LIGHT-TRANSMITTING PLASTIC ROOF PANELS. Structural plastic panels other than skylights that are fastened to structural members, or panels or sheathing and that are used as light-transmitting media in the plane of the roof.

- Plastic roof panels are primarily used in areas where light transmission rather than visual clarity is the goal (e.g., factory and industrial applications). Even though they are used as light-transmitting media, they must support the loads and forces encountered, just like roof surfaces. Typical applications include factories, warehouses and greenhouses where glass breakage is a practical concern.

LIGHT-TRANSMITTING PLASTIC WALL PANELS. Plastic materials that are fastened to structural members, or to structural panels or sheathing, and that are used as light-transmitting media in exterior walls.

- This term is only applicable to plastic wall panels allowing the transmission of light. Even though they are used as light-transmitting media, they must support the loads and forces encountered, just like other wall surfaces. Foam core insulated panels are regu-
DEFINITIONS

LIMIT STATE. A condition beyond which a structure or member becomes unfit for service and is judged to be no longer useful for its intended function (serviceability limit state) or to be unsafe (strength limit state).

This definition is needed for a clear understanding of the load and resistance factor design (LRFD) methodology.

[F] LIQUID. A material that has a melting point that is equal to or less than 68°F (20°C) and a boiling point that is greater than 68°F (20°C) at 14.7 pounds per square inch absolute (psia) (101 kPa). When not otherwise identified, the term "liquid" includes both flammable and combustible liquids.

This definition specifies the criteria to establish when material is considered a liquid based on its melting and boiling points. When the term "liquid" is referred to, it is intended to include both flammable and combustible liquids.

[F] LIQUID STORAGE ROOM. A room classified as a Group H-3 occupancy used for the storage of flammable or combustible liquids in a closed condition.

Liquid storage rooms are utilized exclusively for the storage of flammable and combustible liquids in closed containers in excess of the MAQs permitted by Tables 307.1(1) and 307.1(2). The storage room itself is considered a Group H-3 occupancy in accordance with Section 307.5.

[F] LIQUID USE, DISPENSING AND MIXING ROOM. A room in which Class I, II and IIIA flammable or combustible liquids are used, dispensed or mixed in open containers.

This term refers to all nonstorage rooms utilized exclusively for flammable and combustible liquids other than Class IIIB liquids. Class IIIB liquids have a flash point in excess of 200°F (93°C) and are not considered hazardous.

[A] LISTED. Equipment, materials, products or services included in a list published by an organization acceptable to the building official and concerned with evaluation of products or services that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services and whose listing states either that the equipment, material, product or service meets identified standards or has been tested and found suitable for a specified purpose.

When a product is listed and labeled, it indicates that it has been tested for conformance to an applicable standard and is subject to a third-party inspection quality assurance (QA) program. The QA verifies that the minimum level of quality required by the appropriate standard is maintained. Labeling provides a readily available source of information that is useful for field inspection of installed products. The label identifies the product or material and provides other information that can be further investigated if there is any question as to its suitability for the specific installation. The labeling agency performing the third-party inspection must be approved by the building official, and the basis for this approval may include, but is not limited to, the capacity and capability of the agency to perform the specific testing and inspection. See also the commentary for definitions of "Mark," "Label," "Labeled" and "Manufacturer's designation."

The question is often asked whether the listing of a product can be voided or violated. The use of a listing mark applied to a product is authorized by the listing agency and is a "statement" by the product manufacturer that the product, as manufactured, met all appropriate requirements (such as the criteria contained in a test standard) at the time of manufacture and shipment to a point-of-use or point-of-sale. After that point in time, any alteration or modification makes it impossible for the building official or the listing agency to determine if the product continues to meet the criteria by which its listing was originally attained. Listed products are subject to the review and approval of the building official and, where the building official determines that a field modification or alteration to the product is significant enough to call its impact on the listing into question, an evaluation in the field by representatives of the listing agency may be required in order to verify the continued compliance of the product with the original listing criteria. Such field evaluations or tests would be the responsibility of the permit holder and conducted at no cost to the jurisdiction (see Section 104.11.2).

LIVE/WORK UNIT. A dwelling unit or sleeping unit in which a significant portion of the space includes a nonresidential use that is operated by the tenant.

Live/work dwelling units incorporate both living space and nonresidential use spaces. Live/work units are growing in popularity in urban centers to bring a mix of uses to neighborhoods. The provisions of Section 419 address building code issues, but local zoning regulations may also provide limits on use or location.

LIVE LOAD. A load produced by the use and occupancy of the building or other structure that does not include construction or environmental loads such as wind load, snow load, rain load, earthquake load, flood load or dead load.

This definition identifies the scope of the type of loading included in Section 1607. Generally, live loads are not environmental loads or dead loads, but are transient in nature and will vary in magnitude over the life of a structure.

LIVE LOAD, ROOF. A load on a roof produced:

1. During maintenance by workers, equipment and materials;
2. During the life of the structure by movable objects such as planters or other similar small decorative appreciations that are not occupancy related; or
3. By the use and occupancy of the roof such as for roof gardens or assembly areas.

This definition is needed for the proper application of the load combinations in Chapter 16. This definition clarifies what is considered a roof live load, as well as...
DEFINITIONS

clarifying (implicitly) that snow loads are not considered roof live loads.

LOAD AND RESISTANCE FACTOR DESIGN (LRFD).
A method of proportioning structural members and their connections using load and resistance factors such that no applicable limit state is reached when the structure is subjected to appropriate load combinations. The term “LRFD” is used in the design of steel and wood structures.

- This definition describes the load and resistance factor design (LRFD) method, which is one of the design approaches recognized under the code in Section 1604.1. It is needed for the proper application of the steel design requirements in Chapter 22 and the wood design requirements in Chapter 23.

LOAD EFFECTS.
Forces and deformations produced in structural members by the applied loads.

- This definition is needed to properly apply the structural load requirements in Chapter 16. “Load effects” is a collective term used to refer to the internal member forces and deformations that result from the applied loads.

LOAD FACTOR.
A factor that accounts for deviations of the actual load from the nominal load, for uncertainties in the analysis that transforms the load into a load effect, and for the probability that more than one extreme load will occur simultaneously.

- This definition clarifies the application of the LRFD load combinations in Chapter 16.

LOADS.
Forces or other actions that result from the weight of building materials, occupants and their possessions, environmental effects, differential movement and restrained dimensional changes. Permanent loads are those loads in which variations over time are rare or of small magnitude, such as dead loads. All other loads are variable loads (see also “Nominal loads”).

- This definition is needed for the proper application of the structural load requirements in Chapter 16. It also includes a definition of “Permanent loads” that serves as the distinction between variable loads and permanent loads. This is important in Section 1605.1, which requires all load combinations to be investigated with one or more of the variable loads taken as zero. The distinction made between variable loads and permanent loads is fairly straightforward. Dead load is specifically mentioned because it is an ideal example of a load that does not vary over time. But dead load is not necessarily the only load that could be considered permanent. An additional complication is the definition of certain loads that may include both permanent and variable components. An indicator of this is provided in the load combinations in Section 1605. For instance, in the ASD basic load combinations given by Equations 16-11, 16-13 and 16-14, the variable loads are reduced by a factor of 0.75. Based on the application of the reduction factor in these load combinations, live load, L, roof live load, Lr, snow load, S, rain load, R, wind load, W, and earthquake load, E, are explicitly treated as variable loads. Since they are not reduced in these load combinations, pressure of a well-defined fluid, P, and lateral earth pressure, H, could be considered, at least in part, permanent loads.

[A] LOT.
A portion or parcel of land considered as a unit.

- A lot is a legally recorded parcel of land, the boundaries of which are described on a deed. When code requirements are based on some element of a lot (such as yard area or lot line location), it is the physical attributes of the parcel of land that the code is addressing, not issues of ownership. Adjacent lots owned by the same party are treated as if they were owned by different parties because ownership can change at any time. However, a group of platted lots or subdivision lots could be joined together and “considered as a unit” for the purposes of the code. For example, a collection of platted lots could be used as a single building lot for the construction of a covered mall and its associated anchor buildings. Local jurisdictions may require for taxing or other purposes that the lots be legally joined, or merged, as well.

A condominium form of building ownership, whether a residential or commercial condominium, does not create separate lots (i.e., parcels of land) and such unit owners are treated as separate tenants, not separate lot owners. The lines separating one part of a condominium from another are not lot lines but lines indicating the limits of ownership. As such, walls constructed on lines separating condominium ownership would not need to be fire (or party) walls.

Legal property lines do not always constitute site boundaries (e.g., malls, condominiums, townhouses). A site could contain multiple legal “lot” divisions.

[A] LOT LINE.
A line dividing one lot from another, or from a street or any public place.

- Lot lines are legally recorded divisions between two adjacent land parcels or lots. They are the reference point for the location of buildings for exterior separation and other code purposes (see the definition of “Lot” above).

[F] LOWER FLAMMABLE LIMIT (LFL).
The minimum concentration of vapor in air at which propagation of flame will occur in the presence of an ignition source. The LFL is sometimes referred to as “LEL” or “lower explosive limit.”

- When the vapor-to-air ratio is somewhere between the LFL and the UFL, fires and explosions can occur upon introduction of an ignition source. The UFL is the maximum vapor-to-air concentration above which propagation of flame will not occur. If a vapor-to-air mixture is below the LFL, it is described as being "too lean" to burn, and if it is above the UFL, it is "too rich" to burn. For further discussion of this material definition, see the commentary to it in Chapter 2 of the International Fire Code and Commentary.
LOWEST FLOOR. The floor of the lowest enclosed area, including basement, but excluding any unfinished or flood-resistant enclosure, usable solely for vehicle parking, building access or limited storage provided that such enclosure is not built so as to render the structure in violation of Section 1912.

- The lowest floor is the most important reference point when designing and constructing a building or structure in a flood hazard area. The term is specifically defined to include basements, which are any areas that are below grade on all sides. For elevated buildings, compliance with the flood-resistant design and construction provisions of the code is determined by an elevation survey that documents that the lowest floor, including the basement, is at or above the design flood elevation. It is important to note that enclosures may be built below elevated buildings provided they meet both the design criteria and use limitations (see Section 1612.5, Item 1). If compliant with the design criteria and use limitations, then enclosures are not considered the lowest floor. This distinction is also important because the premium rates used to determine the cost of a federal flood insurance policy is dependent on the elevation of the lowest floor.

MAIN WINDFORCE-RESISTING SYSTEM. An assemblage of structural elements assigned to provide support and stability for the overall structure. The system generally receives wind loading from more than one surface.

- This definition identifies the structural components that are to comply with special inspection requirements. The main windforce-resisting system is the global structural system designed to resist wind loads on the building or structure.

MALL BUILDING, COVERED and MALL BUILDING, OPEN. See "Covered mall building."

- Malls, covered mall buildings, covered malls, open malls and open mall buildings are all terms used to describe various shopping mall buildings and complexes. The terms are all defined under "Covered mall building. (see commentary under that definition).

[F] MANUAL FIRE ALARM BOX. A manually operated device used to initiate an alarm signal.

- Manual fire alarm boxes are commonly known as pull stations. Manual fire alarm boxes include all manual devices used to activate a manual fire alarm system and have many configurations, depending on the manufacturer. All manual fire alarm devices, however, must be approved and installed in accordance with NFPA 72 for the particular application. Manual fire alarm boxes may be combined in guard tour boxes.

[A] MANUFACTURER'S DESIGNATION. An identification applied on a product by the manufacturer indicating that a product or material complies with a specified standard or set of rules (see also "Inspection certificate," "Label" and "Mark").

- This represents terminology for a manufacturer's self-certification that a product complies with a given standard (see commentary, Section 1703.4). See also the commentary for definitions of "Listed," "Mark," "Label" and "Labeled."

[A] MARK. An identification applied on a product by the manufacturer indicating the name of the manufacturer and the function of a product or material (see also "Inspection certificate," "Label" and "Manufacturer's designation").

- A mark represents the manufacturer’s identification placed on a product, stating who made the product and describing its function. There is, however, no certification of compliance to any particular standard and no third-party quality control (see commentary, Section 1703.4). Also see the commentary for definitions of "Listed," "Label," "Labeled" and "Manufacturer's designation."

MARQUEE. A canopy that has a top surface which is sloped less than 25 degrees from the horizontal and is located less than 10 feet (3.05 m) from operable openings above or adjacent to the level of the marquee.

- Marquees, unlike awnings, are fixed, permanent structures that justify sufficiently different requirements from those for other projections (see Section 3106 for code requirements for marquees). This definition also facilitates application of live loads in Table 1607.1

MASONRY. A built-up construction or combination of building units or materials of clay, shale, concrete, glass, gypsum, stone or other approved units bonded together with or without mortar or grout or other accepted methods of joining.

- The materials (other than gypsum) and elements constructed as stated in this definition are considered masonry construction and are regulated by Chapter 21. This term identifies the building elements of plain (unreinforced) masonry, reinforced masonry, grouted masonry, glass unit masonry and masonry veneer.

Ashlar masonry. Masonry composed of various-sized rectangular units having sawed, dressed or squared bed surfaces, properly bonded and laid in mortar.

- Units for ashlar masonry construction are rectangular in shape but variable in size.

Coursed ashlar. Ashlar masonry laid in courses of stone of equal height for each course, although different courses shall be permitted to be of varying height.

- In coursed ashlar masonry, all units in one course are the same height, although different courses may have different heights.
DEFINITIONS

Glass unit masonry. Masonry composed of glass units bonded by mortar.

- Glass unit masonry consists of nonlad-bearing assemblies designed in accordance with Sections 2101.2.5 and 2110.

Plain masonry. Masonry in which the tensile resistance of the masonry is taken into consideration and the effects of stresses in reinforcement are neglected.

- Plain masonry has historically been referred to as "unreinforced masonry." Since such masonry may actually contain some reinforcement, however, the term "unreinforced" has fallen out of favor. When reinforcement is contained in plain masonry, its contribution to the strength of the system is required to be ignored. The bond between the masonry units and mortar is critical in the performance of plain masonry.

Random ashlar. Ashlar masonry laid in courses of stone set without continuous joints and laid up without drawn patterns. When composed of material cut into modular heights, discontinuous but aligned horizontal joints are discernible.

- Random ashlar has discontinuous bed joints because units have different heights.

Reinforced masonry. Masonry construction in which reinforcement acting in conjunction with the masonry is used to resist forces.

- Reinforced masonry contains reinforcement (currently limited to steel reinforcement) and is designed considering the tensile strength of that reinforcement. Not all masonry containing reinforcement is considered reinforced masonry. Some plain masonry contains reinforcement (usually to reduce the size of any cracks that may form), but the contribution of that reinforcement is required to be neglected.

Solid masonry. Masonry consisting of solid masonry units laid contiguously with the joints between the units filled with mortar.

- This term describes single- or multiwythe walls composed of solid masonry units, including the thickness of the collar joint if it is filled with mortar or grout.

Unreinforced (plain) masonry. Masonry in which the tensile resistance of masonry is taken into consideration and the resistance of the reinforcing steel, if present, is neglected.

- See the commentary for "Plain masonry."

MASONRY UNIT. Brick, tile, stone, glass block or concrete block conforming to the requirements specified in Section 2103.

- Masonry units are natural stone units or manufactured units of fired clay, shale, cementitious materials or glass.

Hollow. A masonry unit whose net cross-sectional area in any plane parallel to the load-bearing surface is less than 75 percent of its gross cross-sectional area measured in the same plane.

- Hollow masonry units are those having a specified net cross-sectional area less than 75 percent of their corresponding gross cross-sectional area. Where the specified net cross-sectional area is equal to or greater than 75 percent of the gross cross-sectional area, the unit is considered to be solid.

Solid. A masonry unit whose net cross-sectional area in every plane parallel to the load-bearing surface is 75 percent or more of its gross cross-sectional area measured in the same plane.

- Solid masonry units have a specified net cross-sectional area 75 percent or greater of their corresponding gross cross-sectional area. Where the specified net cross-sectional area is less than 75 percent of the gross cross-sectional area, the unit is considered to be hollow.

Mastic fire-resistant coatings. Liquid mixture applied to a substrate by brush, roller, spray or trowel that provides fire-resistant protection of a substrate when exposed to flame or intense heat.

- Section 1705.14 requires special inspections for mastic fire-resistant coatings in accordance with AWCI 12-B, based on the fire-resistance design. Because AWCI 12-B does not define or describe these materials, this definition facilitates correct application of the special inspections.

MEANS OF EGRESS. A continuous and unobstructed path of vertical and horizontal egress travel from any occupied portion of a building or structure to a public way. A means of egress consists of three separate and distinct parts: the exit access, the exit and the exit discharge.

- The means of egress is the path traveled by building occupants to leave the building and the site on which it is located. It includes all interior and exterior elements that the occupants must utilize as they make their way from every room and usable space within the building to a public way such as a street or alley. The elements that make up the means of egress create the lifeline that occupants utilize to travel out of the structure and to a safe distance from the structure. The means of egress provisions strive to provide a reasonable level of life safety in every structure. The means of egress provisions are subdivided into three distinct portions (see the definitions of "Exit access," "Exit" and "Exit discharge").

MECHANICAL-ACCESS OPEN PARKING GARAGES. Open parking garages employing parking machines, lifts, elevators or other mechanical devices for vehicles moving from and to street level and in which public occupancy is prohibited above the street level.

- These types of garages are constructed with most of the same attributes as other garages. They have numerous parking levels that house motor vehicles; however, public access to these upper levels is not
permitted. Employees take control of the vehicles at the street level and drive into some sort of a vertical mechanical device, which conveys them to the upper parking levels. These structures are still provided with the required openings of Section 406.5.2.

MECHANICAL EQUIPMENT SCREEN. A rooftop structure, not covered by a roof, used to aesthetically conceal plumbing, electrical or mechanical equipment from view.

- These are used mainly for appearance and to conceal roof-mounted equipment from view.

MECHANICAL SYSTEMS. For the purposes of determining seismic loads in ASCE 7, mechanical systems shall include plumbing systems as specified therein.

- This definition clarifies the application of ASCE 7 earthquake-load provisions for mechanical components and systems that may include items that are covered under plumbing systems elsewhere in the I-Codes.

MEDICAL CARE. Care involving medical or surgical procedures, nursing or for psychiatric purposes.

- Persons who need medical care are likely to be incapable of self-preservation or at least extremely limited in their ability to evacuate. In consideration of occupant’s health as well as safety, hospitals and nursing homes at least partially rely on defend-in-place strategies. See also the commentary for Section 308, Group I-2.

Care facilities encompass a full spectrum of acuity and support services and span a wide range of occupancy types including Groups E, I and R. There are three types of care defined in the codes: personal, custodial and medical. On the lower end of the care spectrum (i.e., personal care) is when occupants are supervised but do not need custodial or medical care. Where occupants may be elderly or impaired (i.e., custodial care) they may need occasional daily living assistance such as cooking and cleaning. While they may take longer to evacuate than average, they are capable of self-preservation. On the opposite end of the care spectrum, occupants may be completely bedridden and dependent on medical gases and emergency power to maintain life (i.e., medical care). The level of care provided describes the condition and capabilities of an occupant which then indicates appropriate standards for protection systems, both active and passive. See also the definitions for “24-hour care,” “Custodial care,” “Detoxification facility,” “Foster care facility,” “Group home,” “Hospitals and psychiatric hospitals,” “Nursing home,” “Personal care services” and “incapable of self-preservation.”

MEMBRANE-COVERED CABLE STRUCTURE. A nonpressurized structure in which a mast and cable system provides support and tension to the membrane weather barrier and the membrane imparts stability to the structure.

- This definition identifies a structure in which the membrane fabric is draped over a cable framework. These structures do not involve any interior air pressurization. The cable framework system is supported by a mast or other tower system. The cables are usually pretensioned to provide structural support for the rest of the exterior structure.

MEMBRANE-COVERED FRAME STRUCTURE. A nonpressurized building wherein the structure is composed of a rigid framework to support a tensioned membrane which provides the weather barrier.

- This type of membrane structure is the same as the membrane-covered cable structure, except that a trussed framework constructed of structural shapes provides the support instead of pretensioned cables. Again, no air pressurization is required or provided.

MEMBRANE PENETRATION. A breach in one side of a floor-ceiling, roof-ceiling or wall assembly to accommodate an item installed into or passing through the breach.

- This term refers to the situation where a penetration is made of a single layer of a fire-resistance-rated assembly. Sections 714.3.2 and 714.4.1.2 establish criteria where the penetration of a single membrane of an assembly is permitted while still considering the assembly to have the required fire-resistance rating [see Figure 202.13(1) for an example of a single membrane penetration].

Where a penetration is made completely through a fire-resistance-rated wall or floor/ceiling assembly, it must be protected in accordance with Section 714.3, 714.4.1.1 or 714.4.2, as applicable for the assembly, penetrated.

MEMBRANE PENETRATION FIRESTOP. A material, device or construction installed to resist for a prescribed time period the passage of flame and heat through openings in a protective membrane in order to accommodate cables, cable trays, conduit, tubing, pipes or similar items.

- Sections 714.3.2 and 714.4.1.2 both refer to protection methods for membrane penetrations of fire-resistance-rated walls, floor/ceiling assemblies and roof/ceiling assemblies.

MEMBRANE-PENETRATION FIRESTOP SYSTEM. An assemblage consisting of a fire-resistance-rated floor-ceiling, roof-ceiling or wall assembly, one or more penetrating items installed into or passing through the breach in one side of the assembly and the materials or devices, or both, installed to resist the spread of fire into the assembly for a prescribed period of time.

- Membrane-penetration firestop systems maintain the required protection from the spread of fire, passage of hot gases and transfer of heat. A firestop usually refers to a single item, where a system is a combination of elements. See also the commentary to the definition of “Through-penetration firestop system.”

MERCHANDISE PAD. A merchandise pad is an area for display of merchandise surrounded by aisles, permanent fixtures or walls. Merchandise pads contain elements such as nonfixed and moveable fixtures, cases, racks, counters and
DEFINITIONS

partitions as indicated in Section 105.2 from which customers browse or shop.

- Merchandise pads would most likely be found in large stores with changing displays of clothes or furniture. This is not a raised display-only area. These areas allow customers to move between displays or racks. In regards to means of egress, merchandise pads could be considered analogous to areas of fixed seating or groups of tables. The aisle accessways are within the merchandise pad and lead to the aisles on the outside edges of the merchandise pads. Not all stores will contain merchandise pads (e.g., a typical grocery store with fixed shelves and aisles).

**METAL COMPOSITE MATERIAL (MCM).** A factory-manufactured panel consisting of metal skins bonded to both faces of a plastic core.

- These types of panels are sandwich construction composed of thin metal (usually aluminum or steel) sheets covering a solid plastic core. The panels typically have thicknesses that do not exceed 0.25 inch (6.4 mm). Metal composite material (MCM) panels are different from other types of sandwich panels in that they do not contain foam plastic cores and are not typically intended to provide thermal insulation.

**METAL COMPOSITE MATERIAL (MCM) SYSTEM.**

An exterior wall covering fabricated using MCM in a specific assembly including joints, seams, attachments, substrate, framing and other details as appropriate to a particular design.

- The provisions of Section 1407 provide the components that are typically part of a metal composite material (MCM) installation. The components of the exterior wall-covering system consist of framing members for the attachment and support of the MCM panels; the types of joints and seams used to maintain the weather resistance of the system and the means for attaching the entire system to the building substrate or structural frame.

**METAL ROOF PANEL.** An interlocking metal sheet having a minimum installed weather exposure of 3 square feet (0.279 m²) per sheet.

- There are two general categories of metal roofing systems: architectural metal roofing and structural metal roofing. Architectural metal roofs are generally watersheding roof systems and structural metal roofs have hydrostatic (water barrier) characteristics. The difference between a "metal roof panel" and a "metal roof shingle" is the weather exposure (i.e., that portion of the roofing exposed) (see Section 1507.4).

**METAL ROOF SHINGLE.** An interlocking metal sheet having an installed weather exposure less than 3 square feet (0.279 m²) per sheet.

- See the definition of "Metal roof panel."

**MEZZANINE.** An intermediate level or levels between the floor and ceiling of any story and in accordance with Section 505.

- A common design feature in factories, warehouses and mercantile buildings is an intermediate loft, or platform, between the story levels of a building. This type of feature, or mezzanine, can be found in buildings of all occupancies. The code must deal with whether this intermediate level is another story of the
building or whether it can simply be treated as part of the story in which it is contained. The basic rule is that the intermediate level must be less than one-third of the area of the story below (of the room in which it is located) in order to be considered a mezzanine. Requirements for mezzanines are found in Section 505.

MICROPILE. A micropile is a bored, grouted-in-place deep foundation element that develops its load-carrying capacity by means of a bond zone in soil, bedrock or a combination of soil and bedrock.

- This definition clarifies a term that refers to a specific type of deep foundation element. The term “micropile” is a reference to its relative size compared to conventional deep foundation elements. They are also referred to as “minipiles” or “pin piles.”

MINERAL BOARD. A rigid felted thermal insulation board consisting of either felted mineral fiber or cellular beads of expanded aggregate formed into flat rectangular units.

- This form of insulation is listed in Table 721.1(2), Items 15-1.9, 15-1.10 and 15-1.11.

MINERAL FIBER. Insulation composed principally of fibers manufactured from rock, slag or glass, with or without binders.

- This term provides a definition for a type of insulation that is commonly used or accepted within rated assemblies [see Table 721.1(2), Item 15-1.11] or as a fireblocking material (see Section 718.2.1).

MINERAL WOOL. Synthetic vitreous fiber insulation made by melting predominately igneous rock or furnace slag, and other inorganic materials, and then physically forming the melt into fibers.

- This term provides a definition for a type of insulation that is commonly used or accepted within rated assemblies [see Table 721.1(2), Item 15-1.15] or as a fireblocking material (see Section 718.2.1).

MODIFIED BITUMEN ROOF COVERING. One or more layers of polymer-modified asphalt sheets. The sheet materials shall be fully adhered or mechanically attached to the substrate or held in place with an approved ballast layer.

- These are composite sheets consisting of copolymer-modified bitumen, often reinforced and sometimes surfaced with various types of films, foils and mats.

MORTAR. A mixture consisting of cementitious materials, fine aggregates, water, with or without admixtures, that is used to construct unit masonry assemblies.

- Mortar is the material that bonds units and accessories together and compensates for dimensional variations of the units. Both the plastic and hardened properties of mortar are important for strong, durable, water-tight construction. Material requirements and referenced standards for several permitted mortar types are given in Sections 2103.9 through 2103.12.

MORTAR, SURFACE-BONDING. A mixture to bond concrete masonry units that contains hydraulic cement, glass fiber reinforcement with or without inorganic fillers or organic modifiers and water.

- This mortar is a packaged, dry, combined material permitted for use in the surface bonding of concrete masonry units that have not been prefaced, coated or painted. Masonry units are stacked without mortar joints and surface-bonding mortar is then applied to both sides of the wall surface, creating a structural element.

MULTILEVEL ASSEMBLY SEATING. Seating that is arranged in distinct levels where each level is comprised of either multiple rows, or a single row of box seats accessed from a separate level.

- Assembly rooms may include a sloped seating arrangement (i.e., either ramped or stepped) to improve the viewing of the event for the occupants. These spaces can be single- or multi-level arrangements. For example, for an auditorium with a sloped floor, the entire main floor is a single level. A level can be a balcony or a separate section of seating in an arena or stadium, such as skyboxes. The upper-seating bowl in the coliseum is a separate level, as is the loge in the theater; however, it is not the intent of this provision that each row of seats be considered a separate level.

[F] MULTIPLE-STATION ALARM DEVICE. Two or more single-station alarm devices that can be interconnected such that actuation of one causes all integral or separate audible alarms to operate. It also can consist of one single-station alarm device having connections to other detectors or to a manual fire alarm box.

- This definition refers to a combination of similar or different types of alarm devices that could be interconnected. The actuation of any two devices, whether a smoke detector or manual fire alarm box, will activate the required audible alarms at all interconnected devices.

[F] MULTIPLE-STATION SMOKE ALARM. Two or more single-station alarm devices that are capable of interconnection such that actuation of one causes the appropriate alarm signal to operate in all interconnected alarms.

- In occupancies with sleeping areas, occupants must be notified of a fire so that they can promptly evacuate the premises. In accordance with the requirements of NFPA 72, multiple-station smoke alarms are self-contained, smoke-activated alarm devices built in accordance with UL 217 that can be interconnected with other devices so that all integral or separate alarms will operate when any one device is activated.

MULTISTORY UNIT. A dwelling unit or sleeping unit with habitable space located on more than one story.

- A multistory dwelling or sleeping unit has living, sleeping, eating, cooking or bathroom space on more than one floor level within the unit (see Section 1107.7.2). A residence with only a garage under-

2012 INTERNATIONAL BUILDING CODE® COMMENTARY 2-69
neath or an unfinished basement would not be a multi-
tistory unit.

NAILING, BOUNDARY. A special nailing pattern required by
design at the boundaries of diaphragms.

When designing a diaphragm or a shear wall, the
sheathing for those elements must be attached to
provide the design resistance to the applied load.
Shear capacity tables for wood structural panels
specify the nail size and spacing to be used along the
diaphragm and in the field of each panel. Boundary nailing
is the required nailing pattern for panels located along the
edges of diaphragms and at other boundaries
where the stresses are typically high.

NAILING, EDGE. A special nailing pattern required by
design at the edges of each panel within the assembly of a
diaphragm or shear wall.

When designing a diaphragm or shear panel, the
sheathing for those elements must be attached in a
fashion that will provide design resistance to the
applied load. Shear capacity tables for wood structural panels
used as sheathing specify nail size and spacing. For example, Table 2306.2(1) requires 1/2-
inches (38 mm) staples to penetrate 1 inch (25 mm)
when a 1/2-inch (9.5 mm) panel is used on 2-inch-wide (51 mm) framing. To use a shear capacity of
210 pounds per linear feet (plf) (3064 N/m), the nail
spacing at boundary conditions where the diaphragm
is blocked is required to be 4 inches (102 mm) on
center (o.c.). Edge nailing occurs at diaphragm or
shear wall edges. In some cases, such as at blocked
diaphragm boundaries, the edge of the panel occurs
at the diaphragm boundary in which case the edge
must be boundary nailed.

NAILING, FIELD. Nailing required between the sheathing
panels and framing members at locations other than boundary
nailing and edge nailing.

When designing a diaphragm or shear panel, the
sheathing for those elements must be attached in a
fashion that will provide design resistance to the
applied load. Shear capacity tables for wood structural panels
used as sheathing specify nail size and spacing. For example, Note b in Table 2306.2(1) indi-
cates that the maximum spacing for fasteners along
intermediate framing members must be 12 inches
(305 mm) o.c.

NATURALLY DURABLE WOOD. The heartwood of the
following species except for the occasional piece with corner
sapwood, provided 90 percent or more of the width of each
side on which it occurs is heartwood.

Because of their natural ability to resist deterioration,
the harder portions of some species of wood are
considered to be naturally durable. The code specifies that "occasional" sapwood is permitted if heartwood
constitutes 90 percent of each side.

Decay resistant. Redwood, cedar, black locust and black
walnut.

- Redwood, cedar, black locust and black walnut lumber
  are known to resist deterioration due to the action
  of microbes that enter the wood fibers. The code
  defines these species of lumber as being decay resis-
tant.

Termitic resistant. Redwood, Alaska yellow cedar, East-
ern red cedar and both heartwood and all sapwood of
Western red cedar.

- Alaskan yellow cedar, redwood, Eastern red cedar
  and Western red cedar are considered to be resistant
to infestation by termites and are thus listed as natu-
rally durable.

NOMINAL LOADS. The magnitudes of the loads specified
in Chapter 16 (dead, live, soil, wind, snow, rain, flood and
earthquake).

This definition explains the term "nominal loads" so
that the loads to be applied are clear. For the most
part, the loads determined in Chapter 16 are con-
sidered nominal loads, which are used directly in allow-
able stress design (ASD) or multiplied by a load
factor for use in strength or load and resistance factor
design (LRFD). The exceptions are earthquake-load
effect, $E$, as well as the wind load, $W$, both of which
are considered strength level loads.

NOMINAL SIZE (LUMBER). The commercial size
designation of width and depth, in standard sawn lumber and
 glued-laminated lumber grades, somewhat larger than the
standard net size of dressed lumber, in accordance with
DOCS 20 for sawn lumber and with the AF&PA NDS for
 glued-laminated lumber.

- Unless specifically required by the code, all dimen-
sions listed for wood member sizes are nominal, not
actual. U.S. Department of Commerce (DOC) PS 20
specifies the required minimum dimension of lumber
for each stated nominal size. The process used to
smooth and finish the surfaces of the lumber and to
dry the wood removes a certain thickness of wood on
each side of the piece; therefore, a 2 by 4 is approxi-
mately 1 1/2 inches by 3 1/2 inches (38 mm by 89 mm).
The actual dimension of the lumber, otherwise known
as dressed size, is limited to ensure consistency in
lumber sizes, which is essential to the satisfactory
construction of a wood-frame building.

NONCOMBUSTIBLE MEMBRANE STRUCTURE. A
membrane structure in which the membrane and all compon-
ent parts of the structure are noncombustible.

- Any membrane structure that is constructed of all
noncombustible materials is classified by this defini-
tion. To qualify as noncombustible, the materials,
including the membrane itself, must be tested in
accordance with ASTM E 136 and must satisfy the
criteria in Section 703.4.
DEFINITIONS

[F] NORMAL TEMPERATURE AND PRESSURE (NTP). A temperature of 70°F (21°C) and a pressure of 1 atmosphere [14.7 psia (101 kPa)].

- This term refers to the standard room temperature at atmospheric pressure. Atmospheric pressure results from the weight of air elevated above the earth’s surface. At sea level, the atmosphere exerts a pressure of 14.7 pounds per square inch (psi) (101 kPa). The properties of commercially available compressed gases are indicated at their normal temperature and pressure (NTP).

NOSING. The leading edge of treads of stairs and of landings at the top of stairway flights.

- The front edge of the tread that is exposed to the user’s foot provides the visual clue for the placement of the foot in both ascent and descent. The nosings of a stair are a reference point for the measurement of the tread depth and riser height. The line connecting the nosings serves as the reference for the measurement of handrail and guard heights as well as headroom. The code ensures their uniformity by limiting the projection of the tread and landing nosings that results in a stairway that is easy to use. If too large, they are a tripping hazard when walking up a stair. If too small in relation to tread depth, the effective tread depth required for heel clearance in descent is minimized. The code provides limits for both minimum and maximum nosing projections and establishes a minimum tread depth when no projection is required [see code Figures 1009.7.2 and 1009.7.5(1)]. An exception to these limits exists in the requirements for both alternating tread devices and ship ladders where an exaggerated projected tread depth, required to provide for reasonable foot room, is unique to the steeper gradient and functional use of these devices.

[F] NOTIFICATION ZONE. See "Zone, notification."

- This term is more commonly known as "zone, notification." See also commentary for "Zone, notification."

[F] NUISANCE ALARM. An alarm caused by mechanical failure, malfunction, improper installation or lack of proper maintenance, or an alarm activated by a cause that cannot be determined.

- A nuisance alarm is essentially any alarm that occurs as a result of a condition that does not arise during the normal operation of the equipment. A nuisance alarm is not the same as a false alarm. A person who intentionally initiates an alarm by using a manual pull station or a person who accidentally initiates a smoke detector is not initiating a nuisance alarm. A nuisance alarm is, by nature, a factor of the system itself.

NURSING HOMES. Facilities that provide care, including both intermediate care facilities and skilled nursing facilities where any of the persons are incapable of self-preservation.

- Persons in nursing homes may be physically incapable of self-preservation or at least extremely limited in their ability to evacuate. In dementia wards they may be confined within an area of a building for care or security purposes. In consideration of an occupant’s health as well as safety, hospitals and nursing homes at least partially rely on defend-in-place strategies. See the commentary for Sections 308 and 407, Group I-2.

Care facilities encompass a full spectrum of acuity and support services and span a wide range of occupancy types including Groups B, E, I and R. The level of care provided describes the condition and capabilities of an occupant which then indicates appropriate standards for protection systems, both passive and active. See also the definitions for “24-hour care,” “Care suites,” “Custodial care,” “Detoxification facilities,” “Hospitals and psychiatric hospitals,” “Medical care” and “Incapable of self-preservation.”

OCUPANT LOAD. The number of persons for which the means of egress of a building or portion thereof is designed.

- In addition to the limitation on the maximum occupant load for a space, the code also requires the determination of the occupant load that is to be utilized for the design of the means of egress system. The number for the floor area per occupant (occupant load factor) in Table 1004.1.2 reflects common and traditional occupant densities based on the empirical data for the density of similar spaces. This occupant load is also utilized to determine the required number of plumbing fixtures (see Chapter 29) and when automatic sprinkler systems or fire alarm and detection systems are required (see Chapter 9).

OCUPABLE SPACE. A room or enclosed space designed for human occupancy in which individuals congregate for amusement, educational or similar purposes or in which occupants are engaged at labor, and which is equipped with means of egress and light and ventilation facilities meeting the requirements of this code.

- Occupable spaces are those areas designed for human occupancy. It applies to both residential and nonresidential spaces alike. Most spaces in a building are occupable spaces. Based on the nature of the occupancy, various code sections apply. All habitable spaces are also considered occupable (see the definition of “Habitable space”); however, all occupable spaces are not habitable. Additionally, some spaces are neither habitable nor occupable. The code identifies crawl spaces, attics, penthouses and elevated platforms (mechanical or industrial equipment) as unoccupied spaces. Since the code generally states how these spaces must be accessed, but does not specifically require means of egress, they would not be occupable spaces. If access is limited to maintenance and service personnel, it is likely that a space is not occupable.

OPEN PARKING GARAGE. A structure or portion of a structure with the openings as described in Section 406.5.2 on
two or more sides that is used for the parking or storage of private motor vehicles as described in Section 406.5.3.

- Open parking garages are defined as having uniformly distributed openings on no less than two sides totaling no less than 40 percent of the building perimeter. The aggregate area of the openings is to be a minimum of 20 percent of the total wall area of all perimeter walls (see Figure 406.5.2).

[F] OPEN SYSTEM. The use of a solid or liquid hazardous material involving a vessel or system that is continuously open to the atmosphere during normal operations and where vapors are liberated, or the product is exposed to the atmosphere during normal operations. Examples of open systems for solids and liquids include dispensing from or into open beakers or containers, dip tank and plating tank operations.

- See the commentary to the definition of "Closed system."

[F] OPERATING BUILDING. A building occupied in conjunction with the manufacture, transportation or use of explosive materials. Operating buildings are separated from one another with the use of intraplant or intraline distances.

- Magazines are used for the storage of explosive materials. Manufacturing or operating buildings used for the storage of explosives are not magazines and are not intended to be used for storage, although at times there may be storage incidental to the manufacturing function. This definition is included here to clarify this difference.

ORDINARY PRECAST STRUCTURAL WALL. See Section 1905.1.1.

- This definition is a modification of ACI 318 text and is therefore located in Section 1905.

ORDINARY REINFORCED CONCRETE STRUCTURAL WALL. See Section 1905.1.1.

- This definition is a modification of ACI 318 text and is therefore located in Section 1905.

ORDINARY STRUCTURAL PLAIN CONCRETE WALL. See Section 1905.1.1.

- This definition is a modification of ACI 318 text and is therefore located in Section 1905.

[F] ORGANIC PEROXIDE. An organic compound that contains the bivalent -O-O- structure and which may be considered to be a structural derivative of hydrogen peroxide where one or both of the hydrogen atoms have been replaced by an organic radical. Organic peroxides can pose an explosion hazard (detonation or deflagration) or they can be shock sensitive. They can also decompose into various unstable compounds over an extended period of time.

Class I. Those formulations that are capable of deflagration but not detonation.

Class II. Those formulations that burn very rapidly and that pose a moderate reactivity hazard.

Class III. Those formulations that burn rapidly and that pose a moderate reactivity hazard.

Class IV. Those formulations that burn in the same manner as ordinary combustibles and that pose a minimal reactivity hazard.

Class V. Those formulations that burn with less intensity than ordinary combustibles or do not sustain combustion and that pose no reactivity hazard.

Unclassified detonable. Organic peroxides that are capable of detonation. These peroxides pose an extremely high explosion hazard through rapid explosive decomposition.

- The chemical structure of organic peroxides differs from that of hydrogen peroxide (an oxidizer) in that an organic radical replaces the hydrogen atoms. Organic chemicals are all carbon based. As a result, organic peroxides pose varying degrees of fire or explosion hazards, in addition to their oxidizing properties. The classification of organic peroxides is based on the provisions of NFPA 432 (formerly NFPA 43B). Proper material classification of organic peroxides is essential to determining the appropriate occupancy classification of the structure. Examples of organic peroxides include acetyl cyclohexane, sulfonyl peroxide and benzoyl peroxide. The actual class of these materials is dependent on the percentage of concentration by weight. Most organic peroxides are available as liquids, pastes or solids in a powder form. For further discussion of this material definition, see the commentary to it in Chapter 2 of the International Fire Code and Commentary.

ORTHOGONAL. To be in two horizontal directions, at 90 degrees (1.57 rad) to each other.

- This definition applies to the alternative seismic design category determination permitted under Section 1613.3.5.1. It makes it clear that the directions (axes) that are referred to are in the horizontal plane.

OTHER STRUCTURES. Structures, other than buildings, for which loads are specified in Chapter 16.

- This definition is needed for application of the minimum load requirements to structures other than buildings that are included in Chapter 16. Note that buildings are defined as "Structures used to support or shelter an occupancy."

OUTPATIENT CLINIC. See "Clinic, outpatient."

- Outpatient clinic is defined under "Clinic, outpatient" and is addressed in the commentary for that term. Also see the definition of "Ambulatory health facility."

[A] OWNER. Any person, agent, firm or corporation having a legal or equitable interest in the property.

- This term defines the person or other legal entity who is responsible for a building and its compliance with code requirements.

[F] OXIDIZER. A material that readily yields oxygen or other oxidizing gas, or that readily reacts to promote or initi-
ate combustion of combustible materials and, if heated or contaminated, can result in vigorous self-sustained decomposition.

Class 4. An oxidizer that can undergo an explosive reaction due to contamination or exposure to thermal or physical shock and that causes a severe increase in the burning rate of combustible materials with which it comes into contact. Additionally, the oxidizer causes a severe increase in the burning rate and can cause spontaneous ignition of combustibles.

Class 3. An oxidizer that causes a severe increase in the burning rate of combustible materials with which it comes in contact.

Class 2. An oxidizer that will cause a moderate increase in the burning rate of combustible materials with which it comes in contact.

Class 1. An oxidizer that does not moderately increase the burning rate of combustible materials.

The classification of oxidizers is based on the provisions of NFPA 430. Oxidizers, whether a solid, liquid or gas, yield oxygen or another oxidizing gas during a chemical reaction or readily react to oxidize combustibles. The rate of reaction varies with the class of oxidizer. Specific classification of oxidizers is important because of the varying degree of hazard. Examples of oxidizers include liquid hydrogen peroxide, nitric acid, sulfuric acid and solids such as sodium chlorite, chromic acid and calcium hypochlorite. Many commercially available swimming pool chemicals are indicative of Class 2 or 3 oxidizers. For further discussion of this material definition, see the commentary to it in Chapter 2 of the *International Fire Code and Commentary*.

[F] OXIDIZING GAS. A gas that can support and accelerate combustion of other materials more than air does.

Oxidizers sometimes yield oxidizing gases during a chemical reaction. These gases are capable of supporting and accelerating the combustion of other materials. Examples of oxidizing gases include bromine, chlorine and fluorine.

PANEL (PART OF A STRUCTURE). The section of a floor, wall or roof comprised between the supporting frame of two adjacent rows of columns and girders or column bands of floor or roof construction.

This definition is needed to apply the structural load requirements in Chapter 16.

PANIC HARDWARE. A door-latching assembly incorporating a device that releases the latch upon the application of a force in the direction of egress travel. See also "Fire exit hardware."

Panic hardware is commonly used in educational and assembly-type spaces where the number of occupants who would use a doorway during a short time frame in an emergency is high in relation to an occupancy with a less dense occupant load, such as an office building. The hardware is required so that the door can be easily opened during an emergency when pressure on a door from a crush of people could tender normal hardware inoperable. Not all types of panic hardware are permitted on fire-rated doors (see the definition for "Fire exit hardware" and Section 1008.1.10).

PARTICLEBOARD. A generic term for a panel primarily composed of cellulosic materials (usually wood), generally in the form of discrete pieces or particles, as distinguished from fibers. The cellulosic material is combined with synthetic resin or other suitable bonding system by a process in which the interparticle bond is created by the bonding system under heat and pressure.

Particleboard is one of the family of wood-based products that can be used as wood panels. The definition describes the characteristics unique to particleboard as compared to other types of wood-based composite panels. Note that particleboard is not considered wood structural panel. Particleboard intended for use as wood structural panels is subject to the requirements of Section 2303.1.7, which references ANSI A208.1. Particleboard intended for use in shear panels is regulated by the requirements of Section 2306.3, which references the SDPWS.

PENETRATION FIRESTOP. A through-penetration firestop or a membrane-penetration firestop.

See the definitions of "Membrane-penetration firestop" and "Through-penetration firestop system."

PENTHOUSE. An enclosed, unoccupied rooftop structure used for sheltering mechanical and electrical equipment, tanks, elevators and related machinery, and vertical shaft openings.

Any enclosed structure that is located above the surrounding roof surfaces can be considered a penthouse as long as it meets the criteria within Section 1509.2. By complying with these requirements, the penthouse is considered to not contribute to the height of the building either in number of stories or feet above grade plane. If the penthouse does not meet these requirements, it must be considered as an additional story of the building.

PERFORMANCE CATEGORY. A designation of wood structural panels as related to the panel performance used in Chapter 23.

The term "performance category" reflects the latest versions of the DOC PS 1 and PS 2 standards which use terminologies of bond classification to reference glue type and performance categories to refer the thicknesses tolerance consistent with the nominal panel thicknesses in the code. The performance category value is the "nominal panel thickness" or "panel thickness" (see Section 2303.1.4).

[A] PERMIT. An official document or certificate issued by the authority having jurisdiction which authorizes performance of a specified activity.

The permit constitutes a license issued by the building official to proceed with a specific activity, such as
DEFINITIONS

construction of a building, in accordance with all applicable laws.

[A] PERSON. An individual, heirs, executors, administrators or assigns, and also includes a firm, partnership or corporation, its or their successors or assigns, or the agent of any of the aforesaid.

- Corporations and other organizations listed in the definition are treated as persons under the law. Also, when the code provides for a penalty (see Section 114.4), the definition makes it clear that the individuals responsible for administering the activities of these various organizations are subject to these penalties.

PERSONAL CARE SERVICE. The care of persons who do not require medical care. Personal care involves responsibility for the safety of the persons while inside the building.

- Persons who need personal care may need supervision, but they are capable of self-preservation (see the commentary for Section 305, Group E day care).
  Care facilities encompass a full spectrum of acuity and support services and span a wide range of occupancy types including Groups E, I and R. There are three types of care defined in the codes: personal, custodial and medical. On the lower end of the care spectrum (i.e., personal care) is when occupants are supervised but do not need custodial or medical care. When occupants may be elderly or impaired (i.e., custodial care) they may need occasional daily living assistance such as cooking and cleaning. While occupants may take longer to evacuate than average, they are capable of self-preservation. On the opposite end of the care spectrum, occupants may be completely bedridden and dependent on medical gases and emergency power to maintain life (i.e., medical care). The level of care provided describes the condition and capabilities of an occupant which then indicates appropriate standards for protection systems and building. See also the definitions for “24-hour care,” “Custodial care,” “Detoxification facility,” “Foster care facility,” “Group home,” “Hospitals and psychiatric hospitals,” “Medical care,” “Nursing home,” and “Incapiel of self-preservation.”

PHOTOLUMINESCENT. Having the property of emitting light that continues for a length of time after excitation by visible or invisible light has been removed.

- Examples of photoluminescent material are paint and tape that are charged by exposure to light. When the lights are turned off, the product will “glow” in the dark. Products utilized to meet the requirements for luminous egress path markings in high-rise buildings (see Sections 403.5.5 and 1024) or exit signs (see Section 1011.5) may be photoluminescent or self-luminous. A variety of materials can comply with the referenced standards for egress path markings, including ASTM E 2072 and UL 1994; and for signs, UL 924.

PHOTOVOLTAIC MODULES/SHINGLES. A roof covering composed of flat-plate photovoltaic modules fabricated in sheets that resemble three-tab composite shingles.

- This definition provides clarification of roof-covering requirements that appear in Section 1507.17.

[F] PHYSICAL HAZARD. A chemical for which there is evidence that it is a combustible liquid, cryogenic fluid, explosive, flammable (solid, liquid or gas), organic peroxide (solid or liquid), oxidizer (solid or liquid), oxidizing gas, pyrophoric (solid, liquid or gas), unstable (reactive) material (solid, liquid or gas) or water-reactive material (solid or liquid).

- Those materials that present a detonation hazard, deflagration hazard or readily support combustion are considered physical hazards. Examples of the types of materials that present a physical hazard are included in the definition. Buildings and structures containing materials that present a physical hazard in excess of the MAQ would be classified in Group H-1, H-2 or H-3. Materials that present a physical hazard may also present a health hazard (see the definition of “Health hazard”).

[F] PHYSIOLOGICAL WARNING THRESHOLD LEVEL. A concentration of air-borne contaminants, normally expressed in parts per million (ppm) or milligrams per cubic meter (mg/m³), that represents the concentration at which persons can sense the presence of the contaminant due to odor, irritation or other quick-acting physiological response. When used in conjunction with the permissible exposure limit (PEL) the physiological warning threshold levels are those consistent with the classification system used to establish the PEL. See the definition of “Permissible exposure limit (PEL)” in the International Fire Code.

- The term “physiological warning properties” is not defined. From a practical standpoint, the physiological warning properties are represented by a concentration of a contaminant that allows the average individual to sense its presence by a body warning signal including, but not limited to, odor, irritating effects such as stinging sensations, coughing, scratchy feeling in the throat, running of the eyes or nose and similar signals.

There may be a wide variability reported for some of the more common threshold levels including that of olfactory perception. Variations that may be encountered are due to a number of factors including the methods used in their determination, the population exposed and others. The requirements for gas detection established in the code are tied to the PEL, and there are several methods for determining the PEL inherent in the definition of that term. Including this definition intends to link the determination of the physiological warning threshold level to the data used to determine the PEL.

For example, the PEL as established by DOL 29 CFR, Part 1910.1000 is primarily based on data
developed by the American Conference of Governmental Industrial Hygienists (ACGIH) called threshold limit values (TLVs), as referenced in the definition of PEL found in Chapter 2 of the IFC. To substantiate the TLVs (PELS), the ACGIH publishes the Documentation of the Threshold Limit Values (TLVs®) and Biological Exposure Indices (BEIs®) where the user is provided with data used in their establishment. The significant commercially available toxic and highly toxic gases with published TLVs are listed by ACGIH, and perception thresholds are provided.

These warning properties are considered, as evidenced by the documentation, when the TLV and, hence, the PEL is established. It is appropriate that the data used in the base documents be used as the basis for determining the threshold level when such data is available. The use of data from other sources may be used in the absence of data within the system used for the establishment of the PEL, but where such data has been considered in determining the PEL such data should take precedent.

By providing a definition for “Physiological warning threshold level” and guidance as to how it is to be applied, the code user is given guidance that carries out the intent of the provisions for gas detection that have been established in the code. See the commentary to Section 6004.2.2.10 of the IFC for further discussion of gas detection.

PLACE OF RELIGIOUS WORSHIP. See "Religious worship, place of."

("Place of religious worship is defined under "Religious worship, place of" and is addressed in the commentary for that term.

PLASTIC, APPROVED. Any thermoplastic, thermosetting or reinforced thermosetting plastic material that conforms to combustibility classifications specified in the section applicable to the application and plastic type.

("This term applies to plastic that has properties that conform to the code requirements for its intended use.

PLASTIC GLAZING. Plastic materials that are glazed or set in frame or sash and not held by mechanical fasteners that pass through the glazing material.

("In lieu of glass, plastic is permitted to be used as a glazing material. Plastic glazing is required to meet the same load requirements as glass.

PLATFORM. A raised area within a building used for worship, the presentation of music, plays or other entertainment; the head table for special guests; the raised area for lecturers and speakers; boxing and wrestling rings; theater-in-the-round stages; and similar purposes wherein there are no overhead hanging curtains, drops, scenery or stage effects other than lighting and sound. A temporary platform is one installed for not more than 30 days.

("Platforms are raised areas that are used for public performances and presentations that, except for lighting, do not incorporate any overhead hanging curtains, drops, scenery or stage effects. Additionally, while it is not specified, the fuel load on platforms (e.g., a podium for a lecturer or a boxing ring) is anticipated to be low.

Thus, since the fuel load on platforms is ordinarily low and there is no fuel load overhead in areas that would be difficult to access, the code requirements for platforms are less stringent than for stages.

Since many platforms are installed and used on a temporary basis, this definition specifically defines temporary use as 30 days or less. Temporary use is less likely to accumulate additional fuel loads, storage or waste materials on, beneath or above the platform. Platforms are distinct from equipment platforms (see Section 505.3). A platform addressed by this definition is typically not considered a mezzanine (see Section 505.2).

POLYPROPYLENE SIDING. A shaped material, made principally from polypropylene homopolymer, or copolymer, which in some cases contains fillers or reinforcements, that is used to clad exterior walls of buildings.

("Polypropylene siding is an exterior finish product that is available in many textures, colors and profiles. These products come with specific installation requirements from the various manufacturers that are very important to comply with. Specification and installation requirements for polypropylene siding are discussed in Sections 1404.12 and 1405.18. Proper installation will result in expected product performance at varying temperatures by allowing for the expansion and contraction of the siding materials and its components.

PORCELAIN TILE. Porcelain tile shall conform to the requirements of ANSI 137.1.3 for ceramic tile having an absorption of 0.5 percent or less according to ANSI 137.4.1–Class Table and ANSI 137.1.6.1 Allowable Properties by Tile Type–Table 10.

("Porcelain tile is one of a myriad of types of ceramic tile. Its unique characteristics and extremely low absorption rate requires it be dealt with differently from other materials, especially when applied as an exterior adhered veneer. These materials fall outside the scope of TMS 402/ACI 530/ASCE 6. General installation limitations are found in Section 1405.10.2.

POSITIVE ROOF DRAINAGE. The drainage condition in which consideration has been made for all loading deflections of the roof deck, and additional slope has been provided to ensure drainage of the roof within 48 hours of precipitation.

("The primary purpose of positive roof drainage is to allow for prompt roof drainage, thereby preventing the roof from being damaged or adversely impacting the structural support due to the additional load.

PREFABRICATED WOOD I-JOIST. Structural member manufactured using sawn or structural composite lumber flanges and wood structural panel webs bonded together with
exterior exposure adhesives, which forms an "I" cross-sectional shape.

Wood I-Joists are structural members typically used in floor and roof construction manufactured out of sawn or structural composite lumber flanges and structural panel webs, bonded together with exterior adhesives forming an "I" cross section. This definition explains which engineered wood products are considered prefabricated wood I-Joists in order to clarify the requirements in Section 2303.1.2.

Prestressed Masonry. Masonry in which internal stresses have been introduced to counteract potential tensile stresses in masonry resulting from applied loads.

The definition provides an understanding of the term "prestressed masonry," which is used to define particular types of shear wall systems recognized under the Masonry Standards Joint Committee (MSJC) Code (aka TMS 402/ACI 530/ASCE 5 — Building Code Requirements for Masonry Structures). It should be noted that although the MSJC Code recognizes three types of prestressed shear wall systems, ASCE 7 only has one type in Tables 12.2-1 and 12.14-1. ASCE 7 conservatively combines all prestressed masonry shear walls into one category called "prestressed masonry shear walls" for seismic coefficients and structural system limitations on seismic design categories and height. The design coefficients and limitations in Tables 12.2-1 and 12.14-1 are representative of the ordinary plain ( unreinforced) prestressed masonry shear wall system. The seismic design criteria specific to intermediate and special reinforced prestressed shear walls that were in 2003 IBC Table 1617.6.2 have not yet been added to ASCE 7. To utilize the seismic design criteria from the 2003 IBC, the structure would have to be designed under Section 104.11, Alternative materials, design and methods of construction and equipment, and accepted under Section 1.3, Approval of special systems of design and construction.

Primary Function. A primary function is a major activity for which the facility is intended. Areas that contain a primary function include, but are not limited to, the customer service lobby of a bank, the dining area of a cafeteria, the meeting rooms in a conference center, as well as offices and other work areas in which the activities of the public accommodation or other private entity using the facility are carried out. Mechanical rooms, boiler rooms, supply storage rooms, employee lounges or locker rooms, janitorial closets, entrances, corridors and restrooms are not areas containing a primary function.

Primary function areas contain the major activities for the building or space. Determination of what constitutes a primary function space can be somewhat subjective. There can be multiple areas containing a primary function in a single building. Primary function areas are not limited to public use areas. For example, both a bank lobby and the bank's employee areas, such as the teller areas and walk-in safe, are primary function areas. Areas that are not primary function spaces are support and circulation spaces. Determination of the primary function areas for a building will also determine when the route to that area and associated toilet rooms and drinking fountains must be evaluated for accessibility. If these items are not accessible, additional alterations may be necessary (see also commentary, Section 3411.7).

Primary Structural Frame. The primary structural frame shall include all of the following structural members:

1. The columns;
2. Structural members having direct connections to the columns, including girders, beams, trusses and spandrels;
3. Members of the floor construction and roof construction having direct connections to the columns; and
4. Bracing members that are essential to the vertical stability of the primary structural frame under gravity loading shall be considered part of the primary structural frame whether or not the bracing member carries gravity loads.

The primary structural frame and secondary members must meet different standards of design and protection as specified in Chapters 6 and 7. The definitions of these two terms spell out which elements of a structure's framing system are part of the primary structural framing system essential to carrying the gravity loads of the building. Such elements are generally required to have greater fire-resistance protection (see commentary, Table 601 and Section 704).

Prism. An assemblage of masonry units and mortar with or without grout used as a test specimen for determining properties of the masonry.

Compliance with the specified compressive strength of masonry, <i>f'cm</i>, can be verified by prism tests. The prism configuration and construction methods for such tests are prescribed in ASTM C 1314.

Proscenium Wall. The wall that separates the stage from the auditorium or assembly seating area.

A proscenium wall separates the stage area from the audience. The performance on the stage is viewed through a large opening known as the main proscenium opening. Where the stage height is greater than 50 feet (15 240 mm), a proscenium wall of approved construction is required by Section 410.3.4.

Psychiatric Hospitals. See "Hospitals."

Psychiatric hospitals are included in the definition of "Hospitals and psychiatric hospital." See the commentary for that definition.
PUBLIC ENTRANCE. An entrance that is not a service entrance or a restricted entrance.

- A public entrance is one that provides access for the general public or employees, other than the service entrance or a restricted entrance (see the commentary for the definition of "Service entrance" and "Restricted entrance" and to Section 1105.1).

PUBLIC-USE AREAS. Interior or exterior rooms or spaces that are made available to the general public.

- This term is utilized to describe all interior and exterior spaces or rooms that may be occupied by the general public for any amount of time. Spaces that are utilized by the general public may be located in facilities that are publicly or privately owned. Examples include the lobby in an office building, a high-school gymnasium with assembly seating, an open-air stadium, a multipurpose room, an exposition hall, a restaurant dining room, a health club, etc. (see also the commentary for the definitions of "Common use" and "Employee work area").

[A] PUBLIC WAY. A street, alley or other parcel of land open to the outside air leading to a street, that has been deeded, dedicated or otherwise permanently appropriated to the public for public use and which has a clear width and height of not less than 10 feet (3048 mm).

- Public ways serve a variety of purposes in the code, including the determination of the allowable area of a building (see Section 506.2); the use as an open space for unlimited area buildings (see Section 507); the measurement of fire separation distance (see Section 202); as well as many provisions for the means of egress (Chapter 10).

[F] PYROPHORIC. A chemical with an auto-ignition temperature in air, at or below a temperature of 130°F (54.4°C).

- The definition is derived from DOL 29 CFR, Part 1910.1200. Pyrophoric materials, whether in a gas, liquid, or solid form, are capable of spontaneous ignition at low temperatures. Examples of pyrophoric materials include silane and phosphine gas; liquid diethylaluminum chloride; and inert solids, such as cesium, plutonium, potassium and rubidium. For further discussion of this material definition, see the commentary to it in Chapter 2 of the International Fire Code and Commentary.

[F] PYROTECHNIC COMPOSITION. A chemical mixture that produces visible light displays or sounds through a self-propagating, heat-releasing chemical reaction which is initiated by ignition.

- Pyrotechnic composition consists of those chemical components, including oxidizers, that cause fireworks to make noise or display light when ignited. The definition is derived from NFPA 1124. The amount of pyrotechnic composition is the determining factor in whether the storage area for consumer fireworks is classified as Group H-3. The pyrotechnic content of consumer fireworks is contained within a significant amount of packaging and nonexplosive materials used in their manufacture, which constitute the bulk of the weight of the fireworks devices.

RAMP. A walking surface that has a running slope steeper than one unit vertical in 20 units horizontal (5-percent slope).

- This definition is needed to determine the threshold at which the ramp requirements apply to a walking surface. Walking surfaces steeper than specified in the definition are subject to the ramp requirements in Sections 1010 and 1028.

RAMP-ACCESS OPEN PARKING GARAGES. Open parking garages employing a series of continuously rising floors or a series of interconnecting ramps between floors permitting the movement of vehicles under their own power from and to the street level.

- These types of garages employ vehicular ramps or sloped tiers that connect all of the levels of the structure. Whether the vehicles are self-parked or employee parked is immaterial.

[F] RECORD DRAWINGS. Drawings ("as built") that document the location of all devices, appliances, wiring sequences, wiring methods and connections of the components of a fire alarm system as installed.

- To verify that the system has been installed to comply with the code and applicable referenced standards, complete as-built drawings of the fire alarm system must be available on site for review.

REFLECTIVE PLASTIC CORE FOIL INSULATION. An insulation material packaged in rolls, that is less than 0.5 inches thick, with at least one exterior low emittance surface (0.1 or less) and a core material containing voids or cells.

- This is a product distinct from "foam plastic insulation." Its unique properties dictate the need for a different testing procedure as specified in Section 2613.

[A] REGISTERED DESIGN PROFESSIONAL. An individual who is registered or licensed to practice their respective design profession as defined by the statutory requirements of the professional registration laws of the state or jurisdiction in which the project is to be constructed.

- Legal qualifications for engineers and architects are established by the state having jurisdiction. Licensing and registration of engineers and architects are accomplished by written or oral examinations offered by states or by reciprocity (licensing in other states).

[A] REGISTERED DESIGN PROFESSIONAL IN RESPONSIBLE CHARGE. A registered design professional engaged by the owner to review and coordinate certain aspects of the project, as determined by the building official, for compatibility with the design of the building or structure, including submittal documents prepared by others, deferred submittal documents and phased submittal documents.

- This definition refers to the registered design professional named by the owner where required by Section 107.3.4, which states that the owner must designate a registered design profession when required by the laws applicable to the jurisdiction in which its building is constructed. The role of the regis-
DEFINITIONS

terred design professional in responsible charge includes the review and coordination of the following items for compatibility with a project’s design requirements:

1. Submittal documents prepared by others;
2. Deferred submittal documents;
3. Phases submittal documents; and
4. Special inspection reports.

RELIGIOUS WORSHIP, PLACE OF. A building or portion thereof intended for the performance of religious services.

- This term has been added to the code for the purpose of making the code more broadly applicable to the worship facilities of all religions. Major religions for the world include Christianity, Islam, Hinduism, Buddhism and Judaism, which use different terms to describe the main space used for religious services. The intent in the code is for the same application for all similar types of religious facilities. The term also makes it clear that it defines the room or sanctuary for the performance of religious worship services and not retreat complexes, rectories, convents and classroom or office areas.

[A] REPAIR. The reconstruction or renewal of any part of an existing building for the purpose of its maintenance.

- As indicated in Section 105.2.2, the repair of an item typically does not require a permit. This definition makes it clear that repair is limited to work on the item, and does not include complete or substantial replacement or other new work.

REEROOFING. The process of recovering or replacing an existing roof covering. See "Roof recover" and "Roof replacement."

- This term refers to the process of covering an existing roof system with a new roofing system (see Section 1510).

RESIDENTIAL AIRCRAFT HANGAR. An accessory building less than 2,000 square feet (186 m²) and 20 feet (6096 mm) in building height constructed on a one- or two-family property where aircraft are stored. Such use will be considered as a residential accessory use incidental to the dwelling.

- A residential aircraft hangar is considered an accessory or auxiliary structure to a residential house similar to any other shed or detached garage. One- or two-family dwellings are required to be constructed in accordance with the IRC (see Section 101.2). Although that code is also applicable to accessory structures associated with one- or two-family dwellings, it is clear that Section 412.5 of the code was intended to control aircraft hangars since the IRC is silent on the subject.

A residential aircraft hangar is limited to 2,000 square feet (186 m²) in area and 20 feet (6096 mm) in height. The hangar must be integral to a residential home on the same property. As such, the hangar would be considered the same as the private garage used to store the home’s motor vehicles.

RESISTANCE FACTOR. A factor that accounts for deviations of the actual strength from the nominal strength and the manner and consequences of failure (also called “strength reduction factor”).

- This definition is needed to apply the material strength adjustments by way of the resistance factor that is specified in the structural material chapters and the referenced structural standards.

RESTRICTED ENTRANCE. An entrance that is made available for common use on a controlled basis, but not public use, and that is not a service entrance.

- The key to this provision is that the entrance has a controlled access or some type of limiting basis. This may be an entrance for jurors only at a courthouse, visitors only at a jail or employees only at a factory. A sports facility where there is control at the entrance for ticket holders only, or a building with locked entrances, is not typically considered a restricted entrance (see the commentary for the definitions of “Public entrance” and “Service entrance,” and to Section 1105.1.3).

RETRACTABLE AWNING. A retractable awning is a cover with a frame that retracts against a building or other structure to which it is entirely supported.

- The key to this definition is that it provides for an element of building construction that is popular in residential construction. Retractable awnings are a subcategory of awnings, and therefore are included in the regulations in Section 3105.

RISK CATEGORY. A categorization of buildings and other structures for determination of flood, wind, snow, ice and earthquake loads based on the risk associated with unacceptable performance.

- Risk category is a classification given to all buildings in Section 1604.5 based on the nature of the occupancy. This classification serves as a threshold for the earthquake, flood, snow and wind load requirements (also see the definition of “Essential facilities” and the commentary to Section 1604.5).

RISK-TARGETED MAXIMUM CONSIDERED EARTHQUAKE (MCEg) GROUND MOTION RESPONSE ACCELERATIONS. The most severe earthquake effects considered by this code, determined for the orientation that results in the largest maximum response to horizontal ground motions and with adjustment for targeted risk.

- This term refers to the mapped earthquake ground motions that are provided in Figures 1613.3.1(1) through 1613.3.1(6) for a Site Class B (rock) soil profile. It reflects the maximum level of earthquake ground shaking that is considered reasonable for the design of new structures.
ROOF ASSEMBLY (For application to Chapter 15 only). A system designed to provide weather protection and resistance to design loads. The system consists of a roof covering and roof deck or a single component serving as both the roof covering and the roof deck. A roof assembly includes the roof deck, vapor retarder, substrate or thermal barrier, insulation, vapor retarder and roof covering.

- With respect to its application as it relates to Chapter 15, a roof assembly is an assembly of interacting roof components (including the roof deck) designed to weatherproof and, normally, to insulate a building's top surface.

ROOF COVERING. The covering applied to the roof deck for weather resistance, fire classification or appearance.

- This definition identifies the specific membrane of the entire roof system that provides weather protection and any required resistance to exterior fire exposure. The code has specific performance and prescriptive requirements for this covering to provide a durable, weather-resistant surface for the entire structure. A roof covering is considered the membrane that provides the weather-resistance and fire-performance characteristics required by the code.

ROOF COVERING SYSTEM. See “Roof assembly.”

- See the definition of “Roof assembly.”

ROOF DECK. The flat or sloped surface constructed on top of the exterior walls of a building or other supports for the purpose of enclosing the story below, or sheltering an area, to protect it from the elements, not including its supporting members or vertical supports.

- A roof deck is the structural surface to which the roofing and waterproofing system (including insulation) is applied.

ROOF DRAINAGE, POSITIVE. See “Positive roof drainage.”

- The code specifically uses the phrase “positive roof drainage” and is addressed in the commentary for that term.

ROOF RECOVER. The process of installing an additional roof covering over a prepared existing roof covering without removing the existing roof covering.

- This term refers to the process of covering an existing roof system with a new roofing system.

ROOF REPAIR. Reconstruction or renewal of any part of an existing roof for the purposes of its maintenance.

- Roofs should be maintained for the purpose of protection. If a section is damaged, then it should be repaired immediately.

ROOF REPLACEMENT. The process of removing the existing roof covering, repairing any damaged substrate and installing a new roof covering.

- This definition refers to the process of covering an existing roof system with a new roofing system.

ROOF VENTILATION. The natural or mechanical process of supplying conditioned or unconditioned air to, or removing such air from, attics, cathedral ceilings or other enclosed spaces over which a roof assembly is installed.

- Ventilation of the attic prevents moisture condensation on cold surfaces, and, therefore, will prevent dry rot on the bottom surface of shingles or wood roof decks.

ROOFTOP STRUCTURE. A structure erected on top of the roof deck or on top of any part of a building.

- This definition includes all appurtenances constructed and located above the surrounding roof surfaces. These items (water tanks or cooling towers) or architectural features (spires or cupolas) are regulated by specific code provisions.

RUBBLE MASONRY. Masonry composed of roughly shaped stones.

- Rubble consists of pieces of stone that are irregular in shape and size. Rubble is often laid to form walls, foundations and paving.

- Coursed rubble. Masonry composed of roughly shaped stones fitting approximately on level beds and well bonded.

- Coursed rubble consists of roughly shaped stones that are laid with continuous bed joints.

- Random rubble. Masonry composed of roughly shaped stones laid without regularity of coursing but well bonded and fitted together to form well-divided joints.

- Random rubble has approximately level beds, but discontinuous bed joints because of the varying heights of the individual units.

- Rough or ordinary rubble. Masonry composed of unsquared field stones laid without regularity of coursing but well bonded.

- This type of rubble is laid without regular coursing.

RUNNING BOND. The placement of masonry units such that head joints in successive courses are horizontally offset at least one-quarter the unit length.

- Figure 202.18(1) illustrates the required overlap for running bonds. The minimum overlap is necessary to provide strength between units when masonry spans horizontally. Bed-joint reinforcement or reinforced bond beams are required in Section 1.11 of TMS 402/ACI 530/ASCE 5 for masonry in other than running bond. Masonry not laid in running bond is often referred to as “stack bond” construction.

SALLYPORT. A security vestibule with two or more doors or gates where the intended purpose is to prevent continuous and unobstructed passage by allowing the release of only one door or gate at a time.

- While sallyports are not unique to Group 1-3 occupancies, they are essential to the control and safe movement of inmates in a Group 1-3 facility. Section
408.3.7 allows sallyports to be in the means of egress system. See the commentary for that section for an additional description of sallyport design and use.

**SCISSOR STAIR.** Two interlocking stairways providing two separate paths of egress located within one stairwell enclosure.

- A scissor or interlocking stairway is sometimes used in high-rise buildings or to increase exit capacity of a stairwell enclosure. In this configuration, two independent stairway paths are located within the same exit enclosure and may or may not be visually open to one another. When interlocking stairways are separated from each other with compliant fire barriers and horizontal assemblies, they are not considered scissor stairways (see Section 1015.2.1).

**SCUPPER.** An opening in a wall or parapet that allows water to drain from a roof.

- These devices are for the purpose of allowing overflowing water to drain off the roof. These devices are commonly larger than the roof drain.

**SECONDARY MEMBERS.** The following structural members shall be considered secondary members and not part of the primary structural frame:

1. Structural members not having direct connections to the columns;
2. Members of the floor construction and roof construction not having direct connections to the columns; and
3. Bracing members other than those that are part of the primary structural frame.

- This term works in conjunction with the term "primary structural frame" to distinguish which elements of a building’s structure needs to receive various levels of fire-resistance protection. These requirements are found in Table 601 and Sections 704.

**SEISMIC DESIGN CATEGORY.** A classification assigned to a structure based on its risk category and the severity of the design earthquake ground motion at the site.

- The seismic design category serves as a trigger mechanism for many seismic requirements, including the following:
  1. Permissible seismic-force-resisting systems.
  2. Limitations on height.
  3. Consideration of structural irregularities.
  4. The types of lateral-force analysis that may be used.
  5. The need for additional special inspections.

The first step in the design of a structure for earthquake forces is the determination of its seismic design category. Each building is assigned the more restrictive seismic design category classification depending upon the site soil profile, the mapped spectral response accelerations at the site and the nature of the uses that occupy the building, using both Tables 1613.3.5(1) and 1613.3.5(2). The follow-
DEFINITIONS

ing outlines the procedure used to determine a structure’s seismic design category.

Step 1: Determine the mapped maximum considered earthquake spectral response acceleration at short periods, $S_x$, and at 1-second period, $S_y$, for the site location from Figures 1613.3.1(1) through 1613.3.1(14).

Step 2: Determine the soil site class in accordance with Table 1613.3.2.

Step 3: Determine the site coefficients, $F_x$ and $F_y$, from Tables 1613.3.3(1) and 1613.3.3(2), respectively.

Step 4: Determine the 5-percent damped design spectral response acceleration at short periods, $S_{DS}$, and at 1-second period, $S_{DP}$, as follows:

$S_{DS} = \left(\frac{1}{\nu}\right)(F_x)(S_x)$

$S_{DP} = \left(\frac{1}{\nu}\right)(F_y)(S_y)$

Step 5: Determine the seismic design category as prescribed by Tables 1613.3.5(1) and 1613.3.5(2).

The highest of the seismic design categories from the two tables is the category assigned to the building, unless Section 1613.3.5.1 is applicable. For example, if the seismic design category from Table 1613.3.5(1) is D and from Table 1613.3.5(2) it is C, then the building would be assigned to Seismic Design Category D.

SEISMIC FORCE-RESISTING SYSTEM. That part of the structural system that has been considered in the design to provide the required resistance to the prescribed seismic forces.

- This definition is needed for the correct application of the special inspections of the seismic force-resisting systems for seismic resistance. Unless classified as Seismic Design Category A, the type of seismic-force-resisting system must be selected to conform to Section 12.2 of ASCE 7. Providing a level of detailing that is appropriate for the selected system is critical to complying with the code’s earthquake provisions.

SELF-CLOSING. As applied to a fire door or other opening protective, means equipped with an device that will ensure closing after having been opened.

- A self-closing opening protective refers to a fire or smoke door assembly equipped with a listed closer for doors that must be maintained in the normally closed position. When the door is opened and released, the self-closing feature returns the door to the closed position. It is important to distinguish between the terms “self-closing” and “automatic closing” because they are not interchangeable. “Automatic closing” refers to an opening protective that is normally in the open position (see Section 716.5.9.2). Opening protectives with automatic closers are often held open and then returned to the closed position upon activation of fire detectors or smoke detectors or loss of power, which automatically releases the hold-open device allowing the door to close.

SELF-LUMINOUS. Illuminated by a self-contained power source, other than batteries, and operated independently of external power sources.

- Self-luminous products do not need an outside light source to charge them like photoluminescent materials do. Products utilized to meet the requirements for luminous egress path markings in high-rise buildings (see Sections 403.5.5 and 1024) or exit signs (see Section 1011.5) may be photoluminescent or self-luminous. A variety of materials can comply with the referenced standards for egress path markings—UL 1994, and ASTM E 2072—and for signs—UL 924.

SELF-PRESERVATION, INCAPABLE OF. See “Incapable of self-preservation.”

- The ability of care recipients to get out of a building is key in determining the occupancy category of a building. See the commentary for the definition of “Incapable of self-preservation.”

SELF-SERVICE STORAGE FACILITY. Real property designed and used for the purpose of renting or leasing individual storage spaces to customers for the purpose of storing and removing personal property on a self-service basis.

- A portion or space within these facilities can be rented by persons to store personal property. Movement of items into and out of the space is handled by the individual.

[F] SERVICE CORRIDOR. A fully enclosed passage used for transporting HPM and purposes other than required means of egress.

- Though HPM facility occupants may be exposed to limited HPM quantities during the course of their employment, their means of egress are protected from the HPM hazards by confining the HPM being transferred to its own passageway. A service corridor is only required when the HPM must be carried from a storage room or external area to a fabrication area through a passageway.

SERVICE ENTRANCE. An entrance intended primarily for delivery of goods or services.

- This entrance is utilized primarily for accepting or sending deliveries of goods and services. Often this entrance is directly associated with a loading dock, and is not considered a public or restricted entrance (see the commentary for the definitions of “Service entrance” and “Public entrance” and to Section 1105.1.5).

SHAFT. An enclosed space extending through one or more stories of a building, connecting vertical openings in successive floors, or floors and roof.

- Shafts are successive openings in the floors. A shaft is required to be enclosed with fire-resistance-rated assemblies to help prevent the vertical spread of fire and resist the spread of products of combustion from
DEFINITIONS

story to story. Provisions for vertical shafts are found in Sections 711 and 712. These provisions are applicable to vertical openings required to be enclosed as specified in Sections 711 and 712.1.1.

SHAFT ENCLOSURE. The walls or construction forming the boundaries of a shaft.

- Fire-resistance-rated walls forming shaft enclosures must be constructed as fire barrier walls in accordance with Section 707. Usually, vertical ducts penetrating multiple floors or buildings are required to be in shaft enclosures. Unlike a common chase wall, a shaft wall must be fire-resistance rated from the room side and from the shaft side.

SHALLOW FOUNDATION. A shallow foundation is an individual or strip footing, a mat foundation, a slab-on-grade foundation or a similar foundation element.

- Chapter 18 identifies two major classifications for foundations; either shallow or deep. This definition clarifies the type of foundations that are considered to be shallow foundations. All others are, by default, considered to be deep foundations.

SHEAR WALL (For Chapter 23). A wall designed to resist lateral forces parallel to the plane of a wall.

- Shear walls are the supporting elements for the lateral forces that are applied to a floor or roof diaphragm. They function structurally to provide a path for these loads to the foundation. Typically in wood framing these walls are framed with studs and have wood structural panel sheathing attached to the outside using specific nailing patterns to provide the necessary strength and stiffness. They also may have a tie-down attached at either or both ends of the wall to prevent overturning. Guidance for design of wood shear walls can be found in APA Research Report 154.

Shear wall, perforated. A wood structural panel sheathed wall with openings, that has not been specifically designed and detailed for force transfer around openings.

- This term refers to shear walls that are designed by using the provisions of ANSI/AF&PA Special Design Provisions for Wind and Seismic (SDPWS) as an alternative to the traditional segmented shear wall design methodology. Aspect ratio limits apply to shear wall segments within the perforated shear wall as described by the definition of "Perforated shear wall segment." This method of shear wall design utilizes empirically determined reductions of wood structural panel shear wall capacities that are based on the maximum opening height, as well as the percentage of a particular shear wall that qualifies as a perforated shear wall segment. This method recognizes the strength and stiffness of sheathed areas above and below openings without the need to specifically design and detail for force transfer around the openings. It is not expected that sheathed wall areas above and below openings behave as coupling beams acting end to end, but rather that they provide local restraint at their ends. As a consequence, significantly reduced capacities are attributed to interior perforated shear wall segments with limited overturning restraint. Further background on the development of provisions for perforated shear walls and example problems is provided in the National Earthquake Hazards Reduction Program (NEHRP) Recommended Provisions for Seismic Regulations for New Buildings and Other Structures, Part 2 Commentary (FEMA 450-2). Other resources and articles on perforated shear wall design are available from the American Wood Council at www.awc.org.

Shear wall segment, perforated. A section of shear wall with full-height sheathing that meets the height-to-width ratio limits of Section 4.3.4 of AF&PA SDPWS.

- This term refers to a fully sheathed portion of a perforated shear wall that also meets the limit on height-to-width ratio. Only these portions of the perforated shear wall are considered in determining the percentage of full-height sheathing.

SHEAR WALL (For Chapter 21).

- Shear walls are vertical diaphragms that resist the effects of in-plane lateral loads. They are part of the lateral-force-resisting system that resists wind and seismic loads (also see the definition of "Main wind-force-resisting system" and "Seismic force-resisting system"). The various types of shear wall systems are defined in order to correctly characterize their expected performance level in resisting earthquake forces. These system descriptions correspond to the basic seismic force-resisting system categories that are used to comply with the earthquake load provisions. The seismic design coefficients and limitations for the various types of masonry shear wall systems are given in Tables 12.2-1 and 12.14-1 of ASCE 7. Shear walls must be adequately connected to floor and roof diaphragms, and to the foundation so that loads can be effectively transferred between these elements.

Detailed plain masonry shear wall. A masonry shear wall designed to resist lateral forces neglecting stresses in reinforcement, and designed in accordance with Section 2106.1.

- Such shear walls are designed as plain (unreinforced) masonry, but contain a minimum amount of reinforcement in the horizontal and vertical directions. Because of this reinforcement, these walls have more favorable seismic design parameters, including higher response modification factors, R, than ordinary plain masonry shear walls. See ASCE 7 Table 12.2-1 for seismic design coefficients and limitations for detailed plain masonry shear wall systems.

Intermediate prestressed masonry shear wall. A prestressed masonry shear wall designed to resist lateral
forces considering stresses in reinforcement, and designed in accordance with Section 2106.1.

- The definition of "Intermediate prestressed masonry shear wall" distinguishes it from the other types of prestressed masonry shear walls that are recognized in TMS 402/ACI 530/ASCE 5 (MSJC Code) in order to classify the lateral force-resisting system for determining earthquake loads. See also the general discussion of prestressed masonry shear wall systems under the definition of "Prestressed masonry."

**Intermediate reinforced masonry shear wall.** A masonry shear wall designed to resist lateral forces considering stresses in reinforcement, and designed in accordance with Section 2106.1.

- These shear walls are designed as reinforced masonry and also must contain a minimum amount of prescriptive reinforcement. Because they contain reinforcement, their seismic performance will be better than that of plain masonry shear walls in seismic events and they are accordingly permitted in areas of moderate, as well as low seismic risk. These walls have more favorable seismic design parameters, including higher response modification factors, $R$, than plain masonry shear walls. When used in areas of moderate seismic risk (Seismic Design Category C), however, minimum reinforcement is required as noted in Section 1.18.3.2.4 of the MSJC Code (TMS 402/ACI 530/ASCE 5). See ASCE 7 Tables 12.2-1 and 12.14-1 for seismic design coefficients and limitations for ordinary reinforced masonry shear wall systems.

**Ordinary plain masonry shear wall.** A masonry shear wall designed to resist lateral forces neglecting stresses in reinforcement, and designed in accordance with Section 2106.1.

- Such shear walls meet only minimum requirements, without minimum amounts of horizontal and vertical reinforcement. Thus, they may be used only in areas of low seismic risk. Plain masonry walls are designed as unreinforced masonry (by the noted sections), although they may in fact contain reinforcement. See ASCE 7 Tables 12.2-1 and 12.14-1 for seismic design coefficients and limitations for ordinary plain masonry shear wall systems.

**Ordinary plain prestressed masonry shear wall.** A prestressed masonry shear wall designed to resist lateral forces considering stresses in reinforcement, and designed in accordance with Section 2106.1.

- The definition of ordinary plain prestressed masonry shear walls distinguishes it from the other types of prestressed masonry shear walls that are recognized by the Masonry Standards Joint Committee Code (aka TMS 402/ACI 530/ASCE 5 - Building Code Requirements for Masonry Structures) in order to classify the lateral force-resisting system for determining earthquake loads. See ASCE 7 Tables 12.2-1 and 12.14-1 for seismic design coefficients and limitations for prestressed masonry shear wall systems. See also the general discussion of prestressed masonry shear wall systems under the definition of "Prestressed masonry."

**Ordinary reinforced masonry shear wall.** A masonry shear wall designed to resist lateral forces considering stresses in reinforcement, and designed in accordance with Section 2106.1.

- These shear walls are designed as reinforced masonry. Because they contain reinforcement, their seismic performance is expected to be better than that of plain masonry shear walls, and they are, accordingly, permitted in areas of moderate, as well as low seismic risk. These walls have more favorable seismic design parameters, including higher response modification factors, $R$, than plain masonry shear walls. When used in areas of moderate seismic risk (Seismic Design Category C), however, minimum reinforcement is required as noted in Section 1.18.3.2.4 of the MSJC Code (TMS 402/ACI 530/ASCE 5). See ASCE 7 Tables 12.2-1 and 12.14-1 for seismic design coefficients and limitations for ordinary reinforced masonry shear wall systems.

**Special prestressed masonry shear wall.** A prestressed masonry shear wall designed to resist lateral forces considering stresses in reinforcement and designed in accordance with Section 2106.1 except that only grouted, laterally restrained tendons are used.

- This definition distinguishes special prestressed masonry shear walls from the other types of prestressed masonry shear walls that are recognized by the MSJC code (TMS 402/ACI 530/ASCE 5) in order to classify the lateral force-resisting system in determining earthquake loads. See ASCE 7 Tables 12.2-1 and 12.14-1 for seismic design coefficients and limitations for prestressed masonry shear wall systems. See also the general discussion of prestressed masonry shear wall systems under the definition of "Prestressed masonry."

**Special reinforced masonry shear wall.** A masonry shear wall designed to resist lateral forces considering stresses in reinforcement, and designed in accordance with Section 2106.1.

- These shear walls are designed as reinforced masonry and must also meet prescriptive reinforcement limits and material limitations. Because of these requirements, they are permitted to be used in all seismic risk areas. These walls have the most favorable seismic design parameters, including the highest response modification factors, $R$, of any of the masonry shear wall types. See ASCE 7 Tables 12.2-1 and 12.14-1 for seismic design coefficients and limitations for special reinforced masonry shear wall systems.

**SINGLE-Ply Membrane.** A roofing membrane that is field applied using one layer of membrane material (either homogeneous or composite) rather than multiple layers.

- This is a flexible or semiflexible roof covering or waterproofing layer, whose primary function is the exclusion of water.
[F] SINGLE-STATION SMOKE ALARM. An assembly incorporating the detector, the control equipment and the alarm-sounding device in one unit, operated from a power supply either in the unit or obtained at the point of installation.

- A single-station smoke alarm is a self-contained alarm device that detects visible or invisible particles of combustion. Its function is to detect a fire in the immediate area of the detector location. Single-station smoke alarms are individual units with the capability to stand alone. Where the single-station smoke alarms are interconnected with other single-station devices, they would be considered a multiple-station smoke alarm system. Single-station smoke alarms are not capable of notifying or controlling any other fire protection equipment or systems. They may be battery powered, directly connected to the building power supply or a combination of both. Single-station smoke alarms must be built to comply with UL 217, and are to be installed as required by Section 907.2.11.

SITE. A parcel of land bounded by a lot line or a designated portion of a public right-of-way.

- A site, for purposes of accessibility requirements, is the same as that which is considered in the application of other code requirements. The property within the boundaries of the site is under the control of the owner. The owner can be held responsible for code compliance of the site and all facilities on it. Legal property lines do not always constitute site boundaries (e.g., malls, condominiums, townhouses). A site could contain multiple legal "lot" divisions.

SITE CLASS. A classification assigned to a site based on the types of soils present and their engineering properties as defined in Section 1613.3.2.

- This definition is necessary because the earthquake load on a structure is greatly affected by the soil at the site. There are six site classes in the provisions that are referenced in Section 1613.3.2.

SITE COEFFICIENTS. The values of $F_e$ and $F_v$ indicated in Tables 1613.3.3(1) and 1613.3.3(2), respectively.

- The site coefficients $F_e$ and $F_v$ are used to adjust the mapped ground motions to account for the characteristics of the site's soil profile when determining the soil adjusted earthquake spectral response accelerations in Section 1613.3.3. These coefficients are functions of the soil (site class), as well as the seismicity at the site of the structure.

SITE-FABRICATED STRETCH SYSTEM. A system, fabricated on site and intended for acoustical, tackable or aesthetic purposes, that is comprised of three elements:

1. A frame (constructed of plastic, wood, metal or other material) used to hold fabric in place,
2. A core material (infill, with the correct properties for the application), and
3. An outside layer, comprised of a textile, fabric or vinyl, that is stretched taut and held in place by tension or mechanical fasteners via the frame.

- Site-fabricated stretch systems are interior finish materials that are stretched taut across walls or ceilings with a frame that holds a fabric and core. These systems are now being used extensively because they can stretch to cover decorative walls and ceilings with unusual looks and shapes. The systems consist of three parts: a fabric (or vinyl), a frame and an infill core material. This type of product is not exclusive to any particular manufacturer. It is important to point out that these materials are not curtains or drapes because they are not free hanging (see commentary, Section 803.9).

SKYLIGHT, UNIT. A factory-assembled, glazed fenestration unit, containing one panel of glazing material that allows for natural lighting through an opening in the roof assembly while preserving the weather-resistant barrier of the roof.

- This is a specific type of sloped glazing assembly that is factory assembled. The code contains specific provisions that are appropriate for this type of building component. Factory assembled units, as opposed to site-built skylights, can be designed, tested and rated as one component that incorporates both glazing and framing, if applicable. The individual components of site-built glazing must be designed to resist the design loads of the codes individually, and are not usually rated as an assembly.

SKYLIGHTS AND SLOPED GLAZING. Glass or other transparent or translucent glazing material installed at a slope of 15 degrees (0.26 rad) or more from vertical. Glazing material in skylights, including unit skylights, solariums, sunrooms, roofs and sloped walls, are included in this definition.

- The code regulates skylights and sloped glazing since their failure could result in injury and building damage (see Section 2405 for the code requirements).

SLEEPING UNIT. A room or space in which people sleep, which can also include permanent provisions for living, eating, and either sanitation or kitchen facilities but not both. Such rooms and spaces that are also part of a dwelling unit are not sleeping units.

- This definition is included to coordinate the Fair Housing Act Guidelines with the code. The definition for "sleeping unit" clarifies the differences between sleeping units and dwelling units. In addition, using the term "sleeping unit" for spaces where people sleep will replace a multitude of other terms (i.e., patient room, cell, guestroom) so that there is consistent application across occupancies. Some examples of sleeping units are hotel guestrooms, dormitories, bedrooms in boarding houses, patient sleeping rooms in hospitals, nursing homes or assisted living facilities, or housing cells in a jail. Another example would be a studio apartment with a kitchenette (i.e.,
countertop microwave, sink, refrigerator). Since the cooking arrangements are not the traditional permanent appliances (i.e., a cooktop, range or oven), this configuration would be considered a sleeping unit, and not a dwelling unit. As defined in the code, a "Dwelling unit" must contain permanent facilities for living, sleeping, eating, cooking and sanitation.

[F] SMOKE ALARM. A single- or multiple-station alarm responsive to smoke. See also definitions of "Multiple-station smoke alarm" and "Single station smoke alarm."

- This is a general term that applies to both single- and multiple-station smoke alarms that are not part of an automatic fire detection system. It is the generic term for any device that both detects the products of combustion and initiates an alarm signal for occupant notification.

SMOKE BARRIER. A continuous membrane, either vertical or horizontal, such as a wall, floor or ceiling assembly, that is designed and constructed to restrict the movement of smoke.

- A smoke barrier is a fire-resistance-rated assembly that is different from a fire partition, fire barrier or fire wall. Smoke barriers include walls and floor/ceiling assemblies that are constructed with a 1-hour fire-resistance rating and are one of the components in a smoke compartment. In Group I-2 and I-3 occupancies, the smoke barriers are intended to create adjacent smoke compartments to which building occupants can be safely and promptly relocated during a fire, thus preventing the need to have complete and immediate egress from the building. For these occupancies, complete egress from the building would not be practical in most cases, due to restrictions on the mobility of the occupants. To maintain tenability in the adjacent smoke compartment, the smoke barrier is therefore intended to resist the spread of fire and hinder the movement of smoke. Smoke barriers are also used to compartment a building into separate smoke control zones when using the provisions of Section 909. The construction requirements for a smoke barrier provide resistance to the transmission of smoke [see Figure 202.19(1) and Section 709].

SMOKE COMPARTMENT. A space within a building enclosed by smoke barriers on all sides, including the top and bottom.

- Smoke compartments create spaces that protect occupants from the products of combustion produced by a fire in an adjacent smoke compartment and to restrict smoke to the compartment of fire origin.

SMOKE DAMPER. A listed device installed in ducts and air transfer openings designed to resist the passage of smoke. The device is installed to operate automatically, controlled by a smoke detection system, and where required, is capable of being positioned from a fire command center.

- See the definition of "Damper."

[F] SMOKE DETECTOR. A listed device that senses visible or invisible particles of combustion.

- These devices are considered early-warning devices and have saved many people from smoke inhalation and burns. Smoke detectors have a wide range of
uses, from sophisticated fire detection systems for industrial and commercial uses to residential. A smoke detector is a device, typically listed in accordance with UL 268, that activates a fire alarm system. These system smoke detectors contain only the components required to detect the products of combustion and activate a fire alarm system and are, therefore, different from single- and multiple-station smoke alarms.

Smoke detectors typically consist of two types: ionization and photoelectric. An ionization detector contains a small amount of radioactive material that ionizes the air in a sensing chamber and causes a current to flow through the air between two charged electrodes. When smoke enters the chamber, the particles cause a reduction in the current. When the level of conductance decreases to a preset level, the detector responds with an alarm.

A photoelectric smoke detector consists primarily of a light source, a light beam and a photosensitive device. When smoke particles enter the light beam, they reduce the light intensity in the photosensitive device. When obscuration reaches a preset level, the detector initiates an alarm.

SMOKE-DEVELOPED INDEX. A comparative measure, expressed as a dimensionless number, derived from measurements of smoke obscuration versus time for a material tested in accordance with ASTM E 84.

- The ASTM E 84 test method of measuring the density of smoke emitted from combustible materials determines the smoke-developed index. This value is only comparative and provides only a relative understanding of the smoke generation potential of a material. The smoke-developed index is sometimes abbreviated as SDI.

SMOKE-PROTECTED ASSEMBLY SEATING. Seating served by means of egress that is not subject to smoke accumulation within or under a structure.

- An example of smoke-protected assembly seating is an open outdoor grandstand or an indoor arena with a smoke control system. The code has less stringent requirements for certain aspects of smoke-protected assembly seating than for seating that is not smoke protected, since occupants are subject to less hazard from the accumulation of smoke and fumes during a fire event. For example, an assembly dead-end aisle is permitted to be longer for a smoke-protected assembly area. For smoke control system requirements, see Section 909.

SMOKEPROOF ENCLOSURE. An exit stairway designed and constructed so that the movement of the products of combustion produced by a fire occurring in any part of the building into the enclosure is limited.

- A smokeproof enclosure is intended to provide an effective barrier to the entry of smoke into an exit stairway, thereby offering an additional level of protection for occupants of high-rise and underground structures.

[F] SOLID. A material that has a melting point, decomposes or sublimes at a temperature greater than 68°F (20°C).

- The temperature at which a solid melts is the melting point. A material will begin to melt as heat is added to it and, thus, eventually change to a liquid state.

SPECIAL AMUSEMENT BUILDING. A special amusement building is any temporary or permanent building or portion thereof that is occupied for amusement, entertainment or educational purposes and that contains a device or system that conveys passengers or provides a walkway along, around or over a course in any direction so arranged that the means of egress path is not readily apparent due to visual or audio distractions or is intentionally confounded or is not readily available because of the nature of the attraction or mode of conveyance through the building or structure.

- In general, a special amusement building is a building or portion thereof in which people gather (thus, an assembly occupancy) and in which egress is either not readily apparent due to distractions, is intentionally confounded (i.e., maze) or is not readily available. The definition includes all such facilities, including portable and temporary structures. The hazard associated with such buildings is not related to the permanence or length of use; therefore, seasonal uses (such as haunted houses at Halloween) and portable uses (carnival rides) are included if they meet the criteria in the definition.

SPECIAL FLOOD HAZARD AREA. The land area subject to flood hazards and shown on a Flood Insurance Rate Map or other flood hazard map as Zone A, AE, A1-30, A99, AR, AO, AH, V, AO, VE or V1-30.

- This term is used in the definition of "Flood Insurance Study" and in Section 1612.3, in which the flood hazard area is established. The special flood hazard area is the flood hazard area shown on maps prepared by FEMA.

SPECIAL INSPECTION. Inspection of construction requiring the expertise of an approved special inspector in order to ensure compliance with this code and the approved construction documents.

- This category of inspection is intended to apply to those material installations that require a special level of knowledge and attention. For example, special inspections are required for the installation of high-strength bolts, welded connections, concrete reinforcement, prestressed concrete, fabrication of laminated wood structural elements and pile installations to comply with the contract documents and the standards under which they are assembled.

Continuous special inspection. Special inspection by the special inspector who is present when and where the work to be inspected is being performed.

- Continuous special inspection is the constant monitoring of specific tasks by a special inspector. These inspections must be carried out continuously over the duration of the particular tasks. "Full-time" should not
be construed as requiring the special inspector to be present when these tasks are not being performed.

**Periodic special inspection.** Special inspection by the special inspector who is intermittently present where the work to be inspected has been or is being performed.

- Periodic special inspection allows intermittent monitoring of the specified tasks designated in the statement of special inspections as requiring periodic inspection. To avoid misunderstandings, the frequency or timing of these inspections should be established before a permit is issued.

**SPECIAL INSPECTOR.** A qualified person employed or retained by an approved agency and approved by the building official as having the competence necessary to inspect a particular type of construction requiring special inspection.

- This definition facilitates the application of Chapter 17.

**SPECIAL STRUCTURAL WALL.** See Section 1905.1.1.

- This definition is a modification of ACI 318 text and is therefore located in Section 1905.

**SPECIFIED.** Required by construction documents.

- The construction documents contain material and construction requirements essential to the proper performance of the structure. These requirements are considered minimums and material or construction that does not comply is not permitted by the code.

**SPECIFIED COMPRRESSIVE STRENGTH OF MASONRY, f_m.** Minimum compressive strength, expressed as force per unit of net cross-sectional area, required of the masonry used in construction by the construction documents, and upon which the project design is based. Whenever the quantity f_m is under the radical sign, the square root of numerical value only is intended and the result has units of pounds per square inch (psi) (MPa).

- Engineered design of structural masonry is based on the specified compressive strength of the masonry, f_m. This specified strength is required to be shown on the construction documents in accordance with Section 2101.3. Strength of the constructed masonry, determined by the unit strength method or prism strength method, is required to equal or exceed the specified compressive strength of masonry.

**SPICE.** The result of a factory and/or field method of joining or connecting two or more lengths of a fire-resistant joint system into a continuous entity.

- In many instances, the actual length of a joint required to be protected by a fire-resistant joint system exceeds the length of the joint system, especially when a prefabricated system is used. When two or more lengths of a joint system are necessary to protect a joint, the ends of each section must be joined by a splice to maintain the fire-resistant integrity of the assembly. Splices may be either factory or field installed, but in either case, the splice must be tested in accordance with UL 2079.

**SPRAYED FIRE-RESISTANT MATERIALS.** Cementitious or fibrous materials that are sprayed to provide fire-resistant protection of the substrates.

- The cementitious or fibrous material is pneumatically projected onto a surface such that the density, thickness and cohesion/adhesion of the material will provide fire resistance to the surface.

**STACK BOND.** The placement of masonry units in a bond pattern is such that head joints in successive courses are vertically aligned. For the purpose of this code, requirements for stack bond shall apply to masonry laid in other than running bond.

- Figure 202.18(1) illustrates the required overlap for running bonds. If this required overlap is not provided, the wall is considered to be laid in stack bond. Reinforcement, or reinforced bond beams, are required by Section 1.11 of TMS 402/ACI 530/ASCE 5 for stack bond masonry.

**STAGE.** A space within a building utilized for entertainment or presentations, which includes overhead hanging curtains, drops, scenery or stage effects other than lighting and sound.

- The building feature known as a "stage" is defined as the area or space where the performers are located. The presentation area is usually elevated to provide clear sightlines for the audience. The stage area also includes the wing areas and backstage areas where curtains and scenery are placed.

**STAIR.** A change in elevation, consisting of one or more risers.

- All steps, even a single step, are defined as a stair. This makes the stair requirements applicable to all steps unless specifically exempt in the code.

**STAIR, SCISSOR.** See "Scissor stair."

- A type of stairway prohibited by the code in certain circumstances. It is defined at "Scissor stair" and is addressed in the commentary under that term.

**STAIRWAY.** One or more flights of stairs, either exterior or interior, with the necessary landings and platforms connecting them, to form a continuous and uninterrupted passage from one level to another.

- It is important to note that this definition characterizes a stairway as connecting one level to another. The term "level" is not to be confused with "story." Steps that connect two levels, one of which is not considered a "story" of the structure, would be considered a stairway. For example, a set of steps between the basement level in an area way and the outside ground level would be considered a stairway. A series of steps between the floor of a story and a mezzanine within that story would also be considered a stairway (see definitions for "Flight," "Stairway, exterior" and "Stairway, interior" and Sections 1009, 1022 and 1026).
DEFINITIONS

STAIRWAY, EXIT ACCESS. See "Exit access stairway."

- This category of stairway, exit access is defined under "Exit access stairway," and is addressed in the commentary for that term.

STAIRWAY, EXTERIOR. A stairway that is open on at least one side, except for required structural columns, beams, handrails and guards. The adjoining open areas shall be either yards, courts or public ways. The other sides of the exterior stairway need not be open.

- This definition is needed since the code requirements for an exterior stairway are different than those for an interior stairway. Exterior stairways are typically exits when providing egress from upper and lower stories, or exit discharge when outside the exit door at the level of exit discharge. For general stairway requirements, see Section 1009. For specific openness requirements for exterior stairways, see Section 1026.

STAIRWAY, INTERIOR. A stairway not meeting the definition of an exterior stairway.

- This definition is needed since the requirements for an interior stairway can be more stringent than those for an exterior stairway (see the definition for "Stairway, exterior" and Sections 1016 and 1022). Interior stairways can be exit access elements or exit elements (see definitions for "Interior exit stairway" and "Exit access stairway").

STAIRWAY, INTERIOR EXIT. See "Interior exit stairway."

- This category of stairway, interior exit is defined under "Interior exit stairway," and is addressed in the commentary for that term.

STAIRWAY, SPIRAL. A stairway having a closed circular form in its plan view with uniform section-shaped treads attached to and radiating from a minimum-diameter supporting column.

- Spiral stairways are permitted as part of a means of egress in limited circumstances given in Section 1009.12. Spiral staircases could be used for supplemental/convenience stairways in other locations. Spiral stairways are commonly used where a small number of occupants use the stairway and the floor space for the stair is very limited. Spiral stairways are typically supported by a center pole. Requirements are found with stairways in Section 1009.

[F] STANDPIPE SYSTEM, CLASSES OF. Standpipe classes are as follows:

- A standpipe system is typically an arrangement of vertical piping located in exit stairways that allows fire-fighting personnel to connect hand-carried hoses at each level to manually extinguish fires. Section 905 and NFPA 14 recognize three different classes of standpipe systems. For a further discussion of standpipe classes and types, see the commentary to Section 905.

Class I system. A system providing 2¾-inch (64 mm) hose connections to supply water for use by fire departments and those trained in handling heavy fire streams.

- A Class I standpipe system is intended for use by trained fire service personnel as a readily available water source for manual fire-fighting operations. A Class I standpipe system is equipped with only 2¾-inch (64 mm) hose connections to allow the fire service to attach the appropriate hose and nozzle. A Class I standpipe system is not equipped with hose stations, which include a cabinet, hose and nozzle.

Class II system. A system providing 1¾-inch (38 mm) hose stations to supply water for use primarily by the building occupants or by the fire department during initial response.

- A Class II standpipe system is intended for use by building occupants or by the fire department for manual suppression. The hose stations defined in NFPA 14 as part of the Class II standpipe system include a hose rack, hose nozzle, hose and hose connection. The intent of providing the hose is for use by properly trained personnel. Occupant-use hose stations should only be provided where they can be used by people who have been properly trained in the use of the hose and nozzle.

Class III system. A system providing 1½-inch (38 mm) hose stations to supply water for use by building occupants and 2¾-inch (64 mm) hose connections to supply a larger volume of water for use by fire departments and those trained in handling heavy fire streams.

- A Class III standpipe system is intended for use by building occupants as well as trained fire service personnel. The 1¾-inch (38 mm) hose station is for use by the building occupants or fire department for manual fire suppression and the 2¾-inch (64 mm) hose connection is intended for use primarily by fire service personnel or those who have received training in the use of the larger hoses. Class III systems allow the fire department to select the types of hose necessary based on the fire hazard present. If the fire is effectively controlled by an automatic sprinkler system, the smaller hose size may be all that is necessary for fire department mop-up operations.

[F] STANDPIPE, TYPES OF. Standpipe types are as follows:

- Section 905 recognizes five types of standpipe systems. The use of each type of system depends on specific occupancy conditions and the presence of an automatic sprinkler system. For a further discussion of standpipe classes and types, see the commentary to Section 905.

Automatic dry. A dry standpipe system, normally filled with pressurized air, that is arranged through the use of a device, such as dry pipe valve, to admit water into the system piping automatically upon the opening of a hose
valve. The water supply for an automatic dry standpipe system shall be capable of supplying the system demand.

- A typical automatic dry standpipe system has an automatic water supply retained by a dry pipe valve. The dry pipe valve clapper is kept in place by air placed in the standpipe system under pressure. Once a standpipe hose valve is opened, the air is released from the system, allowing water to fill the system through the dry pipe valve. This system is traditionally used in areas where the temperature falls below 40°F (4°C) where a wet system could freeze and possibly burst, the pipe or simply not be available when needed.

**Automatic wet.** A wet standpipe system that has a water supply that is capable of supplying the system demand automatically.

- An automatic wet standpipe system is used in locations where the entire system would remain above 40°F (4°C). Because the system is pressurized with water, an immediate release of water occurs when a hose connection valve is opened. This is the most generally preferred type of standpipe but it is not necessarily the required type unless so stipulated.

**Manual dry.** A dry standpipe system that does not have a permanent water supply attached to the system. Manual dry standpipe systems require water from a fire department pumper to be pumped into the system through the fire department connection in order to meet the system demand.

- A manual dry standpipe system is filled with water only when the fire service is present. Typically, the fire service connects the discharge from a water source, such as a pumper truck, to the fire department connection of a manual dry standpipe system. When the fire service has suppressed the fire and is preparing to leave, the system is drained of the remaining water. Manual dry standpipe systems are commonly installed in open parking structures.

**Manual wet.** A wet standpipe system connected to a water supply for the purpose of maintaining water within the system but does not have a water supply capable of delivering the system demand attached to the system. Manual wet standpipe systems require water from a fire department pumper (or the like) to be pumped into the system in order to meet the system demand.

- A manual-wet standpipe system is connected to an automatic water supply, but the supply is not capable of providing the system demand. The manual wet system could be one that is connected with the sprinkler system such that it is capable of supplying the demand for the sprinkler system but not for the standpipe. The standpipe system demand is met when the fire service provides additional water through the fire department connection from the discharge of a water source, such as a pumper truck.

**Semiautomatic dry.** A dry standpipe system that is arranged through the use of a device, such as a deluge valve, to admit water into the system piping upon activation of a remote control device located at a hose connection. A remote control activation device shall be provided at each hose connection. The water supply for a semiautomatic dry standpipe system shall be capable of supplying the system demand.

- This type of dry standpipe is a special design that uses a solenoid-activated valve to retain the automatic water supply. Once the standpipe hose valve is opened, a signal is sent to the deluge valve retaining the automatic water supply to allow water to fill the system. This kind of system is used in areas where the temperature falls below 40°F (4°C), where a wet system would otherwise freeze. As such, there is no semiautomatic wet system type.

**START OF CONSTRUCTION.** The date of issuance for new construction and substantial improvements to existing structures, provided the actual start of construction, repair, reconstruction, rehabilitation, addition, placement or other improvement is within 180 days after the date of issuance. The actual start of construction means the first placement of permanent construction of a building (including a manufactured home) on a site, such as the pouring of a slab or footings, installation of pilings or construction of columns.

Permanent construction does not include land preparation (such as clearing, excavation, grading or filling), the installation of streets or walkways, excavation for a basement, footings, piers or foundations, the erection of temporary forms or the installation of accessory buildings such as garages or sheds not occupied as dwelling units or not part of the main building. For a substantial improvement, the actual “start of construction” means the first alteration of any wall, ceiling, floor or other structural part of a building, whether or not that alteration affects the external dimensions of the building.

- This term is used in the definition of “Existing construction,” and is also applicable to improvements of existing buildings in order to capture all improvement work.

**STEEL CONSTRUCTION, COLD-FORMED.** That type of construction made up entirely or in part of steel structural members cold formed to shape from sheet or strip steel such as roof deck, floor and wall panels, studs, floor joists, roof joists and other structural elements.

- This definition is necessary to distinguish structural members of cold-formed steel from other types of steel elements. A distinguishing characteristic is that the forming operation takes place at room temperature without the addition of heat. Specific references to AISI standards and specifications applicable to cold-formed steel construction are provided in Sections 2210 and 2211.

**STEEL JOIST.** Any steel structural member of a building or structure made of hot-rolled or cold-formed solid or open-
DEFINITIONS

web sections, or riveted or welded bars, strip or sheet steel members, or slotted and expanded, or otherwise deformed rolled sections.

- This definition is necessary to distinguish steel joists from other types of steel elements. References to SJI specifications are provided in Section 2207.

STEEL MEMBER, STRUCTURAL. Any steel structural member of a building or structure consisting of a rolled steel structural shape other than cold-formed steel, or steel joist members.

- This definition is necessary to distinguish structural steel members from other types of steel elements. References to AISC standards and specifications for structural steel are provided in Section 2205.

STEEP SLOPE. A roof slope greater than two units vertical in 12 units horizontal (17-percent slope).

- This is the general criterion for roof slope that is used throughout the code. Slope requirements for specific roof covering materials are specified in Chapter 15.

STONE MASONRY. Masonry composed of field, quarried or cast stone units bonded by mortar.

- Stone masonry is comprised of natural marble, limestone, granite, sandstone and slate for building purposes. Ashlar stone is further distinguished as coursed or random. Rubble stone masonry is further distinguished as coursed, random or rough.

Ashlar stone masonry. Stone masonry composed of rectangular units having sawed, dressed or squared bed surfaces and bonded by mortar.

- Units for ashlar masonry construction are rectangular in shape but variable in size.

Rubble stone masonry. Stone masonry composed of irregular-shaped units bonded by mortar.

- Unlike ashlar stone masonry, which has rectangular units, rubble stone masonry units are irregular in shape. Rubble stone masonry is further distinguished as coursed, random or rough.

[F] STORAGE, HAZARDOUS MATERIALS. The keeping, retention or leaving of hazardous materials in closed containers, tanks, cylinders, or similar vessels; or vessels supplying operations through closed connections to the vessel.

- This term refers to all hazardous materials that are essentially being stored in a static condition. The material is considered in use once it is placed into action by either handling or transport or in a closed or open system.

STORM SHELTER. A building, structure or portions thereof, constructed in accordance with ICC 500 and designated for use during a severe wind storm event, such as a hurricane or tornado.

Community storm shelter. A storm shelter not defined as a "Residential Storm Shelter."

Residential storm shelter. A storm shelter serving occupants of dwelling units and having an occupant load not exceeding 16 persons.

- The significance of the definitions is to distinguish between residential shelters and community shelters. Residential shelters are somewhat more basic than community shelters. A residential shelter allows for less floor area per person than that required for a community shelter because the occupants are presumed to be more familiar with each other.

STORY. That portion of a building included between the upper surface of a floor and the upper surface of the floor or roof next above (also see "Basement," "Building height," "Grade plane" and "Mezzanine"). It is measured as the vertical distance from top to top of two successive tiers of beams or finished floor surfaces and, for the topmost story, from the top of the floor finish to the top of the ceiling joists or, where there is not a ceiling, to the top of the roof rafters.

- All levels in a building that conform to this description are stories, including basements. A mezzanine is considered part of the story in which it is located. See Chapter 5 for code requirements regarding limitations on the number of stories in a building as a function of the type of construction.

STORY ABOVE GRADE PLANE. Any story having its finished floor surface entirely above grade plane, or in which the finished surface of the floor next above is:

1. More than 6 feet (1829 mm) above grade plane;
2. More than 12 feet (3658 mm) above the finished ground level at any point.

- The determination of the allowed height of a building under Table 503 is based on the number of stories above grade plane (see definitions of "Grade plane," "Height, building" and "Basement"). The code establishes by this definition which stories of a building are those above grade plane. Clearly, it includes those stories that are fully above grade plane. It also includes stories that may be partially below finished ground level, but the finished floor level is more than 6 feet (1829 mm) above grade plane. It also includes those floor levels that, due to an irregular terrain, have a finished floor level more than 12 feet (3658 mm) above finished ground level at any point surrounding the building. Any building level not qualifying as a story above grade plane is, by definition, a basement. See the commentary for the definitions of "Grade plane," "Height, building" and "Basement" and Figures 202.2(1), 202.7(1) through (4) and 202.8(1).

STRENGTH (For Chapter 21).

- In masonry design under Chapter 21 of the code, the term "strength" is used in both general and specific senses. In the general sense, the strength of a member is its capacity to resist internal forces and moments. In the specific sense, strength is further categorized by type. The tensile strength of a mem-
ber, for instance, refers to how much tensile force the member can support.

In the context of strength design, the force resulting from factored design actions is referred to as the "required strength." An approximation to the "minimum expected" strength of the member is referred to as the "nominal strength" (see the commentary to "Nominal strength"). This nominal strength is then multiplied by a strength reduction factor to account for material, design and construction variabilities to determine the design strength. The design strength must equal or exceed the required strength.

In the context of allowable stress design (ASD), the force resulting from unfactored design loads is referred to as the "applied (actual) force." The anticipated strength would then be reduced by appropriate safety factors to either an allowable stress or an allowable strength (for example, for anchor bolts). This allowable stress or strength is required to equal or exceed the applied (actual) stress or force.

"Design strength," "Nominal strength" and "Required strength" are defined in more detail immediately below. Allowable stresses and strengths are defined in the Building Code for Masonry Structures (TMS 402/ACI 530/ASCE 5).

Strength can also refer to the load at which a test specimen fails (for example, prism strength).

**Design strength.** Nominal strength multiplied by a strength reduction factor.

- The strength design procedures of Section 2108 use the term "design strength" to indicate a realistic capacity of a member considering material, design and construction variabilities. The design strength is obtained by multiplying the "nominal strength" by a strength reduction factor. The design strength must equal or exceed the "required strength."

**Nominal strength.** Strength of a member or cross section calculated in accordance with these provisions before application of any strength-reduction factors.

- The strength design procedures of Section 2108 use the term "nominal strength" to refer to the capacity of a masonry member, which is determined based on the assumptions contained in Section 2108. It is sometimes referred to as the "expected" strength of the member; however, this is a misnomer. The nominal strength would equal the expected strength if: the masonry member were constructed of materials complying exactly with the minimum material requirements; design equations were perfect and construction tolerances were zero. Since material strengths commonly exceed minimum requirements, expected strength is often much higher than nominal strength. For instance, Grade 60 reinforcement often has a yield strength of around 66,000 pounds per square inch (psi) (455 MPa), even though the minimum specified yield strength requirement is 60,000 psi (414 MPa). Therefore, the nominal strength is not the expected strength of the member, although it can be grossly classified as the minimum expected strength. Expected strength design is not included in Chapter 21 and is currently beyond the scope of the code. To determine the design strength, the nominal strength is multiplied by a strength reduction factor to account for material, design and construction variabilities. The design strength is required to equal or exceed the required strength.

**Required strength.** Strength of a member or cross section required to resist factored loads.

- In the strength design of masonry (see Section 2108), the required strength is that which corresponds to the factored design loads on the structure. The design strength (nominal strength times the appropriate strength reduction factor) must equal or exceed the required strength.

**STRENGTH (For Chapter 16).**

**Nominal strength.** The capacity of a structure or member to resist the effects of loads, as determined by computations using specified material strengths and dimensions and equations derived from accepted principles of structural mechanics or by field tests or laboratory tests of scaled models, allowing for modeling effects and differences between laboratory and field conditions.

- This definition is needed to apply the structural analysis and structural material design requirements in Chapter 16 and the structural materials requirements in Chapters 19 through 23.

**Required strength.** Strength of a member, cross section or connection required to resist factored loads or related internal moments and forces in such combinations as stipulated by these provisions.

- This definition is needed to apply the structural analysis requirements in Chapter 16 and the structural material design requirements in Chapters 19 through 23.

**Strength design.** A method of proportioning structural members such that the computed forces produced in the members by factored loads do not exceed the member design strength (also called "load and resistance factor design" (LRFD)). The term "strength design" is used in the design of concrete and masonry structural elements.

- This definition describes the strength design method, which is one of the design approaches recognized under the code in Section 1604.1. It is needed to apply the structural analysis requirements in Chapter 16 and the structural material design requirements in Chapters 19 through 23.

**STRUCTURAL COMPOSITE LUMBER.** Structural member manufactured using wood elements bonded together with exterior adhesives. Examples of structural composite lumber are:

- **Laminated strand lumber (LSL).** A composite of wood strand elements with wood fibers primarily oriented along the length of the member, where the least dimension of the wood strand elements is 0.10 inches (2.54 mm) or less and
DEFINITIONS

their average lengths are a minimum of 150 times the least dimension of the wood strand elements.

Laminated veneer lumber (LVL). A composite of wood veneer sheet elements with wood fibers primarily oriented along the length of the member, where the veneer element thicknesses are 0.25 inches (6.4 mm) or less.

Oriented strand lumber (OSL). A composite of wood strand elements with wood fibers primarily oriented along the length of the member, where the least dimension of the wood strand elements is 0.10 inches (2.54 mm) or less and their average lengths are a minimum of 75 times and less than 150 times the least dimension of the wood strand elements.

Parallel strand lumber (PSL). A composite of wood strand elements with wood fibers primarily oriented along the length of the member where the least dimension of the wood strand elements is 0.25 inches (6.4 mm) or less and their average lengths are a minimum of 300 times the least dimension of the wood strand elements.

This definition identifies which engineered wood products are considered structural composite lumber. This facilitates the application of the requirements of Section 2303.1.9 which references ASTM D 5456 for determination of structural capacities. The four types are: laminated strand lumber (LSL), laminated veneer lumber (LVL), oriented strand lumber (OSL) and parallel strand lumber (PSL). LSL, OSL and PSL are a composite of wood strand elements with wood fibers primarily oriented along the length of the member. What distinguishes between the three is the least dimension of the wood strand elements and their average lengths. Note that in OSL, the limit on the least dimension of the wood stands is the same as LSL. The average length limit on the wood strand is what distinguishes OSL from LSL. LVL is made of composite wood veneer sheet elements with wood fibers primarily oriented along the length of the member where the thicknesses of the veneers are 0.25 inches (6.4 mm) or less.

STRUCTURAL GLUED-LAMINATED TIMBER. An engineered, stress-rated product of a timber laminating plant, comprised of assemblies of specially selected and prepared wood laminations in which the grain of all laminations is approximately parallel longitudinally and the laminations are bonded with adhesives.

This structural wood members can be produced by laminating smaller pieces of lumber together in a specific way using adhesives to create high-performing structural members. Typically, these 2-inch-wide (51 mm) members are arranged in a specific order so that their strength characteristics are used most efficiently. For example, the outer laminations are for tension and compression while the inner laminations are for horizontal shear. Although these members are made of smaller pieces of lumber, they act together to create sizes that are included in the requirements for heavy timber framing members. Section 2303.1.3 references ANSI/AITC A 190.1, which specifies the method of manufacturing these members, and the means of identifying their performance capabilities. ASTM D 3737 covers procedures for establishing their structural properties.

STRUCTURAL OBSERVATION. The visual observation of the structural system by a registered design professional for general conformance to the approved construction documents. Structural observation does not include or waive the responsibility for the inspection required by Section 110, 1705 or other sections of this code.

Where required based on wind or seismic hazards, the registered design professional must visit the site to visually determine general conformance to the approved construction documents. Structural observation is in addition to, and does not substitute for, any inspections required by Section 110, 1705 or other sections of the code.

[A] STRUCTURE. That which is built or constructed.

This definition is intentionally broad so as to include within its scope, and therefore the scope of the code (see Section 101.2), everything that is built as an improvement to real property. See also the definitions for "Building" and "Area, building" for the difference between a building and structure.

SUBDIAPHRAGM. A portion of a larger wood diaphragm designed to anchor and transfer local forces to primary diaphragm struts and the main diaphragm.

Subdiaphragms can be used by the designer to distribute large, out-of-plane wall forces into the main diaphragm. They are especially common in buildings with concrete and masonry walls, and are subject to seismic forces that are supported by the diaphragm. Subdiaphragms are used to transfer out-of-plane wall forces to main cross ties (see ASCE 7 Section 12.11.2).

SUBSTANTIAL DAMAGE. Damage of any origin sustained by a structure whereby the cost of restoring the structure to its before-damaged condition would equal or exceed 50 percent of the market value of the structure before the damage occurred.

This term is used in the definition of "Substantial improvement." Substantial damage is a special case of substantial improvement, and if the cost of repairing damage to predamage condition equals or exceeds 50 percent of the market value of the structure before the damage occurred, then compliance of the existing building is required. The market rate for owner labor, volunteer labor, and donated or discounted supplies, if any, must be estimated when determining the cost of repairing or restoring damage. It is notable that a substantial damage determination is to be made regardless of what causes damage. Buildings may sustain substantial damage due to flood, fire, wind, earthquake, deterioration and other causes. For more guidance, see FEMA P-758.
SUBSTANTIAL IMPROVEMENT. Any repair, reconstruction, rehabilitation, addition or improvement of a building or structure, the cost of which equals or exceeds 50 percent of the market value of the structure before the improvement or repair is started. If the structure has sustained substantial damage, any repairs are considered substantial improvement regardless of the actual repair work performed. The term does not, however, include either:

1. Any project for improvement of a building required to correct existing health, sanitary or safety code violations identified by the building official and that are the minimum necessary to assure safe living conditions.

2. Any alteration of a historic structure provided that the alteration will not preclude the structure’s continued designation as a historic structure.

- One of the long-range objectives of regulating flood hazard areas is to reduce the exposure of older buildings that were built in flood hazard areas before local jurisdictions adopted flood hazard area maps and regulations. Section 105.3 directs the applicant to state the valuation of the proposed work as part of the information submitted to obtain a permit. To make a determination as to whether a proposed repair, reconstruction, rehabilitation, addition or improvement constitutes substantial improvement or repair of substantial damage, the building official compares the cost of the proposed work to the market value of the building or structure before the work is started. In order to determine market value, the building official may require the applicant to provide such information as allowed under Section 105.3. The 50-percent threshold is a compromise that is midway between no regulation of existing buildings and requiring full compliance for any alteration to an existing building. For additional guidance, refer to FEMA P-758 and FEMA P-784 (user’s manual, workbook and software).

SUBSTANTIAL STRUCTURAL DAMAGE. A condition where:

1. In any story, the vertical elements of the lateral force-resisting system have suffered damage such that the lateral load-carrying capacity of the structure in any horizontal direction has been reduced by more than 33 percent from its predamage condition; or

2. The capacity of any vertical gravity load-carrying component, or any group of such components, that supports more than 30 percent of the total area of the structure’s floors and roofs has been reduced more than 20 percent from its predamage condition and the remaining capacity of such affected elements, with respect to all dead and live loads, is less than 75 percent of that required by this code for new buildings of similar structure, purpose and location.

- This definition gives the specific parameters that determine when a building has sustained substantial structural damage. There are two separate criteria provided in the definition, either one of which will qualify a structure as being substantially damaged. It describes conditions of severe or widespread damage, as opposed to local effects or member distress, and distinguishes the damage requiring structural upgrade as opposed to damage to architectural and mechanical components. Its purpose is to facilitate the provisions for repairs in Section 3405.2.

- [E] SUNROOM. A one-story structure attached to a building with a glazing area in excess of 40 percent of the gross area of the structure’s exterior walls and roof.

- This terminology is provided in order to address separate requirements for sunrooms with regard to ventilation of adjoining spaces (see Section 1203.4.1.1). Defined in previous editions as "sunroom addition," sunrooms can be either an addition or part of the original construction. Provisions in Chapter 12 are applicable regardless of whether the sunroom is an addition to an existing structure or is part of the original design and construction. Sunrooms which are provided with "thermal isolation" are also addressed in the International Energy Conservation Code.

- [F] SUPERVISING STATION. A facility that receives signals and at which personnel are in attendance at all times to respond to these signals.

- The supervising station is the location where all fire protection-system-related signals are sent and where trained personnel are present to respond to an emergency. The supervising station may be an approved central station, a remote supervising station, a proprietary supervising station or other constantly attended location approved by the fire code official. Each type of supervising station must comply with the applicable specific provisions described in NFPA 72.

- [F] SUPERVISORY SERVICE. The service required to monitor performance of guard tours and the operative condition of fixed suppression systems or other systems for the protection of life and property.

- The supervisory service is responsible for maintaining the integrity of the fire protection system by notifying the supervising station of a change in protection system status.

- Guard tours are recognized as a nonrequired (voluntary) system. If a guard tour is provided, the signals from that system can be transmitted through the supervisory service to the supervision station. Guard tours are not a required part of a fire alarm system.

- [F] SUPERVISORY SIGNAL. A signal indicating the need of action in connection with the supervision of guard tours, the fire suppression systems or equipment or the maintenance features of related systems.

- Activation of a supervisory signal-initiating device transmits a signal indicating that a change in the status of the fire protection system has occurred and that action must be taken. These signals are the basis for the actions taken by the attendant at the supervising station. These signals do not indicate an emergency condition but indicate that a portion of the system is not functioning in the manner in which it should and that if the condition is not corrected it
DEFINITIONS

could impair the ability of the fire protection system to perform properly. A supervisory signal is also a part of the nonrequired guard tour system.

**[F]** SUPERVisory SIGNAL-INITIATING DEVICE. An initiation device, such as a valve supervisory switch, water-level indicator or low-air pressure switch on a dry-pipe sprinkler system, whose change of state signals an off-normal condition and its restoration to normal of a fire protection or life safety system, or a need for action in connection with guard tours, fire suppression systems or equipment or maintenance features of related systems.

- The supervisory signal-initiating device detects a change in protection system status. Examples of a supervisory signal-initiating device include a flow switch to detect movement of water through the system and a tamper switch to detect when someone shuts off a water control valve.

**SUSCEPTIBLE BAY.** A roof or portion thereof with:

1. A slope less than $1/4$-inch per foot (0.0208 rad); or
2. On which water is impounded upon it, in whole or in part, and the secondary drainage system is functional but the primary drainage system is blocked.

A roof surface with a slope of $1/4$-inch per foot (0.0208 rad) or greater towards points of free drainage is not a susceptible bay.

- This term is needed to identify portions of roofs that must be investigated for the possibility of progressive deflections due to ponding.

**SWIMMING POOL.** Any structure intended for swimming, recreational bathing or wading that contains water over 24 inches (610 mm) deep. This includes in-ground, above-ground and on-ground pools; hot tubs; spas and fixed-in-place wading pools.

- The small above-ground pools frequently found in residential yards are exempt from the provisions of Section 3109, provided that they do not exceed 2 feet (610 mm) in depth.

**T RATING.** The time period that the penetration firestop system, including the penetrating item, limits the maximum temperature rise to 325°F (163°C) above its initial temperature through the penetration on the nonfire side when tested in accordance with ASTM E 814 or UL 1479.

- See the definition of "Through-penetration firestop system." Some through penetrations having a high thermal conductivity (e.g., metal pipes, cables) will not be able to achieve a T rating without some method to prevent the heat from being transmitted from the fire side to the nonfire side. For metallic pipes, insulation must be applied to the through penetrant for some distance on one or, more often, both sides of the fire-resistance-rated assembly. Thus, when a T rating is desired, the seemingly unusual situation can arise of needing to insulate items that would normally not need insulation, such as drain pipes or conduit. Some plastic pipes are also unable to achieve a T rating without some insulation, particularly those used and, therefore, tested as "open" systems, where hot gases from the test furnace are able to flow within the plastic pipe once the pipe burns through. The type and thickness of insulation required, as well as the length over which it must be applied, are all indicated in the through-penetration firestop system listings.

Some highly intumescent firestop products can close (choke down) a plastic pipe early enough during a fire test to prevent hot gases from heating up the pipe from inside, thus allowing plastic pipe through-penetration firestop systems to be developed that have a T rating without the need for any insulation.

To avoid the need for a T rating altogether, through penetrations that pass through floors can be contained within a chase wall (see Section 714.4.1.1.2 exceptions). It is particularly important for the designer to plan ahead to have through penetrations concealed within a chase wall or located in a shaft in cases where adding insulation to the through penetrant is an undesirable or unacceptable option.

In the case of cable through penetrations, the need for heat dissipation would usually make the application of additional insulating material unacceptable. The few cable through-penetration firestop systems that do have a T rating achieve this by enclosing the cables within some protective enclosure for a distance from the rated assembly, thus allowing any heat transmitted through the cables during fire exposure to be dissipated, resulting in the exposed section of cabling to be cool enough for the duration of the fire test exposure to meet the T rating requirement [see Figure 202.20(1)].

Overall, due to the unavoidable difficulty in having a conductive or semiconductive through penetrant obtain a T rating, less than 5 percent of all tested and listed through-penetration firestop systems have a T rating. This is because the T rating indicates that the firestop system is not only capable of stopping the fire, flame and hot gases from passing through the assembly at the penetration as an F rating does, but it also must limit the temperature transfer to the unexposed side of the assembly.

**TECHNICAL PRODUCTION AREA.** Open elevated areas or spaces intended for entertainment technicians to walk on and occupy for servicing and operating entertainment technology systems and equipment. Galleries, including fly and lighting galleries, gridirons, catwalks, and similar areas are designed for these purposes.

- The definition replaces the dated terms and definitions of fly gallery and gridiron. A technical production area encompasses all areas, regardless of their traditional name, used to support entertainment technology from above the performance area. Such areas are sometimes called the backstage. Technical production areas may also be used in venues without stages or platforms, such as sports arenas. Technical production areas are regulated in Section 410.
TECHNICALLY INFEASIBLE. An alteration of a building or a facility that has little likelihood of being accomplished because the existing structural conditions require the removal or alteration of a load-bearing member that is an essential part of the structural frame, or because other existing physical or site constraints prohibit modification or addition of elements, spaces or features which are in full and strict compliance with the minimum requirements for new construction and which are necessary to provide accessibility.

❖ This term is defined in order to provide a basis for the application of accessibility provisions to existing buildings (see Section 3411). Bringing any given existing site or building that is altered into full compliance with all accessibility requirements applicable to new construction may require extraordinary effort because of existing physical characteristics. The code utilizes the concept of technical infeasibility to provide a basis for exceptions from strict compliance with the provisions for new construction in an existing building.

TENT. A structure, enclosure or shelter, with or without sidewalls or drops, constructed of fabric or pliable material supported in any manner except by air or the contents it protects.

❖ Tents can be temporary or permanent structures. When permanent, they are considered membrane-covered structures and are regulated by Section 3102. When erected as temporary enclosures, they are regulated by Section 3103.

[E] THERMAL ISOLATION. A separation of conditioned spaces, between a sunroom and a dwelling unit, consisting of existing or new walls, doors or windows.

❖ This terminology is needed for the same reason provided in the definition of “Sunroom.” A sunroom with thermal isolation according to Section 1203.4 can be a source of natural ventilation.
DEFINITIONS

THERMOPLASTIC MATERIAL. A plastic material that is capable of being repeatedly softened by increase of temperature and hardened by decrease of temperature.

- Thermoplastic materials become plastic and deform easily at high temperatures. Indeed, many of these materials have limited construction value at high temperatures. Examples of thermoplastics are cellulose acetate, nylon, polycarbonates, polyethylene (three different densities), methyl methacrylate (plexiglass), polypropylene, polybutylene, polyethylene, acrylonitrile-butadiene-styrene (ABS), polytetrafluoroethylene (Teflon®), polyvinyl chloride (PVC), chlorinated polyvinyl chloride (CPVC) and polyethylene terephthalate (polyester). Note there are both thermosetting and thermoplastic polyesters. These materials have high thermal expansion coefficients and, while they may burn slowly in a fire, they decompose rapidly to yield a heavy black smoke and acrid, sometimes very toxic, fumes depending on the specific material and burning conditions.

THERMOSETTING MATERIAL. A plastic material that is capable of being changed into a substantially nonreformable product when cured.

- This term is the opposite of a thermoplastic material. Common thermosetting plastic includes epoxy, melamine, urea, polyester and polyurethane.

THIN-BED MORTAR. Mortar for use in construction of AAC unit masonry with joints 0.06 inch (1.5 mm) or less.

- Thin-bed mortar used in the construction of AAC masonry is not conventional mortar, but is instead a mortar manufactured specifically for use in AAC masonry construction.

THROUGH PENETRATION. A breach in both sides of a floor, floor-ceiling or wall assembly to accommodate an item passing through the breaches.

- This term is different from a single "membrane penetration." It defines the situation where an opening (a breach in both membranes of an assembly) is created to accommodate an object that passes completely through an assembly from one side to the other [see Figure 202.20(1) for an example of a through penetration]. It is important to realize that this term applies only to an item that passes all the way through the assembly; back-to-back membrane penetrations, such as outlet boxes on each side of a wall assembly, should not be considered a through penetration.

THROUGH-PENETRATION FIRESTOP SYSTEM. An assemblage consisting of a fire-resistance-rated floor, floor-ceiling, or wall assembly, one or more penetrating items passing through the breaches in both sides of the assembly and the materials or devices, or both, installed to resist the spread of fire through the assembly for a prescribed period of time.

- One method of protection for penetrations through fire walls, fire barriers, fire partitions and fire-resistance-rated floor/ceiling assemblies is to provide a through-penetration firestop system (see Sections 714.3.1.2 and 714.4.1.1.2). Through-penetration firestop systems maintain the required protection from the spread of fire, passage of hot gases and transfer of heat. The protection is often provided by an intumescent material. Upon exposure to high temperatures, this material expands as much as eight to 10 times its original volume, forming a high-strength char.

- This is one of several types of through-penetration firestop systems available. This definition is based on information from three sources: Section 3.1.1 of ASTM E 814; a compilation of definitions from ASTM International standards and the Fire Resistance Directory by Underwriters Laboratories Inc.

TIE-DOWN (HOLD-DOWN). A device used to resist uplift of the chords of shear walls.

- A shear wall resists lateral forces which are typically applied at the top of and parallel to the wall from the floor or roof diaphragm. This load will rack the wall and attempt to turn it over. If the strength of the sheathing and framing is adequate to resist the load and appropriately attached, the sheathing will resist the tendency to rack the wall. To prevent the wall from overturning, the tension chord must be adequately anchored to the foundation or structure below. Anchor bolts in the sill plate are not typically designed to resist these overturning loads. Hold-down devices are often necessary at the ends of the shear wall to resist overturning from high lateral loads due to wind loads or seismic ground motion.

TIE, WALL. Metal connector that connects wythes of masonry walls together.

- Ties are used to connect adjacent masonry wythes and are subject to requirements for strength, durability and installation. Ties are either adjustable or non-adjustable.

TILE, STRUCTURAL CLAY. A hollow masonry unit composed of burned clay, shale, fire clay or mixture thereof, and having parallel cells.

- These clay masonry units are produced as end tiles and side tiles, and differ from clay brick by having required cells with thinner webs between them.

[F] TIRES, BULK STORAGE OF. Storage of tires where the area available for storage exceeds 20,000 cubic feet (566 m³).

- This definition describes a storage space that is larger than what would be found in most typical mercantile and storage occupancies. Because of its size and the volume of combustible material it would house, it poses an extraordinary hazard for fire protection.

The volume is based on the legacy code definition, which was based on 10,000 passenger vehicle tires weighing an average of 25 pounds (11 kg) each, rather than the volume of the stored tires. Assuming a
24-inch by 24-inch space (610 mm by 610 mm) for an average passenger vehicle tire and a 6-inch (152 mm) thickness, the result is 20,000 cubic feet (566 m³):

\[10,000 \text{ tires} \times 2 \text{ ft} \times 2 \text{ ft} \times 0.5 \text{ ft} = 20,000 \text{ ft}^3\]

The 20,000 cubic feet (566 m³) represents the actual volume of stored materials based on an equivalent height and area for passenger vehicle tires as shown in the calculation above and does not include circulation area or other portions of the building. Rather, it focuses on how much of the material is present. Although the definition uses the term “area” rather than “volume,” it is the volume that becomes the threshold consideration. Still, the area where the tires are stored implies the footprint used for storage. It is not the intent to apply this to areas outside of those used for bulk tire storage.

Buildings used for the bulk storage of tires are classified as Group S-1 occupancies in accordance with Section 311.2. All Group S-1 occupancies, regardless of square footage, must be equipped with an NFPA 13 automatic sprinkler system if used for the bulk storage of tires as required by Section 903.2.9.2. Chapter 34 of the IFC also requires that bulk tire storage buildings be further designed to comply with NFPA 13, and Chapter 32 of the IFC includes additional requirements for high-piled rubber tire storage as a high-hazard commodity (see commentary, Chapters 32 and 34 of the IFC).

[A] TOWNHOUSE. A single-family dwelling unit constructed in a group of three or more attached units in which each unit extends from the foundation to roof and with open space on at least two sides.

- This specific configuration of construction is called different things in different parts of the country, such as a rowhouse. A townhouse structure that meets the following four criteria is not regulated by the code, but is regulated by the IRC. Those criteria are:
  1. Each unit extends from foundation to roof with no vertical overlap of any parts of adjoining units;
  2. Each unit must have open space on at least two sides (either two opposite or two adjoining sides);
  3. Each unit must have a separate means of egress; and
  4. The building must not exceed three stories above grade plane.

If all of these criteria are met, then according to the exception to Section 101.2, the structure is within scope of the IRC. (It should also be noted that townhouses within the IRC must be separated by a wall or walls meeting specific criteria.) If a structure does not meet these four criteria, it will need to be regulated under the code and will either be classified as a Group R-2 or Group R-3 structure, depending on how the units are separated. A building containing three or more dwelling units is regulated as a Group R-2 occupancy. To be considered a Group R-3, the structure must have one or two dwelling units, or be subdivided by fire walls between every unit or every two units (see Section 310.1 and the definitions for “Area, building,” “ Dwelling” and “ Dwelling unit”). Finally, the definition of “Townhouse” is not dependent on the presence of individual lots. A townhouse structure could be built with any number of attached units on the same lot, or it could be developed such that a property line lies at each common wall separating two units (see definition for “Lot”).

[F] TOXIC. A chemical falling within any of the following categories:

1. A chemical that has a median lethal dose \( (\text{LD}_{50}) \) of more than 50 milligrams per kilogram, but not more than 500 milligrams per kilogram of body weight when administered orally to albino rats weighing between 200 and 300 grams each.
2. A chemical that has a median lethal dose \( (\text{LD}_{50}) \) of more than 200 milligrams per kilogram, but not more than 1,000 milligrams per kilogram of body weight when administered by continuous contact for 24 hours (or less if death occurs within 24 hours) with the bare skin of albino rabbits weighing between 2 and 3 kilograms each.
3. A chemical that has a median lethal concentration \( (\text{LC}_{50}) \) in air of more than 200 parts per million, but not more than 2,000 parts per million by volume of gas or vapor, or more than 2 milligrams per liter but not more than 20 milligrams per liter of mist, fume or dust, when administered by continuous inhalation for 1 hour (or less if death occurs within 1 hour) to albino rats weighing between 200 and 300 grams each.

- The definition is derived from DOL 29 CFR; Part 1910.1200. These materials are considered dangerous to humans when either inhaled, absorbed or injected through the skin or when orally ingested. Toxic materials differ from highly toxic materials with regard to the specified median lethal dose or concentration of a given chemical. Toxic materials present a health hazard and are subsequently listed as a Group H-4 material in Section 307.6. Examples of toxic materials include gases such as chlorine; phosgene and hydrogen fluoride; liquid alkyl alcohol; methyl isocyanide and phosphorous chloride and barium chloride; benzidine and sodium fluoride in solid form.

TRANSIENT. Occupancy of a dwelling unit or sleeping unit for not more than 30 days.

- The intent of this definition is to establish a time parameter to differentiate between transient and non-transient as listed under Groups R-1 and R-2. Real estate law often dictates that a lease must be created after 30 days and 30-day time periods are typically how extended-stay hotels and motels rent to people. Such a time period gives the occupant time to be
familiar with the surroundings and, therefore, become more accustomed to any hazards of the built environment than an overnight guest would be or a guest who stays for just a few days. Since nontransient occupancies do not have the same level of protection in the code as transient occupancies, it is important to determine what makes an occupancy transient so as to provide consistency in enforcement.

Since the requirements for Type B units are tied to the facilities that are intended to be occupied as a residence under both the Group R-1 and Group R-2, this definition does not have a detrimental effect on matching the Fair Housing Act provisions.

**TRANSIENT AIRCRAFT.** Aircraft based at another location and that is at the transient location for not more than 90 days.

- In the place of the undefined term “private aircraft” previously used in the code, a defined term “transient aircraft” has been added in the 2009 edition. Transient aircraft are those that are merely visiting an airport as compared to those that are based at that location. The definition is used in conjunction with Section 412.4.6 to establish the level of fire suppression needed in various aircraft hangars. Fixed-base operators, especially at larger airports, will have distinct hangars that are used for repair and maintenance of aircraft. The hangars used by transient aircraft are primarily a storage place for aircraft based at another location. This better identifies the intent of this type of aircraft hangar. Most frequently, the owner who wants to develop an aircraft hangar that fits the Group II category will do no “major maintenance” and will only store airplanes in the hangar (see commentary, Section 412.4.6).

**TREATED WOOD.** Wood and wood-based materials that use vacuum-pressure impregnation processes to enhance fire retardant or preservative properties.

- There are two types of treated wood: fire-retardant treated wood and preservative-treated wood. Wood is treated to reduce its ability to propagate flame or resist damage caused by fungus or insects. The American Wood Preservers' Association (AWPA) standards are prescribed in Section 2303.1.8. These include water-borne, as well as oil-borne, materials for treatment, testing and quality control of various wood and wood-based products. The American Lumber Standard Committee (ALSC) also accredits third-party inspection agencies, in a manner similar to their grading rules certification, for the quality control of preservative-treated wood products. Facsimiles of accredited agencies’ quality marks for treatment are available from ALSC.

**Fire-retardant-treated wood.** Pressure-treated lumber and plywood that exhibit reduced surface-burning characteristics and resist propagation of fire.

- The ability of the wood to extinguish itself once the source of ignition is consumed or removed is an important characteristic of this material. Section 2303.2 requires testing in accordance with ASTM E 84 or UL 723. The section requires the test to be continued an additional 20 minutes beyond the 10 minutes required to establish the flame spread. According to Section 2303.2, there can be no significant progressive combustion during this period.

**Preservative-treated wood.** Pressure-treated wood products that exhibit reduced susceptibility to damage by fungi, insects or marine borers.

- Wood that is exposed to high levels of moisture or heat is susceptible to decay both from fungus and other organisms as well as insect attack. The damage caused by decay or insects can reduce the performance of wood members below the minimum level required by the code. Section 2304.11 identifies the locations where the use of naturally durable or preservative-treated wood is required. It is important to note that preservative treatment requires a pressure-treatment process. Painting, coating or other surface treatment does not necessarily produce preservative-treated wood that will perform as required. The treatment process uses pressure to achieve the depth of penetration of preservative into the wood that is needed to verify that the wood will be resistant to decay and insects over time. Surface treatments may be washed away by rain or ground water, or may chip or peel. AWPA is the primary industry standards developer for treated wood. Preservative-treated wood will not reduce susceptibility to all insects, only those that actually eat the wood.

**TRIM.** Picture molds, chair rails, baseboards, handrails, door and window frames and similar decorative or protective materials used in fixed applications.

- As interior trim, this material is usually combustible and permanently affixed. Trim is primarily located around door and window openings (frames), around walls at floors (baseboard) and on walls (chair rail). Interior trim material should only constitute 10 percent of the wall or ceiling area (see Section 806.5).

[F] **TROUBLE SIGNAL.** A signal initiated by the fire alarm system or device indicative of a fault in a monitored circuit or component.

- This type of signal indicates that there has been an abnormal change in the normal status of the fire detection system or devices and that a response is required to determine the nature of the fault condition. The trouble signal is only associated with electronic portions of a fire protection system. Physical conditions such as a closed valve are monitored electronically and would report as a supervisory signal rather than a trouble signal. A valve supervisory switch, or “tamper switch,” for example, would perform such a function.

**TUBULAR DAYLIGHTING DEVICE (TDD).** A non-operable fenestration unit primarily designed to transmit daylight from a roof surface to an interior ceiling via a tubular
conduit. The basic unit consists of an exterior glazed weathering surface, a light-transmitting tube with a reflective interior surface, and an interior-sealing device such as a translucent ceiling panel. The unit can be factory assembled, or field-assembled from a manufactured kit.

- This definition helps to differentiate tubular daylighting devices (TDDs) from unit skylights, both of which are subject to similar requirements in Chapter 24. These devices are typically field assembled from a manufactured kit, unlike a unit skylight which is typically shipped as a factory-assembled unit.

**24-HOUR CARE.** See "24-hour care" located preceding "AAC masonry."

- See the commentary for "24-hour care" at the beginning of the section.

**TYPE A UNIT.** A dwelling unit or sleeping unit designed and constructed for accessibility in accordance with this code and the provisions for Type A units in ICC A117.1.

- There are three levels of accessibility described in the code pertaining to dwelling units. Accessible units (always spelled with a capital "A"), Type A units and Type B units. A Type A unit has some elements that are constructed for accessibility [e.g., 32-inch (813 mm) clear width doors with maneuvering clearances] and some elements that are constructed as adaptable (e.g., blocking for future installation of grab bars). A Type A dwelling unit is designed and constructed to provide accessibility for wheelchair users throughout the unit, and, as such, is considered more accessible than a Type B dwelling unit. Because some adaptable features are permitted in the standard, the Type A unit is considered less wheelchair-user friendly than an Accessible unit. Type A units are only scoped in large apartment buildings of Group R-2 occupancies. The technical requirements for the interior of Type A units are in Section 1003 of ICC A117.1 (see commentary, Section 1107.2). See "24-hour care" at the beginning of the section.

**TYPE B UNIT.** A dwelling unit or sleeping unit designed and constructed for accessibility in accordance with this code and the provisions for Type B units in ICC A117.1, consistent with the design and construction requirements of the federal Fair Housing Act.

- There are three levels of accessibility described in the code pertaining to dwelling units. Accessible units (always spelled with a capital "A"), Type A units and Type B units. A Type B dwelling or sleeping unit is designed and constructed to provide a minimal level of accessibility, and, as such, is considered less accessible than either an Accessible unit or a Type A unit. The requirements for Type B units are intended to be consistent with the Fair Housing Amendments Act (FHA). Type B units are scoped in many types of housing. The technical requirements for the interior of Type B units are in Section 1004 of ICC A117.1 (see commentary, Section 1107.2 and the definition for "intended to be occupied as a residence").

**UNDERLAYMENT.** One or more layers of felt, sheathing paper, nonbituminous saturated felt or other approved material over which a steep-slope roof covering is applied.

- According to Section 1507.2.3, underlayment is required to comply with ASTM D 226 or ASTM D 4869, Type I, which is commonly referred to as No. 15 asphalt felt.

**UNIT SKYLIGHT.** See "Skylight, unit."

- Unit skylight is defined under "Skylight, unit" and is addressed in the commentary for that term.

**[F] UNSTABLE (REACTIVE) MATERIAL.** A material, other than an explosive, which in the pure state or as commercially produced, will vigorously polymerize, decompose, condense or become self-reactive and undergo other violent chemical changes, including explosion, when exposed to heat, friction or shock, or in the absence of an inhibitor, or in the presence of contaminants, or in contact with incompatible materials. Unstable (reactive) materials are subdivided as follows:

  **Class 4.** Materials that in themselves are readily capable of detonation or explosive decomposition or explosive reaction at normal temperatures and pressures. This class includes materials that are sensitive to mechanical or localized thermal shock at normal temperatures and pressures.

  **Class 3.** Materials that in themselves are capable of detonation or of explosive decomposition or explosive reaction but which require a strong initiating source or which must be heated under confinement before initiation. This class includes materials that are sensitive to thermal or mechanical shock at elevated temperatures and pressures.

  **Class 2.** Materials that in themselves are normally unstable and readily undergo violent chemical change but do not detonate. This class includes materials that can undergo chemical change with rapid release of energy at normal temperatures and pressures, and that can undergo violent chemical change at elevated temperatures and pressures.

  **Class 1.** Materials that in themselves are normally stable but which can become unstable at elevated temperatures and pressure.

- The classification of unstable (reactive) materials is based on provisions in NFPA 704. The different classes of unstable (reactive) materials reflect the degree of susceptibility of the materials to release energy. Unstable (reactive) materials polymerize, decompose or become self-reactive when exposed to heat, air, moisture, pressure or shock. Separation from incompatible materials is essential to minimizing the hazards. Examples of unstable (reactive) materials include nitromethane, perchloric acid, sodium perchlorate, vinyl acetate and acetic acid.
DEFINITIONS

[F] USE (MATERIAL). Placing a material into action, including solids, liquids and gases.

- This definition describes the active utilization mode of a material as opposed to the inactive nature of storage or the limited movement or transport involved in handling. This mode tends to be more hazardous in that the material is exposed to human or mechanical contact rather than being confined to a closed container, thus increasing the potential for spills or other releases of liquids, vapors, gases or solids.

VAPOUR PERMEABLE MEMBRANE. The property of having a moisture vapor permeance rating of 10 perms (5.7 x 10^-10 kg/Pa x s x m²) or greater, when tested in accordance with the desiccant method using Procedure A of ASTM E 96. A vapor permeable material permits the passage of moisture vapor.

- Greater demands on the building envelope due to energy considerations now dictate the need for an outer membrane that reduces wind infiltration. The membranes used in this application may need to allow vapor to pass through it, given that a vapor barrier would be needed on the inside of the wall and would be undesirable on the outside of the wall. In such cases, a vapor-permeable membrane would be used. Membranes with a permeance rating lower than 10 perms are considered vapor retarders.

VAPOUR RETARDER CLASS. A measure of a material or assembly’s ability to limit the amount of moisture that passes through that material or assembly. Vapor retarder class shall be defined using the desiccant method of ASTM E 96 as follows:

- Class I: 0.1 perm or less.
- Class II: 0.1 < perm ≤ 1.0 perm.
- Class III: 1.0 < perm ≤ 10 perm.

- Vapor retarders are used to limit moisture intrusion into a building. The definition establishes three classes of vapor retarders based on the amount of moisture that can pass through in a given time period.

- This definition explains vehicle barriers in order to clarify the minimum design loads that must be applied to these components in accordance with Section 1607.8.3.

VEHICULAR GATE. A gate that is intended for use at a vehicular entrance or exit to a facility, building or portion thereof, and that is not intended for use by pedestrian traffic.

- This definition provides the scope for the particular type of gates addressed by Section 3110. They are specifically those gates associated with vehicles at a building or facility as a opposed to a parking lot or access road. In addition it clarifies that these gates are not those used by people.

VENNEER. A facing attached to a wall for the purpose of providing ornamentation, protection or insulation, but not counted as adding strength to the wall.

- Veneers are wall facings or claddings of various materials that are used for environmental protection or ornamentation on the exterior of walls. Veneers are nonstructural in that they do not carry any load other than their own weight.

[M] VENTILATION. The natural or mechanical process of supplying conditioned or unconditioned air to, or removing such air from, any space.

- Ventilation is the process of moving air to or from building spaces. This definition of ventilation requirements is used in the code to establish minimum levels of air movement within a building for the purposes of providing a healthful interior environment. Ventilation would include both natural (openable exterior windows and doors for wind movement) and mechanical (forced air with mechanical equipment) methods.

VINYL SIDING. A shaped material, made principally from rigid polyvinyl chloride (PVC), that is used as an exterior wall covering.

- Vinyl siding is discussed in Sections 1404.9 and 1405.14. This material offers a siding product that does not require regular painting. It is offered in a variety of colors and textures. Some vinyl siding is manufactured with some relief on the face of the product to emulate wood grain. It is important when applying the material to use an attachment method that allows the product to move as it expands and contracts. Static connections will cause the material to crack and warp.

[F] VISIBLE ALARM NOTIFICATION APPLIANCE. A notification appliance that alerts by the sense of sight.

- Visible alarm notification appliances are located anywhere an occupant notification system is required, where occupants may be hearing impaired and in sleeping accommodations of Group I-1 and R-1 occupancies. These alarm notification devices must be located and oriented so that they will display alarm signals throughout the required space. Visible alarms, when provided, are typically installed in the public and common areas of buildings (see commentary, Section 907.5.2.3).

WALKWAY, PEDESTRIAN. A walkway used exclusively as a pedestrian trafficway.

- A pedestrian walkway is an enclosed passageway external to, and not considered part of, the buildings it connects. Intended only for pedestrian use, it can be at grade, below grade or elevated above grade.

WALL. A vertical element with a horizontal length-to-thickness ratio greater than three, used to enclose space.

- Masonry walls typically enclose space and therefore are generally required to be designed and installed
for weather resistance, durability and in addition to adequate strength. The given dimensional requirements differentiate masonry walls from masonry columns.

**Cavity wall.** A wall built of masonry units or of concrete, or a combination of these materials, arranged to provide an airspace within the wall, and in which the interior and outer parts of the wall are tied together with metal ties.

- Cavity walls are made up of solid or hollow masonry units separated by a continuous airspace or cavity. This continuous airspace adds insulating value and acts as a barrier to moisture when detailed with flashing and weep holes. In many cavity walls, thermal insulation is placed between the masonry wythes to further enhance thermal efficiency.

**Composite wall.** A wall built of a combination of two or more masonry units bonded together, one forming the backup and the other forming the facing elements.

- A composite wall is a multiwythe masonry wall with wythes that act together to resist loads. The distinction of having wythes with different mechanical properties is important in engineering design. Walls constructed of different materials must be evaluated for lateral- and vertical-load-bearing performance and for differential movement between the wythes.

**Dry-stacked, surface-bonded wall.** A wall built of concrete masonry units where the units are stacked dry, without mortar on the bed or head joints, and where both sides of the wall are coated with a surface-bonding mortar.

- Although this type of masonry wall is dry stacked, a leveling course set in a full bed of mortar is often used. Dry-stacked walls are also required to be placed in a running bond pattern (see the commentary to the definition of "Mortar, surface-bonding").

**Masonry-bonded hollow wall.** A multi-wythe wall built of masonry units arranged to provide an air space between the wythes and with the wythes bonded together with masonry units.

- Hollow walls are similar to cavity walls in that they are made up of solid or hollow masonry units separated by an airspace. Unlike a cavity wall, however, the wythes are bonded together by masonry units, which cause the wythes to act together under load.

**Parapet wall.** The part of any wall entirely above the roof line.

- These portions of masonry walls project above the roof. A parapet wall is exposed to weather on both sides and is laterally unsupported at the top. Parapets often have copings.

**WALL, LOAD-BEARING.** Any wall meeting either of the following classifications:

1. Any metal or wood stud wall that supports more than 100 pounds per linear foot (1459 N/m) of vertical load in addition to its own weight.

2. Any masonry or concrete wall that supports more than 200 pounds per linear foot (2919 N/m) of vertical load in addition to its own weight.

- This definition is necessary since the structural requirements and fire-resistance-rating requirements in the code vary for nonload-bearing walls and load-bearing walls. The term "load-bearing walls" is intended to refer to wall elements that support part of the structural framework of a building.

**WALL, NONLOAD-BEARING.** Any wall that is not a load-bearing wall.

- This definition is necessary since the structural requirements and fire-resistance-rating requirements in the code vary for nonload-bearing walls and load-bearing walls. Nonload-bearing walls do not support any portion of the building or structure except the weight of the wall itself.

**WALL PIER.** See Section 1905.1.1.

- This definition is a modification of ACI 318 text and is therefore located in Section 1905.

[F] **WATER-REACTIVE MATERIAL.** A material that explodes; violently reacts; produces flammable, toxic or other hazardous gases; or evolves enough heat to cause autoignition or ignition of combustibles upon exposure to water or moisture. Water-reactive materials are subdivided as follows:

- **Class 3.** Materials that react explosively with water without requiring heat or confinement.

- **Class 2.** Materials that react violently with water or have the ability to boil water. Materials that produce flammable, toxic or other hazardous gases or evolve enough heat to cause autoignition or ignition of combustibles upon exposure to water or moisture.

- **Class 1.** Materials that react with water with some release of energy, but not violently.

- These materials liberate significant quantities of heat when reacting with water. Combustible water-reactive materials are capable of self-ignition. Even noncombustible water-reactive materials present a hazard because of the heat liberated during their reaction with water, which is sufficient to ignite surrounding combustible materials. While a definition for Class 1 water-reactive materials is provided for informational purposes, the MAO of these materials in accordance with Table 307.1(1) is not limited. The descriptions of each of the subdivisions is consistent with the approach used for the determination of water hazards in NFPA 704.

**WATER-RESISTIVE BARRIER.** A material behind an exterior wall covering that is intended to resist liquid water that has penetrated behind the exterior covering from further intruding into the exterior wall assembly.

- Protection of the building envelope from moisture intrusion is a primary concern. The ability of the water-resistant barrier to provide weather resistance...
and maintain the integrity of the building envelope is key to controlling water-based problems like mold, decay and deterioration of a structure. Water-resistant barriers are discussed in Section 1404.2.

WEATHER-EXPOSED SURFACES. Surfaces of walls, ceilings, floors, roofs, soffits and similar surfaces exposed to the weather except the following:

1. Ceilings and roof soffits enclosed by walls, fascia, bulkheads or beams that extend a minimum of 12 inches (305 mm) below such ceiling or roof soffits.

2. Walls or portions of walls beneath an unenclosed roof area, where located a horizontal distance from an open exterior opening equal to at least twice the height of the opening.

3. Ceiling and roof soffits located a minimum horizontal distance of 10 feet (3048 mm) from the outer edges of the ceiling or roof soffits.

Outside surfaces of a building or structure are generally exposed to elements of the weather; therefore, it is necessary to take special precautions to protect them from damage. The most common way to protect exterior surfaces from damage caused by rain, sleet, wind, ice and snow or water from other sources is by the use of building materials that are designed, manufactured and installed to resist or withstand the extremes produced by weather. There are many building materials other than those identified in Chapter 25 that provide excellent protection from weather damage, and are permitted by the I-Codes for use on weather-exposed surfaces. Requirements for other approved materials, such as, but not limited to, brick, concrete, precast concrete panels, concrete unit masonry, wood, vinyl, aluminum, glass and steel, are specified in other chapters of the code.

There are isolated surfaces located on the exterior of a building or structure that are not directly exposed to or in contact with the damaging effects of the weather. These areas are identified in Items 1, 2 and 3 above. Although these surfaces are located on the exterior of the building or structure, they are provided with a permissible amount of protection and are not directly exposed to the weather with regards to moisture. This must be taken into consideration when wall and ceiling covering materials are being selected. It is not required to use waterproof materials at these locations, but materials approved by the code and the product manufacturer for exterior applications must be used.

[F] WET-CHEMICAL EXTINGUISHING SYSTEM. A solution of water and potassium-carbonate-based chemical, potassium-acetate-based chemical or a combination thereof, forming an extinguishing agent.

This extinguishing agent is a suitable alternative to the use of a dry chemical, especially when protecting commercial kitchen range hoods. There is less cleanup time after system discharge. Wet chemical solutions are considered to be relatively harmless and normally have no lasting effect on the skin or respiratory system. These solutions may produce temporary irritation, which is usually mild and disappears when contact is eliminated. These systems must be preengineered and labeled. NFPA 17A applies to the design, installation, operation, testing and maintenance of wet-chemical extinguishing systems.

WHEELCHAIR SPACE. A space for a single wheelchair and its occupant.

A wheelchair space is a designated space for a person to be stationary in his or her wheelchair as part of a fixed assembly seating configuration. The wheelchair space must be sized in accordance with ICC A117.1 (see Section 1108.2.4 for wheelchair space dispersion requirements for multievel assembly seating). ICC A117.1 provides additional dispersion criteria within a level (i.e., side-to-side, front-to-back and by type), depending on the number of seats provided in the assembly seating space.

WINDBORNE DEBRIS REGION. Areas within hurricane-prone regions located:

1. Within 1 mile (1.61 km) of the coastal mean high water line where the ultimate design wind speed, \( V_{10} \), is 130 mph (58 m/s) or greater; or

2. In areas where the ultimate design wind speed is 140 mph (63.6 m/s) or greater; or Hawaii.

For Risk Category II buildings and structures and Risk Category III buildings and structures, except health care facilities, the windborne debris region shall be based on Figure 1609A. For Risk Category IV buildings and structures and Risk Category III health care facilities, the windborne debris region shall be based on Figure 1609B.

This definition identifies those areas that require consideration of the impact of windborne debris on the building envelope (see the commentary to Sections 1609.1 and 1609.1.2 for information on the effects of openings in the building envelope). Note that Section 1609.3 makes Figure 1609B applicable to both Risk Category III and IV structures for obtaining the ultimate design wind speed. However, this definition of the windborne debris regions provides somewhat of an exception by allowing Figure 1609B to be used for establishing the windborne debris regions that are applicable to Risk Category III structures, other than health care facilities. This results in windborne debris regions applicable to Risk Category III (other than health care facilities) that are consistent with the areas that were defined in the prior editions of the code. At the same time, it should be noted that the windborne debris region established by Figure 1609B for Risk Category IV, as well as health care facilities that are Risk Category III, is an expansion of the windborne debris region defined in prior editions of the code.
WINDFORCE-RESISTING SYSTEM, MAIN. See "Main Windforce-Resisting System."

WIND SPEED, \( V_{ur} \). Ultimate design wind speeds.
- This term is needed to identify the mapped wind speed in Section 1609 which is one of the primary criteria for determination of wind loading.

WIND SPEED, \( V_{nr} \). Nominal design wind speeds.
- This term is used to identify wind speeds that are converted from the ultimate (mapped) wind speeds in accordance with Section 1609.3.1. Nominal wind speed is used as a wind criteria, rather than the ultimate wind speed, for requirements in Chapters 14, 15 and 23, for example.

WINDER. A tread with nonparallel edges.
- Winders are used as components of stairways that change direction, just as "fliers" (rectangular treads) are components in straight stairways. A winder performs the same function as a tread, but its shape allows the additional function of a gradual turning of the stairway direction. The tread depth of a winder at the walkline and the minimum tread depth at the narrow end control the turn made by each winder. Winders are not landings. Winder treads are limited to curved or spiral stairways with all groups but are all stairways within dwelling units (see Section 1009.7.3).

WIRE BACKING. Horizontal strands of tautened wire attached to surfaces of vertical supports which, when covered with the building paper, provide a backing for cement plaster.
- When metal lath attached to exterior wall studs is used as backing for a plaster base coat, additional reinforcing is necessary to stiffen the wall framing system and minimize unwanted movement to the wall itself. Plaster is a fairly rigid material and excessive movement will cause it to crack. Eighteen-gage metal wire attached horizontally to the face of the wall studs and covered with building paper will provide the additional stiffness required to minimize cracking in the finish surface (see Section 2510.5 for additional commentary on the requirements for wire backing).

[F] WIRELESS PROTECTION SYSTEM. A system or a part of a system that can transmit and receive signals without the aid of wire.
- These systems use radio frequency transmitting devices that comply with the special requirements for supervision of low-power wireless systems in NFPA 72. Wireless devices have the advantage of flexibility in positioning. Consequently, portable wireless notification devices are frequently used in existing facilities where visual devices are not present throughout.

WOOD SHEAR PANEL. A wood floor, roof or wall component sheathed to act as a shear wall or diaphragm.
- Wood shear panels are horizontal (diaphragms) or vertical (wood shear walls) panels, which transmit forces in the plane of the sheathing caused by lateral loads transmitted from one component of the structure to another. Wood shear panels usually consist of wood framing (studs or joists), either singly or doubly sheathed. The code has design provisions for shear panels that are sheathed with 4-foot by 8-foot (1219 mm by 2438 mm) wood structural panels.

WOOD STRUCTURAL PANEL. A panel manufactured from veneers, wood strands or wafer's or a combination of veneer and wood strands or wafers bonded together with waterproof synthetic resin or other suitable bonding systems. Examples of wood structural panels are:
- The code defines wood structural panels in terms of the materials commonly used in their manufacture. Wood structural panels intended for structural use must comply with DOC PS 1, DOC PS 2 or ANSI/ APA PRP 210 in accordance with Section 2303.1.4. These documents specify the required structural performance characteristics of wood structural panels, and detail the requirements for the third-party label each panel is required to bear (see Section 2303.1.4 for a more detailed discussion).

Composite panels. A wood structural panel that is comprised of wood veneer and reconstituted wood-based material and bonded together with waterproof adhesive;
- Composite panels are structural panels that are made up of a combination of wood veneers and wood-based materials. The wood veneer usually forms the two outer layers and may also be used in the core of the panel. These layers of veneer and wood flakes or strands, called "furnish," may be cross laminated.

Oriented strand board (OSB). A mat-formed wood structural panel comprised of thin rectangular wood strands arranged in cross-aligned layers with surface layers normally arranged in the long panel direction and bonded with waterproof adhesive; or
- Oriented strand board (OSB) is one of three types of wood structural panels. OSB panels are fabricated out of multiple layers made up of wood flakes or strands called "furnish." Like plywood, these layers of furnish are oriented at 90 degrees (1.57 rad) to each other. This gives OSB panels properties very similar to those of plywood.

Plywood. A wood structural panel comprised of plies of wood veneer arranged in cross-aligned layers. The plies are bonded with waterproof adhesive that cures on application of heat and pressure.
- Plywood is one of three types of wood structural panels. It is manufactured by gluing together three or more cross-laminated layers of wood veneer. The code does not differentiate between OSB and plywood, since manufacturing is done according to either the DOC PS 1 standard for construction and industrial plywood or for OSB, DOC PS 2 performance standard for wood-based structural panels.

[F] WORKSTATION. A defined space or an independent principal piece of equipment using HPM within a fabrication area where a specific function, laboratory procedure or
research activity occurs. Approved or listed hazardous materials storage cabinets, flammable liquid storage cabinets or gas cabinets serving a workstation are included as part of the workstation. A workstation is allowed to contain ventilation equipment, fire protection devices, detection devices, electrical devices and other processing and scientific equipment.

- Workstations further subdivide a fabrication area and provide relatively self-contained, specialized areas where HPM processes are conducted. Workstation controls limit the quantity of materials and impose limitations on the design of these processes to include, but not be limited to, protection by local exhaust; sprinklers; automatic and emergency shutoffs; construction materials and HPM compatibility. Excess materials are prohibited and must be contained in storage rooms designed to accommodate such hazards.

**WYTHE.** Each continuous, vertical section of a wall, one masonry unit in thickness.

- Sometimes referred to as a "leaf" or "tier," each wythe is one thickness of a masonry unit.

**YARD.** An open space, other than a court, unobstructed from the ground to the sky, except where specifically provided by this code, on the lot on which a building is situated.

- This definition is used, similar to the definition of "Court," to establish the applicability of code requirements when yards are utilized for natural light or natural ventilation purposes (see Section 1206.1). Whereas a court is bounded on three or more sides with the building or structure, a yard is bounded on two or less sides by the building or structure (see also the definition of "Egress court").

**Z** **ZONE.** A defined area within the protected premises. A zone can define an area from which a signal can be received, an area to which a signal can be sent or an area in which a form of control can be executed.

- Zoning a system is important to emergency personnel in locating a fire. When an alarm is designated to a specific zone, it allows the fire service to immediately respond to the area where the fire is in progress instead of searching the entire building for the origin of an alarm.

**ZONE, NOTIFICATION.** An area within a building or facility covered by notification appliances which are activated simultaneously.

- This definition is provided to clarify the code by making a clear distinction between fire alarm system initiation device zones required by Section 907.6.3 and the zones that may be designed into occupant notification device systems in a building. The term is used primarily in the exceptions for sprinkler systems found in the manual fire alarm system requirements in Section 907.2 and its subsections. Note that the code does not require audible and visible occupant notification device systems to be zoned; if such zones are provided, it is a matter of the system design engineer's judgment. The voice paging component in high-rise building emergency voice/alarm communication systems is, however, required to be zoned in accordance with Section 907.5.2.2.

DEFINITIONS

Chapter 3
Use and Occupancy Classification

General Comments

Chapter 3 provides for the classification of buildings, structures and parts thereof based on the purpose or purposes for which they are used.

Section 302 identifies the occupancy groups into which all buildings, structures and parts thereof must be classified.

Sections 303 through 312 identify the occupancy characteristics of each group classification. In some sections, specific group classifications having requirements in common are collectively organized such that one term applies to all. For example, Groups A-1, A-2, A-3, A-4 and A-5 are individual groups. The general term Group A, however, includes each of these individual groups. For this reason, each specific assembly group classification is included in Section 303.

Definitions play a key role in determining the occupancy classification. All definitions are located in Chapter 2. This chapter lists key definitions for classification of occupancies.

In the early years of building code development, the essence of regulatory safeguards from fire was to provide a reasonable level of protection to property. The idea was that if property was adequately protected from fire, then the building occupants would also be protected.

From this outlook on fire safety, the concept of equivalent risk has evolved in the code. This concept maintains that, in part, an acceptable level of risk against the damages of fire respective to a particular occupancy type (group) can be achieved by limiting the height and area of buildings containing such occupancies according to the building’s construction type (i.e., its relative fire endurance).

The concept of equivalent risk involves three interdependent considerations: (1) the level of fire hazard associated with the specific occupancy of the facility; (2) the reduction of fire hazard by limiting the floor areas and the height of the building based on the fuel load (combustible contents and burnable building components); and (3) the level of overall fire resistance provided by the type of construction used for the building.

The interdependence of these fire safety considerations can be seen by first looking at Tables 601 and 602, which show the fire-resistance ratings of the principal structural elements comprising a building in relation to the five classifications for types of construction. Type I construction is the classification that generally requires the highest fire-resistance ratings for structural elements, whereas Type V construction, which is designated as a combustible type of construction, generally requires the least amount of fire-resistance-rated structural elements. If one then looks at Table 503, the relationship among group classification, allowable heights and areas and types of construction becomes apparent. Respective to each group classification, the greater the fire-resistance rating of structural elements, as represented by the type of construction, the greater the floor area and height allowances. The greater the potential fire hazards indicated as a function of the group, the lesser the height and area allowances for a particular construction type.

As a result of extensive research and advancements in fire technology, today’s building codes are more comprehensive and complex regulatory instruments than they were in the earlier years of code development. While the principle of equivalent risk remains an important component in building codes, perspectives have changed and life safety is now the paramount fire issue. Even so, occupancy classification still plays a key part in organizing and prescribing the appropriate protection measures. As such, threshold requirements for fire protection and means of egress systems are based on occupancy classification (see Chapters 9 and 10).

Other sections of the code also contain requirements respective to the classification of building groups. For example, Section 102.6 deals with applicability of the code to existing structures; Section 705 deals with requirements for exterior wall fire-resistance ratings that are tied to the occupancy classification of a building and Section 803.9 contains interior finish requirements that are dependent upon the occupancy classification.

Purpose

The purpose of this chapter is to classify a building, structure or part thereof into a group based on the specific purpose for which it is designed or occupied. Throughout the code, group classifications are considered a fundamental principle in organizing and prescribing the appropriate features of construction and occupant safety requirements for buildings, especially general building limitations, means of egress, fire protection systems and interior finishes.
USE AND OCCUPANCY CLASSIFICATION

SECTION 301
GENERAL

301.1 Scope. The provisions of this chapter shall control the classification of all buildings and structures as to use and occupancy.

As used throughout the code, the classification of an occupancy into a group is established by the requirements of this chapter. The purpose of these provisions is to provide rational criteria for the classification of various occupancies into groups based on their relative fire hazard and life safety properties. This is necessary because the code utilizes group classification as a fundamental principle for differentiating requirements in other parts of the code related to fire and life safety protection.

SECTION 302
CLASSIFICATION

302.1 General. Structures or portions of structures shall be classified with respect to occupancy in one or more of the groups listed in this section. A room or space that is intended to be occupied at different times for different purposes shall comply with all of the requirements that are applicable to each of the purposes for which the room or space will be occupied. Structures with multiple occupancies or uses shall comply with Section 508. Where a structure is proposed for a purpose that is not specifically provided for in this code, such structure shall be classified in the group that the occupancy most nearly resembles, according to the fire safety and relative hazard involved.

2. Business (see Section 304): Group B
3. Educational (see Section 305): Group E
4. Factory and Industrial (see Section 306): Groups F-1 and F-2
6. Institutional (see Section 308): Groups I-1, I-2, I-3 and I-4
7. Mercantile (see Section 309): Group M
8. Residential (see Section 310): Groups R-1, R-2, R-3 and R-4
9. Storage (see Section 311): Groups S-1 and S-2
10. Utility and Miscellaneous (see Section 312): Group U

This section requires all structures to be classified in one or more of the groups listed according to the structure's purpose and function (i.e., its occupancy). By organizing occupancies with similar fire hazard and life safety properties into groups, the code has incorporated the means to differentiate occupancies such that various fire protection and life safety requirements can be rationally organized and applied. Each specific group has an individual classification. Each represents a different characteristic and level of fire hazard that requires special code provisions to lessen the associated risks. There are some group classifications that are very closely related to other specific groups and, therefore, are collectively referred to as a single group (e.g., Group F applies to Groups F-1 and F-2). In these cases, there are requirements within the code that are common to each specific group classification. These common requirements are applicable based on the reference to the collective classification. For example, the automatic sprinkler system requirement of Section 903.2.8 applies to each specific group classification (R-1, R-2, R-3 and R-4) listed under the term "Group R." Although many requirements applicable to a general occupancy classification are the same for all of the subclassifications with the occupancy group, there are enough differences to warrant the division of the general category into two or more specific classifications.

Example: Both a restaurant (Group A-2) and a church (Group A-3) are included in Group A, but they have different specific group classifications. Both Groups A-2 and A-3 are subject to the same travel distance limitations (see Table 1016.1) and corridor fire-resistance ratings (see Table 1018.1), but have different thresholds for when automatic sprinkler systems are required (see Section 903).

Buildings that contain more than one occupancy group are mixed occupancy buildings. Buildings with mixed occupancies must comply with one of the design options contained in Section 508. Options established in Section 508 include the regulation of the mixed-occupancy conditions as accessory occupancies, nonseparated occupancies or separated occupancies.

Occasionally, a building or space is intended to be occupied for completely different purposes at different times. For instance, a church hall might be used as a day care center during weekdays and as a reception hall for weddings and other similar events at other times. In these cases, the code provisions for each occupancy must be satisfied.

In cases where a structure has a purpose that is not specifically identified within any particular occupancy classification, that structure is to be classified within the group that it most closely resembles. Before an accurate classification can be made, however, a detailed description of the activities or processes taking place inside the building, the occupant load and the materials and equipment used and stored therein must be submitted to the building official. The building official must then compare this information to the various occupancy classifications, determine which one the building most closely resembles and classify the building as such.

Example: A designer presents the building official with a building needing an occupancy group classification. The building official is informed that the building is to be used as an indoor shooting gallery, open
to the public but used mostly by police officers. After reviewing the code, the official cannot find a specific reference to a shooting gallery in Sections 303 through 312 or in the associated tables. The building official asks the designer for additional information about the activities to be conducted in the building and is told that there will be a small sign-in booth, patron waiting/viewing area and the actual shooting area. Based on this information, the building official can determine that the most logical classification of the building is Group A-3, assembly. This classification is based on the fact that the building is used for the congregation of people for recreation. A shooting gallery is similar in many respects to a bowling center, which is classified as Group A-3 (see Figure 302.1).

SECTION 303
ASSEMBLY GROUP A

303.1 Assembly Group A. Assembly Group A occupancy includes, among others, the use of a building or structure, or a portion thereof, for the gathering of persons for purposes such as civic, social or religious functions; recreation, food or drink consumption or awaiting transportation.

Because of the arrangement and density of the occupant load associated with occupancies classified in the Group A assembly category, the potential for multiple fatalities and injuries from fire is comparatively high. For example, no other use listed in Section 302.1 contemplates occupant loads as dense as 5 square feet (0.46 m²) per person (see Table 1004.1.1). Darkened spaces in theaters, nightclubs and the like serve to increase hazards. In sudden emergencies, the congestion caused by large numbers of people rushing to exits can cause panic conditions. For these and many other reasons, there is a relatively high degree of hazard to life safety in assembly facilities. The relative hazards of assembly occupancies are reflected in the height and area limitations of Table 503 that are, in comparison, generally more restrictive than for buildings in other group classifications.

There are five specific assembly group classifications, Groups A-1 through A-5, described in this section. Where used in the code, the general term "Group A" is intended to include all five classifications.

The fundamental characteristics of all assembly occupancies are identified in this section. Structures that are designed or occupied for assembly purposes must be placed in one of the assembly group classifications. There are buildings and spaces that are used for assembly purposes, but are not classified as Assembly occupancies. The "exceptions" to this rule include small assembly buildings, tenant spaces and assembly spaces in mixed-use buildings. These exceptions to the Group A classification are addressed in Sections 303.1.1 through 303.1.4.

303.1.1 Small buildings and tenant spaces. A building or tenant space used for assembly purposes with an occupant load of less than 50 persons shall be classified as a Group B occupancy.

There are often small establishments that typically serve food and have a few seats that technically meet the definition of an assembly Group A occupancy but due to the low occupant load pose a lower risk than a typical assembly occupancy. These types of buildings and tenant spaces are to be considered as Group B occupancies when the occupant load is determined to be less than 50 persons. Examples of this include small "fast food" establishments and small "mom-and-pop" cafes or coffee shops.

303.1.2 Small assembly spaces. The following rooms and spaces shall not be classified as Assembly occupancies:

1. A room or space used for assembly purposes with an occupant load of less than 50 persons and accessory to another occupancy shall be classified as a Group B occupancy or as part of that occupancy.

2. A room or space used for assembly purposes that is less than 750 square feet (70 m²) in area and accessory to
another occupancy shall be classified as a Group B occupancy or as part of that occupancy.

- Assembly rooms or spaces within larger buildings that house other uses may be classified as other than Group A depending on occupant load or the size of the space. Where the occupant load of the assembly space is less than 50, or where the floor area of the space used for assembly purposes is less than 750 square feet (65 m²), a classification of other than Group A is permitted. In both cases, the purpose of the assembly space must be accessory to the principal occupancy of the structure (i.e., the activities in the assembly space are subordinate and secondary to the primary occupancy). If either the occupant load or floor area requirement is satisfied and the purpose of the assembly space is accessory to the principal occupancy, the space is permitted to either be classified as a Group B occupancy or as part of the principal occupancy. In either case, the assembly space is not required to be less than 10 percent of the area of the story on which it is located as is specified for accessory occupancies in Section 508.2 (IBC Interpretation No. 20-04).

The allowances given to assembly spaces in buildings containing multiple uses is a practical code consideration that permits a mixed-use condition to exist without requiring compliance with the provisions for mixed occupancies (see Section 508). Although the term "accessory" is used in describing the relationship of the uses, the intent of the term here is that the use of the space is related to, or part of, the main use of the space. These exceptions are not limited by the accessory use requirements found in Section 508.2.

**Example 1:** An office building, classified as a Group B occupancy, has a conference room used for staff meetings with an occupant load of 40 [see Figure 303.1.2(1)]. The occupancy classification of a conference room is generally considered a Group A-3. Since the occupant load of the conference room is less than 50 and its function is clearly accessory to the business area, the room is permitted to be classified the same as the main occupancy, Group B.

**Example 2:** A 749-square-foot (70 m²) assembly area is located adjacent to a mercantile floor area of 5,000 square feet (465 m²) [see Figure 303.1.2(2)]. Although the assembly area occupies 15 percent of the 5,000-square foot (465 m²) floor area, it does not exceed 750 square feet (70 m²) and is not considered a Group A occupancy, but rather is classified as part of the Group M occupancy.

![Figure 303.1.2(1) Accessory Assembly Use Limited by Occupant Load](image)

![Figure 303.1.2(2) Accessory Assembly Use Greater Than 10% of Floor Area But Less Than 750 Sq. Ft.](image)

For SI: 1 foot = 304.8 mm, 1 square foot = 0.0929 m².
303.1.3 Associated with Group E occupancies. A room or space used for assembly purposes that is associated with a Group E occupancy is not considered a separate occupancy.

- A typical educational facility for students in the 12th grade and below invariably contains many types of assembly spaces other than classrooms, including auditoriums, cafeterias, gymnasiums and libraries. These assembly spaces in a Group E building are not intended to be regulated as separate Group A occupancies, regardless of their floor area, but rather an extension of the Group E classification. It is worth mentioning, for these assembly functions to be considered part of the primary Group E occupancy, the assembly functions must be ancillary and supportive to the educational operation of the building. Otherwise, they would be classified into the appropriate Group A occupancy based upon their specific function. These assembly spaces, where classified as a portion of the Group E occupancy, are still considered as assembly in nature and must comply with assembly space requirements specified for accessibility and means of egress. However, often these school facilities are used for other functions such as a meeting of a community service organization or a community crafts fair. These types of uses fall outside of the intent of this section, and therefore such assembly spaces would need to be classified as a Group A.

303.1.4 Accessory to places of religious worship. Accessory religious educational rooms and religious auditoriums with occupant loads of less than 100 are not considered separate occupancies.

- Places of religious worship are listed as a Group A-3 occupancy. In addition to the worship hall, it is common for these facilities to contain smaller rooms used for educational activities. This provision allows such spaces to be considered as part of the Group A-3 classification rather than create a mixed-occupancy condition. For example, classrooms are normally classified as Group E if occupied by persons of ages through the 12th grade, or as Group B if the education is provided to adults. These types of classrooms could be considered as a part of the Group A-3 occupancy under the provisions of this section. It should be noted that this section does not modify the general provision requiring that assembly spaces are to be classified as Group A occupancies unless they have an occupant load of less than 50.

303.2 Assembly Group A-1. Assembly uses, usually with fixed seating, intended for the production and viewing of the performing arts or motion pictures including, but not limited to:

- Motion picture theaters
- Symphony and concert halls
- Television and radio studios admitting an audience
- Theaters

- Some of the characteristics of Group A-1 occupancies are large, concentrated occupant loads, low lighting levels, above-normal sound levels and a moderate fuel load.

Group A-1 is characterized by two basic types of activities. The first type is one in which the facility is occupied for the production and viewing of theatrical or operatic performances. Facilities of this type ordinarily have fixed seating; a permanent raised stage; a proscenium wall and curtain; fixed or portable scenery drops; lighting devices; dressing rooms; mechanical appliances or other theatrical accessories and equipment [see Figure 303.2(1)].

The second type is one in which the structure is primarily occupied for the viewing of motion pictures. Facilities of this type ordinarily have fixed seating, no stage, a viewing screen, motion picture projection booths and equipment [see Figure 303.2(2)].

Group A-1 presents a significant potential life safety hazard because of the large occupant loads and the concentration of people within confined spaces. The means of egress is an important factor in the design of such facilities. Theaters for the performing arts that require stages are considered particularly hazardous because of the amount of combustibles such as curtains, drops, scenery, construction materials and other accessories normally associated with stage operation. As such, special protection requirements applicable to stages and platforms are provided in Section 410 and Chapter 10.
303.3 Assembly Group A-2. Assembly uses intended for food and/or drink consumption including, but not limited to:

- Banquet halls
- Casinos (gaming areas)
- Nightclubs
- Restaurants, cafeterias and similar dining facilities (including associated commercial kitchens)
- Taverns and bars

- Group A-2 includes occupancies in which people congregate in high densities for social entertainment, including drinking and dancing (e.g., nightclubs, banquet halls, cabarets) and food and drink consumption (e.g., restaurants). The uniqueness of these occupancies is characterized by some or all of the following:
  - Low lighting levels;
  - Entertainment by a live band or recorded music generating above-normal sound levels;
  - No theatrical stage accessories;
  - Later-than-average operating hours;
  - Tables and seating arranged or positioned so as to create ill-defined aisles;
  - A specific area designated for dancing;
  - Service facilities for alcoholic beverages and food; and
  - High occupant load density.

The fire records are very clear in identifying that the characteristics listed above often cause a delayed awareness of a fire situation and confuse occupants regarding the appropriate response, resulting in an increased egress time and sometimes panic. Together, these factors may result in extensive life and property losses. These characteristics are only advisory in determining whether Group A-2 is the appropriate classification. Often there are additional characteristics that are unique to a project, which also must be taken into consideration when a classification is made.

Not all restaurants have all of these characteristics. Most fast food restaurants will only have two or three of these, yet they are appropriately classified as Group A-2.

Example: The Downtown Club, a popular local nightclub/dance hall, features a different band every weekend [see Figure 303.3]. It is equipped with a bar.
and basic kitchen facilities so that beverages and appetizers can be served. There is a platform for a band to perform, a dance floor in front of the platform and numerous cocktail tables and chairs. The tables and chairs are not fixed, resulting in a hazardous arrangement because there are no distinct aisles. When the band performs, the house lights are dimmed and spotlights are keyed in on the performers. The club is equipped with a sound system that is used at loud levels. The club is open until 3:00 a.m.—the latest time the local jurisdiction will allow.

From this description of the Downtown Club, one can readily see that the appropriate classification is Group A-2. Sometimes, however, it is not this easy to determine the appropriate classification. In such cases, the building official must seek additional information regarding the functions of the building and each area within the building.

Two of the specific uses listed as Group A-2 occupancies are typically not considered as facilities primarily used for food and/or drink consumption, however their classification as such has been deemed appropriate for varying reasons. The placement of casino gaming areas in the Group A-2 classification is because they share many hazard characteristics with nightclubs and, to some extent, the other uses in the category. The presence of distracting lights, sounds and decorations, along with the potential for alcohol consumption, create an assembly environment that is best addressed under the Group A-2 provisions. The classification is specific to the gaming areas of casino, therefore other related uses such as administrative, storage and lodging areas are to be individually classified based upon their specific use.

Commercial kitchens, when associated with a Group A-2 dining and drinking establishment, are also classified as Group A-2. Although commercial kitchens do not pose the same conditions and concerns as the other uses classified as Group A-2, their classification as such recognizes the relationship that exists between the dining and cooking areas. Providing a physical fire-resistive separation between the kitchen and the dining area that it serves is often found to be impractical. Assigning a single occupancy classification for both the commercial kitchen and its associated dining area eliminates any potential for an unnecessary mixed-occupancy condition. This single classification approach can also be applied where the occupant load of the dining area is below 50, allowing for a Group B classification. Under such circumstances, the kitchen would be considered an extension of the Group B dining facility. See also commercial kitchens in Group F-1.

303.4 Assembly Group A-3. Assembly uses intended for worship, recreation or amusement and other assembly uses not classified elsewhere in Group A including, but not limited to:

- Amusement arcades
- Art galleries
- Bowling alleys
- Community halls
- Courtrooms
- Dance halls (not including food or drink consumption)
- Exhibition halls
- Funeral parlors
- Gymnasiums (without spectator seating)
- Indoor swimming pools (without spectator seating)
- Indoor tennis courts (without spectator seating)
- Lecture halls
- Libraries
- Museums
- Places of religious worship
- Pool and billiard parlors
- Waiting areas in transportation terminals

Structures in which people assemble for the purpose of social activities (such as entertainment, recreation and amusement) that are neither classified in Group A-1 or A-2 nor appropriately classified in Group A-4 or A-5 are to be classified in Group A-3. Exhibition halls, libraries, dance halls (not including food and drink), places of religious worship, museums, gymnasiums, recreation centers, health clubs, fellowship halls, indoor shooting galleries, bowling centers and billiard halls are among the facilities often classified in Group A-3. Also, since they most nearly resemble this occupancy classification, public and private spaces used for assembly are often classified in Group A-3. These include large courtrooms, meeting rooms and conference centers. Similarly, lecture rooms located in colleges, universities or in schools for students above the 12th grade that have an occupant load of 50 or more are also classified in Group A-3, as well as structures in which people gather exclusively for worship and other religious purposes. Although such worship and religious purposes are without restriction to any particular sect or creed, the intent of the code is to limit Group A-3 classification to occupancies that are specifically related to worship services, devotions and religious rituals.

The fire hazard in terms of combustible contents (fuel load) in structures classified in Group A-3 is most often expected to be moderate to low. Since structures classified in Group A-3 vary widely as to the purpose for which they are used, the range of fuel load varies widely. For example, the fuel load in a library or an exhibition hall usually is considerably greater than that normally found in a gymnasium. While the code specifically addresses kitchens associated with Group A-2 restaurants and similar dining facilities, it is silent regarding accessory kitchens one might find associated with community centers or a fellowship hall of a place of religious worship. These kitchens should be considered carefully by the building official. Each facility and its use will be somewhat unique. The intensity and frequency of the use of the space for serving of food as well as the type of cooking equipment installed are important factors. The occasional use of the fellowship hall for a fundraising dinner where food is brought in and warmed is one end of the spectrum and may warrant keeping a Group A-3 classification. But when the same hall
303.5 Assembly Group A-4. Assembly uses intended for viewing of indoor sporting events and activities with spectator seating including, but not limited to:

- Arenas
- Skating rinks
- Swimming pools
- Tennis courts

Structures provided with spectator seating in which people assemble to watch an indoor sporting event are to be classified as Group A-4. Arenas, skating rinks, swimming pools and tennis courts are among the facilities often classified as Group A-4. The distinguishing factor between Group A-4 and A-5 structures is whether the event is indoors or outdoors. Group A-4 facilities are limited to indoor structures only. The distinguishing factor between Group A-4 and Group A-3 facilities is the presence of a defined seating area. While Group A-3 facilities are indoors (i.e., tennis courts, swimming pools), they typically do not have a defined seating area in which to view the event. Only facilities that are both indoors and have a defined seating area are to be classified as Group A-4.

303.6 Assembly Group A-5. Assembly uses intended for participation in or viewing outdoor activities including, but not limited to:

- Amusement park structures
- Bleachers
- Grandstands
- Stadiums

Structures classified in Group A-5 are outdoor facilities where people assemble to view or participate in social and recreational activities (e.g., stadiums, grandstands, bleachers, coliseums). In order to qualify as an outdoor facility, the structure must be one where the products of combustion are freely and rapidly vented to the atmosphere (i.e., a structure without enclosures that would prevent the free movement of smoke from the occupied area to the outside). Any recreation facility that has exterior walls that enclose the facility and a roof that fully covers the area would not be classified in Group A-5, but rather in Group A-3 or A-4 depending on whether a seating area has been provided. In the case of a structure with a retractable roof, the more stringent occupancy classification (i.e., Group A-4) would be required.

Since occupancies classified in Group A-5 are primarily viewing and sports participation areas, the fuel load associated with them is very low (i.e., the structure itself and seats). Since the fuel load present is relatively low and the expectation is that smoke will be quickly evacuated from the structure, the relative fire hazard of occupancies classified in Group A-5 is expected to be low. The life safety hazard from panic that might occur in an emergency, however, is a serious concern; hence, the capability of large crowds to exit the structure quickly and orderly during emergencies is an important design consideration (see Section 1028).

Both Group A-4 and A-5 occupancies will include a variety of uses that support the viewing of sports and similar activities. There will likely be luxury seating suites, locker rooms, toilet facilities and press boxes, which are clearly part of the overall use of the facility. There will also be offices, food concession stands and merchandise stands which by their use are different occupancies, but are probably within the accessory occupancy limits established in Section 508.2. Because of the multitenier design of most Group A-4 and A-5 occupancies, the limit for accessory occupancies to account for less than 10 percent of the story will need to be creatively applied. There may be full-fledged restaurants that are in the same building, but may be open to guests not limited to those attending an event. A Group A-2 occupancy designation is likely the most appropriate classification and the mixed-occupancy conditions would most typically be addressed under the accessory occupancy provisions of Section 508.2.

SECTION 304
BUSINESS GROUP B

304.1 Business Group B. Business Group B occupancy includes, among others, the use of a building or structure, or a portion thereof, for office, professional or service-type transactions, including storage of records and accounts. Business occupancies shall include, but not be limited to, the following:

- Airport traffic control towers
- Ambulatory care facilities
- Animal hospitals, kennels, and pounds
- Banks
- Barber and beauty shops
- Car wash
- Civic administration
- Clinic, outpatient
- Dry cleaning and laundries: pick-up and delivery stations and self-service
- Educational occupancies for students above the 12th grade
- Electronic data processing
- Laboratories: testing and research
- Motor vehicle showrooms
- Post offices
- Print shops
- Professional services (architects, attorneys, dentists, physicians, engineers, etc.)
- Radio and television stations
- Telephone exchanges
- Training and skill development not within a school or academic program

The risks to life safety in the business occupancy classification are relatively low. Exposure to the potential effects of fire is limited because business-type facilities most often have low fuel loads, are nor-
mally occupied only during the daytime and, with some exceptions, are usually occupied for a set number of hours. The occupants, because of the nature of the use, are typically alert, ambulatory, conscious, aware of their surroundings and generally familiar with the building's features, particularly the means of egress. Historically, this occupancy has one of the better fire safety records for the protection of life and property.

This section identifies the general characteristics and lists examples of occupancies that are classified in Group B. Note that the description recognizes the need for limited storage spaces that are incidental to office occupancies. Classrooms and laboratories that are located in colleges, universities and academies for educating students above the 12th grade and that have an occupant load of less than 50 are classified in Group B. Classrooms with an occupant load of 50 or more are classified in Group A-3 (see Section 303.4). When lecture facilities for large groups (i.e., occupant load of 50 or more) are located within the same building where classrooms with an occupant load less than 50 are found, the building is a mixed occupancy (Groups A-3 and B) and is subject to the provisions of Section 508.

While civic administration covers a broad range of state and local government buildings, many such buildings will have a variety of uses and need to be considered under mixed occupancy provisions. Frequently police stations will include jails or holding cells. Fire stations will be a mix of offices, parking and maintenance facilities for the fire engines and living spaces for the fire fighters. Often a meeting room that is open to the public is also included. This type of facility is a mix of Group A, B, R and S occupancies.

Ambulatory care facilities are those used to provide medical, or similar care, on less than a 24-hour basis to patients who are rendered incapable of self-preservation (see Section 202). Frequently called “day surgery centers” or “ambulatory surgical centers,” ambulatory care facilities perform procedures that render care recipients (patients) temporarily incapable of self-preservation due to the use of nerve blocks, sedation or anesthesia. Because of the condition of the care recipients, the need for medical staff to stabilize the patients before evacuation and the use of medical gases such as oxygen and nitrous oxide, these types of facilities pose greater fire and life safety hazards than other business occupancies. Accordingly, additional fire protection and means of egress requirements specific to ambulatory care are provided in Section 422.

Facilities that provide medical services for inpatient care where the care recipients (patients) stay for more than 24 hours would be classified as Group I-2. Buildings used as sleep clinics would be classified as Group B since these spaces are not typical dwelling or sleeping units where people live, the occupants are assumed to be capable of self-preservation and the occupants are not living in a supervised environment. Although the patients in a sleep clinic may be sleeping, they can be easily awakened and alerted to an emergency as compared to the patients at an ambulatory care facility.

Training and skill development is classified as a B occupancy due to the similarity in use of spaces to education above the 12th grade and with professional consultation. Often unions provide training facilities for their members so they can keep up with new materials and updates of regulations. Other facilities can provide one-on-one tutoring such as remedial reading or math skills for students. Where those receiving the training or skill development are of the ages typically associated with grades 12 or earlier, the determination of the appropriate classification requires the building official to consider whether the training is given to larger groups in a classroom setting or part of a traditional educational program. The presence of children does not automatically mean a classification as a Group E.

304.2 Definitions. The following terms are defined in Chapter 2:

AMBULATORY CARE FACILITY.

CLINIC, OUTPATIENT.

This section lists terms that are specifically associated with the subject matter of this section. It is important to emphasize that these terms are not exclusively related to this section but may or may not also be applicable where the term is used elsewhere in the code.

Definitions of terms can help in the understanding and application of the code requirements. The purpose for including a list within this chapter is to provide more convenient access to terms which may have a specific or limited application within this chapter. For the complete definition and associated commentary, refer back to Chapter 2. Terms that are italicized provide a visual identification throughout the code that a definition exists for that term. The use and application of all defined terms are set forth in Section 201.

SECTION 305
EDUCATIONAL GROUP E

305.1 Educational Group E. Educational Group E occupancy includes, among others, the use of a building or structure, or a portion thereof, by six or more persons at any one time for educational purposes through the 12th grade.

The risks to life safety in this occupancy vary with the composition of the facilities and also with the ages of the occupants. In general, children require more safeguards than do older, more mature persons.

This section identifies the criteria for classification of a building in Group E. The two fundamental characteristics of a Group E facility are as follows:

1. The facility is occupied by more than five persons (excluding the instructor); and
2. The purpose of the facility is for educating persons at the 12th-grade level and below, but not including more than five occupants 2½ years of age or less.

Occupancies used for the education of persons above the 12th grade level are not included in Group E. These facilities are occupied by adults who are not expected to require special supervision, direction or instruction in a fire or other emergency. By the same measure; however, they are also not closely supervised. Therefore, classrooms and laboratories located in colleges, universities and academies for students above the 12th grade are classified in Group B, because the occupancy characteristics and potential hazards to life safety present in these facilities more nearly resemble those of a business occupancy than educational occupancy. Please note, lecture halls for students above the 12th grade with an occupant load of 50 or more are classified in Group A-3 (see Section 303.4).

It is common for a school to also have gymnasiums (Group A-3), auditoriums (Group A-1), libraries (Group A-3), offices (Group B) and storage rooms (Group S-1). When this occurs, the building is considered as a mixed occupancy condition and is subject to the provisions of Section 508. In accordance with Section 303.1.3, assembly spaces, such as the gymnasium, auditorium, library and cafeteria, do not have to be considered separate occupancies if used for school purposes (see commentary, Section 303.1.3). For such assembly functions to be considered part of the primary Group E occupancy, the assembly functions must be ancillary and supportive to the educational operation of the building.

305.1.1 Accessory to places of religious worship. Religious educational rooms and religious auditoriums, which are accessory to places of religious worship in accordance with Section 303.1.4 and have occupant loads of less than 100, shall be classified as Group A-3 occupancies.

In places of religious worship, worship halls, religious educational rooms and religious auditoriums are often all provided in the same building complex. Such religious educational rooms and auditoriums are not to be considered separate occupancies (i.e., Group E) (see commentary, Section 303.1.4).

305.2 Group E, day care facilities. This group includes buildings and structures or portions thereof occupied by more than five children older than 2½ years of age who receive educational, supervision or personal care services for fewer than 24 hours per day.

Group E day care occupancies include facilities intended to be used for the care and supervision of more than five children older than 2½ years of age where individual care is for a period of less than 24 hours per day. Day care centers are a special concern since they are generally occupied by preschool children who are less capable of responding to an emergency. The hazards found in a day care center are far greater than in normal educational facilities, not so much because of the occupant or fuel load, but because of the inability of the occupants to respond. Per Section 1015.6 these day care facilities with more than 10 children must be provided with two means of egress.

Children 2½ years of age or less usually are not able to recognize an emergency situation, may not respond appropriately or simply may not be able to egress without assistance; thus, facilities that have more than five children 2½ years of age or less are classified as child care facilities and considered to be Group I-4 (see Section 308.6) unless the provisions of Sections 308.6.1 through 308.6.4 allow for a different classification.

305.2.1 Within places of religious worship. Rooms and spaces within places of religious worship providing such day care during religious functions shall be classified as part of the primary occupancy.

Cry rooms and other types of child care areas within places of worship need not be classified as Group E day care facilities. Such rooms and spaces may take on the classification of the primary occupancy, which in most cases would be Group A-3. The limited occupant load makes the need for classification as a Group E occupancy unnecessary.

305.2.2 Five or fewer children. A facility having five or fewer children receiving such day care shall be classified as part of the primary occupancy.

Where a child care facility has no more than five children receiving care at any one time, the classification of the main occupancy may extend to the child care use. The limited number of occupants requiring care services does not warrant classification as a separate and distinct occupancy from that of the major use.

305.2.3 Five or fewer children in a dwelling unit. A facility such as the above within a dwelling unit and having five or fewer children receiving such day care shall be classified as a Group R-3 occupancy or shall comply with the International Residential Code.

Where the child care services are performed within a single-family dwelling or within a dwelling unit of a two-family dwelling, residential provisions are applicable provided the number of children receiving care does not exceed five. The facility may be classified under the code as a Group R-3 occupancy or may be regulated under the provisions of the International Residential Code® (IRC®). Where this use occurs within a dwelling unit of a Group R-2 multi-family building, it is expected that the child care facility be considered as an extension of the Group R-2 classification as addressed in Section 305.2.2.

SECTION 306
FACTORY GROUP F

306.1 Factory Industrial Group F. Factory Industrial Group F occupancy includes, among others, the use of a building or
structure, or a portion thereof, for assembling, disassembling, fabricating, finishing, manufacturing, packaging, repair or processing operations that are not classified as a Group H hazardous or Group S storage occupancy.

- The purpose of this section is to identify the characteristics of occupancies that are classified in factory and industrial occupancies and to differentiate Groups F-1 and F-2.

Because of the vast number of diverse manufacturing and processing operations in the industrial community, it is more practical to classify such facilities by their level of hazard rather than their function. In industrial facilities, experience has shown that the loss of life or property is mostly directly related to fire hazards, particularly the fuel load contributed by the materials being fabricated, assembled or processed.

Statistics show that property losses are comparatively high in factory and industrial occupancies, but the record of fatalities and injuries from fires has been remarkably low. This excellent life safety record can, in part, be attributed to fire protection requirements of the code.

This section requires that all structures that are used for fabricating, finishing, manufacturing, packaging, assembling or processing products or materials are to be classified in either Group F-1 (moderate hazard) or F-2 (low hazard). These classifications are based on the relative level of hazard for the types of materials that are fabricated, assembled or processed. Where the products and materials in a factory present an extreme fire, explosion or health hazard, such facilities are classified in Group H (see Section 307). It should be noted that the term "Group F" is not a specific occupancy, but is a term that collectively applies to Groups F-1 and F-2.

### 306.2 Moderate-hazard factory industrial, Group F-1

Factory industrial uses which are not classified as Factory Industrial F-2 Low Hazard shall be classified as F-1 Moderate Hazard and shall include, but not be limited to, the following:

- Aircraft (manufacturing, not to include repair)
- Appliance
- Athletic equipment
- Automobiles and other motor vehicles
- Bakeries
- Beverages: over 16-percent alcohol content
- Bicycles
- Boats
- Brooms or brushes
- Business machines
- Cameras and photo equipment
- Canvas or similar fabric
- Carpets and rugs (includes cleaning)
- Clothing
- Construction and agricultural machinery
- Disinfectants
- Dry cleaning and dyeing
- Electric generation plants
- Electronics
- Engines (including rebuilding)
- Food processing and commercial kitchens not associated with restaurants, cafeterias and similar dining facilities
- Furniture
- Hemp products
- Jute products
- Launderies
- Leather products
- Machinery
- Metals
- Millwork (sash and door)
- Motion pictures and television filming (without spectators)
- Musical instruments
- Optical goods
- Paper mills or products
- Photographic film
- Plastic products
- Printing or publishing
- Recreational vehicles
- Refuse incineration
- Shoes
- Soaps and detergents
- Textiles
- Tobacco
- Trailers
- Upholstering
- Wood; distillation
- Woodworking (cabinet)

- Structures classified in Group F-1 (moderate hazard) are occupied for the purpose of fabrication, finishing, manufacturing, packaging, assembly or processing of materials that are combustible or that use combustible products in the production process.

### 306.3 Low-hazard factory industrial, Group F-2

Factory industrial uses that involve the fabrication or manufacturing of noncombustible materials which during finishing, packaging or processing do not involve a significant fire hazard shall be classified as F-2 occupancies and shall include, but not be limited to, the following:

- Beverages: up to and including 16-percent alcohol content
- Brick and masonry
- Ceramic products
- Foundries
- Glass products
- Gypsum
- Ice
- Metal products (fabrication and assembly)

- Structures classified in Group F-2 (low hazard) are occupied for the purpose of fabrication, manufacturing or processing of noncombustible materials. It is acceptable for noncombustible products to be packaged in a combustible material, provided that the fuel load contributed by the packaging is negligible when compared to the amount of noncombustible product. The use of a significant amount of combustible material to package or finish a noncombustible product, however, will result in a Group F-1 (moderate-
hazard factory and industrial) classification.

To distinguish when the presence of combustible packaging constitutes a significant fuel load, possibly requiring the reclassification of the building or structure as Group F-1, a reasonable guideline to follow is the "single thickness" rule, which is when a noncombustible product is put in one layer of packaging material.

Examples of acceptable conditions in Group F-2 include:
- Vehicle engines placed on wood pallets for transportation after assembly;
- Washing machines in corrugated cardboard boxes; and
- Soft-drink glass bottles packaged in pressed paper boxes.

Occupancies involving noncombustible items packaged in more than one layer of combustible packaging material are most appropriately classified in Group F-1.

Typical examples of packaging that would result in a Group F-1 classification include:
- Chinaware wrapped in corrugated paper and placed in cardboard boxes;
- Glassware set in expanded foam forms and placed in cardboard boxes; and
- Fuel filters individually packed in pressed paper boxes, placed by the gross in a cardboard box and stacked on a pallet for transportation.

Factories and industrial facilities often have offices and areas where large quantities of materials are kept in the same building as manufacturing operations, fabrication processes and assembly processes. The stock areas are classified as either Group S-1 or S-2, depending on the combustibility of the materials stored. Areas used for offices are classified in Group B. When these combinations of occupancies occur, as well as other combinations of occupancies, the building is subject to the mixed occupancy provisions in Section 508.

SECTION 307
HIGH-HAZARD GROUP H

[F] 307.1 High-hazard Group H. High-hazard Group H occupancy includes, among others, the use of a building or structure, or a portion thereof, that involves the manufacturing, processing, generation or storage of materials that constitute a physical or health hazard in quantities in excess of those allowed in control areas complying with Section 414, based on the maximum allowable quantity limits for control areas set forth in Tables 307.1(1) and 307.1(2). Hazardous occupancies are classified in Groups H-1, H-2, H-3, H-4 and H-5 and shall be in accordance with this section, the requirements of Section 415 and the International Fire Code. Hazardous materials stored, or used on top of roofs or canopies shall be classified as outdoor storage or use and shall comply with the International Fire Code.

Exceptions: The following shall not be classified as Group H, but shall be classified as the occupancy that they most nearly resemble.

1. Buildings and structures occupied for the application of flammable finishes, provided that such buildings or areas conform to the requirements of Section 416 and the International Fire Code.
2. Wholesale and retail sales and storage of flammable and combustible liquids in mercantile occupancies conforming to the International Fire Code.
3. Closed piping system containing flammable or combustible liquids or gases utilized for the operation of machinery or equipment.
4. Cleaning establishments that utilize combustible liquid solvents having a flash point of 140°F (60°C) or higher in closed systems employing equipment listed by an approved testing agency, provided that this occupancy is separated from all other areas of the building by 1-hour fire barriers constructed in accordance with Section 707 or 1-hour horizontal assemblies constructed in accordance with Section 711, or both.
5. Cleaning establishments that utilize a liquid solvent having a flash point at or above 200°F (93°C).
7. Refrigeration systems.
8. The storage or utilization of materials for agricultural purposes on the premises.
9. Stationary batteries utilized for facility emergency power, uninterruptable power supply or telecommunication facilities, provided that the batteries are provided with safety venting caps and ventilation is provided in accordance with the International Mechanical Code.
10. Corrosives shall not include personal or household products in their original packaging used in retail display or commonly used building materials.
11. Buildings and structures occupied for aerosol storage shall be classified as Group S-1, provided that such buildings conform to the requirements of the International Fire Code.
12. Display and storage of nonflammable solid and nonflammable or noncombustible liquid hazardous materials in quantities not exceeding the maximum allowable quantity per control area in Group M or S occupancies complying with Section 414.2.5.
13. The storage of black powder, smokeless propellant and small arms primers in Groups M and R-3 and special industrial explosive devices in Groups B, F, M and S, provided such storage conforms to the Institute of Electrical and Electronics Engineers (IEEE) standard.
USE AND OCCUPANCY CLASSIFICATION

quantity limits and requirements prescribed in the International Fire Code.

- This section identifies the various types of facilities contained in the high-hazard occupancy. This occupancy classification relates to those facilities where the storage of materials or the operations are deemed to be extremely hazardous to life and property, especially when they involve the use of significant amounts of highly combustible, flammable or explosive materials, regardless of their composition (i.e., solids, liquids, gases or dust). Although they are not explosive or highly flammable, other hazardous materials, such as corrosive liquids, highly toxic materials and poisonous gases, still present an extreme hazard to life. Many materials possess multiple hazards, whether physical or health related.

There is a wide range of high-hazard operations in the industrial community; therefore, it is more practical to categorize such facilities in terms of the degree of hazard they present, rather than attempt to define a facility in terms of its function. This method is similar to that used to categorize factory (see Section 306) and storage (see Section 311) occupancies.

Group H is handled as a separate classification because it represents an unusually high degree of hazard that is not found in the other occupancies. It is important to isolate those industrial or storage operations that pose the greatest dangers to life and property and to reduce such hazards by providing systems or elements of protection through the regulatory provisions of building codes.

There are numerous provisions and exceptions throughout the code that cannot be used when one or more Group H occupancies are present.

Operations that, because of the materials utilized or stored, cause a building or portion of a building to be classified as a high-hazard occupancy are identified in this section. While buildings classified as Group H may not have a large occupant load, the unstable chemical properties of the materials contained on the premises constitute an above-average fuel load and serve as a potential danger to the surrounding area.

The dangers created by the high-hazard materials require special consideration for the abatement of the danger. The classification of a material as high hazard is based on information derived from National Fire Protection Association (NFPA) standards and the Code of Federal Regulations (DOL 29 CFR).

The wide range of materials utilized or stored in buildings creates an equally wide range of hazards to the occupants of the building, the building proper and the surrounding area. Since these hazards range from explosive to corrosive conditions, the high-hazard occupancy has been broken into four subcategories: Groups H-1 through H-4. A fifth category, Group H-5, is used to represent structures that contain hazardous production material (HPM) facilities.

Each of these subcategories addresses materials that have similar characteristics and the protection requirements attempt to address the hazard involved. These subcategories are defined by the properties of the materials involved with only occasional reference to specific materials. This performance-based criterion may involve additional research to identify a hazard, but it is the only way to remain current in a rapidly changing field. Material Safety Data Sheets (MSDS) will be a major source for information.

Additional information on hazardous materials can be found in Section 415 as well as the commentary to the International Fire Code® (IFC®).

Section 307.1 acknowledges that a building is not classified as a high-hazard occupancy unless the maximum allowable quantities per control area as prescribed in Tables 307.1(1) and 307.1(2) are exceeded, subject to the applicable control area provisions of Section 414.2. The maximum quantity limitations per control area prescribed in Tables 307.1(1) and 307.1(2) have been determined to be relatively safe when maintained in accordance with the IFC. Therefore, a building containing less than the maximum allowable quantities specified in Tables 307.1(1) and 307.1(2) would not be classified as a Group H occupancy but rather as the occupancy group it most nearly resembles. The materials in these tables, which are listed in Section 307.2 are defined in detail in Section 202.

Section 414.2 establishes the control area concept for regulating hazardous materials. This concept would allow the maximum allowable quantities of hazardous materials per control area in Tables 307.1(1) and 307.1(2) to be exceeded within a given building without classifying the building as a high-hazard occupancy by utilizing a multiple control area approach. The permitted number of control areas, maximum percentage of allowable quantities of hazardous materials per control area and degree of fire separation between control areas is regulated by Section 414.2 (see commentary, Section 414.2).

Section 307.1 also clarifies that hazardous materials outside of the building envelope should be classified as outdoor storage. As such, hazardous material quantities on roofs or canopies are not included in evaluating the occupancy classification of a building or structure. Canopies used to support gaseous hydrogen systems must comply with Section 406.7.2.1.

The exceptions list uses and conditions that are exempt from a high-hazard (Group H) classification because of the building's construction, use, the packaging of materials, the quantity of materials or the precautions taken to prevent fire. Even if a high-hazard material meets one of the exceptions, its storage and use must comply with the applicable provisions of Section 414 and the IFC.

Exception 1 exempts spray painting and similar
USE AND OCCUPANCY CLASSIFICATION

operations within buildings from being classified as a high-hazard occupancy. This exception requires that all such operations, as well as the handling of flammable finishes, are in accordance with the provisions of Section 416 and the IFC; therefore, an adequately protected typical paint spray booth in a factory (Group F-1) would not result in a high-hazard occupancy classification for either the building or the paint spray area.

Exception 2 relies on the provisions of Section 3404.3.4.1 of the IFC to regulate the storage of flammable and combustible liquids for wholesale and retail sales and storage in mercantile occupancies. The overall permitted amount of flammable and combustible liquids is dependent on the class of liquid, storage arrangement, container size and level of sprinkler protection. For nonsprinklered buildings, the maximum allowable quantity per control area permitted by Table 3404.3.4.1 of the IFC is 1,600 gallons (6057 L) of Class IB, IC, II, and IIIA liquids with a maximum of 60 gallons (227 L) of Class IA liquids. Depending on storage and ceiling heights, buildings equipped with a sprinkler system with a minimum design density for an Ordinary Hazard Group 2 occupancy may have an aggregate total of 7,500 gallons (28 391 L) of Class IB, IC, II, and IIIA liquids with a maximum of 60 gallons (227 L) of Class IA liquids. The quantities of Class IB, IC, II and IIIA liquids could be further increased depending on the potential storage conditions and enhanced degree of sprinkler protection. (See Section 3403.4.3.1 of the IFC for additional design information.) Again, it should be noted, that despite the increased quantities which far exceed the base quantity limitations of Table 307.1(1), compliance with this exception would result in the building not being classified as a Group H occupancy.

Exception 3 exempts closed systems that are used exclusively for the operation of machinery or equipment. The closed piping systems, which are essentially not open to the atmosphere, keep flammable or combustible liquids from direct exposure to external sources of ignition as well as prevent the users from coming in direct contact with liquids or harmful vapors. This exception would include systems such as oil-burning equipment, piping for diesel fuel generators and LP-gas cylinders for use in forklift trucks.

Exception 4 exempts cleaning establishments that utilize a closed system for all combustible liquid solvents with a flash point at or above 140°F (60°C). The reference to using equipment listed by an approved testing laboratory does not mean that the entire system needs to be approved, but rather the individual pieces of equipment. As with any mechanical equipment or appliance, it should bear the label of an approved agency and be installed in accordance with the manufacturer's installation instructions [see the International Mechanical Code® (IMC®)].

Exception 5 covers cleaning establishments that use solvents that have very high flash points [at least 200°F (93°C)] and that are exceedingly difficult to ignite. Such liquids can be used openly, but with due care.

Exception 6 exempts all retail liquor stores and liquor distribution facilities from the high-hazard occupancy classification, even though most of the contents are considered combustible liquids. The exception takes into account that alcoholic beverages are packaged in individual containers of limited size.

Exception 7 refers to refrigeration systems that utilize refrigerants that may be flammable or toxic.

Refrigeration systems do not alter the occupancy classification of the building, provided they are installed in accordance with the IMC. The IMC has specific limitations on the quantity and type of refrigerants that can be used, depending on the occupancy classification of the building.

Exception 8 exempts materials that are used for agricultural purposes, such as fertilizers, pesticides, and fungicides, when used on the premises. Agricultural materials stored for direct or immediate use are not usually of large enough quantity that would constitute a large fuel load or an exceptionally hazardous condition.

Exception 9 addresses battery storage rooms when used as part of an operating system, such as for providing standby power. The batteries used in installations of this type do not represent a significant health, safety or fire hazard. The electrolyte and battery casing contribute little fuel load to a fire. The release of hydrogen gas during the operation of battery systems is minimal. Ventilation in accordance with the IMC will disperse the small amounts of liberated hydrogen. This exception also assumes that rooms containing stationary storage battery systems are in compliance with Section 608 of the IFC.

Without Exception 10 certain products that technically are corrosive could cause grocery stores and other mercantile occupancies to be inappropriately classified as Group H-4. This exception allows the maximum allowable quantity per control area in Table 307.1(2) for corrosives to be exceeded in the retail display area. This would include such things as bleaches, detergents and other household cleaning supplies in normal-size containers. The exception also exempts the storage or manufacture of commonly used building materials, such as Portland cement, from being inappropriately classified as Group H.

Exception 11 exempts buildings and structures used for the storage of aerosol products, provided they are protected in accordance with the provisions of NFPA 30B and the IFC. The aerosol storage requirements in the IFC, referred to in this exception, are based on the provisions of NFPA 30B. Compliance with the exception exempts buildings from com-
plying with the code provisions for Group H, provided the storage of aerosol products comply with the applicable separation, storage limitations and sprinkler design requirements specified in the IFC and NFPA 30B.

Exception 12 permits certain products found in mercantile and storage occupancies, which may be comprised of hazardous materials, to exceed the maximum allowable quantity per control area of Tables 307.1(1) and 307.1(2). The products, however, must be comprised of nonflammable solids or liquids that are nonflammable or noncombustible. Materials could include swimming pool chemicals, which are typically Class 2 or 3 oxidizers or industrial corrosive cleaning agents (see commentary, Section 414.2.5).

Exception 13 permits the base maximum allowable quantity per control area of black powder, smokeless propellant and small arms primers in Group M and R-3 occupancies to be exceeded, provided the material is stored in accordance with Chapter 33 of the IFC. The requirements are based on the provisions in NFPA 495. Similarly, special industrial explosive devices are found in a number of occupancies other than Group H (Groups B, F, M and S). Storage of these devices in accordance with the IFC is not required to have a high-hazard occupancy classification. Power drivers are commonly used in the construction industry, and there are stocks of these materials maintained for sale and use by the trade. The automotive airbag industry has evolved with the use of these devices, and they are located in automotive dealerships and personal use vehicles throughout society. The IFC currently exempts up to 50 pounds (23 kg) of these materials from regulation under Chapter 33 (explosives).

**TABLE 307.1(1).** See page 3-17.

The maximum allowable quantities (MAQ) of high-hazard materials allowed in each control area before having to classify a part of the (or the entire) building as a high-hazard occupancy are given in the table. This table is referenced in Section 307.1. The materials listed in this table (see Chapter 2 for definitions of the materials) are classified according to their specific occupancy in Sections 307.3 through 307.5. This table only contains materials applicable to Groups H-1, H-2 and H-3. The maximum allowable quantities per control area for Group H-4 materials are listed in Table 307.1(2).

The presence of any one of the materials listed in Table 307.1(1) in an amount greater than allowed requires that the building or area in which the material is contained be classified as a Group H, high-hazard occupancy.

If a building or area contains only the materials listed in either Table 307.1(1) or 307.1(2) in the maximum allowable quantity per control area or less, then that building or area would not be classified as a Group H, high-hazard occupancy. The possible increase in overall danger that might exist should this occur because of the storage and use of incompatible materials is an issue that the code does not specifically address. In such situations, the building official can seek the advice of chemical engineers, fire protection engineers, fire service personnel or other experts in the use of hazardous materials. Based on their advice, the building official can deem the building a high-hazard occupancy.

Table 307.7(1) is subdivided based on whether the material is in storage or in use in a closed or open system. Definitions of both closed and open systems are found in Section 202. Within these subdivisions, the appropriate maximum allowable quantity per control area is listed in accordance with the physical state (solid, liquid or gas) of the material. A column for gas in open systems is not indicated because hazardous gaseous materials should not be allowed in a system that is continuously open to the atmosphere. While hazardous materials within a closed or open system are considered to be in use, Note b clearly indicates that the aggregate quantity of hazardous materials in use and storage within a given control area should not exceed the quantity listed in Table 307.7(1) for storage. Without Note c, many common alcoholic beverages and household products containing a negligible amount of a hazardous material could result in a Group M occupancy being classified as a high hazard. Note c recognizes the reduced hazard of the materials based on their water miscibility and limited container size.

Notes d and e of Table 307.1(1) are significant in that, for certain materials, the maximum allowable amount may be increased due to the use of approved hazardous material storage cabinets, where the building is fully protected by an automatic sprinkler system, or both. The notes are intended to be cumulative in that up to four times the base maximum quantity may be allowed per control area, if both sprinklered and in cabinets, without classifying the building as Group H. While the use of cabinets is not always a feasible or practical method of storage, they do provide additional protection to warrant an increase if provided. Construction requirements for hazardous material storage cabinets are contained in the IFC. Note that the use of day boxes, gas cabinets, exhausted enclosures or listed safety cans would allow the same increase as for cabinets. Listed safety cans, which are primarily intended for flammable and combustible liquids, must be in compliance with UL 30 when used to increase the maximum allowable quantities permitted by Table 307.1(1).

While classified as a hazardous material, the code recognizes the relative hazard of Class IIIIB liquids as compared to that of other flammable and combustible liquids by establishing a base maximum allowable
USE AND OCCUPANCY CLASSIFICATION

quantity per control area of 13,200 gallons (49,962 L).
As indicated in Note f, the quantity of Class I oxidizers
and Class III B liquids would not be limited, provided
the building is fully sprinkled in accordance with
NFPA 13. Since any building that exceeds this maxi-

mum amount would be required to be classified as
Group H and these buildings are required to be sprin-
klered, the maximum allowable amount would then
be unlimited. As such, a Group H classification would
not be warranted. The hazard presented by Class I
oxidizers is that they slightly increase the burning rate
of combustible materials that they may come into
contact with during a fire. Class III B combustible liq-
uids have flash points at or above 200°F (93°C).
Motor oil is a typical example of a Class III B com-

bustible liquid.

Note g recognizes that the hazard presented by
certain materials is such that they may be stored or
used only inside buildings that are fully sprinklered.

Note h clarifies for the user that while there is a
combination maximum allowable quantity for flamma-
ble liquids, no individual class of liquid (Class I, IA, IB
or IC) may exceed its own individual maximum allow-
able quantity.

Note i is a specific exception for inside storage
tanks of combustible liquids that are connected to a
fuel-oil piping system in accordance with Section
603.3.2 of the IFC. This exception applies to most oil-

fired stationary equipment, whether in industrial, com-

mercial or residential occupancies. NFPA 31 and
NFPA 37 provide further guidance on the type of
installations this exception is intending to permit. This
exception would permit fuel-oil storage tanks contain-
ing a maximum of 660 gallons (2498 L) of combust-
ible liquids within a building without being classified as
a Group H-3 occupancy. This quantity limitation could
be further increased to 3,000 gallons (11,356 L) for
combustible liquids stored in protected above-ground
tanks in rooms protected by an automatic sprinkler
system complying with NFPA 13.

Note k permits a larger amount of Class 3 oxidizers
in a building when used for maintenance and sanita-
tion purposes. An example is the use of 51 percent
hydrogen peroxide (H₂O₂) during industrial-scale food
production operations. In a diluted form, 51 percent
hydrogen peroxide is used for disinfecting piping sys-
tems and machinery used for manufacturing and
packaging dairy products, such as ice cream, cheese
and milk, to effectively sterilize all surfaces that are in
contact with these milk products. The method used to
store the oxidizers is subject to the evaluation and
approval of the building official. Note k also provides
consistency with Note k of Table 2703.1.1(1) of the
IFC.

Note l clarifies that the 125 pounds (57 kg) of stor-
age permitted for consumer fireworks represents the
net weight of the pyrotechnic composition of the fire-
works in a nonsprinklered building. This amount rep-
resents approximately 121/2 shipping cases (less than

one and one-half pallet loads) of fireworks in a non-
sprinklered storage condition. In cases where the net
weight of the pyrotechnic composition of the fire-
works is unknown, 25 percent of the gross weight of the
fireworks is to be used. The gross weight is to include
the weight of the packaging.

Note n provides an exception when the amount of
hazardous material in storage and display in Group M
and S occupancies meet the requirements of Section
414.2.5.

Note o clarifies that densely packed baled cotton is
not considered a hazardous material when meeting
the size and weight requirements of ISO 8115 and,
as such, is not subject to the maximum allowable
quantity per control area specified for combustible
fibers.

Note p clarifies that vehicles with closed fuel sys-
tems should be treated no differently than machinery
or equipment when considering the allowable quanti-
ties of materials within a building. This note also clari-
ifies that the fuels contained within the fuel tanks of
vehicles or motorized equipment are not to be consid-
ered when calculating the aggregate quantity of haz-
ardous materials within a control area of a building.
For example, when evaluating a parking garage with
several hundred cars parked inside, the fuel tanks of
vehicles are not counted. When motorized equip-
ment, such as a floor buffer or forklift, is used, those
fuels are not included as long as other code require-
ments are satisfied.

Note q directs code users to Section 414.1.3 in an
effort to determine the appropriateness of a Group H-
2 classification for facilities where combustible dust
is manufactured, generated or used. The presence of
combustible dust may or may not result in a high-haz-
ard condition. In order to determine if a potential dust
hazard exists that would warrant a Group H-2 occu-
pancy classification, the conditions must be evalu-
ated and a report submitted to the building official that
sets forth a determination of the degree of hazard
and recommended safeguards, including the appro-
priate occupancy classification.

**TABLE 307.1(2).** See page 3-19.

Table 307.1(2), similar to Table 307.1(1), specifies
the maximum quantities of hazardous materials, liq-
uids or chemicals allowed per control area before
having to classify building, or a portion of a building,
as a high-hazard occupancy. Table 307.1(2), as ref-
ereved in Section 307.1, contains materials classi-
ified as Group H-4 in accordance with Section 307.6.
While the materials listed in this table are considered
health hazards, some materials may also possess
physical hazard characteristics more indicative of
materials classified as Group H-1, H-2 or H-3.
The maximum allowable quantities per control area
listed in Table 307.1(2) are indicative of industry prac-
tice and assume the materials are properly stored
and handled in accordance with the IFC. Group H-4

2012 INTERNATIONAL BUILDING CODE® COMMENTARY
USE AND OCCUPANCY CLASSIFICATION

materials, while indeed hazardous, are primarily considered a handling problem and do not possess the same fire, explosion or reactivity hazard associated with other hazardous materials. The base maximum allowable quantity per control area of 810 cubic feet (23 m³) for gases that are either corrosive or toxic is based on a standard-size chlorine cylinder. The use of 150 pounds (68 kg) as the baseline quantity for liquefied corrosive and toxic gases is intended to be consistent with the philosophical approach to the same maximum quantity permitted for liquefied oxidizing gases in Table 307.1(1). The 150-pound (68 kg) limitation allows a single cylinder of chlorine, which could be considered both a corrosive and oxidizing gas, to not result in either a Group H-3 or H-4 occupancy classification.

Without Note b, many common household products, such as household bleach and window clean-
ers, containing a negligible amount of a hazardous material could result in a Group M occupancy being classified as a high hazard. Note b recognizes the reduced hazard of the materials based on their water miscibility and limited container size.

Note c provides an exception when the amount of hazardous material in storage and display in Group M and S occupancies meets the requirements of Section 414.2.5.

Note d clearly indicates that the aggregate quantity of hazardous materials in use and storage, within a given control area, cannot exceed the quantity listed in the table for storage. Notes e and f are identical to Notes d and e to Table 307.1(1) and allow up to four times the maximum allowed quantities. See the commentary for Notes d and e of Table 307.1(1).

Note g is significant in that, for certain materials,

For SI: 1 cubic foot = 0.028 m³, 1 pound = 0.454 kg, 1 gallon = 3.785 L.
NL = Not Limited; N/A = Not Applicable; UD = Unclassified Detectors

a. For use of control areas, see Section 414.2.
b. The aggregate quantity in use and storage shall not exceed the quantity listed for storage.
c. The quantities of alcoholic beverages, in retail and wholesale sales operations, shall not be limited provided the liquids are packaged in individual containers not exceeding 1.3 gallons. In retail and wholesale sales operations, the quantities of medicines, foodstuffs, consumer or industrial products, and other goods containing not more than 50 percent by volume of water-miscible liquids with the remainder of the solutions not being flammable, shall not be limited, provided that such materials are packaged in individual containers not exceeding 1.3 gallons.
d. Maximum allowable quantities shall be increased 100 percent in buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1. Where Note e also applies, the increase for both notes shall be applied accumulatively.
e. Maximum allowable quantities shall be increased 100 percent when stored in approved storage cabinets, day boxes, gas cabinets or exhausted enclosures or in listed safety cans in accordance with Section 5003.9.10 of the International Fire Code. Where Note d also applies, the increase for both notes shall be applied accumulatively.
f. The permitted quantities shall not be limited in buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1.
g. Permitted only in buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1.
h. Containing not more than the maximum allowable quantity per control area of Class IA, IB or IC flammable liquids.
i. The maximum allowable quantity shall not apply to fuel oil storage complying with Section 603.3.2 of the International Fire Code.
j. Quantities in parentheses indicate quantity units in parenthesis at the head of each column.
k. A maximum quantity of 200 pounds of solid or 20 gallons of liquid Class 3 oxidizers is allowed when such materials are necessary for maintenance purposes, operation or sanitation of equipment. Storage containers and the manner of storage shall be approved.
l. Net weight of the pyrotechnic composition of the fireworks. The net weight of the pyrotechnic composition of the fireworks is not known, 25 percent of the gross weight of the fireworks, including packaging, shall be used.
m. For gallons of liquids, divide the amount by 10 in accordance with Section 5003.1.2 of the International Fire Code.
n. For storage and display quantities in Group M and storage quantities in Group S occupancies complying with Section 414.2.5, see Tables 414.2.5(1) and 414.2.5(2).
o. Densely packed baled cotton that complies with the packing requirements of ISO 8115 shall not be included in this material class.
p. The following shall not be included in determining the maximum allowable quantities:
   1. Liquid or gaseous fuel in fuel tanks on vehicles.
   2. Liquid or gaseous fuel in fuel tanks on motorized equipment operated in accordance with this code.
   4. Liquid fuels in piping systems and fixed appliances regulated by the International Mechanical Code.
q. Where manufactured, generated or used in such a manner that the concentration and conditions create a fire or explosion hazard based on information prepared in accordance with Section 414.1.3.

</tbody>
</table>

For SI: 1 cubic foot = 0.028 m³, 1 pound = 0.454 kg, 1 gallon = 3.785 L.

- **a.** For use of control areas, see Section 414.2.
- **b.** In retail and wholesale sales occupancies, the quantities of medicines, foodstuffs, consumer or industrial products, and cosmetics, containing not more than 50 percent by volume of water-miscible liquids and with the remainder of the solutions not being flammable, shall not be limited, provided that such materials are packaged in individual containers not exceeding 1.3 gallons.
- **c.** For storage and display quantities in Group M and storage quantities in Group S occupancies complying with Section 414.2.5, see Tables 414.2.5(1) and 414.2.5(2).
- **d.** The aggregate quantity in use and storage shall not exceed the quantity listed for storage.
- **e.** Maximum allowable quantities shall be increased 100 percent in buildings equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1. Where Note f also applies, the increase for both notes shall be applied accumulatively.
- **f.** Maximum allowable quantities shall be increased 100 percent when stored in approved storage cabinets, gas cabinets or exhausted enclosures as specified in the International Fire Code. Where Note e also applies, the increase for both notes shall be applied accumulatively.
- **g.** Allowed only when stored in approved exhausted gas cabinets or exhausted enclosures as specified in the International Fire Code.
- **h.** Quantities in parenthesis indicate quantity units in parenthesis at the head of each column.
- **i.** For gallons of liquids, divide the amount in pounds by 10 in accordance with Section 5003.1.2 of the International Fire Code.

Their hazard is so great that their maximum allowable quantity per control area may be stored in the building only when approved exhausted enclosures or gas cabinets are utilized.

**[F] 307.1.1 Hazardous materials.** Hazardous materials in any quantity shall conform to the requirements of this code, including Section 414, and the International Fire Code.

- **The use of high-hazard materials must be regulated in accordance with Sections 414 and 415 as well as the applicable requirements of the IFC. While the building may be exempt from a high-hazard occupancy classification (i.e., Group H-1, H-2, H-3, H-4 or H-5), any potential hazard with regard to the use of storage of any hazardous material, regardless of quantity, must be abated.**

This section lists terms that are specifically associated with the subject matter of this section. It is important to emphasize that these terms are not exclusively related to this section but may or may not also be applicable where the term is used elsewhere in the code.

Definitions of terms can help in the understanding and application of the code requirements. The purpose for including a list within this chapter is to provide more convenient access to terms which may have a specific or limited application within this chapter. For the complete definition and associated commentary, refer back to Chapter 2. Terms that are italicized provide a visual identification throughout the code that a definition exists for that term. The use and application of all defined terms are set forth in Section 201.

[F] 307.3 High-hazard Group H-1. Buildings and structures containing materials that pose a detonation hazard shall be classified as Group H-1. Such materials shall include, but not be limited to, the following:

Detonable pyrophoric materials
Explosives:
  Division 1.1
  Division 1.2
  Division 1.3
  Division 1.4
  Division 1.5
  Division 1.6

Organic peroxides, unclassified detonable
Oxidizers, Class 4
Unstable (reactive) materials, Class 3 detonable and Class 4

The contents of occupancies in Group H-1 present a detonation hazard. Examples of materials that create this hazard are listed in the section. The definitions for Group H-1 materials are listed in Section 307.2 and defined in Chapter 2. Because of the explosion hazard potential associated with Group H-1 materials, occupancies in Group H-1, which exceed the maximum allowable quantity per control area indicated in Table 307.1(1), are required to be located in detached one-story buildings without basements (see
commentary, Sections 415.5.2, 415.6 and 508.3). Group H-1 occupancies cannot be located in a mixed occupancy building.

[F] 307.3.1 Occupancies containing explosives not classified as H-1. The following occupancies containing explosive materials shall be classified as follows:

1. Division 1.3 explosive materials that are used and maintained in a form where either confinement or configuration will not elevate the hazard from a mass fire to mass explosion hazard shall be allowed in H-2 occupancies.

2. Articles, including articles packaged for shipment, that are not regulated as a Division 1.4 explosive under Bureau of Alcohol, Tobacco, Firearms and Explosives regulations, or unpatched articles used in process operations that do not propagate a detonation or deflagration between articles shall be allowed in H-3 occupancies.

✧ There are certain explosive materials that pose a hazard level less than than anticipated for a Group H-1 occupancy. A Group H-2 classification is permitted for Division 1.3 explosive materials used or maintained under conditions where the hazard level will not rise from that of a mass fire hazard to a mass explosion hazard. A Group H-3 occupancy classification is permitted for packaged and unpatched articles not regulated as Division 1.4 explosives by the Bureau of Alcohol, Tobacco and Firearms, as well as unpatched articles used in process operations, provided there is no concern regarding the propagation of a detonation or deflagration between the articles during process operations.

[F] 307.4 High-hazard Group H-2. Buildings and structures containing materials that pose a deflagration hazard or a hazard from accelerated burning shall be classified as Group H-2. Such materials shall include, but not be limited to, the following:

Class I, II or IIIA flammable or combustible liquids which are used or stored in normally open containers or systems, or in closed containers or systems pressurized at more than 15 psi (103.4 kPa) gage

Combustible dusts where manufactured, generated or used in such a manner that the concentration and conditions create a fire or explosion hazard based on information prepared in accordance with Section 414.1.3

Cryogenic fluids, flammable

Flammable gases

Organic peroxides, Class I

Oxidizers, Class 3, that are used or stored in normally open containers or systems, or in closed containers or systems pressurized at more than 15 psi (103.4 kPa) gage

Pyrophoric liquids, solids and gases, nonetonable

Unstable (reactive) materials, Class 3, nonetonable

Water-reactive materials, Class 3

✧ The contents of occupancies in Group H-2 present a deflagration or accelerated burning hazard. Examples of materials that create this hazard are listed. The definitions for Group H-2 materials are contained in Section 202. Because of the severe fire or reactivity hazard associated with these types of materials, proper classification is essential in determining the applicable requirements with regard to the mitigation of these hazards.

[F] 307.5 High-hazard Group H-3. Buildings and structures containing materials that readily support combustion or that pose a physical hazard shall be classified as Group H-3. Such materials shall include, but not be limited to, the following:

Class I, II or IIIA flammable or combustible liquids that are used or stored in normally closed containers or systems pressurized at 15 pounds per square inch gage (103.4 kPa) or less

Combustible fibers, other than densely packed baled cotton

Consumer fireworks, 1.4G (Class C, Common)

Cryogenic fluids, oxidizing

Flammable solids

Organic peroxides, Class II and III

Oxidizers, Class 2

Oxidizers, Class 3, that are used or stored in normally closed containers or systems pressurized at 15 pounds per square inch gage (103.4 kPa) or less

Oxidizing gases

Unstable (reactive) materials, Class 2

Water-reactive materials, Class 2

✧ The contents of occupancies in Group H-3 present a hazard inasmuch as they contain materials that readily support combustion or that present a physical hazard. Examples of materials that create this hazard are listed. The definitions for Group H-3 materials are contained in Section 202. While Group H-3 materials are generally less of a fire or reactivity hazard than Group H-2 materials, they still present a greater physical hazard than materials not currently regulated as high hazard.

[F] 307.6 High-hazard Group H-4. Buildings and structures which contain materials that are health hazards shall be classified as Group H-4. Such materials shall include, but not be limited to, the following:

Corrosives

Highly toxic materials

Toxic materials

✧ The contents of occupancies in Group H-4 present a hazard inasmuch as they contain materials that are health hazards. Examples of these hazards are listed in this section. The definitions for Group H-4 materials are contained in Section 202. While reference is made to chemicals that cause these hazards, the data sheets for these chemicals, which are furnished by the applicant, will need considerable subjective evaluation. Some materials falling into the category of health hazard may also present a physical hazard and, therefore, require the structure to be designed for multiple hazards in accordance with Section 307.8.

[F] 307.7 High-hazard Group H-5. Semiconductor fabrica-
tion facilities and comparable research and development
areas in which hazardous production materials (HPM) are used and the aggregate quantity of materials is in excess of those listed in Tables 307.1(1) and 307.1(2) shall be classified as Group H-5. Such facilities and areas shall be designed and constructed in accordance with Section 415.10.

- **HPM includes flammable liquids and gases, corrosives, oxidizers and, in many instances, highly toxic materials** (see the definition for "Hazardous production material" in Section 202). In determining the applicable requirements of other sections of the code, HPM facilities are considered to be Group H-5 occupancies. It is intended that the quantities of materials permitted in Table 415.10.1.1.1 will take precedence over Tables 307.1(1) and 307.1(2).

[F] **307.8 Multiple hazards.** Buildings and structures containing a material or materials representing hazards that are classified in one or more of Groups H-1, H-2, H-3 and H-4 shall conform to the code requirements for each of the occupancies so classified.

- If materials are present that possess characteristics of more than one Group H, high-hazard occupancy, then the structure must be designed to protect against the hazards of each relevant high-hazard occupancy classification. For example, a material could be classified as both a Class 2 oxidizer (Group H-3) and a corrosive (Group H-4). If the given quantity exceeded the maximum allowable quantity per control area individually for both a Class 2 oxidizer and a corrosive, the structure is required to conform to the applicable requirements of both Groups H-3 and H-4.

### SECTION 308

**INSTITUTIONAL GROUP I**

308.1 Institutional Group I. Institutional Group I occupancy includes, among others, the use of a building or structure, or a portion thereof, in which care or supervision is provided to persons who are or are not capable of self-preservation without physical assistance or in which persons are detained for penal or correctional purposes or in which the liberty of the occupants is restricted. Institutional occupancies shall be classified as Group I-1, I-2, I-3 or I-4.

- Institutional occupancies are comprised of two basic types. The first relates to health care facilities that are intended to provide medical care or treatment for people who have physical or mental disabilities or diseases and other infirmities. This includes persons who are ambulatory and are capable of self-preservation as well as those who are restricted in their mobility or totally immobile and need assistance to escape a life-threatening situation, such as a fire (i.e., children 2½ years of age or less and infirm persons). The second type of occupancy relates primarily to detention and correctional facilities. Since security is the major operational consideration in these kinds of facilities, the occupants (inmates) are under some form of restraint and may be rendered incapable of self-preservation without assistance in emergency situations.

The degree of hazards in each type of institutional facility identified in this section varies respective to each kind of occupancy. The code addresses each occupancy separately and the regulatory provisions throughout the code provide the proper means of protection so as to produce an acceptable level of safety to life and property.

This section identifies the occupancies that are included in the general term “Group I.” Institutional occupancies are divided into four individual occupancy classifications: Groups I-1, I-2, I-3 and I-4. These classifications are based on the degree of detention and physical mobility of the occupants. The term “Group I” includes each of the individual institutional occupancy classifications.

Group I occupancies are distinguished from other occupancies and within the subgroups of the Group I occupancies based on whether the care is provided on a 24-hour basis. The intent is that these criteria are not specific to the hours of operation of the facility, but the length of time that care is provided for the patients, residents or those in day care. For example, an outpatient clinic that is open 24 hours a day is a Group B occupancy provided care recipients are treated as outpatients and there are no in-patients that would stay at the facility 24 hours or longer. Another example would be a “day care” facility that is open 24 hours to serve workers who work any shift and need to have children in “day care” while they work. Provided that individual children receive care for less than 24 hours, the occupancy would be classified as a Group I-4 or possible a Group E.

308.2 Definitions. The following terms are defined in Chapter 2:

- **24-HOUR CARE.**
- **CUSTODIAL CARE.**
- **DETOXIFICATION FACILITIES.**
- **FOSTER CARE FACILITIES.**
- **HOSPITALS AND PSYCHIATRIC HOSPITALS.**
- **INCAPABLE OF SELF-PRESERVATION.**
- **MEDICAL CARE.**
- **NURSING HOMES.**

- This section lists terms that are specifically associated with the subject matter of this section. It is important to emphasize that these terms are not exclusively related to this section but may or may not also be applicable where the term is used elsewhere in the code.

Definitions of terms can help in the understanding and application of the code requirements. The purpose for including a list within this chapter is to provide more convenient access to terms which may have a specific or limited application within this chapter. For the complete definition and associated com-
308.3 Institutional Group I-1. This occupancy shall include buildings, structures or portions thereof for more than 16 persons who reside on a 24 hour basis in a supervised environment and receive custodial care. The persons receiving care are capable of self preservation. This group shall include, but not be limited to, the following:

- Alcohol and drug centers
- Assisted living facilities
- Congregate care facilities
- Convalescent facilities
- Group homes
- Halfway houses
- Residential board and custodial care facilities
- Social rehabilitation facilities

An occupancy classified in Group I-1 is characterized by four conditions: it is a custodial care facility, the number of persons receiving care and residing in such facilities is greater than 16, there is 24-hour-a-day supervision and the care recipients are capable of reaching safety in an emergency situation without the need of physical assistance by staff or others. The supervision for Group I-1 buildings is for counseling and assistance purposes, not for medical purposes.

The occupant load for occupancy classification purposes refers to the number of care recipients only. The number of guests or staff is not included. Please note, however, that the number of guests and staff is included for means of egress purposes.

A Group I-1 occupancy is intended to contain care recipients capable of self-preservation. When such an occupancy begins to house care recipients who are not capable of self-preservation, then the occupancy classification would likely need to be changed to a Group I-2 due to the 24-hour nature of such facilities. This same situation would be true of an existing Group R-4 assisted living facility that began to house more than five persons not capable of self-preservation. Such occupancies would also need to be reevaluated and reclassified as Group I-2. Such buildings could be dealt with as mixed occupancies. Generally, Groups I-1 and R-4 were not intended to contain care recipients not capable of self-preservation.

For clarification purposes, a dormitory or apartment complex that houses only elderly people and has a nonmedically trained live-in manager is not classified as an institutional occupancy but rather as a residential occupancy (see Section 310). A critical phrase in the code to consider when evaluating this type of facility is “live in a supervised residential environment.” Such dormitories or apartment complexes may contain features such as special emergency call switches, that are located in each dwelling unit, and that are monitored by health center staff. These emergency call switches are a convenience and do not necessarily indicate infirmity of the care recipients.

308.3.1 Five or fewer persons receiving care. A facility such as the above with five or fewer persons receiving such care shall be classified as Group R-3 or shall comply with the International Residential Code provided an automatic sprinkler system is installed in accordance with Section 903.3.1.3 or with Section P2904 of the International Residential Code.

- Any building that has the characteristics of a Group I-1 occupancy but has five or fewer persons receiving custodial care is classified as Group R-3 (see Section 310.5) or may be constructed in accordance with the International Residential Code® (IRC®) (see Section 310.5.1). When the code allows compliance in accordance with the IRC, the only requirements that would apply would be those of the IRC including the installation of automatic sprinkler protection. The intent is to allow persons to be cared for in a residential, or home, environment, often under the care of family members. Please note similar provisions for Group E occupancies as well as Groups I-2 and I-4.

308.3.2 Six to sixteen persons receiving care. A facility such as above, housing not fewer than six and not more than 16 persons receiving such care, shall be classified as Group R-4.

- Any building that has the characteristics of a Group I-1 occupancy but that has more than five and not more than 16 persons receiving custodial care is classified as Group R-4 (see Section 310.6). Ninety-eight percent of households in the U.S. have less than 16 occupants; thus the limit of 16 is considered appropriate for a residential occupancy.

308.4 Institutional Group I-2. This occupancy shall include buildings and structures used for medical care on a 24-hour basis for more than five persons who are incapable of self-preservation. This group shall include, but not be limited to, the following:

- Foster care facilities
- Detoxification facilities
- Hospitals
- Nursing homes
- Psychiatric hospitals

An occupancy classified in Group I-2 is characterized by three conditions: it is a health care facility, there is 24-hour-a-day medical supervision for the individuals receiving care, and more than five of those persons require physical assistance by staff or others to reach safety in an emergency situation. Determining whether care recipients are capable of self-preservation may be a difficult aspect of classifying an occupancy as Group I-1 or I-2. This assessment needs to be taken with caution and reliance on other state and federal guidelines and associated regulations may be necessary. Also, it is important to keep in mind that facilities that may be classified initially as Group I-1
(capable of self-preservation) or R-4 can very easily need to be reclassified as Group I-2 if the abilities of the persons receiving care are not carefully evaluated and addressed.

The most common examples of facilities classified in Group I-2 are hospitals and nursing homes [see Figures 308.4(1) and 308.4(2)]. Other facilities included are detoxification facilities, foster care facilities and psychiatric hospitals.

It is not uncommon to find dining rooms (Group A-2), staff offices (Group B), gift shops (Group M) and other nonmedically related areas in buildings otherwise classified as Group I-2. Where such other occupancies occur, the building is considered as a mixed occupancy and subject to the provisions of Section 508. In addition to the general requirements contained in this section, Section 407 contains specific requirements for Group I-2.

308.4.1 Five or fewer persons receiving care. A facility such as the above with five or fewer persons receiving such care shall be classified as Group R-3 or shall comply with the International Residential Code provided an automatic sprinkler system is installed in accordance with Section 903.3.1.3 or with Section P2904 of the International Residential Code.

Any facility that has the characteristics of a Group I-2 occupancy but does not have more than five persons receiving care at any one time is to be classified as a Group R-3 occupancy (see Section 310.5). As an option, the facility may be designed and constructed...
under the provisions of the IRC provided the building has a sprinkler system (see Section 310.5.1). The intent is to allow persons to be cared for in a residential, or home, environment, often under the care of family members. The persons receiving the care do not need to be capable of self-preservation. The sprinkler system is to comply with the requirements for an NFPA 13D system or those of Section P2904 of the IRC. Please note similar provisions for Group E occupancies as well as Groups I-1 and I-4.

308.5 Institutional Group I-3. This occupancy shall include buildings and structures that are inhabited by more than five persons who are under restraint or security. An I-3 facility is occupied by persons who are generally incapable of self-preservation due to security measures not under the occupants’ control. This group shall include, but not be limited to, the following:

- Correctional centers
- Detention centers
- Jails
- Prerelease centers
- Prisons
- Reformatories

Buildings of Group I-3 shall be classified as one of the occupancy conditions indicated in Sections 308.5.1 through 308.5.5 (see Section 408.1).

An occupancy classified in Group I-3 is characterized by three conditions: it is a location where persons are under restraint or where security is closely supervised, there are more than five such persons and they are not capable of self-preservation because the conditions of confinement are not under their control (i.e., they require assistance by the facilities’ staff to reach safety in an emergency situation). For occupancy classification purposes, the provision refers to the number of persons being secured or restrained only. The number of guests or staff are not included. Please note, however, that the number of guests and staff are included for means of egress purposes.

Buildings that have these characteristics but that contain no more than five persons who are being secured or restrained are to be classified based upon the function to which they are associated. For example, the small holding cell in a Group B police station having only the one cell would simply be classified as a portion of the Group B occupancy. Regardless of the occupancy classification, the means of egress provisions for places of restraint are still applicable (see Chapter 10).

It is recognized that not all Group I-3 occupancies have the same level of restraint; thus, to distinguish these different levels, the code defines five different conditions of occupancy based on the degree of access to the exit discharge.

The five occupancy conditions are summarized in Figure 308.5.

308.5.1 Condition 1. This occupancy condition shall include buildings in which free movement is allowed from sleeping

![Figure 308.5](image-url)

**GROUP I-3—OCCUPANCY CONDITIONS**
USE AND OCCUPANCY CLASSIFICATION

areas, and other spaces where access or occupancy is permitted, to the exterior via means of egress without restraint. A Condition 1 facility is permitted to be constructed as Group R.

- Condition 1 areas are those where the secured persons have unencumbered access to the exterior of the building. As such, a key or remote control release device is not needed for any occupant to reach the exterior of the building (exit discharge) at any time. These types of buildings are referred to as low-security facilities. A work-release center is a typical Condition 1 facility (see Figure 308.5.1).

Because of the lack of restraint associated with a Condition 1 building, it resembles a residential use more than a detention facility and, therefore, is permitted to be classified in Group R (see Section 310).

308.5.2 Condition 2. This occupancy condition shall include buildings in which free movement is allowed from sleeping areas and any other occupied smoke compartment to one or more other smoke compartments. Egress to the exterior is impeded by locked exits.

- Condition 2 areas are those in which the movement of the persons under restraint is not controlled within the exterior walls of the building (i.e., the occupants have unencumbered access within the building). As such, there is free movement by such persons between smoke compartments (as created by smoke barriers); however, the restrained persons must rely on someone else to allow them to exit the building to the area of discharge. This is illustrated in Figure 308.5.2.

308.5.3 Condition 3. This occupancy condition shall include buildings in which free movement is allowed within individual smoke compartments, such as within a residential unit comprised of individual sleeping units and group activity spaces, where egress is impeded by remote-controlled release of means of egress from such a smoke compartment to another smoke compartment.

- Condition 3 areas are those in which free movement by the persons under restraint is permitted within an individual smoke compartment; however, movement of such persons from one smoke compartment (as created by smoke barriers) to another smoke compartment and from within the building to the exterior (exit discharge) is controlled by remote release locking devices. As such, the restrained persons in the facility are dependent on the staff for their release from each smoke compartment or to the exterior (exit discharge). This condition is illustrated in Figure 308.5.3.

308.5.4 Condition 4. This occupancy condition shall include buildings in which free movement is restricted from an occupied space. Remote-controlled release is provided to permit movement from sleeping units, activity spaces and other occupied areas within the smoke compartment to other smoke compartments.

- Condition 4 areas are those in which the movement of restrained persons from any room or space within a smoke compartment (as created by smoke barriers) to another smoke compartment or to the exterior (exit discharge) is controlled by remote release locking devices. Any movement within the facility requires activation of a remote control lock system to release the designated area (see Figure 308.5.4). The persons being restrained or secured within a Condition 4 area must rely on an activation system in the event of an emergency in order to evacuate the area.

Condition 4 facilities most often are penal facilities where the restrained persons are considered relatively safe to handle in large groups. As such, many persons can be released simultaneously from their individual sleeping areas when they need to travel to dining areas or move to another area.
Figure 308.5.2
CONDITION 2

Figure 308.5.3
CONDITION 3
308.5.5 Condition 5. This occupancy condition shall include buildings in which free movement is restricted from an occupied space. Staff-controlled manual release is provided to permit movement from sleeping units, activity spaces and other occupied areas within the smoke compartment to other smoke compartments.

- Condition 5 areas are those in which the persons being secured or restrained are not allowed free movement to any other room or space within a smoke compartment (as created by smoke barriers) to another smoke compartment or to the exterior (exit discharge) unless the locking device controlling their area of confinement is manually released by a staff member. Once released from an individual space, a staff member is responsible for unlocking all doors from that location to the next smoke compartment. This is the most restrictive occupancy condition, as each secured person must be released on an individual basis and escorted to other areas.

Condition 5 facilities are most often used for maximum security or solitary confinement areas where the persons are considered to be dangerous to others, including staff members, and cannot safely be handled in large groups (see Figure 308.5.5).

308.6 Institutional Group I-4, day care facilities. This group shall include buildings and structures occupied by more than five persons of any age who receive custodial care for fewer than 24 hours per day by persons other than parents or guardians, relatives by blood, marriage or adoption, and in a place other than the home of the person cared for. This group shall include, but not be limited to, the following:

- Adult day care
- Child day care

- Facilities that contain provisions for the custodial care of more than five persons of any age are classified as Group I-4. Group I-4 facilities are less restrictive in some of the requirements (e.g., height and area) than the other Group I occupancies. Group I-4 facilities are intended to be used for less than 24 hours and are not intended to provide medical supervision. Day care facilities are not intended to be a residence for the people receiving care. The staff members are assumed not to be related to the individuals in the day care facilities. The premise of the provisions is that the numbers receiving care are exclusive of staff. The care recipients in a Group I-4 occupancy are not expected to respond to an emergency without physical assistance from others. Group I-4 occupancies include both adult day care and child day care.

Adult care facilities are assumed to be for people other than children that require some type of personal care (i.e., nonmedical). A facility where adults gather for social activities such as a community center or a YMCA is not an adult care facility (Group I) and would be regulated under other provisions of the code (Group A-3 or B). In addition, there must be more...
than five adults accommodated in the facility and they must not be related in any manner. The classification of Group I-4 for an adult day care facility does not apply to facilities that provide services for adults who are capable of responding to an emergency unassisted. In that case, the facility is simply classified into the occupancy group it most resembles. A facility providing a similar degree of custodial care for children on a less than a 24-hour-per-day basis would be considered as a Group I-4 day care facility.

**308.6.1 Classification as Group E.** A child day care facility that provides care for more than five but no more than 100 children 2 1/2 years or less of age, where the rooms in which the children are cared for are located on a level of exit discharge serving such rooms and each of these child care rooms has an exit door directly to the exterior, shall be classified as Group E.

- Children 2 1/2 years of age or less are not typically capable of independently responding to an emergency and must be led or carried to safety. Under such circumstances, the children are considered non-ambulatory. Therefore, a Group I-4 classification is given to those facilities where six or more toddlers and/or infants receive custodial care for less than 24 hours per day. A similar condition is found in Group I-2 occupancies where the young children stay for extended periods of time. The distinguishing factor between the two occupancies is the amount of time the facility provides care for each individual. Group I-2 facilities provide care on a 24-hour basis while in Group I-4 facilities, individual care must be less than 24 hours. It is also assumed that medical supervision is not present in Group I-4 facilities.

A child care facility in which the number of children whose age does not exceed 2 1/2 years is greater than five but not more than 100 is permitted to be classified as Group E, provided the children are all located in rooms on the level of exit discharge that serve such rooms and all of the rooms have exit doors directly to the exterior. This exception is only applicable to rooms and spaces used for child care and is not intended to apply to accessory spaces such as restrooms, offices and kitchens. Many day care facilities primarily catering to those under primary school age tend to divide the children into three general categories based on state laws and regulations. These include infant, toddler and preschool.

Some variations do occur in that larger day care facilities will have transition rooms for mobile infants or pre-K oriented rooms for those entering kindergarten. But basically there is a mixture of children 2 1/2 years or less and older children. The older children can automatically be in a facility classified as a Group E occupancy, but for the younger children the exception as discussed above would need to be applied to classify the entire occupancy as Group E. The total number of children can exceed 100 and the Group E classification is retained, provided that the number of children 2 1/2 years or less is limited to 100 or fewer. The infant and toddler rooms would need to have exits directly to the outside on the level of exit discharge. If the exception is not applied, the entire facility would need to be classified as Group I-4 or a

![Figure 308.5.5](image)
mixed occupancy classification would be necessary. By permitting the facility to be classified as Group E, the building would not be required to be sprinklered unless the fire area was greater than 12,000 square feet (115 m²). A Group I-4 facility would be required to be sprinklered regardless of the area. But as a Group E occupancy, panic hardware would be required in rooms and spaces exceeding 50 occupants.

308.6.2 Within a place of religious worship. Rooms and spaces within places of religious worship providing such care during religious functions shall be classified as part of the primary occupancy.

- The Group I-4 provisions do not apply to places of religious worship simply providing care services during worship and related religious functions. If the space is used at other times simply as a day care facility, then it would be classified as Group I-4 or E as applicable.

308.6.3 Five or fewer persons receiving care. A facility having five or fewer persons receiving custodial care shall be classified as part of the primary occupancy.

- Where five or fewer persons receive custodial care in a facility other than a dwelling unit, the classification of the care area is to be consistent with that of the primary occupancy. The limited number of care recipients reduces the hazard level to the point that classification as a Group I-4 occupancy is not warranted.

308.6.4 Five or fewer persons receiving care in a dwelling unit. A facility such as the above within a dwelling unit and having five or fewer persons receiving custodial care shall be classified as a Group R-3 occupancy or shall comply with the International Residential Code.

- Buildings that have five or fewer persons receiving custodial care within a dwelling unit are to be classified as Group R-3, or shall be constructed in accordance with the IRC. The assumption is that this type of activity is possible in a residential environment where one or more family members require the high level of care regulated by Section 308.6. Please note similar provisions for Group E occupancies as well as Groups I-1 and I-2.

SECTION 309

MERCANTILE GROUP M

309.1 Mercantile Group M. Mercantile Group M occupancy includes, among others, the use of a building or structure or a portion thereof, for the display and sale of merchandise and involves stocks of goods, wares or merchandise incidental to such purposes and accessible to the public. Mercantile occupancies shall include, but not be limited to, the following:

- Department stores
- Drug stores
- Markets
- Motor fuel-dispensing facilities

Retail or wholesale stores
Sales rooms

- The characteristics of occupancies classified in Group M are contained in this section. Because mercantile occupancies normally involve the display and sale of large quantities of combustible merchandise, the fuel load in such facilities can be relatively high, potentially exposing the occupants (customers and sales personnel) to a high degree of fire hazard. Mercantile operations often attract large crowds (particularly in large department stores and covered and open malls and especially during weekends and holidays). There are two factors that alleviate the risks to life safety: the occupant load normally has a low to moderate density and the occupants are alert, mobile and able to respond in an emergency situation. The degree of openness and the organization of the retail display found in most mercantile occupancies are generally orderly and do not present an unusual difficulty for occupant evacuation.

Listed here are general descriptions of the kinds of occupancies that are classified in Group M. Mercantile buildings most often have both a moderate occupant load and a high fuel load, which is in the form of furnishings and the goods being displayed, stored and sold [see Figure 309.1(1)].

The key characteristics that differentiate occupancies classified in Group M from those classified in Group B (see Section 304) are the larger quantity of goods or merchandise available for sale and the lack of familiarity of the occupants with the building, particularly its means of egress. To be classified in Group M, the goods that are on display must be accessible to the public. If a patron sees an item for sale, then that item is generally available for purchase at that time (i.e., there is a large stock of goods). If a store allows people to see the merchandise but it is not available on the premises, such as an automobile showroom, then the occupancy classification of business (Group B) should be considered. A mercantile building is open to the public, many of whom may not be regular visitors. A business building, however, is primarily occupied by regular employees who are familiar with the building arrangement and, most importantly, the exits. This awareness of the building and the exits can be an important factor in a fire emergency.

Automotive, fleet-vehicle, marine and self-service fuel-dispensing facilities, as defined in the IFC, are classified in the mercantile occupancy, as are the convenience stores often associated with such occupancies [see Figure 309.1(2)]. Quick-lube, tune-up, muffler and tire shops are not included in this classification. Those facilities that typically conduct automotive service and repair work are treated as a repair garage (Group S-1, also defined in the IFC).

Simply because a building containing a mercantile-type occupancy has a dense occupant load does not necessitate the need to classify the building as an
assembly occupancy unless the activity includes an assembly-type area where purchasing of goods is a group activity versus individual shoppers independently considering and purchasing merchandise. For example, a building in which auction sales occur may have a highly concentrated occupant load where the sales occur, but Section 309.1 describes mercantile occupancies as "the use of a building or structure or portion thereof for the display and sale of merchandise and involves stocks of goods, wares or merchandise incidental to such purposes and accessible to the public." In an auction, however, the activity is dominated by an assembly use of the space as people gather to conduct and participate in the auction. As such, auction spaces need to be assigned a Group A-3 occupancy (IBC Interpretation No. 38-03). The presence of highly concentrated occupant loads does not in itself mandate an assembly use classification unless the activity is assembly in nature versus large numbers of people pursuing individual activities of acquisition.

309.2 Quantity of hazardous materials. The aggregate quantity of nonflammable solid and nonflammable or noncombustible liquid hazardous materials stored or displayed in
USE AND OCCUPANCY CLASSIFICATION

a single control area of a Group M occupancy shall not exceed the quantities in Table 414.2.5(1).

This section addresses an exception for control areas of mercantile occupancies containing certain nonflammable or noncombustible materials and health hazard gases that are stored in accordance with Table 414.2.5(1). This section allows Group H-4 materials, which pose a health hazard rather than a physical hazard, as well as limited Group H-2 and H-3 materials, to be stored in both the retail display and stock areas of mercantile occupancies in excess of the maximum allowable quantity per control area of Tables 307.1(1) and 307.1(2) without classifying the building as Group H. To correctly classify a building where products that have hazardous properties are stored and sold, the code user must also be aware of the provisions contained in Section 307.1, Notes c and n of Table 307.1(1) and Notes b and c of Table 307.1(2). These provisions give the quantity limitations for specific high-hazard products in mercantile display areas, including medicines, foodstuffs, cosmetics and alcoholic beverages.

Without this option, many mercantile occupancies could technically be classified as Group H. The increased quantities of certain hazardous materials are based on the recognition that, while there is limited risk in mercantile occupancies, the packaging and storage arrangements can be controlled. For further information on the storage limitations required for these types of materials in mercantile occupancies, see Section 2703.11 of the IFC.

SECTION 310
RESIDENTIAL GROUP R

310.1 Residential Group R. Residential Group R includes, among others, the use of a building or structure, or a portion thereof, for sleeping purposes when not classified as an Institutional Group I or when not regulated by the International Residential Code.

Residential occupancies represent some of the highest fire safety risks of any of the occupancies listed in Chapter 3. There are several reasons for this condition.

Structures in the residential occupancy house the widest range of occupant types, i.e., infants to the aged, for the longest periods of time. As such, residential occupancies are more susceptible to the careless acts of the occupants; therefore, the consequences of exposure to the effects of fire are the most serious.

Most residential occupants are asleep approximately one-third of every 24-hour period. When sleeping, they are not likely to become immediately aware of a developing fire. Also, if awakened from sleep by the presence of fire, the residents often may not immediately react in a rational manner and delay their evacuation.

The fuel load in residential occupancies is often quite high, both in quantity and variety. Also, in the construction of residential buildings, it is common to use extensive amounts of combustible materials.

Another portion of the fire problem in residential occupancies relates to the occupants’ lack of vigilance in the prevention of fire hazards. In their own domicile or residence, people tend to relax and are often prone to allow fire hazards to go unabated; thus, in residential occupancies, fire hazards tend to accrue over an extended period of time and go unnoticed or are ignored.

Most of the nation’s fire problems occur in Group R buildings and, in particular, one- and two-family dwellings, which account for more than 80 percent of all deaths from fire in residential occupancies and about two-thirds of all fire fatalities in all occupancies. One- and two-family dwellings also account for more than 80 percent of residential property losses from fire and more than one-half of all property losses from fire.

Because of the relatively high fire risk and potential for loss of life in buildings classified in Groups R-1 (hotels and motels) and R-2 (apartments and dormitories), the code has stringent provisions for the protection of life in these occupancies. Group R-3 occupancies, however, are not generally considered to be in the same domain and, thus, are not subject to the same level of regulatory control as is provided in other occupancies.

Because of the growing trend to care for people in a residential environment, residential care-assisted living facilities are also classified as Group R. Specifically, these facilities are classified as Group R-4. Mainstreaming people who are recovering from alcohol or drug addiction and people who are developmentally disabled is reported to have therapeutic and social benefits. A residential environment often fosters this mainstreaming.

A building or part of a building is considered to be a residential occupancy if it is intended to be used for sleeping accommodations (including assisted living facilities) and is not an institutional occupancy. Institutional occupancies are similar to residential occupancies in many ways; however, they differ from each other in that institutional occupants are in a supervised environment, and, in the case of Groups I-2 and I-3 occupancies, are under some form of restraint or physical limitation that makes them incapable of complete self-preservation. The number of these occupants who are under supervision or are incapable of self-preservation is one distinguishing factor for being classified as an institutional or residential occupancy.

The term Group R refers collectively to the four individual residential occupancy classifications: Groups R-1, R-2, R-3 and R-4. These classifications are differentiated in the code based on the following criteria: (1) whether the occupants are transient or nontransient in nature; (2) the type and number of dwelling units or sleeping units contained in a single building and (3) the number of occupants in the facility.

310.2 Definitions. The following terms are defined in Chapter 2:

BOARDING HOUSE.

CONGREGATE LIVING FACILITIES.

DORMITORY.

GROUP HOME.
PERSONAL CARE SERVICE.

TRANSIENT.

- This section lists terms that are specifically associated with the subject matter of this section. It is important to emphasize that these terms are not exclusively related to this section but may or may not also be applicable where the term is used elsewhere in the code.

Definitions of terms can help in the understanding and application of the code requirements. The purpose for including a list within this chapter is to provide more convenient access to terms which may have a specific or limited application within this chapter. For the complete definition and associated commentary, refer back to Chapter 2. Terms that are italicized provide a visual identification throughout the code that a definition exists for that term. The use and application of all defined terms are set forth in Section 201.

310.3 Residential Group R-1. Residential occupancies containing sleeping units where the occupants are primarily transient in nature, including:

- Boarding houses (transient) with more than 10 occupants
- Congregate living facilities (transient) with more than 10 occupants
- Hotels (transient)
- Motels (transient)

- The key characteristic of Group R-1 that differentiates it from other Group R occupancies is that the occupants are considered transient in nature (i.e., those whose length of stay is not more than 30 days). There is an expectation that the occupants are not as familiar with the building as those residents in nontransient facilities such as apartment buildings and single-family dwellings. If occupants are unfamiliar with their surroundings, they may not recognize potential hazards or be able to use the means of egress effectively.

The most common building types classified in Group R-1 are hotels, motels and boarding houses. Facilities classified as Group R-1 occupancies may include dwelling units, sleeping units, or a combination of both. Group R-1 occupancies do not typically have cooking facilities in the unit. When a unit is not equipped with cooking facilities, it does not meet the definition of a "dwelling unit" in Section 202. When this occurs, such units are treated as sleeping units for the application of code provisions (see Figure 310.3). A recent trend in development is the construction of "extended-stay hotels." While these units may have all of the characteristics of a typical dwelling unit.
USE AND OCCUPANCY CLASSIFICATION

(i.e., cooking, living, sleeping, eating, sanitation), the length of stay is still typically not more than 30 days. As such, these buildings would still be classified as Group R-1. If the length of stay is more than 30 days, these buildings would be classified as Group R-2.

Other occupancies are often found in buildings classified in Group R-1. These occupancies include nightclubs (Group A-2), restaurants (Group A-2), gift shops (Group M), business offices (Group B), health clubs (Group A-3) and storage facilities (Group S-1). When this occurs, the building is a mixed occupancy and is subject to the provisions of Section 508.

Transient congregate living facilities and boarding houses with 10 or fewer occupants can be constructed to the standards of Group R-3 occupancies rather than the general category of Group R-1. The primary intent of this provision is to permit bed-and-breakfast-type facilities to be established in existing single-family (one-family) structures. In comparison to the provision under Group R-2 which permits congregate living facilities with fewer than 16 nontransient occupants to be built as a Group R-3, the Group R-3 "transient" facility is limited to 10 or fewer occupants in reflection of the limited number of occupants.

310.4 Residential Group R-2. Residential occupancies containing sleeping units or more than two dwelling units where the occupants are primarily permanent in nature, including:

- Apartment houses
- Boarding houses (nontransient) with more than 16 occupants
- Congregate living facilities (nontransient) with more than 16 occupants
- Convents
- Dormitories
- Fraternities and sororities
- Hotels (nontransient)
- Live/work units
- Monasteries
- Motels (nontransient)
- Vacation timeshare properties

- The length of the occupants’ stay plus the arrangement of the facilities provided are the basic factors that differentiate occupancies classified in Group R-2 from other occupancies in Group R. The occupants of facilities or areas classified in Group R-2 are primarily nontransient, capable of self-preservation and share their means of egress in whole or in part with other occupants outside of their sleeping area or dwelling unit. Building types ordinarily classified in Group R-2 include apartments, boarding houses (where the occupants are not transient) and nontransient congregate living facilities, such as dormitories, where there are more than 16 occupants [see Figures 310.4(1) and 310.4(2)].

Individual dwelling units in Group R-2 are either rented by tenants or owned by the occupants. The code does not make a distinction between either type of tenancy. Residential condominiums are treated in the code the same as Group R-2 apartments. Such condominiums are based on shared ownership of a building and related facilities. While an individual owner will have exclusive rights to a certain unit, the building, the lot the building sits upon, parking, common recreational facilities and similar features are owned in common by all the owners of individual dwelling units. In most cases condominiums do not establish separate lots and the walls between units are not setting on lot lines. Another type of shared ownership is referred to as a "co-op," short for cooperative. Occasionally a condominium will establish actual lots and lot lines distinguishing individual ownership. When the dwelling unit is located on a separate parcel of land, lot lines defining the parcel exist and the requirements for fire separation must be met.

Dormitories are generally associated with university or college campuses for use as student housing, but dormitory uses continue to evolve. Many dormitories are now being built as housing for elderly people who wish to live with other people their own age and who do not need 24-hour-a-day medical supervision. The only difference between the dormitory that has just been described and the dormitory found on a college campus is the age of its occupants. If the elderly people must have 24-hour-a-day medical supervision (i.e., a nurse or doctor on the premises), the building is no longer considered a residential occupancy but an institutional occupancy and would have to comply with institutional occupancy regulations.
with the applicable provisions of the code for the appropriate Group I occupancy.

Similar to Group R-1, individual rooms in dormitories are sleeping units. When college classes are not in session, the rooms in dormitories are sometimes rented out for periods of less than 30 days to convention attendees and other visitors. When dormitories undergo this type of transient use, they more closely resemble Group R-1.

Buildings containing dormitories often contain other occupancies, such as cafeterias or dining rooms (Group A-2), recreation rooms (Group A-3), offices (Group B) and study and meeting rooms (Group A-3). When this occurs, the building is considered a mixed occupancy and is subject to the provisions of Section 508 [see Figure 310.4(2)].

Included in the listing of Group R-2 are live/work units. A live/work unit is a dwelling unit or sleeping unit in which a significant portion of the space includes a nonresidential use operated by the tenant. Reflecting a growing trend in urban neighborhoods and the reuse of existing buildings, live/work units must comply with the provisions of Section 419.

The intent of the congregate living facility reference is to better define when a congregate living facility is operating as a single-family home. Blended families are now commonplace and not necessarily defined strictly by blood or marriage. Small boarding houses, convents, dormitories, fraternities, sororities, monasteries and nontransient hotels and motels may be small enough to operate as a single-family unit and would be permitted to be constructed as Group R-3 occupancies as intended by the code. The threshold of 16 persons is consistent with the results of the most recent census, which has 98 percent of all homes in the U.S. containing less than 16 persons.

310.5 Residential Group R-3. Residential occupancies where the occupants are primarily permanent in nature and not classified as Group R-1, R-2, R-4 or I, including:

- Buildings that do not contain more than two dwelling units
- Boarding houses (nontransient) with 16 or fewer occupants
- Boarding houses (transient) with 10 or fewer occupants
- Care facilities that provide accommodations for five or fewer persons receiving care
- Congregate living facilities (nontransient) with 16 or fewer occupants

Figure 310.4(2)
GROUP R-2—DORMITORY
(OCCUPANTS PRIMARILY NONTRANSIENT)
Congregate living facilities (transient) with 10 or fewer occupants

- Group R-3 facilities include all detached one- and two-family dwellings and multiple (three or more) single-family dwellings (townhouses) more than three stories in height. Those buildings three or less stories in height are not classified as Group R-3 and are regulated by the IRC. Each pair of dwelling units in multiple single-family dwellings greater than three stories in height must be separated by fire walls (see Section 706) or by two exterior walls (see Table 602) in order to be classified as Group R-3. (Duplexes, buildings with two dwelling units, must be detached from other structures in order to be regulated by the IRC.) A duplex attached to another duplex would be required to comply with the code and be classified as Group R-2 or R-3, depending on the presence of fire walls.

- Buildings that are classified as Group R-3, while limited in height, are not limited in the allowable area as indicated in Table 503.

- Buildings that are one- and two-family dwellings and multiple single-family dwellings less than three stories in height and that contain another occupancy (e.g., Groups B, M, I-4) must be regulated as a mixed occupancy in accordance with this code and are not permitted to be regulated by the provisions of the IRC (see Figures 310.5(1) and 310.5(2)). Some mixed use dwelling units may qualify as live/work units under Section 419 and be classified as a Group R-2 occupancy.

- In addition, all congregate living facilities with no more than 16 nontransient occupants or no more than 10 transient occupants, are to be classified as Group R-3.

- R-3 occupancies include small care facilities where care is provided to 5 or fewer persons. The intent is to allow persons to be cared for in a residential, or home, environment, often under the care of family members that is typical within a single-family-type home. Allowances for the Group R-3 classification of smaller care facilities are established in Sections 305.2.3 (Group E), 308.3.1 (Group I-1), 308.4.1 (Group I-2) and 308.6.4 (Group I-4). Because the intent is to accommodate persons who might otherwise be in other group occupancies including I-2, the R-3 care facility is not limited to just persons who are capable of self-preservation. The only limit is the number receiving care, not the total number of occupants in the dwelling unit. If two people are receiving care, and the rest of the family is four people, the total of six occupants of the dwelling does not move this out of being an R-3. See also Section 310.5.1.

310.5.1 Care facilities within a dwelling. Care facilities for five or fewer persons receiving care that are within a single-family dwelling are permitted to comply with the International Residential Code provided an automatic sprinkler system is installed in accordance with Section 903.3.1.3 or with Section P2024 of the International Residential Code.

- Section 310.5 already states that care facilities that accommodate five or fewer persons receiving care can be classified as a Group R-3 occupancy. Sections 305.2.3 (Group E), 308.3.1 (Group I-1), 308.4.1 (Group I-2) and 308.6.4 (Group I-4) each state the option of providing the care of five or fewer persons within a structure regulated under the IRC. The intent is to allow persons to be cared for in a residential, or
home, environment, often under the care of family members that is typical within a single-family-type home. As stated for those care facilities allowed within the R-3 occupancy, the persons receiving care in a building designed according to the IRC are not limited to those who are capable of self-preservation. Similar to Sections 308.3.1 and 308.4.1, this section specifies that such IRC-regulated facility be provided with a sprinkler system.

310.6 Residential Group R-4. This occupancy shall include buildings, structures or portions thereof for more than five but not more than 16 persons, excluding staff, who reside on a 24-hour basis in a supervised residential environment and receive custodial care. The persons receiving care are capable of self-preservation. This group shall include, but not be limited to, the following:

- Alcohol and drug centers
- Assisted living facilities
- Congregate care facilities
- Convalescent facilities
- Group homes
- Halfway houses
- Residential board and custodial care facilities
- Social rehabilitation facilities

Group R-4 occupancies shall meet the requirements for construction as defined for Group R-3, except as otherwise provided for in this code.

▼ When a limited number of people who require custodial care live in a facility where more than 5 but not more than 16 persons are receiving care, such facility is no longer classified as Group I-1 but as a Group R-4. Ninety-eight percent of households in the U.S. have no more than 16 occupants; thus the limit of 16 was established as an appropriate limit. The number of persons used in the determination includes those who receive care and is not intended to include staff.

A Group R-4 occupancy is not permitted to include any occupants that "are not capable of self-preservation." If an existing Group R-4 facility has residents added who are not capable of self-preservation, then the occupancy has changed and a permit to change the occupancy must be obtained (IBC Interpretation No.16-03). Group R-4 facilities must satisfy the construction requirements of Group R-3. Facilities with 5 or fewer persons receiving care will be either a Group R-3 occupancy (see Section 310.5), or can be built under the IRC (see Section 310.5.1).

SECTION 311
STORAGE GROUP S

311.1 Storage Group S. Storage Group S occupancy includes, among others, the use of a building or structure, or a portion thereof, for storage that is not classified as a hazardous occupancy.

▼ This section requires that all structures (or parts thereof) designed or occupied for the storage of moderate- and low-hazard materials are to be classified in either Group S-1 (moderate hazard) or S-2 (low hazard).

The life safety problems in structures used for storage of moderate- and low-hazard materials are minimal because the number of people involved in a storage operation is usually small and normal work patterns require the occupants to be dispersed throughout the facility.

The problems of fire safety, particularly as they relate to the protection of stored contents, are directly associated with the amount and combustibility of the materials (including packaging) that are housed on the premises.

Storage facilities typically contain significant amounts of combustible or noncombustible materials.
that are kept in a common area. Because of the combustion, flammability or explosive characteristics of certain materials (see Section 307), a structure (or portion thereof) that is used to store high-hazard materials, which exceeds the maximum allowable quantities (MAQ) or that does not meet one of the exceptions identified in Section 307.1, cannot be classified as Group S and is to be classified as Group H, high-hazard use, and is to comply with Section 307.

Hazardous materials may be located in Group S occupancy buildings, provided the amount of materials in each control area does not exceed the MAQ specified in Tables 307.1(1) and 307.1(2). Control areas must comply with Section 414. Storage occupancies consist of two basic types.

Groups S-1 and S-2, which are based on the properties of the materials being stored. The distinction between Groups S-1 and S-2 is similar to that between Groups F-1 and F-2, as outlined in Section 306.

311.2 Moderate-hazard storage, Group S-1. Buildings occupied for storage uses that are not considered to be Group S-2, including, but not limited to, storage of the following:

- Aerosols, Levels 2 and 3
- Aircraft hangar (storage and repair)
- Bags: cloth, burlap and paper
- Bamboo and rattan
- Baskets
- Belting: canvas and leather
- Books and paper in rolls or packs
- Boots and shoes
- Buttons, including cloth covered, pearl or bone
- Cardboard and cardboard boxes
- Clothing, woolen wearing apparel
- Cordage
- Dry boat storage (indoor)
- Furniture
- Furs
- Glues, mucilage, pastes and size
- Grains
- Horns and combs, other than celluloid
- Leather
- Linoleum
- Lumber
- Motor vehicle repair garages complying with the maximum allowable quantities of hazardous materials listed in Table 307.1(1) (see Section 406.8)
- Photo engravings
- Resilient flooring
- Silks
- Soaps
- Sugar
- Tires, bulk storage of
- Tobacco, cigars, cigarettes and snuff
- Upholstery and mattresses
- Wax candles

Buildings in which combustible materials are stored and that burn with ease are classified in Group S-1, moderate-hazard storage occupancies. Examples of the kinds of materials that, when stored, are representative of occupancies classified in Group S-1 are also listed in this section.

As defined by the IFC, a repair garage is any structure used for servicing or repairing motor vehicles. Therefore, regardless of the extent of work done (e.g., quick lube, tune-up, muffler and tire shops, painting, body work, engine overhaul), repair garages are classified as Group S-1 (see Figure 311.2) and must be in compliance with Section 406.8. In addi-
tion, to avoid a Group H classification, the amounts of hazardous materials in the garage must be less than the maximum allowable quantity per control area permitted in Tables 307.1(1) and 307.1(2).

Aircraft hangars for storage, repair or both would be classified as Group S-1. This classification correlates with the actual use of such hangars which very frequently would include some level of repair work and also works with the requirements of NFPA 409. Aircraft hangars accessory to one- and two-family structures are classified as a Group U occupancy.

311.3 Low-hazard storage, Group S-2. Includes, among others, buildings used for the storage of noncombustible materials such as products on wood pallets or in paper cartons with or without single thickness divisions; or in paper wrappings. Such products are permitted to have a negligible amount of plastic trim, such as knobs, handles or film wrapping. Group S-2 storage uses shall include, but not be limited to, storage of the following:

- Asbestos
- Beverages up to and including 16-percent alcohol in metal, glass or ceramic containers
- Cement in bags
- Chalk and crayons
- Dairy products in nonwaxed coated paper containers
- Dry cell batteries
- Electrical coils
- Electrical motors
- Empty cans
- Food products
- Foods in noncombustible containers
- Fresh fruits and vegetables in nonplastic trays or containers
- Frozen foods
- Glass
- Glass bottles, empty or filled with noncombustible liquids
- Gypsum board
- Inert pigments
- Ivory
- Meats
- Metal cabinets
- Metal desks with plastic tops and trim
- Metal parts
- Metals
- Mirrors
- Oil-filled and other types of distribution transformers
- Parking garages, open or enclosed
- Porcelain and pottery
- Stoves
- Talc and soapstones
- Washers and dryers

- Buildings in which noncombustible materials are stored are classified as Group S-2, low-hazard storage occupancies (see Figure 311.3). It is acceptable for stored noncombustible products to be packaged in combustible materials as long as the quantity of packaging is kept to an insignificant level.

As seen in Group F-1 and F-2 classifications, it is important to be able to distinguish when the presence of combustible packaging constitutes a significant fuel load. As such, a fuel load might require the building to be classified in Group S-1, moderate-hazard storage. A simple guideline to follow is the "single thickness" rule, which is when a noncombustible product is put in one layer of packaging material.

Examples of materials qualified for storage in Group S-2 storage facilities are as follows:

- Vehicle engines placed on wood pallets for transportation after assembly;
- Washing machines in corrugated cardboard boxes; and
- Soft-drink glass bottles packaged in pressed paper boxes.

Structures used to store noncombustible materials packaged in more than one layer of combustible packaging material are to be classified in Group S-1.
Examples of materials that, because of packaging, do not qualify for classification in Group S-2 are:

- Chinaware wrapped in corrugated paper and placed in cardboard boxes;
- Glassware set in expanded foam forms and placed in a cardboard box; and
- Fuel filters individually packed in pressed paper boxes, placed by the gross in a cardboard box and then stacked on a wood pallet for transportation.

An area of the IFC that is often related to Group S occupancies is Chapter 23, which regulates high-piled combustible storage (storage over 12 feet (3658 mm) in height or 6 feet (1829 mm) if the material is considered high hazard). Chapter 23 of the IFC is focused not only on the type of materials being stored but also the height and configuration of such storage. It is important to note that not all Group S occupancies will contain high-piled storage and that high-piled storage is not limited to Group S occupancies. High-piled storage can be found in occupancies such as Group H or F.

Open and enclosed parking garages are classified as Group S-2 occupancies as long as no repair activities as discussed in the commentary to Section 311.2 occur in such buildings. A garage in a fire station, for example, that undertakes maintenance and repairs limited to cleaning, hose change, water fill, fire equipment upgrades or wheel removal for repair off premise would not constitute the same hazard associated with repair garages and would be appropriately classified as a Group S-2 classification.

SECTION 312
UTILITY AND MISCELLANEOUS GROUP U

312.1 General. Buildings and structures of an accessory character and miscellaneous structures not classified in any specific occupancy shall be constructed, equipped and maintained to conform to the requirements of this code commensurate with the fire and life hazard incidental to their occupancy. Group U shall include, but not be limited to, the following:

- Agricultural buildings
- Aircraft hangars, accessory to a one- or two-family residence (see Section 412.5)
- Barns
- Carports
- Fences more than 6 feet (1829 mm) in height
- Grain silos, accessory to a residential occupancy
- Greenhouses
- Livestock shelters
- Private garages
- Retaining walls
- Sheds
- Stables
- Tanks
- Towers

This section identifies the characteristics of occupancies classified in Group U. Structures that are classified in Group U are typically accessory to another building or structure and are not more appropriately classified in another occupancy. Miscellaneous storage buildings accessory to detached one- and two-family dwellings and multiple single-family dwellings (townhouses) not more than three stories in height, however, are intended to be designed and built in accordance with the IRC (see Section 101.2).

Structures classified as Group U, such as fences, equipment, foundations, and retaining walls are somewhat outside the primary scope of the code (i.e., means of egress, fire resistance). They are not usually considered to be habitable or occupiable. Nevertheless, many code provisions do apply and need to be enforced (e.g., structural design and material performance).

Structures housing accessory equipment that is part of a utility or communications system are often classified as Group U occupancies when there is no intent that these structures be occupied except for servicing and maintaining the equipment within the structure. A pump house for a water or sewage system or an equipment building at the base of a telecommunications tower are examples of such buildings.

Group U occupancies are subject to the same structural loadings such as snow loads as other occupancies. Section 312.1 establishes that occupancies classified as utility and miscellaneous structures shall be constructed, equipped and maintained to conform to the code requirements that are commensurate with the fire and life hazards incidental to their occupancy. The structural design requirements for roofs are the minimum deemed necessary to withstand such elements. Allowing construction of a building with an accessory occupancy that could reasonably be expected to collapse under the snow loads known to prevail in a certain area is not in the best interest of public safety.

Bibliography

The following resource materials are referenced in this chapter or are relevant to the subject matter addressed in this chapter.

Chapter 4: Special Detailed Requirements Based On Use and Occupancy

General Comments
The provisions of Chapter 4 are supplemental to the remainder of the code. Chapter 4 contains provisions that may alter requirements found elsewhere in the code; however, the general requirements of the code still apply unless modified within the chapter. For example, the height and area limitations established in Chapter 5 apply to all special occupancies unless Chapter 4 contains height and area limitations. In this case, the limitations in Chapter 4 supersede those in other sections. An example of this is the height and area limitations given in Section 406.5.4, which supersede the limitations given in Table 503 and Section 503 for open parking garages.

The International Fire Code® (IFC®) contains provisions applicable to the storage, handling and use of hazardous substances, materials or devices and, therefore, must also be complied with when addressing such occupancies as those involving flammable and combustible liquids. Similarly, the International Mechanical Code® (IMC®) and the International Plumbing Code® (IPC®) include provisions for specific applications, such as hazardous exhaust systems and hazardous material piping.

In some instances, it may not be necessary to apply the provisions of Chapter 4. For example, if a covered mall building complies with the provisions of the code for the occupancies within the building, then Section 402 does not apply. However, other sections that address a use, process or operation must be applied to that specific occupancy, such as Sections 410, 411 and 414.

Purpose
The purpose of Chapter 4 is to combine in one chapter the provisions of the code applicable to special uses and occupancies. Hazardous materials and operations may occur in more than one group; therefore, the applicable provisions for the specific hazardous occupancy or operation apply to multiple groups. Also, while the provisions for all structures are interrelated to form an overall protection system, by providing requirements for specific occupancies in Chapter 4 the package of protection features is more easily identified.

Chapter 4 contains the requirements for protecting special uses and occupancies. The provisions in this chapter reflect those occupancies and groups that require special consideration and are not addressed elsewhere in the code. The chapter includes requirements for buildings and conditions that apply to one or more groups, such as high-rise buildings or atriums. Special uses may also imply specific occupancies and operations, such as for Groups H-1, H-2, H-3, H-4 and H-5, application of flammable finishes and combustible storage; or for a specific occupancy within a much larger occupancy, such as covered mall buildings, motor-vehicle-related occupancies, special amusement buildings and aircraft-related occupancies. Finally, in order that the overall package of protection features can be easily understood, occupancies, such as Groups I-2 and I-3, live/work units and underground buildings, are addressed.

SECTION 401
SCOPE

401.1 Detailed use and occupancy requirements. In addition to the occupancy and construction requirements in this code, the provisions of this chapter apply to the special uses and occupancies described herein.

This section provides guidance on how Chapter 4 is to be applied with respect to other sections of the code. Section 401.1 indicates that all other provisions of the code apply except as modified by Chapter 4.

The requirements contained in Chapter 4 are intended to apply to special uses and occupancies, as well as special construction features as defined in various sections in this chapter. These requirements are applicable in addition to other chapters of the code.

SECTION 402
COVERED MALL AND OPEN MALL BUILDINGS

Section 402 has been completely reorganized from the 2009 code; therefore, the * and ** margin indicators have not been included for clarity.

402.1 Applicability. The provisions of this section shall apply to buildings or structures defined herein as covered or
open mall buildings not exceeding three floor levels at any point nor more than three stories above grade plane. Except as specifically required by this section, covered and open mall buildings shall meet applicable provisions of this code.

Exceptions:

1. Foyers and lobbies of Groups B, R-1 and R-2 are not required to comply with this section.

2. Buildings need not comply with the provisions of this section where they totally comply with other applicable provisions of this code.

This section primarily addresses shopping centers with a maximum of three levels that consist of one or more sizeable anchor businesses, typically department stores, known as anchor buildings, and numerous smaller retail stores, all of which are interconnected by means of a mall or common pedestrian way. See Figure 402.1. The mall may be covered, providing a climate-controlled environment, or open to the sky. The complex may include movie theaters, bowling lanes, ice arenas, offices, and dining and drinking establishments. Historically, anchor buildings were large department stores, and malls remain attached to department stores, but under this section anchor buildings can contain any occupancy with the exception of a Group H. The complex may also include single- or multiple-level buildings, with a vast majority of shopping centers being one or two levels, and with an occasional mezzanine. Many malls contain large food courts with a variety of food vendors surrounding a common seating area.

This section addresses the special considerations associated with covered or open mall buildings, including construction, egress and fire protection systems. It does not, in general, apply to the anchor buildings around the perimeter of the covered or open mall building. To be considered an anchor building for purposes of applying the code, the building must have complete egress facilities, including the required number and capacity of exits, independent of the covered or open mall building.

Originally, the provisions of this section applied to the typical covered mall building: a one- to three-level structure consisting primarily of retail space and a covered pedestrian way. More recently, other types of covered mall buildings, such as airport passenger terminals and office centers, have also been constructed in accordance with this section.

Malls with an unroofed common pedestrian way, or open malls, are becoming common in the "sun belt" areas of the country and in similar climates around the world. The code includes open malls within the broader definition of covered mall building and allows the same benefits of the covered mall provisions, because an open-to-the-sky mall provides equivalent or better life safety and property protection. The key to the open mall concept is to have everything a cov-

![Figure 402.1 Covered Mall Building](image-url)

For SI: 1 foot = 304.8 mm.
ered mall building would have, except for the roof over the mall area. Without a roof over the mall area and with required openings from the grade level to the sky above, natural ventilation is provided and mechanical smoke control is no longer necessary in the mall area and adjoining tenant spaces.

This section is not intended to apply to the foyers and lobbies of business and residential occupancies that may contain retail spaces, small restaurants and offices unrelated to the use of upper stories. If these lobbies have multiple levels open to each other, the provisions of Section 404, Atriums, may apply. In all such cases, the provisions for mixed occupancies found in Section 508 would apply. This section is also not intended to apply to large footprint retail buildings, which may include smaller retail spaces, such as banks, florists or coffee stands, around the perimeter of a central sales area. These buildings do not provide the intended concept of a central pedestrian mall that is distinct from the surrounding tenant spaces.

Covered or open mall buildings that comply with all other applicable provisions of the code need not comply with the provisions of this section; however, covered or open mall buildings that are designed and constructed to comply with the provisions of this section must also comply with the provisions of the code that are not otherwise modified in this section. For example, the egress provisions in Section 402.8 are applicable to covered or open mall buildings designed in accordance with this section. The provisions in Chapter 10 related to door swing and stairways are also applicable, however, since Section 402 contains no similar provisions.

402.1.1 Open space. A covered mall building and attached anchor buildings and parking garages shall be surrounded on all sides by a permanent open space or not less than 60 feet (18 288 mm). An open mall building and anchor buildings and parking parking garages adjoining the perimeter line shall be surrounded on all sides by a permanent open space of not less than 60 feet (18 288 mm).

Exception: The permanent open space of 60 feet (18 288 mm) shall be permitted to be reduced to not less than 40 feet (12 192 mm), provided the following requirements are met:

1. The reduced open space shall not be allowed for more than 75 percent of the perimeter of the covered or open mall building and anchor buildings;
2. The exterior wall facing the reduced open space shall have a fire-resistance rating of not less than 3 hours;
3. Openings in the exterior wall facing the reduced open space shall have opening protectives with a fire protection rating of not less than 3 hours; and
4. Group E, H, I or R occupancies are not located within the covered or open mall building or anchor buildings.

One of fundamentals aspects of the covered mall building concept is that significant open space be provided around the perimeter of the entire building. The open space serves two key roles: separation of these buildings from other buildings and ample space on all sides for fire-fighting operations. The required minimum open space of 60 feet (18 288 mm) must also be provided at any anchor buildings and parking garages attached to the covered mall building. In all cases the open space can occur either within public ways surrounding the site, or by yards provided on the lot between the covered mall building and the lot lines, or a combination of yards and public ways. Where a yard is used to achieve the open space, it must be on the same lot as the building receiving the benefit. With respect to the 60-foot (18 288 mm) requirement, the entire width of the public way can be included. The open space must be provided in all directions around the perimeter of the building, not just measured at right angles to the building. A similar degree of open space is required to surround open mall buildings and any adjacent anchor buildings and parking garages.

The exception allows covered or open mall buildings to reduce the required open space around the building in the same manner as unlimited area buildings regulated in Section 507. Where permitted in Section 507, unlimited area buildings require an open space around the building of 60 feet (18 288 mm) to prevent exposure fire spread. Section 507.5 permits five of the nine categories of unlimited area buildings to have a reduced open space of only 40 feet (12 192 mm). This reduction is permitted in these locations when the exterior wall in the required space area is rated for 3 hours and does not include more than 75 percent of the building perimeter. A significant majority of the uses described in Section 507 are found in the definition of a covered or open mall building. Therefore, it can be assumed that the fire load within a mall is similar to the fire load permitted in a code-compliant unlimited area building. Since the intent of the open space requirement is to prevent fire spread from one building to another and the fire loads are similar, allowing covered or open mall buildings to be subject to the separation requirements as other unlimited area buildings does not reduce the level of fire protection afforded. The fourth requirement of the exception aligns this section with the occupancies permitted to use the unlimited area provisions of Section 507.5. Group E, H, I and R occupancies are not prohibited from being within a covered or open mall building or an anchor store, but the exception would prohibit the use of reduced open space if one of these occupancies was a part of the covered or open mall building or anchor building.

402.1.2 Open mall building perimeter line. For the purpose of this code, a perimeter line shall be established. The perimeter line shall encircle all buildings and structures which comprise the open mall building and shall encompass any open-air interior walkways, open-air courtyards or similar open-air spaces. The perimeter line shall define the extent of the open mall building. Anchor buildings and parking struc-
tasures shall be outside of the perimeter line and are not considered as part of the open mall building.

- Where the intent is to apply the open mall building provisions of Section 402, it is necessary to establish a building perimeter line that can be used for the application of various special requirements, such as those regarding travel distance in Section 402.8.5. As shown in Figure 402.1.2, the perimeter line encloses all portions of the open mall building, including open-air walkways and spaces, but does not enclose any anchor buildings or parking garages adjacent to the open mall building. The designer has the discretion as to the relative location of the perimeter line, similar to the discretion they have to place an assumed imaginary line between two buildings located on the same lot. But even with that discretion, it is anticipated that the perimeter line will, in essence, enclose the same space as exterior walls would in a covered mall building.

402.2 Definitions. The following terms are defined in Chapter 2:

ANCHOR BUILDING.

COVERED MALL BUILDING.

- Mall.
- Open mall.
- Open mall building.

FOOD COURT.

GROSS LEASABLE AREA.

- This section lists terms that are specifically associated with the subject matter of Section 402. It is important to emphasize that these terms are not exclusively related to this chapter but may or may not also be applicable where the term is used elsewhere in the code.

Definitions of terms can help in the understanding and application of the code requirements. The purpose for including a list within this chapter is to provide more convenient access to terms which may have a specific or limited application within this chapter. For the complete definition and associated commentary, refer back to Chapter 2. Terms that are italicized provide a visual identification throughout the code that a definition exists for that term. The use and application of all defined terms are set forth in Section 201.

402.3 Lease plan. Each owner of a covered mall building or of an open mall building shall provide both the building and fire departments with a lease plan showing the location of each occupancy and its exits after the certificate of occupancy has been issued. No modifications or changes in occupancy or use shall be made from that shown on the lease plan without prior approval of the building official.

- The required lease plan is permitted to be submitted after the certificate of occupancy has been issued because many times the developer does not have the information at the time of construction. The location of tenant separations may not be known until leases are negotiated with prospective tenants. This may occur after the mall has opened.

During initial construction, it is anticipated that the building department will require tenant improvements to be submitted through the building permit process. After tenant spaces are prepared for occupancy and the lease plan is developed, subsequent modifications and changes must be submitted for approval prior to commencing construction or changing the use. It is important that the fire department receives

OPEN MALL PERIMETER
copies of current lease plans, since not only does this help the fire department while performing fire prevention inspections, but also the lease plans assist in fire department response to an emergency.

402.4 Construction. The construction of covered and open mall buildings, anchor buildings and parking garages associated with a mall building shall comply with Sections 402.4.1 through 402.4.3.

- A number of construction-related provisions are specific to covered and open mall buildings, anchor buildings and associated parking garages. Such buildings are regulated in this section for allowable floor area and height, type of construction, and fire-resistance-rated separations. The various requirements in these code sections are illustrated in Figure 402.4

402.4.1 Area and types of construction. The building area of any covered mall or open building, including anchor buildings, of Types I, II, III and IV construction shall not be limited provided the anchor buildings do not exceed three stories above grade plane.

The construction type of open parking garages and enclosed parking garages shall comply with Sections 406.5 and 406.6, respectively.

Exception: The type of construction allowable building height and building area of anchor buildings greater than three stories above grade plane shall comply with Section 503, as modified by Sections 504 and 506.

- Covered or open mall buildings, as well as anchor buildings, are considered to be special types of unlimited area buildings and are exempt from the allowable area limitations of Table 503 when they are limited to not more than three stories above grade plane. It should be noted that the height limitations in feet, specified in Table 503 based on the type of construction classification, are applicable to covered or open mall buildings. The allowance of an unlimited area anchor building is based on the restriction of construction types to noncombustible (Types I and II), noncombustible/combustible (Type III) and heavy timber (Type IV), and the effectiveness of the automatic sprinkler system. When the anchor building is over three stories above grade plane, it must comply with the general provisions of Chapter 5, such as Sections 503, 504 and 506. A reminder is provided that the construction of parking garages is regulated by the general provisions found in Sections 406.5 and 406.6 and that they are not regulated by the covered mall building’s type of construction. It also clarifies that the garage is not included in the unlimited area allowance given to the mall building and anchor stores.

402.4.2 Fire-resistance-rated separation. Fire-resistance-rated separation is not required between tenant spaces and the mall. Fire-resistance-rated separation is not required between a food court and adjacent tenant spaces or the mall.

- From an operational point of view, separating the tenant space from the mall is not practical in that customer flow would be restricted and, therefore, detract from the merchandising purpose of covered or open malls. Historical experience and reliability data on automatic sprinkler performance indicate that a separation between the tenant space and the mall is not warranted.

402.4.2.1 Tenant separations. Each tenant space shall be separated from other tenant spaces by a fire partition complying with Section 708. A tenant separation wall is not required between any tenant space and the mall.

- Covered mall buildings are essentially large unlimited area mixed-occupancy buildings. Rather than complying with Section 508.3 or 508.4, the building has a series of protections including the tenant separations specified in this section. In order to limit the spread of smoke, tenant separation walls are required to be fire partitions (see Section 708) having a fire-resistance rating of at least 1 hour and extending from the floor to the underside of the ceiling (see Figure 402.4). Extending tenant separations to the floor slab or roof deck above is not always practical or possible because of operation of the heating, ventilating and air-conditioning (HVAC) system. The effectiveness of the automatic sprinkler system is also a reason for not requiring tenant separations to extend above the ceiling, including attic spaces (see Section 708.4, Exception 4).

The open mall "building" provides a unique question regarding separation of tenant spaces. The open mall building may likely be a collection of separate structures treated as one open mall "building." The extent of the open mall building will be established by the perimeter line. Where a separate structure within an open mall contains multiple tenant spaces, those spaces need to be separated as required in this section.

Within the perimeter line the walls between the tenant spaces and the mall will be "interior walls" to the whole open mall building complex, but they are also exterior walls as they separate interior from exterior environments. As part of a complex of buildings, the exterior walls of each individual tenant space facing the mall will not need to meet the wall and opening protection of Section 705, but do need to comply with other exterior wall provisions of Chapter 14. In most cases where there are separate "buildings" within the perimeter line, there will be a walkway – or pedestrian mall – between the buildings. Even where these are off the main mall, these are still considered tenant walls facing the mall. The walls on the exterior face of the open mall "building," those adjoining the perimeter line, would be subject to the provisions of Section 705.

402.4.2.2 Anchor building separation. An anchor building shall be separated from the covered or open mall building by fire walls complying with Section 706.

Exceptions:

1. Anchor buildings of not more than three stories above grade plane that have an occupancy classifi-
ication the same as that permitted for tenants of the mall building shall be separated by 2-hour fire-resistance-rated fire barriers complying with Section 707.

2. The exterior walls of anchor buildings separated from an open mall building by an open mall shall comply with Table 602.

In general, anchor buildings are typically viewed as being separate from the covered or open mall building (see commentary, Sections 402.1 and 402.4.1). As separate buildings, the code requires that a fire wall complying with Section 706 be constructed.

The first exception to this section may be used in situations where the occupancy and size limitations of the anchor building are the same as what would be permitted for any other tenant within the covered mall building. In those situations, the code permits the separation to be constructed as a fire barrier instead of as a fire wall. The exception would not be applicable if the anchor building was over three stories above grade plane or if it contained an occupancy that was not normally permitted within the mall. An example would be a high-rise office building or a hotel that was connected with the covered mall building (see Figure 402.4 and commentary, Section 402.4.2.2.1).

For an open mall building where the anchor building is actually a separate building, the application of a fire wall may not be appropriate, but since it is considered a separate structure even under the covered mall scenario, it is appropriate to have the anchor building provide exterior wall protection set in Table 602. This allowance is set forth in Exception 2.

A growing trend in the development of mall buildings and anchor buildings is the desire of the operators of the businesses in an anchor building to own the structure of the anchor building as well as a distinct parcel of land on which the anchor building sits. The original intent of the mall provisions was to apply to one building, or a collection of buildings, located on one lot under the control of one owner. Various provisions assume a single "lot" for the covered mall and associated anchor buildings and parking structures. If the mall and associated buildings are managed as a single complex, strict interpretation would eliminate the application of these provisions to such a complex. Application of the Section 402 mall provisions to a sit-

---

**Figure 402.4**

TENANT SPACE AND ANCHOR BUILDING SEPARATIONS

1. WALL CONSTRUCTED AS REQUIRED FOR AN EXTERIOR WALL
2. WALL CONSTRUCTED AS REQUIRED FOR A TENANT SEPARATION BY SECTION 402.4.2.1
3. WALL CONSTRUCTED AS REQUIRED BY SECTION 402.4.2.2 (FIRE WALL OR FIRE BARRIER)
4. UNPROTECTED OPENING
5. WALL CONSTRUCTED AS REQUIRED BY SECTION 402.4.2
uation where the mall and anchor buildings are separate ownership lots would be problematic, requiring special legal and technical considerations and treatment by the authority having jurisdiction.

402.4.2.2.1 Openings between anchor building and mall. Except for the separation between Group R-1 sleeping units and the mall, openings between anchor buildings of Type IA, IB, IIA or IIB construction and the mall need not be protected.

- As with tenant separations, openings between the anchor building and the pedestrian area of the mall need not be protected. Such separations would defeat the merchandising purpose of covered malls by restricting customer flow and visual access. While the openings may be unprotected, the separations between the anchor building and all tenant spaces in the covered mall building are to be constructed as required in Section 402.4.2.2 for a fire wall (see commentary, Section 706) or fire barrier (see commentary, Section 707) since the anchor building is considered a separate building (see Figure 402.4).

402.4.2.3 Parking garages. An attached garage for the storage of passenger vehicles having a capacity of not more than nine persons and open parking garages shall be considered as a separate building where it is separated from the covered or open mall building or anchor building by not less than 2-hour fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both.

Parking garages, open or enclosed, which are separated from covered mall buildings, open mall buildings or anchor buildings shall comply with the provisions of Table 602.

Pedestrian walkways and tunnels which connect garages to mall buildings or anchor buildings shall be constructed in accordance with Section 3104.

- Buildings adjacent to mall buildings are typically considered separate buildings provided they are separated by exterior walls or fire walls. In recognition of the limited hazard presented by attached garages and open parking garages, this section permits such structures to be considered separate buildings, provided that fire barriers and horizontal assemblies having a fire-resistance rating of at least 2 hours are provided. See the commentary to Section 707 relative to the construction of fire barriers and Section 711 relative to the construction of horizontal assemblies.

The 2-hour fire-resistance rating is consistent with the requirements of Table 508.4 for Groups M and S-2. If the 2-hour fire barrier or horizontal assembly is not provided, the parking structure can be considered part of the covered mall building and be limited. Table 602 regulating exterior wall protection is applicable for those parking garages that are not attached to the covered or open mall building or anchor buildings. See the commentary to Section 3104 for the requirements related to any pedestrian walkways or tunnels which connect the garages to mall buildings or anchor stores.

402.4.3 Open mall construction. Floor assemblies in, and roof assemblies over, the open mall of an open mall building shall be open to the atmosphere for not less than 20 feet (9096 mm), measured perpendicular from the face of the tenant spaces on the lowest level, from edge of balcony to edge of balcony on upper floors and from edge of roof line to edge of roof line. The openings within, or the unroofed area of, an open mall shall extend from the lowest grade level of the open mall through the entire roof assembly. Balconies on upper levels of the mall shall not project into the required width of the opening.

- An open mall requires a minimum open area width of 20 feet (9096 mm) between opposing structures from the lowest grade level to the sky above. This dimension aligns with Section 402.8.1.1, minimum width for egress. The width of the opening is measured perpendicular from the face of the tenant spaces, essentially across the pedestrian mall. This is similar to the mall width for covered malls. The opening, or the unroofed area, must extend from the lowest grade level of the common open mall to the sky above. This will provide natural ventilation to all levels. Balconies on the upper levels are permitted but may not project into the required 20-foot (9096 mm) width. Pedestrian walkways and overhangs at the end locations of the open mall are permitted (see Figure 402.4.3).

402.4.3.1 Pedestrian walkways. Pedestrian walkways connecting balconies in an open mall shall be located not less than 20 feet (9096 mm) from any other pedestrian walkway.

- Where pedestrian walkways are provided, they must be spatially separated in order to maintain the expected openness of the open mall area. The minimum required distance of 20 feet (9096 mm) is consistent with the minimum open space required between various buildings that make up an open mall building.

[F] 402.5 Automatic sprinkler system. Covered and open mall buildings and buildings connected shall be protected throughout with an automatic sprinkler system in accordance with Section 903.3.1.1, which shall comply with all of the following:

1. The automatic sprinkler system shall be complete and operative throughout occupied space in the mall building prior to occupancy of any of the tenant spaces. Unoccupied tenant spaces shall be similarly protected unless provided with approved alternative protection.

2. Sprinkler protection for the mall of a covered mall building shall be independent from that provided for tenant spaces or anchor buildings.
3. Sprinkler protection for the tenant spaces of an open mall building shall be independent from that provided for anchor buildings.

4. Sprinkler protection shall be provided beneath exterior circulation balconies located adjacent to an open mall.

5. Where tenant spaces are supplied by the same system, they shall be independently controlled.

Exception: An automatic sprinkler system shall not be required in spaces or areas of open parking garages separated from the covered or open mall building in accordance with Section 402.4.2.3 and constructed in accordance with Section 406.5.

The covered or open mall building and connected buildings, such as anchor buildings, must be protected with an automatic sprinkler system to protect life and property effectively. As has been discussed throughout the section, numerous allowances (such as reduced tenant separations and elimination of area limitations) are based on the effectiveness of the automatic sprinkler system.

The sprinkler system is to be designed, installed, tested and maintained in accordance with Chapter 9, the IFC and NFPA 13. Additionally, the system must be installed such that any portion serving tenant spaces in a covered mall building may be shut down independently without affecting the operation of the systems protecting the mall area. This special feature is in recognition of the frequent need to shut down the system so that changes can be made to it as a result of tenant improvements and modifications.

In an open mall building, the sprinkler systems for the tenant spaces are to be separate from those provided for the anchor buildings. It is necessary that sprinkler protection for open mall buildings be extended to the underneath side of pedestrian walk-
ways and exterior balconies used for circulation and egress purposes. Although the open mall itself requires no sprinkler protection, it is important that those areas below overhead walkways be provided with sprinklers.

Section 909.12.3 requires operation of the sprinkler system to activate automatically the mechanical smoke control system (where an automatic control system is utilized). It is imperative that the zoning of the sprinkler system match the zoning of the smoke control system. This is necessary so that the area where water flow has occurred will also be the area from which smoke is removed. Smoke control is only required where an atrium is present (see Section 402.7.2).

The exception clarifies that sprinkler protection need not be extended to complying open parking garages that are adequately separated from the covered mall building, open mall building or anchor store. The allowance is consistent with the automatic sprinkler provisions of Section 903.2 where no sprinkler protection is required in open parking garages based on occupancy classification (Group S-2).

402.6 Interior finishes and features. Interior finishes within the mall and installations within the mall shall comply with Sections 402.6.1 through 402.6.4.

This section addresses one general fire safety feature (interior finishes) and three specific features commonly found in covered mall buildings. Such features are also addressed where applicable within the perimeter line of an open mall building.

402.6.1 Interior finish. Interior wall and ceiling finishes within the mall of a covered mall building and within the exits of covered or open mall buildings shall have a minimum flame spread index and smoke-developed index of Class B.

402.6.2 Kiosks. Kiosks and similar structures (temporary or permanent) located within the mall of a covered mall building or within the perimeter line of an open mall building shall meet the following requirements:

1. Combustible kiosks or other structures shall not be located within a covered or open mall unless constructed of any of the following materials:

   1.1. Fire-retardant-treated wood complying with Section 2303.2.

   1.2. Foam plastics having a maximum heat release rate not greater than 100 kW (105 Btu/h) when tested in accordance with the exhibit booth protocol in UL 1975 or when tested in accordance with NFPA 289 using the 20 kW ignition source.

   1.3. Aluminum composite material (ACM) meeting the requirements of Class A interior finish in accordance with Chapter 8 when tested as an assembly in the maximum thickness intended.

2. Kiosks or similar structures located within the mall shall be provided with approved automatic sprinkler system and detection devices.

3. The horizontal separation between kiosks or groupings thereof and other structures within the mall shall be not less than 20 feet (6096 mm).

4. Each kiosk or similar structure or groupings thereof shall have an area not greater than 300 square feet (28 m²).

Other potential sources of combustibles within the mall area are kiosks and similar structures. As with the restrictions of Section 402.6.4 on plastic signs, in order to maintain the mall as a viable means of egress, the amount of combustibles within the mall must be minimized. The restriction on kiosk construction and location is also intended to minimize the potential for fire spread through the mall area. These restrictions apply to both permanent and temporary structures and are applicable to both covered and open mall buildings.

Kiosks and similar structures are permitted to be of noncombustible construction or may be of combustible construction where the provisions of Item 1 are followed. The code allows combustible kiosks to be made of fire-retardant-treated wood or certain foam plastics and aluminum composites that provide performance comparable to that of the fire-retardant-treated wood. As such, the amount of combustibles within the mall and the potential for fire spread through the mall are minimized.

If the kiosk or similar structure has a cover, the automatic sprinkler system within the covered mall building will not be able to control effectively a fire within the kiosk (or similar structure) in the early stages of development. Suppression and detection devices must, therefore, be installed within such
structures when there is anything that shields the mall sprinkler system from areas within the kiosk.

In order to minimize a fire exposure hazard, kiosks and similar structures must be located at least 20 feet (6096 mm) from each other or be situated in groups that are appropriately separated from other kiosks. Although the structure itself is often noncombustible or of the limited types of acceptable combustible materials, it is recognized that combustibles may be displayed within the structure and, therefore, the separation minimizes the potential for fire spread from kiosk to kiosk. If a series of kiosks do not have 20 feet (6096 mm) separating them, they can be treated as a group and would be limited to 300 square feet (28 m²), as a group. The open space between individual kiosks in the group can be excluded from the aggregate area for determining the area of the group (see IBC Interpretation No. 11-07). Within a group of kiosks treated as one, there can be multiple "tenants" or one, and there are no specifics about the relative size of individual kiosks within the group (see IBC Interpretation Nos. 13-07 and 14-07). As required by Section 402.8.1, the kiosk must also be located at least 10 feet (3048 mm) from any projection of a tenant space.

To further control the use of kiosks and similar structures within the mall, their size is restricted to 300 square feet (28 m²) or less. This area restriction attempts to minimize the potential for a significant fire within the mall area. A kiosk larger than 300 square feet (28 m²) must be considered as a tenant space.

402.6.3 Children's play structures. Children’s play structures located within the mall of a covered mall building or within the perimeter line of an open mall building shall comply with Section 424. The horizontal separation between children’s play structures, kiosks and similar structures within the mall shall not be less than 20 feet (6096 mm).

- A common attraction found within covered and open mall buildings is one or more dedicated play areas for children. These attractions include such things as jungle gyms, playhouses and activity areas. If these structures exceed 10 feet (3048 mm) in height and 150 square feet (14 m²) in area, then the provisions of Section 424 must be followed. Children’s play structures have to be separated from each other, as well as from kiosks and similar structures, by at least 20 feet (6096 mm) in order to limit the aggregate combustible fire loading created by such structures.

402.6.4 Plastic signs. Plastic signs affixed to the storefront of any tenant space facing a mall or open mall shall be limited as specified in Sections 402.6.4.1 through 402.6.4.5.

- In order that the mall can be used as an exit access, combustible materials in the mall must be restricted; therefore, the size, area, location and amount of exposed plastic signs are restricted. This section restricts only plastic signs that are along the wall separating the tenant space from the mall (see Figure 402.6.4). The limit applies to both covered and open mall buildings. While the potential hazard of a plastic sign are somewhat dissipated in an open air mall, the pedestrian malls within an open mall are still considered space within a mall and are used for egress from the complex, therefore appropriate protections are needed. If the sign housing and face panels are noncombustible or glass, there are no limitations. Light-transmitting plastic interior signs not located in the mall, such as those located within an individual tenant space, must comply with the requirements of Chapter 28.

402.6.4.1 Area. Plastic signs shall be not more than 20 percent of the wall area facing the mall.

- The signs located on the wall facing the mall must not exceed 20 percent of the wall area. The restrictions on size, coupled with the restrictions on location and height, are intended to prevent fire spread via the plastic signs.

402.6.4.2 Height and width. Plastic signs shall not be greater than 36 inches (914 mm) in height, except that if the sign is vertical, the height shall be not greater than 96 inches (2438 mm) and the width shall be not greater than 36 inches (914 mm).

- Signs that are wider than they are high (horizontal panels) must not be more than 36 inches (914 mm) in height. The width of signs is controlled by the maximum area (see Section 402.6.4.1) and the location restrictions with respect to adjacent tenant spaces (see Section 402.6.4.3). Vertical signs must not be more than 36 inches (914 mm) in width and 96 inches (2438 mm) in height and are also subject to the area and location restrictions of other sections. The restrictions are intended to minimize horizontal and vertical fire spread through the mall area via the signs.

402.6.4.3 Location. Plastic signs shall be located not less than 18 inches (457 mm) from adjacent tenants.

- To minimize the potential for fire spread, plastic signs must be located at least 18 inches (457 mm) from adjacent tenant spaces.

402.6.4.4 Plastics other than foam plastics. Plastics other than foam plastics used in signs shall be light-transmitting plastics complying with Section 2606.4 or shall have a self-ignition temperature of 650°F (343°C) or greater when tested in accordance with ASTM D 1929, and a flame spread index not greater than 75 and smoke-developed index not greater than 450 when tested in the manner intended for use in accordance with ASTM E 84 or UL 723 or meet the acceptance criteria of Section 803.1.2.1 when tested in accordance with NFPA 286.

- To minimize the potential fire hazard, light-transmitting plastic signs located in a mall must comply with the specific material requirements of Section 2606.4 (see commentary, Section 2606.4) or must meet one of the alternative test methods that are permitted. Additionally, the backs and edges of the sign must be encased to reduce the likelihood of ignition and fire spread.

2012 INTERNATIONAL BUILDING CODE® COMMENTARY
402.6.4.1 Encasement. Edges and backs of plastic signs in the mall shall be fully encased in metal.

- In order that the amount of exposed plastic materials in the mall is minimized, as well as to reduce the potential for ignition of a plastic panel, the edges and backs of plastic signs must be encased in metal. To conceptually understand this requirement, consider how easily a piece of paper ignites when a flame is held to its edge versus being held in the middle of the paper.

402.6.4.5 Foam plastics. Foam plastics used in signs shall have flame-retardant characteristics such that the sign has a maximum heat-release rate of 150 kilowatts when tested in accordance with UL 1975 or when tested in accordance with NFPA 289 using the 20 kW ignition source, and the foam plastics shall have the physical characteristics specified in this section. Foam plastics used in signs installed in accordance with Section 402.6.4 shall not be required to comply with the flame spread and smoke-developed indices specified in Section 2603.3.

- Foam plastics that are used in signs located in a mall must comply with the provisions of Sections 402.6.4.5.1 and 402.6.4.5.2. The provisions of the code include specific material requirements for the foam plastics, such as the allowable heat-release rate, density and thickness permitted.

402.6.4.5.1 Density. The density of foam plastics used in signs shall be not less than 20 pounds per cubic foot (pcf) (320 kg/m³). This limitation lessens the likelihood that the sign will add a significant fuel load to the tenant space entrance.

402.6.4.5.2 Thickness. The thickness of foam plastic signs shall not be greater than 1/4 inch (12.7 mm).

- The thickness of the foam plastic sign is also limited to lessen the likelihood that the sign will add a significant fuel load to the tenant space entrance.

[F] 402.7 Emergency systems. Covered and open mall buildings, anchor buildings and associated parking garages shall be provided with emergency systems complying with Sections 402.7.1 through 402.7.5.

- The special allowances for covered and open mall buildings are available in part to the presence of several emergency fire protection systems within the building. In addition to the automatic sprinkler system required by Section 402.5, this section identifies those systems and methods by addressing standpipe systems, smoke control, standby power, emergency voice/alarm communication and fire department access to equipment.

[F] 402.7.1 Standpipe system. Covered and open mall buildings shall be equipped throughout with a standpipe system as required by Section 905.3.3.

- This section provides a reminder to the code user and a direct reference to the section that regulates the need for standpipes or hose connections for covered or open mall buildings (see commentary, Section 905.3.3).

Figure 402.6.4
STOREFRONT SIGNAGE WITH PLASTIC SIGNS

2012 INTERNATIONAL BUILDING CODE® COMMENTARY 4-11
SPECIAL DETAILED REQUIREMENTS BASED ON USE AND OCCUPANCY

[F] 402.7.2 Smoke control. Where a covered mall building contains an atrium, a smoke control system shall be provided in accordance with Section 404.5.

Exception: A smoke control system is not required in covered mall buildings where an atrium connects only two stories.

- A smoke control system must be provided for all covered mall buildings that contain an atrium which connects more than two stories. An "atrium" is defined (Section 202) as an opening connecting two or more stories other than enclosed stairways, elevators, hoistways, escalators, plumbing, electrical, air-conditioning or other equipment, which is closed at the top. Malls inherently contain unenclosed floor openings that may allow for the migration of smoke and hot gases resulting from a fire. See Sections 404.5 and 909 for a discussion of the requirements of the smoke control system, noting the exceptions listed for floor openings. Open malls and adjoining tenant spaces are not required to have a smoke control system because they are open at the top and would not meet the definition of an "atrium." However, individual tenant spaces that contain an atrium and are part of an open mall "building" are not exempted from the smoke control requirement.

[F] 402.7.3 Standby power. Covered mall buildings greater than 50,000 square feet (4645 m²) in area and open mall buildings greater than 50,000 square feet (4645 m²) within the established perimeter line shall be provided with standby power systems that are capable of operating the emergency voice/alarm communication system.

- Covered and open mall buildings of a substantial size are required to have a standby power system for the emergency voice/alarm communication system. See Section 2702.2.14 of the commentary for further discussion of when a mall building exceeds 50,000 square feet (4645 m²). For open mall buildings, the threshold of 50,000 square feet (4645 m²) is based on the floor area within the building's perimeter line as described in Section 402.1.2.

[F] 402.7.4 Emergency voice/alarm communication system. Where the total floor area is greater than 50,000 square feet (4645 m²) within either a covered mall building or within the perimeter line of an open mall building, an emergency voice/alarm communication system shall be provided.

Emergency voice/alarm communication systems serving a mall, required or otherwise, shall be accessible to the fire department. The systems shall be provided in accordance with Section 907.5.2.2.

- An emergency voice/alarm communication system is required to allow the fire department control and communication during an emergency situation. Such a system is required when the covered or open mall building exceeds a floor area of 50,000 square feet (4645 m²) (see commentary, Section 907.5.2.2). For open mall buildings, the threshold of 50,000 square feet (4645 m²) is based on the floor area within the building's perimeter line as described in Section 402.1.2.

[F] 402.7.5 Fire department access to equipment. Rooms or areas containing controls for air-conditioning systems, automatic fire-extinguishing systems, automatic sprinkler systems or other detection, suppression or control elements shall be identified for use by the fire department.

- Consideration should be given to fire department access during an emergency. Fire department personnel may need to either determine that the fire protection systems are functioning properly or override the automatic features to manually activate or shut down a particular system. For this reason, the fire department must have access to controls for the air-conditioning and fire protection systems. The controls are to be clearly identified so that fire department personnel can properly operate them.

402.8 Means of egress. Covered mall buildings, open mall buildings and each tenant space within a mall building shall be provided with means of egress as required by this section and this code. Where there is a conflict between the requirements of this code and the requirements of Sections 402.8.1 through 402.8.8, the requirements of Sections 402.8.1 through 402.8.8 shall apply.

- Covered mall buildings and open mall buildings, as well as each individual tenant space within the covered or open mall building, is required to have means of egress that complies with other provisions of the code—especially Chapter 10. Keep in mind that the requirements of Section 402.8 will supersede some of the provisions of Chapter 10. In order to comply, travel through the mall area is considered as exit access and must comply with Section 402.8.5. Travel distance within a tenant space need only be measured to the entrance of the mall from the space (see Figure 402.8). As such, two distinct criteria must be met with regard to exit access travel distance: travel within the mall and travel within the tenant space.

402.8.1 Mall width. For the purpose of providing required egress, malls are permitted to be considered as corridors but need not comply with the requirements of Section 1005.1 of this code where the width of the mall is as specified in this section.

- The pedestrian malls that serve as the exit access routes for the tenant space occupants are not required to comply with Section 1005.1. The design capacity of the mall width is already established by Section 402.8.1. No further egress width calculations are required by the code for mall corridors.

402.8.1.1 Minimum width. The aggregate clear egress width of the mall in either a covered or open mall building shall be not less than 20 feet (6096 mm). The mall width shall be sufficient to accommodate the occupant load served. No portion of the minimum required aggregate egress width shall be less than 10 feet (3048 mm) measured to a height of 8 feet (2438 mm) between any projection of a tenant space bordering the mall and the nearest kiosk, vending machine, bench, display
opening, food court or other obstruction to means of egress travel.

- The minimum 200-foot (6096 mm) clear egress width of a mall is based on the need to provide adequate access to exits or, for open malls, the "building perimeter line" which is the point where people transition from within the open mall "building" to outside of the "building." Together with the automatic sprinkler system, the physical separation further reduces the need for a separation between tenant spaces and the mall.

So that an aggregate clear width of 20 feet (6096 mm) is always provided in the mall, a minimum 10-foot (3048 mm) clear and unobstructed space is to be maintained to a height of 8 feet (2438 mm) in front of, adjacent to and parallel to the storefronts. The requirement applies to kiosks, vending machines, benches, small stands, merchandise displays and any other potential obstruction to egress (see Figure 402.8.1.1).

402.8.2 Determination of occupant load. The occupant load permitted in any individual tenant space in a covered or open mall building shall be determined as required by this code. Means of egress requirements for individual tenant spaces shall be based on the occupant load thus determined.

- Since the tenant spaces of covered or open mall buildings can be used for varied occupancies, the design occupant loads will also vary. Although each tenant space contributes to the gross leasable area of Section 402.8.2.1, each must have its own occupant load calculated along with the applicable means of egress requirements. For example, a restaurant with its own dining area may occupy a tenant space. The design occupant load for this space is calculated in

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

Figure 402.8
MEANS OF EGRESS
SPECIAL DETAIL REQUIREMENTS BASED ON USE AND OCCUPANCY

accordance with Table 1004.1.1 based on the assembly occupancy of the dining areas and on the commercial kitchen occupancy of the food preparation areas. Door swing direction and panic and fire exit hardware requirements would be based on this occupant load.

402.8.2.1 Occupant formula. In determining required means of egress of the mall, the number of occupants for whom means of egress are to be provided shall be based on gross leasable area of the covered or open mall building (excluding anchor buildings) and the occupant load factor as determined by Equation 4-1.

\[
OLF = (0.00007) (GLA) + 25 \quad \text{(Equation 4-1)}
\]

where:

\[
OLF = \text{The occupant load factor (square feet per person)}.
\]

\[
GLA = \text{The gross leasable area (square feet)}.
\]

Exception: Tenant spaces attached to a covered or open mall building but with a means of egress system that is totally independent of the open mall of an open mall building or of a covered mall building shall not be considered as gross leasable area for determining the required means of egress for the mall building.

\[\checkmark\] The capacity of the exits serving the covered and open mall buildings must satisfy the calculated occupant load based on the gross leasable area. The occupant load factors (OLF) were determined empirically by surveying more than 270 covered mall shopping centers, studying mercantile occupancy parking requirements [5.0 cars per 1,000 square feet (93 m²) of gross leasable area] and observing the number of occupants per vehicle during peak seasons (4.0 per car).

The formula used for determining occupant load results in a smooth transition between the occupant load and the gross leasable area with a range of 30 to 50.

For example, if the gross leasable area of the covered or open mall building is 400,000 square feet (37160 m²), the calculated OLF is determined as follows:

\[
OLF = (0.00007) (400,000) + 25
\]

\[
OLF = 53 \text{ square feet (4.9 m²) per person}
\]

Since the design occupant load factor cannot exceed 50 in accordance with Section 402.8.2.2, the required OLF would be 50 square feet (4.6 m²) per person.

If the gross leasable area of the mall building is 55,000 square feet (5109 m²), the calculated OLF is determined as follows:

\[
OLF = (0.00007) (55,000) + 25
\]

\[
OLF = 29 \text{ square feet (2.7 m²) per person}
\]

Since the OLF need not be less than 30 in accordance with Section 402.8.2.2, the required occupant load factor would be 30 square feet (2.8 m²) per person. The code would permit the use of an occupant load factor of 29, since it would result in a higher design occupant load and consequently increased width of exits.

402.8.2.2 OLF range. The occupant load factor (OLF) is not required to be less than 30 and shall not exceed 50.

\[\checkmark\] Although not mandatory, an OLF of less than 30 may be used at the designer's discretion (see Section 1004.2). In no case should an OLF greater than 50 be used, since it would result in too small a design occupant load.

For SI: 1 foot = 304.8 mm, 1 inch = 25.4 mm.

Figure 402.8.1.1
COVERED MALL MINIMUM WIDTH

4-14
2012 INTERNATIONAL BUILDING CODE® COMMENTARY
402.8.2.3 Anchor buildings. The occupant load of anchor buildings opening into the mall shall not be included in computing the total number of occupants for the mall.

- Although anchor buildings are allowed access to the mall portions of the covered or open mall building, the occupant load of the mall does not have to be increased for this access. People may certainly discharge from the anchor building into the mall on their own accord; however, the anchor building is required to provide sufficient exits for its occupant load at locations other than the mall.

402.8.2.4 Food courts. The occupant load of a food court shall be determined in accordance with Section 1004. For the purposes of determining the means of egress requirements for the mall, the food court occupant load shall be added to the occupant load of the covered or open mall building as calculated above.

- The occupant load for food courts must be determined in accordance with Section 1004. Typically, tables and chairs are provided for the public's use in a food court. As such, the design occupant load for a food court is usually calculated at a rate of one person for every 15 square feet (1.4 m²) of net floor space for an unconcentrated assembly occupancy. The occupant loads for all food courts are added to the mall occupant load calculated in accordance with Section 402.8.2.1 and Equation 4.1. Food courts are not considered part of the gross leasable area of the mall; therefore, the occupant loads of the food courts must be calculated separately and then added to the overall covered or open mall building occupant load.

402.8.3 Number of means of egress. Wherever the distance of travel to the mall from any location within a tenant space used by persons other than employees is greater than 75 feet (22 860 mm) or the tenant space has an occupant load of 50 or more, no fewer than two means of egress shall be provided.

- This section applies within each tenant space. It dictates the minimum number of paths of travel an occupant is to have available to avoid a fire incident in the occupied tenant space. While providing multiple egress doorways from every tenant space is unrealistic, a point does exist where alternative egress paths must be provided, based on the number of occupants at risk, the distance occupants must travel to reach the mall and the relative hazards associated with the occupancy of the space.

  The 75-foot (22 860 mm) travel distance and the 49-person occupant load limitations represent an empirical judgment of the risks associated with a single means of egress from a tenant space based on the inherent risks associated with the occupancy (such as occupant mobility, occupant familiarity with the mall, occupant response and the fire growth rate). The requirement for two exits for 50 or more occupants applies to all occupants of the tenant space, including employees. The 75-foot (22 860 mm) travel distance does not apply to employees. Employee-only areas of the tenant space can require travel greater than 75 feet (22 860 mm) to reach the mall or other exit and a second means of egress is not required in spaces with an occupant load less than 50.

402.8.4 Arrangements of means of egress. Assembly occupancies with an occupant load of 500 or more located within a covered mall building shall be so located such that their entrance will be immediately adjacent to a principal entrance to the mall and shall have not less than one-half of their required means of egress opening directly to the exterior of the covered mall building. Assembly occupancies located within the perimeter line of an open mall building shall be permitted to have their main exit open to the open mall.

- Tenant spaces which are assembly occupancies with an occupant load of 500 or more must be carefully located to minimize the hazards of egress. Movie theaters, nightclubs and large restaurants must be located on an exterior wall of the covered mall building and adjacent to the mall's exits if their occupant loads exceed 499. A maximum of 50 percent of the means of egress from these assembly occupancies is permitted to discharge into the mall. Other means of egress from these tenant spaces must discharge directly to the exterior with a capacity of at least one-half the occupant load. For open mall buildings, any assembly occupancy located with the building perimeter line is permitted to have their main exits open directly into the mall due to the decreased hazard level of an open, unroofed, mall compared to an enclosed and covered mall.

402.8.4.1 Anchor building means of egress. Required means of egress for anchor buildings shall be provided independently from the mall means of egress system. The occupant load of anchor buildings opening into the mall shall not be included in determining means of egress requirements for the mall. The path of egress travel of malls shall not exit through anchor buildings. Malls terminating at an anchor building where no other means of egress has been provided shall be considered as a dead-end mall.

- As indicated in the definition of anchor building (See Section 202), the required means of egress for an anchor building must be provided independently of the mall and the means of egress from the mall. Since independent means of egress are provided, the occupant load of anchor buildings is not included in determining the means of egress requirements for the mall. If independent means of egress are not provided, the space cannot be considered an anchor building and is to be treated as any other tenant space of the mall. As such it would need to be included in the gross leasable area under Section 402.8.2.1.

402.8.5 Distance to exits. Within each individual tenant space in a covered or open mall building, the distance of travel from any point to an exit or entrance to the mall shall be no greater than 200 feet (60 960 mm).
402.8.6 Access to exits. Where more than one exit is required, they shall be so arranged that it is possible to travel in either direction from any point in a mall of a covered mall building to separate exits or from any point in an open mall of an open mall building to two separate locations on the perimeter line, provided neither location is an exterior wall of an anchor building or parking garage. The width of an exit passageway or corridor from a mall shall be not less than 66 inches (1676 mm).

Exception: Access to exits are permitted by way of a dead-end mall which does not exceed a length equal to twice the width of the mall measured at the narrowest location within the dead-end portion of the mall.

In order to accommodate the many occupants anticipated in a covered or open mall building, exits are to be distributed equally throughout the mall. If exits were congested in certain areas, egress would be compounded by the convergence of a large number of people to one or more areas of the building. In an open mall building, the distribution of exits must occur at separate locations on the perimeter line that are open and provide continued egress to the public way. The corridors and exit access passageways from a mall must be at least 66 inches (1676 mm) wide.

The maximum dead end permitted in a mall is twice the width of the mall. For a mall with a minimum width of 20 feet (6096 mm), dead ends are permitted to be 40 feet (12 192 mm) or less in length. The allowance for dead ends is in recognition of the reduced hazard represented by a dead end in a mall and because the relatively large minimum width provides alternative paths of travel. Additionally, dead ends are not as critical in a mall, since the volume of the space and the automatic sprinkler system minimize the potential for the space to become untenable in a fire condition.

402.8.6.1 Exit passageways. Where exit passageways provide a secondary means of egress from a tenant space, doorways to the exit passageway shall be protected by 1-hour fire door assemblies that are self- or automatic-closing by smoke detection in accordance with Section 716.5.9.3.

If exit passageways must be provided because of either travel distance limitations or the number of means of egress required from a tenant space, the passageways must be enclosed as required by the code. Additionally, the doors opening from the tenant spaces into the exit enclosures must be not less than 1-hour rated. These doors must be self-closing or automatic-closing by smoke detection to provide the necessary protection as the occupants of a tenant space flee a fire situation.

402.8.7 Service areas fronting on exit passageways. Mechanical rooms, electrical rooms, building service areas and service elevators are permitted to open directly into exit passageways, provided the exit passageway is separated from such rooms with not less than 1-hour fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both. The fire protection rating of openings in the fire barriers shall be not less than 1 hour.

In a covered mall building, it is necessary to provide for services to the tenant spaces that are maintained by the mall management (e.g., water, electricity, telephone and fire protection). These services must be located in a common space controlled by the mall management and, therefore, cannot be located within the tenant spaces. Frequently, these services are logically located with direct access to exit passageways at the rear of the tenant spaces. For open mall buildings, the use of exit passageways will probably not occur as frequently, but where they do, they also need to comply with this section.

Exit passageways are generally treated similar to exit stairways in that only openings from normally occupied spaces are permitted. This would prohibit doors or utility penetrations to such mechanical/electrical rooms. In the case of malls, the code allows an exception to that general rule, provided that the fire-resistance rating of the exit enclosure is maintained by appropriate opening protection, such as fire doors, fire dampers and through-penetration firestopping.

402.8.8 Security grilles and doors. Horizontal sliding or vertical security grilles or doors that are a part of a required means of egress shall conform to the following:

1. They shall remain in the full open position during the period of occupancy by the general public.

2. Doors or grilles shall not be brought to the closed position when there are 10 or more persons occupying spaces served by a single exit or 50 or more persons occupying spaces served by more than one exit.

3. The doors or grilles shall be openable from within without the use of any special knowledge or effort where the space is occupied.
4. Where two or more exits are required, not more than one-half of the exits shall be permitted to include either a horizontal sliding or vertical rolling grille or door.

- When improperly installed or when their use is not properly supervised, security grilles and doors can prohibit or delay egress beyond an acceptable time period. Such security devices are common in covered mall buildings. In every case, the grille must be openable to permit egress from the inside without the use of tools, keys or special knowledge or effort when the grille spans across a means of egress. For example, during business hours in a mercantile use, the grille must remain in its full, open position. The grille may be taken to a partially closed position when it provides the sole means of egress and no more than nine persons occupy the space. If a second means of egress is required, the grille may not be closed, as long as more than 49 persons occupy the space.

Because security grilles represent such a threat to prompt egress, the number of occupants exposed to the risk of a lack of supervision of the devices is limited. Except where a single means of egress is permitted, alternative means of egress must be available and not equipped with such devices. Security grilles must not be used on more than 50 percent of the exits.

SECTION 403
HIGH-RISE BUILDINGS

403.1 Applicability. High-rise buildings shall comply with Sections 403.2 through 403.6.

Exception: The provisions of Sections 403.2 through 403.6 shall not apply to the following buildings and structures:

1. Airport traffic control towers in accordance with Section 412.3.

2. Open parking garages in accordance with Section 406.5.

4. Special industrial occupancies in accordance with Section 503.1.1.

5. Buildings with a Group H-1, H-2 or H-3 occupancy in accordance with Section 415.

- "High-rise buildings" are defined in Chapter 2 as buildings with occupied floors located more than 75 feet (22 860 mm) above the lowest level of fire department vehicle access. Such buildings require special consideration relative to fire protection and occupant safety because of difficulties associated with smoke movement (stack effect), egress time, access by fire department personnel and perceived vulnerability to terrorist attack. This section contains provisions for high-rise buildings to address these special considerations.

While most of the provisions in Section 403 apply to all high-rise buildings, additional elevator requirements apply to high-rises in excess of 120 feet (36 576 mm). Further standards apply to high-rise buildings greater than 420 feet (128 m). These "super high-rises" must comply with enclosure structural integrity requirements (see Section 403.2.3), increased bond strength for sprayed fire-resistant materials (see Section 403.2.4), additional sprinkler risers (see Section 403.3.1) and have an additional exit stairway (see Section 403.5.2). In addition, these taller high-rises are not allowed to be designed with the reduced fire-resistance ratings permitted in Section 403.2.1.

The provisions of Section 403 apply to all high-rise buildings except those identified in the five exceptions. Exception 1 addresses airport control towers and is based on the limited fuel load and the limited number of persons occupying the tower (see Section 412.3). Places of outdoor assembly (Group A-5) and stand-alone open parking garages are exempted because of the free ventilation to the outside that exists in such structures. Low-hazard special industrial occupancies, which meet the criteria of Section 503.1.1, are exempt from the high-rise provisions. Finally, buildings with occupancies in Groups H-1, H-2 and H-3 are excluded from the provisions of this section because the fire hazard characteristics of such occupancies in a high-rise context have not yet been considered.

High-rise buildings must comply with all provisions of the code. Section 403 provides additional requirements for high-rise development.

- Section 403.2 specifies additional construction requirements, as well as some requirement reductions, applicable to constructing a high-rise building.

- Section 403.3 states the basic requirement for all high-rise buildings that an automatic sprinkler system be provided throughout the building. Specific standards unique to high-rise development are also provided.

- Section 403.4 specifies the various emergency detection and response systems that are required in a high-rise building.

- Section 403.5 provides additional means of egress system requirements for the occupants of a high-rise building.

- Section 403.6 provides elevator-related requirements for these structures.

The provisions are applicable to all buildings when the highest occupied floor is more than 75 feet (22 860 mm) above the lowest level of fire department vehicle access [see Figure 403.1(1)]. The lowest level of fire department vehicle access refers to the lowest ground level at which the fire department vehicle could be staged at the exterior of the building for carrying out fire-fighting operations. The definition of a "High-rise building" comes from the International Symposium on Fire Safety in High-Rise Buildings.
sponsored by the General Services Administration (GSA). The definition developed at the symposium is as follows:

- "A high-rise building is one in which emergency evacuation is not practical and in which fire must be fought internally because of height. The usual characteristics of such a building are:
  - Beyond the reach of fire department equipment;
  - Poses a potential for significant stack effect; and
  - Requires unreasonable evacuation time."

The 75-foot (22 860 mm) height threshold was determined from the effective reach of a 100-foot (30 480 mm) aerial apparatus based on the assumptions that the building will be set back from the curb, that access might be restricted by such things as parked cars and that obstructions, such as utility lines, would be present. The applicability of this section, however, is not based on the availability of such apparatus within the community.

Stack effect is illustrated in Figure 403.1(2), while typical evacuation times for buildings are shown in Figure 403.1(3).

**403.2 Construction.** The construction of high-rise buildings shall comply with the provisions of Sections 403.2.1 through 403.2.4.

- Section 403.2 includes subsections allowing the reduction of fire-resistance rating in some high-rise buildings, requiring minimum structural integrity for exit and elevator enclosures and setting bond strength for sprayed fire-resistant materials.

**403.2.1 Reduction in fire-resistance rating.** The fire-resistance rating reductions listed in Sections 403.2.1.1 and 403.2.1.2 shall be allowed in buildings that have sprinkler control valves equipped with supervisory initiating devices and water-flow initiating devices for each floor.

- Since the overall reliability of the sprinkler system is greatly improved by the required control valves and water-flow devices, certain code modifications are allowed.

Sprinkler control valves with supervisory initiating devices and water-flow initiating devices must be provided for each floor to realize the reduction in rating. Annunciation by floor is intended to allow rapid identification of the fire location by the fire department. Sprinkler control valves on each floor are intended to allow servicing activated systems without impairing the water supply to large portions of the building. It is, therefore, necessary to equip the valves with supervisory initiating devices. NFPA 13 does not require annunciation per floor, since some systems may take on configurations that would not lend themselves to this type of zoning. In accordance with Section 102.4, the criteria for this section takes precedence over the permissive language of NFPA 13; therefore, in order to use the reductions allowed by this section, the sprinkler system must comply with these features. Without these sprinkler system enhancements, no reductions are permissible.

**403.2.1.1 Type of construction.** The following reductions in the minimum fire-resistance rating of the building elements in Table 601 shall be permitted as follows:

1. For buildings not greater than 420 feet (128 000 mm) in building height, the fire-resistance rating of the building elements in Type IA construction shall be permitted to be reduced to the minimum fire-resistance ratings for the building elements in Type IB.

**Exception:** The required fire-resistance rating of columns supporting floors shall not be permitted to be reduced.

---

For SI: 1 foot = 304.8 mm.

![Figure 403.1(1)
HIGH-RISE BUILDING](image-url)
2. In other than Group F-1, M and S-1 occupancies, the fire-resistance rating of the building elements in Type IB construction shall be permitted to be reduced to the fire-resistance ratings in Type IIA.

3. The building height and building area limitations of a building containing building elements with reduced fire-resistance ratings shall be permitted to be the same as the building without such reductions.

- This section specifies the allowed reductions of fire-resistance rating of building elements specified in Table 601, without this being considered a reduction in the construction type.
  - Item 1 allows high-rise buildings that must be of Type IA construction for building height and building area purposes to have building elements which comply with the fire-resistance rating of the Type IIB construction type as shown in Table 601. This reduction is not applicable to buildings with a height in excess of 420 feet (128 m) and does not apply to columns which are supporting floors in any building classified as a high-rise building.
  - Item 2 allows high-rise buildings that must be of Type IB construction for building height and area purposes to have elements that comply with the fire-resistance rating of Type IIA construction as shown in Table 601. This reduction is not allowed if the building contains Group F-1, M or S-1 occupancies. This reduction is not allowed for these moderate-hazard buildings because of their customary higher fuel loads.
  - Item 3 states that even though the fire-resistance ratings have been reduced to the equivalent of the next lower construction type, the construction type of the building is not considered reduced. A Type IB building with 1-hour fire-resistant protection of the structural frame is still a Type IB building.

Figure 403.1(2)
HIGH-RISE BUILDINGS—STACK EFFECT
In determining the minimum allowable type of construction for a high-rise building, Table 503 is applied in the usual fashion (see Section 503 and Table 503). Item 3 reminds the code user that even though reductions are taken, the allowable area for the building is that of the "original" type of construction and is not reduced because building elements have reduced fire protection. Section 403.2.1.1 is applied once the minimum type of construction has been determined.

For example, an eight-story high-rise office building is to be constructed and equipped with an automatic sprinkler system in accordance with Sections 403.2.1 and 403.3. The minimum allowable construction type is Type IB. In accordance with Section 403.2.1.1; however, the required fire-resistance ratings for the structural elements would be determined using the column for Type IIA construction in Tables 601 and 602. It should be noted that Table 503 does not permit the use of unprotected noncombustible construction in a high-rise building.

403.2.1.2 Shaft enclosures. For buildings not greater than 420 feet (128 000 mm) in building height, the required fire-resistance rating of the fire barriers enclosing vertical shafts, other than exit enclosures and elevator hoistway enclosures, is permitted to be reduced to 1 hour where automatic sprinklers are installed within the shafts at the top and at alternate floor levels.

As with previous sections, based on the effectiveness and reliability of a complete automatic sprinkler system in accordance with Sections 403.2.1 and 403.3, the fire-resistance rating of shaft enclosures may be reduced to 1 hour, provided the sprinklers are also installed within the shafts at the top and at alternate floor levels. This reduction is not applicable to shafts within buildings with a building height in excess of 420 feet (128 m).

The reduced fire-resistance rating also does not apply to shafts which are either exit enclosures or elevator hoistways (see also Section 403.2.3 for requirements applicable to these shafts.) The reduction does not apply to exit and elevator shafts since they may continue to be used for egress or for firefighter access during a fire; therefore, the integrity of the shaft must be maintained. If, for some reason, the fire penetrates the 1-hour shaft, it will affect conditions on other floors, hence, the need to maintain the protection for exit and elevator shafts. By the time the fire penetrates a 1-hour fire-resistance-rated shaft, the affected floors should be evacuated.

403.2.2 Seismic considerations. For seismic considerations, see Chapter 16.

A reminder is provided in this section of the code that high-rise buildings are required to be designed for the effects of seismic activity. The reminder was primarily placed in Section 403.2.2, in addition to general design for seismic forces, to note that mechanical and electrical components are required to be designed for forces determined by Section 1613. This would also require that elevators be designed to resist the effects of the seismic forces. These elements are critical for the safety of high-rise buildings so that all of the required fire protection systems and

2012 INTERNATIONAL BUILDING CODE® COMMENTARY
the electrical components that secure them will be designed for the applicable seismic loads.

403.2.3 Structural integrity of interior exit stairways and elevator hoistway enclosures. For high-rise buildings of Risk Category III or IV in accordance with Section 1604.5, and for all buildings that are more than 420 feet (128 000 mm) in building height, enclosures for interior exit stairways and elevator hoistway enclosures shall comply with Sections 403.2.3.1 through 403.2.3.4.

- This section specifies a minimum standard for the integrity of the walls of interior exit stairways and elevator hoistway enclosures. The requirement applies to all high-rises with a building height in excess of 420 feet (128 m). It also applies to any high-rise building, regardless of height, that is either a Risk Category Class III or IV as specified in Section 1604.5. Risk Category Class IV are those uses that are considered to be essential in that their continuous use is needed, particularly in response to disasters. Risk Category Class III buildings include those occupancies that have relatively large numbers of occupants, where there is an elevated life safety hazard, or where the occupants' ability to respond to an emergency is limited. Also see the commentary for Sections 3007 and 3008

403.2.3.1 Wall assembly. The wall assemblies making up the enclosures for interior exit stairways and elevator hoistway enclosures shall meet or exceed Soft Body Impact Classification Level 2 as measured by the test method described in ASTM C 1629/C 1629M.

- The requirement applies to all wall assemblies enclosing interior exit stairways, as well as elevator hoistway enclosures in the buildings specified in Section 403.2.3. The requirement applies regardless of the height or location of the particular enclosure. The standard applies to exit passageways that connect the enclosures of interior exit stairways to the exterior of the building, as well as those that connect an "offset" in an interior exit stairway. While this section of the code doesn't specifically include these exit passageways, Section 1020.1 requires that the level of protection in an exit be maintained until discharge.

The code relies on ASTM C 1629 and C 1629M for determining compliance with this requirement. The standard was developed specifically to test gypsum and fiber-reinforced cement panels; however, it can readily be used to test the impact resistance of other board and panel materials. For concrete and masonry walls, see Section 403.2.3.3. The code requires the entire wall assembly to withstand an impact of 195 pound force (867 N), as measured by the ASTM C 1629 Soft Body Impact Test. The test method used in ASTM C1629 is conducted in accordance with the ASTM E 695 test method, which covers the measurement of the relative resistance of wall, floor and roof construction to impact loading.

403.2.3.2 Wall assembly materials. The face of the wall assemblies making up the enclosures for interior exit stairways and elevator hoistway enclosures that are not exposed to the interior of the enclosures for interior exit stairways or elevator hoistway enclosure shall be constructed in accordance with one of the following methods:

1. The wall assembly shall incorporate no fewer than two layers of impact-resistant construction board each of which meets or exceeds Hard Body Impact Classification Level 2 as measured by the test method described in ASTM C 1629/C 1629M.

2. The wall assembly shall incorporate no fewer than one layer of impact-resistant construction material that meets or exceeds Hard Body Impact Classification Level 3 as measured by the test method described in ASTM C 1629/C 1629M.

3. The wall assembly incorporates multiple layers of any material, tested in tandem, that meets or exceeds Hard Body Impact Classification Level 3 as measured by the test method described in ASTM C 1629/C 1629M.

- Section 403.2.3.2 requires that the face of the wall assembly that is not exposed to the shaft enclosure containing the interior exit stairway or elevators (or exit passageway)—the outside face—be protected by a material or materials that comply with a level of impact resistance. To comply with the requirement, at least two layers of Level 2 material or one layer of Level 3 material must be incorporated into the system. Level 2 material must withstand a Hard Body impact of 100 lb (445 N) to comply with the standard. Level 3 material must withstand a Hard Body impact of 150 lb (667 N). The code also permits the use of a system composed of multiple layers of different materials, provided the composite system can comply with a Level 3 Hard Body test.

403.2.3.3 Concrete and masonry walls. Concrete or masonry walls shall be deemed to satisfy the requirements of Sections 403.2.3.1 and 403.2.3.2.

- Concrete and masonry walls used for such enclosures are deemed to be adequate to meet the intent of this requirement without any testing under ASTM C 1629.

403.2.3.4 Other wall assemblies. Any other wall assembly that provides impact resistance equivalent to that required by Sections 403.2.3.1 and 403.2.3.2 for Hard Body Impact Classification Level 3, as measured by the test method described in ASTM C 1629/C 1629M, shall be permitted.

- This section allows other assemblies to be tested and approved for application in these walls. If a designer wished to include materials or a combination of materials not specified in Section 403.2.3.2 or 403.2.3.3, and wished to have the assembly tested, it would be acceptable as a wall for these enclosures if it complies with the Level 3 Hard Body test.

403.2.4 Sprayed fire-resistant materials (SFRM). The bond strength of the SFRM installed throughout the building shall be in accordance with Table 403.2.4.

- For buildings other than high-rise buildings, the minimum bond strength required for sprayed fire-resistant materials (SFRM) required by the code is 150 psf
(667 N) when tested in accordance with ASTM E 736. Recommendation 6 of the National Institute of Standards and Technology (NIST) Investigation of the World Trade Center (WTC) Report called for improvement of the in-place performance of SFRM. For high-rises with a building height in the 75- to 420-foot (23 to 128 m) range, SFRM must have a minimum bond strength of 430 psf (1913 N) wherever applied in the building. For high-rise buildings over 420 feet (128 m), the bond strength must be at least 1,000 psf (4448 N) wherever SFRM is applied in the building. While the NIST report was based on the specific events of the WTC fire and collapse, events far less dramatic can dislodge SFRM, such as elevator movement, building sway or maintenance activities. Using greater bond strengths will increase the probability that the protection will stay in place. These factors should provide for a longer time of safety.

TABLE 403.2.4
MINIMUM BOND STRENGTH

a. Above the lowest level of fire department vehicle access.

❖ See the commentary to Section 403.2.4.

[F] 403.3 Automatic sprinkler system. Buildings and structures shall be equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 and a secondary water supply where required by Section 903.3.5.2.

Exception: An automatic sprinkler system shall not be required in spaces or areas of:

1. Open parking garages in accordance with Section 406.5.

2. Telecommunications equipment buildings used exclusively for telecommunications equipment, associated electrical power distribution equipment, batteries and standby engines, provided that those spaces or areas are equipped throughout with an automatic fire detection system in accordance with Section 907.2 and are separated from the remainder of the building by not less than 1-hour fire barriers constructed in accordance with Section 707 or not less than 2-hour horizontal assemblies constructed in accordance with Section 711, or both.

❖ Because of the difficulties associated with manual suppression of a fire in a high-rise building, all high-rise buildings regulated by this section are required to be protected throughout with an automatic sprinkler system. The sprinkler system is to be in accordance with Section 903.3.1.1, which requires compliance with NFPA 13. If a high-rise building contains an open parking garage along with Group B occupancies above, then the open parking garage portion of the building need not be protected with an automatic sprinkler system. See the commentary to Section 406.3 for a discussion of the fire hazards associated with open parking garages.

If a telecommunications equipment facility is part of a high-rise building, automatic sprinkler protection can be eliminated from certain areas if an automatic sprinkler fire detection system is provided and the telecommunication equipment areas are separated from other building areas with fire-resistance-rated construction of the specified ratings. This same exception is provided in Section 903.2, but is restated here to emphasize its application to all buildings, including high-rise buildings. This exception is based on the need to maintain uninterrupted operation of telecommunications equipment, which frequently includes emergency telephone and similar communication services. The presence of an automatic sprinkler system or other automatic fire suppression system may be detrimental to public safety should disruption of emergency services occur.

In order to increase the reliability of the sprinkler system should an earthquake disable the primary water supply, a secondary water supply is required for buildings at sites with the specified seismic design category listed in Section 903.3.5.2. The secondary water supply must be equal to the hydraulically calculated sprinkler demand and must have a duration of no less than 30 minutes.

[F] 403.3.1 Number of sprinkler risers and system design. Each sprinkler system zone in buildings that are more than 420 feet (128 000 mm) in building height shall be supplied by no fewer than two risers. Each riser shall supply sprinklers on alternate floors. If more than two risers are provided for a zone, sprinklers on adjacent floors shall not be supplied from the same riser.

❖ For all high-rise buildings with a building height in excess of 420 feet (128 m), this section requires the sprinkler system to be designed with additional risers for each sprinkler zone. This redundancy provides increased reliability of the automatic sprinkler system. At least two risers must be provided for each sprinkler zone. Recommendation 12 of the NIST WTC report called for the redundancy of active fire suppression systems to be increased to accommodate the greater risks associated with increasing building height and population. Providing two risers in each zone allows that if one riser is taken out of service, the other will be able to supply sprinklers on the floors above and below. This will impede any fire spread and allow the fire department time to respond and extinguish the fire.

[F] 403.3.1.1 Riser location. Sprinkler risers shall be placed in interior exit stairways and ramps that are remotely located in accordance with Section 1015.2.

❖ This section requires the sprinkler risers to be located in the interior exit stairways of the building which must be separated in accordance with the requirements of Section 1015.2. This separation reduces the possibility that one incident could incapacitate both risers and additionally provides the protection of the rated enclosures. While the section references the
separation requirements of Chapter 10, Section 403.5.1 can result in an even greater separation of the exit enclosures in these taller high-rises. Also, Section 403.2.3 regarding the integrity of the interior exit stairways is intended to make sure that the walls of the enclosures protecting the risers meet a minimum impact standard.

[F] 403.3.2 Water supply to required fire pumps. Required fire pumps shall be supplied by connections to no fewer than two water mains located in different streets. Separate supply piping shall be provided between each connection to the water main and the pumps. Each connection and the supply piping between the connection and the pumps shall be sized to supply the flow and pressure required for the pumps to operate.

Exception: Two connections to the same main shall be permitted provided the main is valved such that an interruption can be isolated so that the water supply will continue without interruption through no fewer than one of the connections.

Fire pumps are installed in sprinkler and standpipe systems to pressurize the water supply for the minimum required sprinkler and standpipe operation. Fire pumps are only “required” to meet the system needs. Therefore, whether a particular high-rise building includes fire pumps will depend on interaction of the height of the building, the local water system and the designs of the sprinkler and standpipe systems in the building (see Section 913 of the IFC for more information on fire pumps).

Where the systems require a fire pump, this section requires the fire pumps to be supplied by two water mains located in separate streets. Having two connections will greatly reduce the possibility of the loss of water due to a main break, given the valving which is a feature of a public water system. Each connection must be adequate to provide the flow and pressure needed for the fire pumps to operate. The requirement is not written to be limited in application; therefore, it is applicable to all high-rise buildings subject to Section 403. The exception is a performance-based provision that is not tied to any specific configuration.

[F] 403.3.3 Fire pump room. Fire pumps shall be located in rooms protected in accordance with Section 913.2.1.

Where fire pumps are provided, they must be properly isolated from other portions of the high-rise building with fire-resistance-rated construction in accordance with Section 913.2.1. The separation must consist of minimum 2-hour fire barriers or horizontal assemblies, or both. Such separation is not required where the fire pumps are physically separated from the building in accordance with NFPA 20.

[F] 403.4 Emergency systems. The detection, alarm and emergency systems of high-rise buildings shall comply with Sections 403.4.1 through 403.4.9.

Section 403.4 lists the requirements for detection and emergency response systems applicable to high-rise buildings. These systems detect smoke and heat in these buildings and provide systems to notify occupants of the hazards and how to respond to the fire or other event. Systems and facilities are provided for emergency responders to assist the occupants and fight a fire. Finally, the section provides requirements for standby and emergency power to keep vital systems operating in case of power loss, either during an event or power loss to the building.

[F] 403.4.1 Smoke detection. Smoke detection shall be provided in accordance with Section 907.2.13.1.

Automatic smoke detectors are required in all high-rise buildings in locations so that a fire will be detected in its early stages of development. Smoke detectors must be installed in rooms that are not typically occupied, such as mechanical equipment rooms, elevator equipment rooms and similar spaces. Smoke detectors are also required in elevator lobbies. Finally, smoke detectors are required at various locations in the HVAC ducts. See Section 907.2.13 for the specific requirements for high-rise buildings.

[F] 403.4.2 Fire alarm system. A fire alarm system shall be provided in accordance with Section 907.2.13.

Fire alarm systems must be provided in high-rise buildings in accordance with the provisions of Section 907.2.13. Although a fire alarm system is not specifically listed as a requirement in Section 907.2.13, this section does require an automatic smoke detection system. Section 907.2.13.1.1 requires that the smoke detectors be connected to an automatic fire alarm system. Therefore, regardless of the occupancy category or categories in the high-rise building, a fire alarm system must comply with the code and NFPA 72, as applicable.

[F] 403.4.3 Standpipe system. A high-rise building shall be equipped with a standpipe system as required by Section 905.3.

Section 905.3 provides the applicable provisions for standpipes in buildings, including high-rise buildings. At a minimum, a Class I standpipe system is required based upon Exception 1 to Section 905.3.1.

[F] 403.4.4 Emergency voice/alarm communication system. An emergency voice/alarm communication system shall be provided in accordance with Section 907.5.2.2.

By definition, one characteristic of high-rise buildings is longer evacuation times. As such, the traditional fire alarm system, which usually results in simultaneous total building evacuation, is not practical; therefore, the alarm communication system should be able to:

- Direct the occupants of the fire zone to an area of refuge or exit;
- Notify the fire department of the existence of the fire; and
- Sound no alarms outside the fire zone until deemed desirable.
The alarm signal to the fire zone may include continuous sounding devices (e.g., bells, horns, chimes), as well as voice direction, which may momentarily silence the continuous sounding devices so as to be heard clearly. In accordance with Section 907.5.2.3, visible alarm notification appliances are required in the common and public areas of the high-rise buildings. Visible alarm appliances are also required in certain dwelling units and sleeping units, such as hotel guest rooms. The message of the voice/alarm is to be predetermined but need not be a recorded message. It would typically indicate that a fire has been reported at a specific location and that occupants should await further instructions or evacuate in accordance with the building’s fire safety and evacuation plan. The voice/alarm signal will usually commence with a 3- to 10-second alert signal followed by the message. See the commentary to Section 907.5.2.2 for further requirements of the emergency voice/alarm communication system.

403.4.5 Emergency responder radio coverage. Emergency responder radio coverage shall be provided in accordance with Section 510 of the International Fire Code.

- High-rise buildings have posed a challenge to the traditional communication systems used by the fire service for fire-to-ground communications; therefore, emergency responder radio coverage complying with Section 510 of the IFC must be provided. The coverage is needed to coordinate with the fire department radio system to allow fireground officers to remain in communication with fire fighters working in various areas of a building.

As facilities grow larger and more complex, they become more challenging for effective fire response. Therefore, more fire protection features must be provided within the building. While modeling and other techniques may provide a good prediction as to whether a building will interfere with radio communications, the reality is that it is unknown if a building will need to have an enhanced radio system installed until after the building is constructed. The presumption is that high-rise buildings will more likely than not need to be provided with an emergency responder system. Section 510.1 of the IFC does offer three exceptions which may be considered by the building official and fire code official.

403.4.6 Fire command. A fire command center complying with Section 911 shall be provided in a location approved by the fire department.

- Fireground operations usually involve establishing an incident command post where the fire official can observe what is happening, control arriving personnel and equipment, and direct resources and fire-fighting operations effectively. Because of the difficulties in controlling a fire in a high-rise building, a separate room (enclosed in 1-hour-rated construction) within the building must be established as a fire command center. The room must be provided at a location that is acceptable to the fire department, usually along the front of the building or near the main entrance. The room must contain equipment necessary to monitor or control fire protection and other building service systems (see Section 911 for further information).

403.4.7 Smoke removal. To facilitate smoke removal in post-fire salvage and overhaul operations, buildings and structures shall be equipped with natural or mechanical ventilation for removal of products of combustion in accordance with one of the following:

1. Easily identifiable, manually operable windows or panels shall be distributed around the perimeter of each floor at not more than 50-foot (15 240 mm) intervals. The area of operable windows or panels shall not be less than 40 square feet (3.7 m²) per 50 linear feet (15 240 mm) of perimeter.

Exceptions:

1. In Group R-1 occupancies, each sleeping unit or suite having an exterior wall shall be permitted to be provided with 2 square feet (0.19 m²) of venting area in lieu of the area specified in Item 1.

2. Windows shall be permitted to be fixed provided that glazing can be cleared by fire fighters.

2. Mechanical air-handling equipment providing one exhaust air change every 15 minutes for the area involved. Return and exhaust air shall be moved directly to the outside without recirculation to other portions of the building.

3. Any other approved design that will produce equivalent results.

- Section 403.4.7 requires new high-rise buildings to be provided with a smoke removal system to exhaust products of combustion following a fire incident. The intent of the requirement as clearly specified in the code is to facilitate the removal of smoke during the salvage and overhaul of a building after a fire has ended. "Overhaul and salvage operations" are generally understood to include searching the fire scene to detect and extinguish hidden fires or "hot spots." They also include controlling additional losses, stabilizing the incident scene by providing for fire-fighter safety and securing the structure. The smoke removal system is not a smoke control system similar to those required for atriums or underground buildings. The smoke removal system in a high-rise is not intended for use during a fire event. It is not intended to serve any health and life safety function, and, therefore, is only required to operate after, and not during, a fire event. In comparison, a smoke control system for an atrium is a life safety function and is designed to operate during a fire event to control smoke that is generated by the fire and keep it from migrating to other portions of the structure. This is not a smoke control system required elsewhere in the code; therefore, Section 909 is not referenced and is not applicable.
A smoke removal system can be a whole building system or a floor-by-floor localized system. It can also be provided by either natural means or a mechanical system. When a mechanical ventilation system is utilized, the controls for the smoke removal system are allowed to be independent of the building's HVAC system, or it may be an integral part of that or other ventilation systems present in the building. The technical requirements for smoke removal design for high-rise buildings are included in Section 403.4.7. Two primary options for accomplishing post-fire smoke removal are provided.

1. Natural Ventilation System. This design option relies on reasonably spaced and sized openings to allow air movement through a story. This is accomplished by providing operable windows or panels of a minimum size and spacing around the exterior of each story.

There are two exceptions to this design option. Exception 1 applies to Group R-1 occupancy hotels. It permits each guestroom or suite to have a single 2-square-foot (0.19 m²) operable window or panel in lieu of the 40 square feet (3.7 m²). Exception 2 allows fixed windows to be used in lieu of operable windows or panels, if the glazing can be cleared by fire fighters. Traditional tempered glass may be an appropriate type of glazing for this exception provided it is not coated, or has an applied film that modifies its natural breaking characteristics. Designers should work with the building official and the fire department to determine what type of glazing might meet the intent of this exception.

2. Mechanical Ventilation System. This design option requires a mechanical air-handling system capable of exhausting the equivalent of one air change every 15 minutes. The code requires both the air being exhausted from the building and any return air that might be coming from the fire salvage areas to be exhausted outside of the building. When using the mechanical ventilation option, the design will most likely result in the use of dampers to zone floors and to introduce fresh air.

Since the smoke removal system is meant to be used after a fire for cleanup and recovery and not during a fire event, it is not necessary to connect this system to standby or emergency power.

In Item 3 of this section, a third design option is given. It simply states that any system that can provide results similar to the prescribed natural or mechanical systems in Item 1 or 2 can be used when such alternative has been approved by the building official. This provision restates the general code allowance for alternative methods permitted by Section 104.11.

[F] 403.4.8 Standby power. A standby power system complying with Chapter 27 and Section 3003 shall be provided for standby power loads specified in 403.4.8.2. Where elevators are provided in a high-rise building for accessible means of egress, fire service access or occupant self-evacuation, the standby power system shall also comply with Sections 1007.4, 3007 or 3008, as applicable.

Standby power is required to increase the probability that the fire protection systems and elevators will continue to function in the event of failure of normal building service. By referencing Chapter 27, these provisions pick up the requirements of not only the National Electrical Code (NEC), but also NFPA 110 and 111. Section 3003 is also referenced regarding the special operational requirements for elevators provided with standby power. Additional references involving standby systems are made regarding elevators used as accessible means of egress (Section 1007.4), fire service access elevators (Section 3007) and occupant self-evacuation elevators (Section 3008).

[F] 403.4.8.1 Special requirements for standby power systems. If the standby system is a generator set inside a building, the system shall be located in a separate room enclosed with 2-hour fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both. System supervision with manual start and transfer features shall be provided at the fire command center.

Standby power systems are intended to supply power automatically to selected loads in the event of failure of the normal power source. The system is to be capable of supplying the connected loads within 60 seconds of normal power failure. If the standby power system is a generator set in the building, the generator must be located in a room that is separated from the rest of the buildings by fire barriers or horizontal assemblies having a fire-resistance rating of at least 2 hours. The purpose of the enclosure is to decrease the probability that a fire can affect both the normal and standby power systems. It is important to note that this requirement is more restrictive than the provisions found in the NEC (NFPA 70). NFPA 70 would only require either the 2-hour fire protection or a sprinkler system, but not both. Because high-rise buildings are required to be sprinkler protected, these standby systems end up with both the sprinkler protection and the separation. Although not specifically stated, consideration should also be given to the routing of the conduit to minimize the impact of a single fire on both primary and standby electrical systems. The provisions of Chapter 27 are applicable to standby power systems.

[F] 403.4.8.2 Standby power loads. The following are classified as standby power loads:

1. Power and lighting for the fire command center required by Section 403.4.6;
2. Ventilation and automatic fire detection equipment for smokeproof enclosures; and

3. Elevators.

- All fire protection and emergency systems required in Sections 403.4.6, 403.5.4 and 403.6 must be connected to the standby power system.

   Elevators in a high-rise must be provided with emergency power. Where fire service access elevators are required by Section 403.6.1, standby power is required for such elevators by Section 3007. Where occupant evacuation elevators are provided under Section 403.6.2, standby power is required for these elevators by Section 3008. Where elevators are being used as an accessible means of egress, they shall be provided with standby power as specified in Section 1007 (see the commentaries of those respective sections).

   When standby power is required for elevators, Section 3003 describes how it is to be provided. Under Section 3003, an arrangement must be made such that any elevator may be connected to the standby power with elevator designated as the primary recipient of power once the standby system is activated. The primary elevator must be capable of serving all floors of a building. In extremely tall buildings, it may, therefore, be necessary to designate multiple elevators as being primary recipients in order to permit usage of both local and express elevators. Based on language in the NEC, the capacity of the standby system must be such that all equipment that has to be operational at the same time will be able to function. The system need not, however, be capable of supplying the load for all connected equipment simultaneously if automatic load shedding is provided. For example, if multiple elevators are connected to the system, the standby power system need only be capable of supplying one elevator such that the elevator provides access to all floors and that central controls restrict operation of other elevators at the same time. The intent of the provisions of Section 3003 is not only to keep one elevator in operation, but also to make sure that all elevators at least initially make it to the designated level and allow passengers to exit the elevators (see commentary, Section 3003).

   Note that the requirements for elevators designated as fire service access elevators or elevators used for occupant evacuation have different and generally more restrictive requirements for standby power (see commentary, Sections 3007.9 and 3008.9).

   See also the commentary to Section 403.5.3 regarding standby power for the release of stairway door locks.

[F] 403.4.9 Emergency power systems. An emergency power system complying with Chapter 27 shall be provided for emergency power loads specified in Section 403.4.9.1.

- Emergency power is required to ensure that fire protection systems and means of egress illumination systems will continue to function with only a very minor interruption in the event of a failure of normal building service. By referencing Chapter 27, these provisions pick up not only the requirements of the NEC, but also NFPA 110 and 111.

[F] 403.4.9.1 Emergency power loads. The following are classified as emergency power loads:

1. Exit signs and means of egress illumination required by Chapter 10;
2. Elevator car lighting;
3. Emergency voice/alarm communications systems;
4. Automatic fire detection systems;
5. Fire alarm systems; and
6. Electrically powered fire pumps.

- The illumination of exit signs and the means of egress as required by Sections 1006 and 1011, elevator car lighting, alarm and detection systems and electrically powered fire pumps must be considered emergency electrical systems. As such, the systems are to comply with the provisions of Chapter 27, NFPA 70 and the referenced standards. Because of the critical nature of these systems and the potential for panic in the areas covered, the electrical load of these systems must be picked up within 10 seconds after failure of the normal power supply.

403.5 Means of egress and evacuation. The means of egress in high-rise buildings shall comply with Sections 403.5.1 through 403.5.6.

- Section 403.5 lists the requirements for means of egress systems applicable to high-rise buildings. Because of the size and height of high-rise buildings, they will contain large occupant loads which, when a building is evacuated, have longer evacuation times than low-rise buildings. Therefore, additional standards for egress systems are imposed for high-rise buildings. These include greater separation of the exit stairways in all high-rise buildings, requiring most stairways to be smokeproof enclosures, and for the tall high-rises over 420 feet (128 m), an extra stairway, in addition to those provided based on the occupant load, is required. Luminous egress path markings are required for both vertical and horizontal exit enclosures. Section 403.5.3 addresses the practice of locking doors of an interior exit stairway.

403.5.1 Remoteness of interior exit stairways. Required interior exit stairways shall be separated by a distance not less than 30 feet (914 mm) or not less than one-fourth of the length of the maximum overall diagonal dimension of the building or area to be served, whichever is less. The distance shall be measured in a straight line between the nearest points of the interior exit stairways. In buildings with three or more interior exit stairways, no fewer than two of the interior exit stairways shall comply with this section. Interlocking or scissor stairs shall be counted as one interior exit stairway.

- This section requires that two of the interior exit stairways be separated from each other by a minimum distance. Requiring a minimum separation, even as

4-26  2012 INTERNATIONAL BUILDING CODE® COMMENTARY
little as 30 feet (9144 mm), reduces the probability that a fire or other event, which damages one interior exit stairway, will also cause the second interior exit stairway to be unusable. This separation requirement must be met, as well as the separation standards of Section 1015.2. The separation should be measured between the enclosures surrounding the interior exit stairways. If the design of a building under Section 1015.2 results in two interior exit stairways being separated by 30 feet (9144 mm) or more, then Section 403.5.1 is also satisfied. While Section 1015.2 requires that two means of egress be separated by at least one-half or one-third of the diagonal measurement of the area served, the distance is measured between the doors into those interior exit stairways. Depending on the size and configuration of the building, two interior exit stairways could directly adjoin each other and still comply with Section 1015. For high-rise buildings, Section 403.5.1 requires that the interior exit stairways at all points be completely separated by the distance prescribed (see Figure 403.5.1).

Section 403.5.1 applies to all high-rise buildings subject to Section 403, regardless of the height of the building above 75 feet (22 860 mm). The requirement is either 30 feet (9144 mm), or one-fourth of the diagonal measurement of the area served, whichever is less. This is the same diagonal that is measured for compliance with Section 1015.2. For any building with a diagonal exceeding 120 feet (36 576 mm), the enclosures of interior exit stairways must be at least 30 feet (9144 mm) apart at their closest points. Only where the diagonal is less than 120 feet (36 576 mm) will the one-fourth of the diagonal come into play. For example, a building with a 100-foot (30 480 mm) maximum diagonal would only need 25 feet (7620 mm) between the two interior exit stairways. In larger buildings, with an occupant load per story in excess of 500, a third stairway is required. Also in buildings in excess of 420 feet (128 m), an additional stairway is required. The separation required by Section 403.5.1 only applies to two of the interior exit stairways. Any required third or fourth stairway could be directly adjacent to one of the first two interior exit stairways.

Interlocking interior exit stairways (two interior exit stairways "wrap" around each other as they descend through the building) or scissor stairways (two stairways in the same shaft enclosure) have to be considered as one interior exit stairway for the purposes of this section. Clearly a scissor stairway does not create two independent interior exit stairways, and therefore would not meet the needs of this requirement. Similarly, interlocking interior exit stairways often share a common enclosure wall with an interior exit stairway.
stairway on each side. Obviously, two interior exit stairways sharing a common enclosure wall would not meet the minimum separation requirement.

403.5.2 Additional exit stairway. For buildings other than Group R-2 that are more than 420 feet (128 000 mm) in building height, one additional exit stairway meeting the requirements of Sections 1009 and 1022 shall be provided in addition to the minimum number of exits required by Section 1021.1. The total width of any combination of remaining exit stairways with one exit stairway removed shall be not less than the total width required by Section 1005.1. Scissor stairs shall not be considered the additional exit stairway required by this section.

Exception: An additional exit stairway shall not be required to be installed in buildings having elevators used for occupant self-evacuation in accordance with Section 3008.

For buildings in excess of 420 feet (128 m) in height, this provision requires an extra stairway to be provided in addition to the number of stairways (means of egress) required based on occupant load of the building as well as travel distance (see Sections 1015 and 1016). This requirement does not apply to high-rise buildings that are occupied as Group R-2 apartments or condominiums, but would apply to R-1 hotels. If a building is a mixed-occupancy structure, the building official should consider which occupancies are located above the 420-foot (128 m) level.

The intent of this provision is to accommodate a simultaneous occurrence of evacuation of the occupants of a high-rise building and fire-fighting operations. The traditional approach to emergencies in a high-rise is to allow people on a floor affected by a fire to move up or down in the building to another story that is relatively safe from the effects of the fire. Fire fighters will usually set up a staging point one or two stories below the fire and commander one of the two stairways to move up to the fire floor. If for some reason it becomes necessary to evacuate the building during active fire fighting, the capacity of the means of egress system can be cut in half. This section implements, in part, Recommendation 17 of the NIST report. The report states that buildings should be designed to accommodate timely full-building evacuation of occupants when required by building-specific or large-scale emergencies, such as widespread power outages, major earthquakes, tornadoes, hurricanes without sufficient advance warning, fires, explosions or terrorist attacks.

The code requires that the extra stairway be sized so that the loss of any one stairway will still result in the remaining stairways being of sufficient size to accommodate the occupant load served by the stairways. For example, in a high-rise office building that has a calculated occupant load of 250 on each story, two stairways each designed to accommodate 125 occupants will be the minimum requirement for interior exit stairways in accordance with Chapter 10. The minimum stairway width of 44 inches (1118 mm) is sufficient to accommodate 146 people, or slightly more than needed for this building. In this building a third interior exit stairway would therefore need to be provided that was also at least 44 inches (1118 m) in width. The result is that if the fire fighters need to commandeer stairway 1, stairways 2 and 3, which each have a capacity to serve 146 people, will still be large enough to meet the occupant load requirements for the means of egress system. In larger buildings with occupant loads in excess of 500, a third stairway is required by Section 1015. In such buildings, Section 403.5.2 would require a fourth exit stairway.

The "additional" stairway has to comply with all the same requirements of any stairway in a high-rise building, including a design complying with smokeproof enclosures required by Section 403.5.4.

The additional stairway is not affected by the remoteness requirement of Section 403.5.1. That section applies to the first two exit stairway enclosures required in a building. Additional stairways, whether required for occupant load, travel distance or this section, also do not need to comply with the remoteness requirement of Section 403.5.1.

Finally, the exception to this section permits the installation of occupant evacuation elevators as an alternative to providing the additional exit stairway (see also the commentary to Sections 403.6.2 and 3008). The intent behind the exception is recognition that the reason behind the requirement for an additional stairway is the loss of egress capacity under the unusual circumstance of simultaneous total building evacuation and fire fighting. Recognizing that occupant evacuation elevators provide an alternative way to meet a portion of the evacuation needs in these circumstances, the code allows the elevators as a substitute for the additional capacity provided by a third or fourth stairway. Where occupant evacuation elevators are proposed, the requirements of Section 3008 apply to all passenger elevators for general public use in the building (see commentary, Section 3008).

403.5.3 Stairway door operation. Stairway doors other than the exit discharge doors shall be permitted to be locked from the stairway side. Stairway doors that are locked from the stairway side shall be capable of being unlocked simultaneously without unlatching upon a signal from the fire command center.

Section 1008.1.9.11 requires that all egress doors for interior stairways be readily openable from both sides. It is often desirable to control movement of people within a building and to provide additional security from external threats. This section permits locking of stairway doors from the stair side when all doors are capable of being simultaneously unlocked. Since high-rise buildings are difficult to evacuate and people are often relocated to another floor level during an emergency, access from the stairway to a floor could be essential in a fire or other emergency. Therefore, all stairway doors that are to be locked
from the stairway side must have the capability of being unlocked on a signal from the fire command center. The unlocking of the door must not negate the latching feature, which is essential to the operation of the door as a fire door. Section 403.4.8.2, Item 1, by its reference to Section 403.4.6, requires the locking feature to be connected to the standby power system. When the door is unlocked during an emergency, it should not automatically relock on closure. Electrically powered locks should be designed such that when power to the locking device is interrupted, the lock is released. This is intended to enable doors to be operable from the inside of the stairway, and not locked, if power to the lock is interrupted. The building official should review the emergency release operation of stairway doors to determine that they remain unlocked.

**403.5.3.1 Stairway communication system.** A telephone or other two-way communications system connected to an approved constantly attended station shall be provided at not less than every fifth floor in each stairway where the doors to the stairway are locked.

- If the stairway doors are locked to restrict reentry as permitted in Section 403.5.3, a two-way communication system must be provided at no less than every fifth floor and must be connected to the standby power system. This system is required to be connected to a constantly attended location, which could be within the building, or to a central station that monitors fire alarms and is manned 24 hours a day, 7 days a week. Use of the fire command center is not recommended, since it may not be constantly attended. The system will permit occupants in the stairway to notify the attended location that the stairway doors need to be unlocked to access another floor or because conditions in the stairway prevent its continued use.

**403.5.4 Smokeproof enclosures.** Every required exit stairway serving floors more than 75 feet (22 860 mm) above the lowest level of fire department vehicle access shall be a smokeproof enclosure in accordance with Sections 909.20 and 1022.10.

- This section serves as a reminder that the smokeproof enclosure provisions of Section 1022.10 are applicable to high-rise buildings. Section 909.20 provides the standards on the construction of a smokeproof enclosure. It is important to understand that this requirement is only applicable in the portions of the building where the stack effect is more of a factor and the resulting spread of smoke will be the greatest. For example, if the high-rise building consists of a tower portion with a larger area on the bottom that is only a couple of stories in height, these requirements would only be applicable to stairways in the tower portion that serve floors that are more than 75 feet (22 860 mm) above the level where fire department vehicles would be located. The requirement would not apply to stairways in a low-rise portion of a building not exceeding 75 feet (22 860 mm), nor to stairways within the tower which do not serve floors more than 75 feet (22 860 mm) above the lowest level of fire department access.

**403.5.5 Luminous egress path markings.** Luminous egress path markings shall be provided in accordance with Section 1024.

- This section requires the provision of luminous egress path markings in all high-rise buildings containing any Group A, B, E, I, M or R-1 occupancy. The specific requirements are found in Section 1024. The requirements apply only to exit enclosures, vertical or horizontal. The markings are not required in the exit access or exit discharge portions of the means of egress system, nor at a horizontal exit.

**403.5.6 Emergency escape and rescue.** Emergency escape and rescue openings required by Section 1029 are not required.

- This section of the code reinforces other tradeoffs or allowances permitted in the code for buildings equipped with automatic sprinkler systems. Previous editions of Section 1029.1 required emergency escape and rescue windows for windows located four stories or less, but then exempted high-rise buildings. Section 1029 now only requires the windows in R-3 buildings and single exit R-2 occupancy buildings, neither of which likely to occur in a high-rise building. This section is a left over reference from previous editions of the code.

**403.6 Elevators.** Elevator installation and operation in high-rise buildings shall comply with Chapter 30 and Sections 403.6.1 and 403.6.2.

- This section explicitly states that elevator installation and operation are to be in accordance with Chapter 30, which contains provisions for the design, construction, installation, operation and maintenance of elevators. While a vital purpose of the elevator requirements in high-rise buildings has always been for the use of the fire department, this role has been enhanced (see Section 403.6.1). Elevators have been one method of providing an accessible means of egress under the requirements of Section 1007, but have never been considered part of the means of egress system for the nondisabled occupants of a building or for those with a disability to self-evacuate. However elevators are now allowed to augment the egress system for all occupants in buildings over 420 feet (128 m) in height. The allowance for self-evacuation is based on occupants using the elevators prior to the elevators being recalled. This is much different from the requirements of Section 1007, under which fire department personnel use the elevators to assist in the rescue of occupants while those elevators are on Phase II emergency operation.

Chapter 30 provides important standards for the size of elevators, allowing ambulance stretchers to easily fit into at least one elevator serving high-rise buildings. Protection of the hoistway and machine room are also addressed.
403.6.1 Fire service access elevator. In buildings with an occupied floor more than 120 feet (36 576 mm) above the lowest level of fire department vehicle access, no fewer than two fire service access elevators, or all elevators, whichever is less, shall be provided in accordance with Section 3007. Each fire service access elevator shall have a capacity of not less than 3500 pounds (1588 kg).

For buildings with occupied floors in excess of 120 feet (36 576 mm) above the lowest level of fire department vehicle access, at least two of the elevators must comply with the fire service access elevator requirements, which are detailed in Section 3007 (see Figure 403.6.1). The allowance to have a single fire service access elevator only applies where it is the only elevator within the building. The requirements in Section 3007 are another result of the NIST research following the WTC fire and collapse. The fire service access provisions work with already existing emergency operation requirements for elevators to allow elevators that comply with Section 3007 to remain in service for trained fire fighters to reach the upper levels of a building within a reasonable amount of time and to stage their fire-fighting operations at a level below the actual fire. These elevators must be provided with a lobby of a minimum size which is protected by at least 1-hour fire-resistance-rated smoke barriers. The lobby must be directly connected to one of the interior exit stairways which must contain a standpipe as required by Section 905. These lobbies may also serve as the area of refuge required as part of an accessible means of egress. People waiting for assistance in egress will need to be helped to a safe location before one lobby or another is used as the staging location for fire fighting.

The need for at least two elevators complying with Section 3007 is based on past experience that has shown that on many occasions elevators are not available due to shutdowns for various reasons, including problems in operation, routine maintenance, modernization programs and EMS operations in the building prior to fire fighter arrival. A minimum of two fire service elevators provided with all of the benefits afforded by such elevators better ensures that there will be a fire service access elevator available for the firefighters’ use in the performance of their duties.

The requirement for a minimum capacity of 3500 pounds (1588 kg) for fire service access elevators allows for design flexibility in the selection of elevator

---

**Figure 403.6.1**

HIGH-RISE BUILDINGS: FIRE SERVICE ACCESS ELEVATORS

For SI: 1 foot = 304.8 mm; 1 inch = 25.4 mm.
cars while still providing the necessary capacity and size for emergency responder needs.

**403.6.2 Occupant evacuation elevators.** Where installed in accordance with Section 3008, passenger elevators for general public use shall be permitted to be used for occupant self-evacuation.

- Section 3008 provides the requirements for occupant evacuation elevators. When part of a fire safety and evacuation plan, occupant evacuation elevators are allowed in a building. A key element of applying Section 3008 is that all passenger elevators for general public use in the building must comply. Similar to the fire service access elevators, the occupant evacuation elevators must be provided with a lobby constructed of 1-hour fire-resistance-rated smoke barriers. The occupant evacuation elevators also require signs and other indicators, as well as a communication system connected to the fire command center to help occupants use the elevators. When provided, the requirements of the occupant evacuation elevators make for a substantially improved accessible means of egress over the requirements provided in Section 1007. Section 1007 is strictly for fire-fighter-assisted evacuation versus occupant self-evacuation as Section 3008 allows.

For any high-rise building, elevators may be designed for occupant self-evacuation. In fact, Section 3008 could be applied to any building as long as the design complies with all of the requirements.

Elevators are still prohibited by Section 1003.7 from serving as a means of egress for the general population of a building. However, in high-rise buildings in excess of 420 feet (128 m) in height, Section 403.5.2 requires there be an additional exit stairway provided in addition to those needed for egress capacity or travel distance purposes. This additional stairway is not required when the elevators in the building comply with Section 3008 and allow occupant self-evacuation.

### SECTION 404

**ATRIUMS**

**404.1 General.** In other than Group H occupancies, and where permitted by Section 712.1.6, the provisions of Sections 404.1 through 404.9 shall apply to buildings or structures containing vertical openings defined as "Atriums."

- Unprotected vertical openings are often identified as the factor responsible for fire spread in incidents involving fire fatalities or extensive property damage. Section 404 addresses one method for protection of these specific building features in lieu of providing a complete floor separation. As noted in this section, the atrium provisions are primarily one of eighteen options for addressing vertical openings as set forth in Section 712. Atriums are regulated by this section and are considered acceptable when in compliance with the criteria of this section. Additionally, the code permits other types of vertical openings that are not addressed by this section. For example, Section 712 permits openings within residential dwelling units to be unprotected. Other unprotected vertical openings that are permitted by the code include covered malls (see Section 402); communicating spaces in buildings of Group I-3 (see Section 408.5); mezzanines (see Section 505); escalator or supplemental stairway openings (see Section 712.1.3); open parking garages (see Section 406.5); enclosed parking garages (see Section 406.6) or as otherwise noted in Section 712.

An atrium is a space within a building that extends vertically and connects two or more stories. Atriums are not to be considered unprotected vertical openings; rather, the vertical openings are protected by means other than enclosure of the shaft or a complete floor assembly. This section does not apply to spaces that comply with Section 712 based on the itemized options, other than Section 712.1.6. In other words, if compliance with Section 712 is achieved by applying one of the options other than Section 712.1.6 that permits an atrium, then compliance with Section 404 is not required. Likewise, if the provisions of Section 404 have been complied with, then the other options listed in Section 712 do not need to be addressed. Spaces that are separated from the atrium by shaft enclosure assemblies complying with the provisions of Section 713 are not considered as part of the atrium. Section 404 applies only to the spaces that are contained within the atrium. Atriums are permitted in all buildings except Group H.

The options listed in Section 712 are all considered legitimate methods of appropriately addressing vertical openings within buildings, but were not developed with specific consideration of the application of multiple options in the same building/space. In most cases this will be appropriate but can become complicated where, for example, an atrium is open to a space that is applying Section 712.1.3 for escalator openings. More discussion of this particular scenario is found in the commentary to Section 404.6.

**404.1.1 Definition.** The following term is defined in Chapter 2:

**ATRIUM.**

- This section lists terms that are specifically associated with the subject matter of Section 404. It is important to emphasize that these terms are not exclusively related to this chapter but may or may not also be applicable where the term is used elsewhere in the code.

Definitions of terms can help in the understanding and application of the code requirements. The purpose for including a list within this chapter is to provide more convenient access to terms which may have a specific or limited application within this chapter. For the complete definition and associated commentary, refer back to Chapter 2. Terms that are italicized provide a visual identification throughout the code that a definition exists for that term. The use and
application of all defined terms are set forth in Section 201.

404.2 Use. The floor of the atrium shall not be used for other than low fire hazard uses and only approved materials and decorations in accordance with the International Fire Code shall be used in the atrium space.

Exception: The atrium floor area is permitted to be used for any approved use where the individual space is provided with an automatic sprinkler system in accordance with Section 903.3.1.1.

Because an automatic sprinkler system at the ceiling of an atrium may not be effective for a fire on the floor of the atrium due to the ceiling height or obstructions to the sprinkler discharge, the use and activities of the floor level and the type of materials in the atrium space must be controlled. This section applies to all atriums regardless of their height or area. Low fire-hazard uses would limit the atrium floor to such functions as pedestrian walk-through areas, security desks and reception areas. Storage areas, fabrication areas and office areas would not be low fire-hazard uses. Chapter 8 regulates the use of decorative materials and furnishings.

If the floor area is equipped with an automatic sprinkler system that can provide the required protection, then its use is not restricted. The exception stipulates that such areas must be equipped with an automatic sprinkler system as is required throughout the remainder of the atrium.

[F] 404.3 Automatic sprinkler protection. An approved automatic sprinkler system shall be installed throughout the entire building.

Exceptions:

1. That area of a building adjacent to or above the atrium need not be sprinklered provided that portion of the building is separated from the atrium portion by not less than 2-hour fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both.

2. Where the ceiling of the atrium is more than 55 feet (16 764 mm) above the floor, sprinkler protection at the ceiling of the atrium is not required.

One means of controlling the spread of fire and smoke through vertical openings is to control and extinguish the fire as early as possible; therefore, all floor areas that are connected by the atrium are to be protected with an approved sprinkler system, including the atrium space itself. The system is to be designed, installed and maintained in accordance with the provisions of Section 903.3 and the IFC. Since Chapter 9 requires that the sprinkler system be supervised, the reliability of the sprinkler system is improved. Exception 1 clarifies that since the atrium protection is one of the various options for protecting vertical openings, typically an alternative to a shaft enclosure, the sprinkler system is not required in areas that are separated from the atrium by 2-hour fire barrier walls or horizontal assemblies that would otherwise be required for a shaft enclosure. Such fire barrier walls must conform to Section 707, while the horizontal assemblies must comply with Section 711. Exception 2 permits the required sprinkler system to be deleted from the ceiling areas of atriums where the vertical distance between the atrium floor and atrium ceiling is greater than 55 feet (16 764 mm). A ceiling height of more than 55 feet (16 764 mm) is the height at which the system is no longer effective and installing such systems provides little benefit. This exception does not alter the use limitations of the atrium as stated in Section 404.2, nor does it exempt any adjacent floor areas with lower ceiling heights that are included in the atrium boundary in accordance with Exception 1. It is important to note that if a smoke control system is required by Section 404.5, the smoke control design should not take sprinkler activation into account for design fires that are located in areas not protected with sprinklers or in areas where sprinklers are installed but, due to their location, may not be able to control a fire.

[F] 404.4 Fire alarm system. A fire alarm system shall be provided in accordance with Section 907.2.14.

Section 907.2.14 of the code contains a requirement for a fire alarm system in atriums connecting more than two stories. In addition, when such atriums are located in Group A, E and M occupancies, an emergency voice communication system is required.

404.5 Smoke control. A smoke control system shall be installed in accordance with Section 909.

Exception: Smoke control is not required for atriums that connect only two stories.

In order to prevent the migration of smoke throughout interconnected levels of a building via the atrium, a mechanical smoke control system is to be installed in atriums connecting more than two stories. The smoke control system is to be designed and installed in accordance with the provisions of Section 909. See Figure 404.6(1) for examples of when smoke control is and is not required. For spaces such as atriums, the primary method of smoke control in accordance with Section 909, is the exhaust method. Pressure differences in such a large space will be difficult to achieve and the area of fire origin when undertaking the pressurization method is not required to be tenable in accordance with Section 909.6. The airflow method is impractical with such large spaces. The airflow method is sometimes used in combination with the exhaust methods to protect openings into the atrium (see commentary, Section 909). The smoke control system for the atrium is required to be connected to a standby source of power in accordance with Sections 404.7 and 909.11.

Section 402.7.2 for covered mall buildings also references Section 404.5 for smoke control provisions when a covered mall building contains an atrium. It
should be noted that when a covered mall building contains an atrium, all areas adjacent to the atrium without separation would need to be addressed when designing the smoke control system as required by Section 404.6, Exception 3.

As discussed in the commentary to Section 404.1, the atrium provisions are basically one of many options provided in the vertical opening requirements in Section 712. Therefore, if another option in Section 712 is chosen, such openings would not be considered atriums and smoke control would not be required.

404.6 Enclosure of atriums. Atrium spaces shall be separated from adjacent spaces by a 1-hour fire barrier constructed in accordance with Section 707 or a horizontal assembly constructed in accordance with Section 711, or both.

Exception: A fire barrier is not required where a glass wall forming a smoke partition is provided. The glass wall shall comply with all of the following:

1. Automatic sprinklers are provided along both sides of the separation wall and doors, or on the room side only if there is not a walkway on the atrium side. The sprinklers shall be located between 4 inches and 12 inches (102 mm and 305 mm) away from the glass and at intervals along the glass not greater than 6 feet (1829 mm). The sprinkler system shall be designed so that the entire surface of the glass is wet upon activation of the sprinkler system without obstruction;

   1.1. The glass wall shall be installed in a gasketed frame in a manner that the framing system deflects without breaking (loading) the glass before the sprinkler system operates; and

   1.2. Where glass doors are provided in the glass wall, they shall be either self-closing or automatic-closing.

2. A fire barrier is not required where a glass-block wall assembly complying with Section 2110 and having a 1/2-hour fire protection rating is provided.

3. A fire barrier is not required between the atrium and the adjoining spaces of any three floors of the atrium provided such spaces are accounted for in the design of the smoke control system.

One of the basic premises of atrium requirements is that an engineered smoke control system combined with an automatic fire sprinkler system that is properly supervised provide an adequate alternative to the fire-resistance rating of a shaft enclosure. It is also recognized that some form of a boundary is required to assist the smoke control system in containing smoke to just the atrium area. The basic requirement, therefore, is that the atrium space be separated from adjacent areas by fire barriers and horizontal assemblies having a fire-resistance rating of at least 1 hour. Also, openings in the wall are required to be protected, in accordance with Section 707.6. In accordance with Section 713.4, shafts are required to have a fire-resistance rating of at least 2 hours if connecting more than three stories, and 1 hour when connecting two or three stories. The basis for the 1-hour requirement in Section 404.6 is that an automatic sprinkler system can be substituted for the 1 hour of fire resistance of a shaft enclosure. The allowance is consistent with the 1-hour fire-resistance-rating reduction permitted in high-rise buildings (see Section 403.2.1.2).

In lieu of a 1-hour fire-resistance-rated fire barrier separation, Exception 1 allows adjacent spaces to be separated by glass walls where automatic sprinklers have been installed to protect the glass. The sprinklers are to be located so as to wet the entire surface of the glass wall. If there is a floor surface on each side of the wall, both sides of the glass must be protected. The glass must be in a gasketed frame such that the framing system can deflect without breaking the glass. Although this exception does not address obstructions or other window treatments, consideration must be given to locating such items to avoid interference with the required sprinkler heads. Without specific test evidence, curtain rods, traverse rods, curtains and draperies must be located at least 12 inches (305 mm) from the window surface [see Figure 404.6(1)]. The sprinkler system required for Exception 1 is not intended to be a deluge system. Instead it is intended to protect the glazing material from breakage as a result of thermal shock. It is not necessary to activate all the sprinklers along the glazing material to provide such protection as long as the entire surface of the glazed panel is designed such that it can be wetted by the sprinkler system.

Any doors through the required 1-hour fire barrier wall must be 1/2-hour rated in accordance with Table 715.4. However, where glass doors occur within the complying glass wall system established in Exception 1, such doors need not be fire-protection rated but they must be either self-closing or automatic-closing.

Exception 2 allows a glass-block wall assembly conforming to Section 2110 in lieu of a 1-hour fire barrier. It is important to note that these glass-block assemblies do not require the sprinkler protection that is required by Exception 1.

Exception 3 recognizes the desire to have at least some floors open to the atrium, and permits a maximum of three. The three-floor restriction is consistent with the basic premise that the life safety hazard becomes significant when more than three floors are open and is also consistent with the allowances for covered mall buildings. It should be noted that the three floor levels may be at any height and need not be consecutive floor levels [see Figure 404.6(2)]. The exception also states that the smoke control design must account for these spaces. This particular reference to the smoke control design does not require that the 6-foot-high (1829 mm) layer required by Section 909.8.1 be maintained in these spaces. Instead it
is saying that if a smoke control system is required by Section 404.5, such spaces must be accounted for in terms of the hazard they pose to the atrium and to smoke migrating to other adjacent spaces on other stories open to the atrium. Essentially these spaces have simply increased the possible design fires that
may send smoke into the atrium, thus threatening to send smoke throughout the building and other adjoining spaces. If the atrium smoke control system is not designed to handle fires in these areas, the system may become overpowered. This exception can also permit a two-story atrium to have adjacent areas open to the atrium. In this case, since there is no required smoke control system, obviously there is no need to account for the added space (see IBC Interpretation No. 54-07).

As discussed in the commentary to Section 404.1, the atrium requirements are basically one of many options for protecting vertical openings through floors as established in the requirements of Section 712. More specifically, Section 712 has multiple options that are all legitimate approaches to addressing vertical openings. If there are portions of the building applying other options in Section 712 that are not separated from the atrium, they can be considered part of the atrium themselves and be subject to the smoke control layer height of 6 feet (1829 mm) or could be considered as adjacent spaces and need to be accounted for when designing the smoke control system, as discussed above. It should be noted that if the space is considered part of the atrium itself, the other options in Section 712 need not be considered as the atrium provisions are already being applied.

[F] 404.7 Standby power. Equipment required to provide smoke control shall be connected to a standby power system in accordance with Section 909.11.

To enhance the reliability of the required smoke control system, this section of the code mandates that the mechanical smoke control system must be connected to a standby power system. The reference to Section 909.11 allows the atrium's equipment to receive its primary power from the building's power system. A secondary standby power source is required should the building's primary system fail.

404.8 Interior finish. The interior finish of walls and ceilings of the atrium shall be not less than Class B with no reduction in class for sprinkler protection.

Although Chapter 8 contains provisions governing the use of interior finishes, trim and decorative materials, specific limitations are provided for an atrium. Similar to the use limitations contained in Section 404.2, a minimum interior finish classification is specified to limit the fuel load within the atrium spaces. At least a Class B finish is mandated for the walls and ceilings of the atrium. This finish classification limits the material's flame spread index to a range of 26 through 75 and a smoke-developed index rating of 450 or less. The sprinkler reductions shown in Table 803.9 are not applicable to the interior finishes of an atrium space.

404.9 Travel distance. In other than the lowest level of the atrium, where the required means of egress is through the atrium space, the portion of exit access travel distance within the atrium space shall be not greater than 200 feet (60,960 mm). The travel distance requirements for areas of buildings open to the atrium and where access to the exit is not through the atrium, shall comply with the requirements of Section 1016.

On all floors with direct communication to the atrium for exit access (other than the floor level of the atrium), the total exit access travel distance through the atrium is limited to 200 feet (60,960 mm). Since smoke is being drawn to the atrium, the time allowed to reach an exit through the atrium is limited. Travel distance at the atrium floor level and the levels that do not communicate with the atrium for exit access in the building is regulated by Table 1016.2.

SECTION 405
UNDERGROUND BUILDINGS

405.1 General. The provisions of Sections 405.2 through 405.10 apply to building spaces having a floor level used for human occupancy more than 30 feet (9144 mm) below the finished floor of the lowest level of exit discharge.

Exception: The provisions of Section 405 are not applicable to the following buildings or portions of buildings:

1. One- and two-family dwellings, sprinklered in accordance with Section 903.3.1.3.
2. Parking garages provided with automatic sprinkler systems in compliance with Section 405.3.
3. Fixed guideway transit systems.
4. Grandstands, bleachers, stadiums, arenas and similar facilities.
5. Where the lowest story is the only story that would qualify the building as an underground building and has an area not greater than 1,300 square feet (139 m²) and has an occupant load less than 10.
6. Pumping stations and other similar mechanical spaces intended only for limited periodic use by service or maintenance personnel.

An underground building presents a unique hazard to life safety. Because of its isolation and inaccessibility, occupants within the structure and fire fighters attempting to locate and suppress a fire are presented with a unique fire protection challenge.

Underground buildings that require the occupants of the lowest floor level to travel upwards for more than 30 feet (9144 mm) to reach the finished floor of the lowest level of exit discharge present a significant hazard to the occupants. As such, Section 405 is applicable to buildings with a floor level more than 30 feet (9144 mm) below the finished floor surface of the lowest level of exit discharge (see Figure 405.1).

To egress the structure, occupants must travel in an upward direction. The direction of occupant travel is the same as the direction that the products of combustion travel. As such, the occupants are potentially exposed to the products of combustion along the entire means of egress.

Fire fighters are also confronted by constant exposure to the products of combustion. Beginning their
descent above the actual location of the fire source, fire fighters encounter an increasing amount of smoke, heat and flame as they attempt to locate and extinguish the fire source. These extreme conditions could significantly hinder the effectiveness of the fire department if not offset by appropriate fire protection requirements. The requirements for underground buildings are, in some ways, similar to those for high-rise structures. Both types of structures present an unusual hazard, since they are virtually inaccessible to exterior fire department suppression and rescue operations with the increased potential to trap occupants inside. To counteract these hazards, such structures are required by Section 405.2 to be built of noncombustible, fire-resistance-rated construction.

Additionally, they are required by Section 405.3 to be equipped with an automatic sprinkler system and a smoke control system in accordance with Section 405.5. Standby and emergency power systems are also required in these structures by Sections 405.8 and 405.9.

Structures regulated by Section 405 are also subject to all other applicable code provisions. Additionally, underground buildings to which this section does not apply are still subject to all other code provisions, including fire suppression (see Section 903); standpipe systems (see Section 905); and fire alarm and detection (see Section 907).

There are six exceptions to the applicability of Section 405. These exceptions are in consideration of specific types of structures to which the requirements of this section are impractical, unnecessary or to which alternative provisions apply.

**405.2 Construction requirements.** The underground portion of the building shall be of Type I construction.

*Two of the key goals with underground construction are to limit the fuel load and to increase the fire resistance of underground buildings. To reasonably ensure that the building elements will remain structur-
ally sound during exposure to fire, all structural elements of the underground portions are required to be of noncombustible, protected construction; therefore, any portion of the structure located below grade level is required to be of Type I construction (see Figure 405.1).

Portions of the structure above grade, however, are permitted to be of any type of construction.

Any portion of the structure above ground level must conform to the height and area limitations of Table 503. This table does not regulate the maximum depth of an underground structure; therefore, the height, area and depth of most Type I structures are not limited.

[F] 405.3 Automatic sprinkler system. The highest level of exit discharge serving the underground portions of the building and all levels below shall be equipped with an automatic sprinkler system installed in accordance with Section 903.3.1.1. Water-flow switches and control valves shall be supervised in accordance with Section 903.4.

- One of the most effective preventive measures to fire growth is the installation of an automatic sprinkler system. Because of the unique conditions for occupant egress and fire department access in the underground portion of a building, automatic sprinkler protection is required. The level of exit discharge and all floor levels below are required to be sprinklered throughout in accordance with Section 903.3.1.1. This section does permit a portion of a building to extend above the level of exit discharge and not be equipped with an automatic sprinkler system. If, however, another code section (see Section 403.3 or 903) requires an automatic sprinkler system in the above-ground portion, such a requirement would still be applicable. Note that a smoke control system is required in accordance with Section 405.5. Automatic sprinkler systems are essential elements of any smoke control system. Without suppression, the size of the fire or the resulting products of combustion will rapidly overwhelm most mechanical smoke control systems. The pressurization system requirements in Section 909 are based upon the use of sprinklers. Pressure differences needed to maintain the smoke to the area of origin would need to be higher in an nonsprinklered building.

405.4 Compartmentation. Compartmentation shall be in accordance with Sections 405.4.1 through 405.4.3.

- Compartmentation is a key element in the egress and fire access plan for floor areas in an underground building. Subdivision into separate compartments through the use of smoke barriers (see Section 709) permits occupants to travel horizontally to escape the fire condition and provides a staging area for the fire service (see Figure 405.4).

405.4.1 Number of compartments. A building having a floor level more than 60 feet (18 288 mm) below the finished floor of the lowest level of exit discharge shall be divided into no fewer than two compartments of approximately equal size. Such compartmentation shall extend through the highest level of exit discharge serving the underground portions of the building and all levels below.

Exception: The lowest story need not be compartmented where the area is not greater than 1,500 square feet (139 m²) and has an occupant load of less than 10.

- The 60-foot (18 288 mm) threshold is based on establishing a reasonable limitation on the required vertical travel distance for the occupants and fire service before the added protection of compartmentation is beneficial.

It is important to realize that the code requires, at a minimum, two compartments of approximately equal size. The maximum size of each compartment is not limited and is, therefore, a design decision subject to the approval of the building official.

An exception is permitted at the lowest level of the underground building as long as that level is relatively small in area [less than or equal to 1,500 square feet (139 m²)] and serves a low occupant load (less than 10), since an evacuation to the next higher level would not be expected to adversely affect that level. Note that this exception coordinates with Exception 5 to Section 405.1.

It should be noted that smoke control would be required for all underground buildings in accordance with Section 405.5 that fall under the scope of Section 405.1. Smoke control systems, which are required to be designed in accordance with Section 909, would generally require the use of smoke barriers to create compartments to achieve the design goals stated in Section 405.5.1. Therefore, even when compartmentation is not required for a building that has a floor level that is less than 60 feet (18 288 mm) below the finished floor of the level of exit discharge, compartmentation will probably still be utilized within a building to achieve the goals of Section 909. These compartments may be utilized in a different manner than as mandated in Section 405.4.1. In other words, such compartments may not span vertically from the finished floor of the level of exit discharge to the lowest level of the underground building. The compartments may be designated by story (see Figure 405.4.1).

The provisions for smoke control and compartmentation found in Section 405 were historically focused on smoke exhaust versus smoke control. More specifically, smoke control is for the safety of the occupants only, whereas smoke exhaust tends to focus on the needs of the fire department in managing smoke in underground conditions. The compartmentation requirements in Section 405.4 were meant to work with the smoke exhaust requirements and, at the very least, provide passive smoke management for the building for both the occupants and the fire department. As noted, the requirements of Section 909 as required by Section 405.5 have a different focus and will result in many compartments within the building.
405.4.2 Smoke barrier penetration. The compartments shall be separated from each other by a smoke barrier in accordance with Section 709. Penetrations between the two compartments shall be limited to plumbing and electrical piping and conduit that are firestopped in accordance with Section 714. Doorways shall be protected by fire door assemblies that are automatic-closing by smoke detection in accordance with Section 716.5.9.3 and are installed in accordance with NFPA 105 and Section 716.5.3. Where provided, each compartment shall have an air supply and an exhaust system independent of the other compartments.

- The smoke barrier walls and floor/ceiling assemblies that create the compartments must be fire-resistance rated for 1-hour and must meet the requirements of Section 709. Penetrations through the smoke barrier wall are limited to plumbing, piping and penetrations that are vital to the fire protection systems (i.e., sprinkler piping and electrical raceways). Special fire-resistance-rated doors are required to maintain the intended compartmentation, including gasketing and drop sills. Separate air distribution systems are required for each compartment. Components of the air distribution system are not permitted to penetrate the smoke barrier walls. These requirements are intended to help provide for the independence of the compartments separated by the smoke barrier walls by minimizing the penetrations therein. Note also that Section 711.9 addresses horizontal assemblies that are used as smoke barriers.

The separate air distribution systems required by this section are focused on the smoke compartments specifically required by this section and would not necessarily require separate systems for each compartment as created by the requirements of Section 405.5.

405.4.3 Elevators. Where elevators are provided, each compartment shall have direct access to an elevator. Where an elevator serves more than one compartment, an elevator

---

**Figure 405.4**

**EXAMPLE OF COMPARTMENTATION, ELEVATOR PROTECTION AND EGRESS OF AN UNDERGROUND BUILDING**

For SI: 1 foot = 304.8 mm, 1 inch = 25.4 mm.
lobby shall be provided and shall be separated from each compartment by a smoke barrier in accordance with Section 709. Doors shall be gasketed, have a drop sill and be automatic-closing by smoke detection in accordance with Section 716.5.9.3.

- Elevators are permitted to serve more than one compartment when properly protected. When different compartments utilize a common elevator, a smoke barrier consisting of a 1-hour fire-resistance-rated elevator lobby is required. This lobby provides additional separation between adjacent compartments, thus helping to create their independence from the immediate effects of fire (see Figure 405.4). Essentially the elevator lobby as prescribed in this section creates another smoke compartment within the building.

405.5 Smoke control system. A smoke control system shall be provided in accordance with Sections 405.5.1 and 405.5.2.

- A smoke control system is required for all underground buildings. The smoke control system is an integral part of the required fire protection systems for underground buildings and is focused upon the safety of occupants while exiting the building during a fire. In the case where the building contains both underground and above-ground portions, such specific details and requirements are listed in Sections 405.5.1 and 405.5.2.

405.5.1 Control system. A smoke control system is required to control the migration of products of combustion in accordance with Section 909 and the provisions of this section. Smoke control shall restrict movement of smoke to the general area of fire origin and maintain means of egress in a usable condition.

- The general design requirements, special inspection and test requirements along with the applicable smoke control methods are contained within Section 909. The performance goal of the smoke control system is to contain the smoke and hot gases generated by a fire condition to the immediate area of origin. “Containing to the immediate area of origin” is usually

![Image](image-url)

For SI: 1 foot = 304.8.

Figure 405.4.1
EXAMPLE OF HORIZONTAL COMPARTMENTATION
taken to mean the compartment of origin. This allows
the building occupants to access their required exits
and evacuate the building before smoke movement
traps them below grade. Generally the type of system
will be a pressurization system where the smoke is
managed by maintaining pressure differences across
smoke barriers. It could be possible that a different
type of system such as an exhaust system is required
in larger more open spaces such as an atrium. It is
important to note that the systems in Section 909 are
intended for the protection of occupants and do not
necessarily provide longer term capacity for the fire
department. In addition, such systems are not
intended as a method of smoke exhaust for salvage
and overhaul after a fire. It is recognized that over-
haul in underground buildings after a fire is far more
complex due to the fact that the structure is entirely
underground, but as Section 909 is currently written,
such systems are not specifically designed with this
role in mind.

As discussed in the commentary to Section
405.4.1, the smoke control system required by Sec-
tion 405.5 will likely result in many smoke compart-
ments in order to meet the design criteria of Section
909.

**405.5.2 Compartment smoke control system.** Where com-
partmentation is required, each compartment shall have an
independent smoke control system. The system shall be
automatically activated and capable of manual operation in accor-
dance with Sections 907.2.18 and 907.2.19.

- The compartmentation referred to in this section is
  that required in Section 405.4.1 which requires the
  building be separated from the story of level of exit
discharge to the lowest level in the building. It is not
the intent that each smoke compartment (smoke
zone) as created through the application of Section
405.5.1 would be required to have independent
smoke control systems (see commentary, Section
405.4.2).

[F] **405.6 Fire alarm systems.** A fire alarm system shall be
provided where required by Sections 907.2.18 and 907.2.19.

- The ability to communicate and offer warning of a fire
  scenario can increase the time available for egress
  from the building. Underground buildings with a floor
  level greater than 60 feet (18 288 mm) below the fin-
ished floor of the level of exit discharge are, there-
fore, required to be provided with a manual fire alarm
system. An emergency voice/alarm communication
system is required as part of this system.

**405.7 Means of egress.** Means of egress shall be in ac-
cordance with Sections 405.7.1 and 405.7.2.

- This section is simply the introduction for means of
  egress requirements in underground buildings.
  Egress from underground buildings can be more
  challenging than buildings above grade and addi-
tional requirements are necessary.

**405.7.1 Number of exits.** Each floor level shall be provided
with no fewer than two exits. Where compartmentation is
required by Section 405.4, each compartment shall have no
fewer than one exit and shall also have no fewer than one exit
access doorway into the adjoining compartment.

- The means of egress from underground buildings is
  an integral part of the safety precautions necessary to
  abate the hazards of people being located more than
  30 feet (9144 mm) below the level of exit discharge.
  Sections 405.7.1 and 405.7.2 provide the minimum
  number of exits and requirements for smokeproof
  enclosures. These provisions create safe and usable
  elements that the building occupants can enter to flee
the immediate effects of a fire located well below
grade.

The arrangement of exits and exit access doors for
an underground building is regulated by this section
(see Figure 405.4).

Based on the requirements of this section and Sec-
tion 405.4, an underground building having a floor
level more than 30 feet (9144 mm) below the level of exit
discharge requires a minimum of two exits, and
cannot qualify as a single-exit building. Additional
exits may be required in accordance with Section
1021.2.4. Underground buildings requiring compart-
mentation in accordance with Section 405.4.1 must
have an exit in each and every compartment plus a
doorway into the adjoining compartment.

**405.7.2 Smokeproof enclosure.** Every required stairway
serving floor levels more than 30 feet (9144 mm) below the
finished floor of its level of exit discharge shall comply with
the requirements for a smokeproof enclosure as provided in
Section 1022.10.

- In order for interior exit stairways to provide the nec-
essary means of egress, all stairways of an under-
ground building must be constructed as smokeproof
enclosures. The requirements for smokeproof enclo-
sures are contained in Section 1022.10, which in turn
references Section 909.20, and include a 2-hour
enclosure along with limited access via a vestibule
where the mechanical ventilation alternative described
in Section 909.20 is provided. Another alternative is a pressurized stairway. The require-
ments for pressurized stairways are also listed in
Section 909.20. Pressurized interior exit stairways do
not require a vestibule, but pressure differences as
prescribed in Section 909.20.5 need to be provided
and demonstrated through testing. These provisions
for a smokeproof enclosure are intended to maintain
a protected path of travel for building occupants to
egress the underground building and also allow the
fire department to enter for rescue and fire-fighting
operations.

[F] **405.8 Standby power.** A standby power system comply-
ing with Chapter 27 shall be provided standby power loads
specified in Section 405.8.1.

- All underground buildings regulated by this section
are required to be provided with a standby power sys-
tem to increase the probability that critical systems
will be operational in the event of a loss of normal
power supply. The purpose of the standby power system is to provide an alternative means of supplying power to selected building systems should the normal electrical source fail.

[F] 405.8.1 Standby power loads. The following loads are classified as standby power loads:
1. Smoke control system.
2. Ventilation and automatic fire detection equipment for smokeproof enclosures.
3. Fire pumps.
Standby power shall be provided for elevators in accordance with Section 3003.

- The standby power system is required to supply electrical power to equipment that is essential to emergency egress, fire-fighting and rescue operations.

[F] 405.8.2 Pick-up time. The standby power system shall pick up its connected loads within 60 seconds of failure of the normal power supply.

- This section of the code specifies how quickly the standby power system must be activated to provide the necessary power for the loads specified in Section 405.8.1. The standby power systems must be capable of providing full power to those items within 60 seconds of when the main electrical power source goes down. This maintains the level of safety necessary to evacuate the building and begin fire-fighting operations. The maximum time of 60 seconds is consistent with the requirements of the NFPA 70.

[F] 405.9 Emergency power. An emergency power system complying with Chapter 27 shall be provided for emergency power loads specified in Section 405.9.1.

- In addition to the standby power system, underground buildings regulated by this section are also required to be provided with an emergency power system for certain building systems. These systems include fire warning devices, lighting and other equipment required in underground buildings.

[F] 405.9.1 Emergency power loads. The following loads are classified as emergency power loads:
1. Emergency voice/alarm communications systems.
2. Fire alarm systems.
3. Automatic fire detection systems.
4. Elevator car lighting.
5. Means of egress and exit sign illumination as required by Chapter 10.

- The emergency power system is required to supply electrical power to equipment that is essential to detecting and warning others of a fire condition and to provide for illuminated evacuation of the underground building. Because of the critical nature of the systems and the potential for panic in the areas covered, the loads must be picked up within 10 seconds after failure of the normal power supply. This maximum time is consistent with the requirements of NFPA 70.

[F] 405.10 Standpipe system. The underground building shall be equipped throughout with a standpipe system in accordance with Section 905.

- Just as high-rise buildings or other large buildings with special features are required to be provided with a standpipe system, so are underground buildings. A Class I automatic wet or manual wet standpipe system must be provided. Standpipe systems allow the fire department or other trained personnel to fight the fires at basement levels where it is impractical to run supply lines from the fire department trucks or outside hydrants. A quick and convenient water source for fire department use is essential to containing an underground fire.

SECTION 406
MOTOR-VEHICLE-RELATED OCCUPANCIES

Section 406 has been completely reorganized from the 2009 code; therefore, the * and ** margin indicators have not been included for clarity.

- Included in this section of the code are all the special use and occupancy requirements for those buildings and structures that house motor vehicles. Corresponding requirements for aircraft-related occupancies can be found in Section 412. By definition, all structures that provide services or are used for the storage or parking of motor vehicles are regulated by these provisions. These requirements are applicable regardless of the types of fuel source used to power the vehicles' motors, the number of vehicles present, whether the vehicles are privately or commercially owned and whether they are used strictly for passengers or for freight. Typically, fire hazards for motor vehicle occupancies are low because of the limited amounts of combustibles present along with the steel frame and metal clad bodies. Motor vehicle structures normally have sufficient space around each vehicle for parking purposes, which serves to further limit the fuel load. The design occupant loads are usually low and pose little if any life safety risks.

This section contains requirements for five different motor-vehicle occupancies along with general requirements for parking garages. Section 406.3 addresses private garages and carports, which are classified as a Group U occupancies. All other parking garages are considered to be public parking garages and divided into either open parking garages or enclosed parking garages. These Group S-2 structures represent a slightly higher hazard than private garages or carports. As such, the heights and areas of these structures along with their type of construction classification are rigorously controlled. Requirements are also provided for those buildings and structures that provide service, care and repair of the vehicles. Stations where motor fuels are sold and dispensed are classified as Group M occupancies. The requirements for such facilities are contained in Section 406.7. Garages that provide repair services for
vehicles also represent a slightly higher hazard; therefore, Section 406.8 identifies those additional code requirements necessary to abate the hazards of repair garages and their Group S-1 occupancy classification.

Although not specifically referenced in the code, both Section 304 of the International Mechanical Code® (IMC®) and Section 305 of the International Fuel Gas Code® (IFGC®) address the location of mechanical equipment in both private and public garages.

406.1 General. Motor-vehicle-related occupancies shall comply with Sections 406.1 through 406.8.

The special provisions for motor vehicle-related occupancies address private garages and carparks, public parking (both open and unenclosed) garages, motor fuel-dispensing facilities, and repair garages.

406.2 Definitions. The following terms are defined in Chapter 2:

MECHANICAL-ACCESS OPEN PARKING GARAGES.

OPEN PARKING GARAGE.

RAMP-ACCESS OPEN PARKING GARAGES.

This section lists terms that are specifically associated with the subject matter of Section 406. It is important to emphasize that these terms are not exclusively related to this chapter but may or may not also be applicable where the term is used elsewhere in the code.

Definitions of terms can help in the understanding and application of the code requirements. The purpose for including a list within this chapter is to provide more convenient access to terms which may have a specific or limited application within this chapter. For the complete definition and associated commentary, refer back to Chapter 2. Terms that are italicized provide a visual identification throughout the code that a definition exists for that term. The use and application of all defined terms are set forth in Section 201.

406.3 Private garages and carparks. Private garages and carparks shall comply with Sections 406.3.1 through 406.3.5.

Whereas private garages are smaller than parking garages by definition, the impact of the fuel load represented by the vehicle is somewhat higher. Such garages are frequently attached to residential-type occupancies, with the potential for fire exposure to the residential area and the occupants therein. However, it is not mandatory that a private garage be accessory to a Group R occupancy. The code does not specifically prohibit the servicing of vehicles in private garages, since it would be impractical to enforce. For example, the occupant of a residential dwelling unit will occasionally work on a vehicle in an attached private garage. For this reason, there are special provisions for private garages.

406.3.1 Classification. Buildings or parts of buildings classified as Group U occupancies because of the use or character of the occupancy shall be not greater than 1,000 square feet (93 m²) in area or one story in height except as provided in Section 406.3.2. Any building or portion thereof that exceeds the limitations specified in this section shall be classified in the occupancy group other than Group U that it most nearly resembles.

Private garages and carparks are usually considered accessory to the building they serve. Section 312 classifies these utility and miscellaneous uses as Group U. The code limits these structures to 1,000 square feet (93 m²) in area and one story in height. Those limitations correspond to a fuel load associated with the passenger motor vehicles that is matched by the specified separation requirements. Separation and construction details for private garages attached to dwelling units are provided in Section 406.3.4. This separation includes the 1/2-inch (12.7 mm) regular or 3/4-inch (15.9 mm) Type X gypsum board applied to the garage side (see Section 406.3.4 for further details).

Any garage that exceeds the height and area limits of Section 406.3.1 or the area increase of Section 406.3.2 must be reclassified. Once the specified height and area limits have been exceeded, the garage must be classified for the increased hazards. This results in the garage being classified as Group S-2, and the provisions of Sections 406.4 and 406.5 or 406.6 must now be met.

406.3.2 Area increase. Group U occupancies used for the storage of private or pleasure-type motor vehicles where no repair work is completed or fuel is dispensed are permitted to be 3,000 square feet (279 m²) where the following provisions are met:

1. For a mixed occupancy building, the exterior wall and opening protection for the Group U portion of the building shall be as required for the major occupancy of the building. For such a mixed occupancy building, the allowable floor area of the building shall be as permitted for the major occupancy contained therein.

2. For a building containing only a Group U occupancy, the exterior wall shall not be required to have a fire-resistance rating and the area of openings shall not be limited where the fire separation distance is 5 feet (1524 mm) or more.

More than one 3,000-square-foot (279 m²) Group U occupancy shall be permitted to be in the same structure, provided each 3,000-square-foot (279 m²) area is separated by fire walls complying with Section 706.

The area of a private garage can be increased to 3,000 square feet (279 m²) when all of the conditions of this section are met. If the garage will only be used for the parking and storage of private or pleasure-type motor vehicles, then the area increase may be used. Care must be taken such that no repair work or
fuel dispensing is done within these areas. The limitations to private- or pleasure-type motor vehicles prevent commercial motor vehicles and their increased hazards from being located in this larger private garage. As part of the increased area provisions for private garages, the exterior walls and any openings therein must be properly protected. If the garage is part of another occupancy, then the exterior wall ratings for that occupancy apply to the garage. For example, an automobile insurance office may have several parking bays attached to it. These bays will be used to bring damaged cars in for purposes of evaluating the damage and estimating the cost of repairs for the vehicle owner. The insurance office spaces are usually classified as Group B. In this case, the allowable building area is based on the Group B occupancy, the garage area is limited to 3,000 square feet (279 m²) and the exterior walls and openings in the garages are rated as part of the Group B occupancy.

For other applications, where the buildings only will be used to park vehicles, the building is classified as Group U. The exterior walls and openings therein are not required to be rated or limited if the fire separation distance is 5 feet (1524 mm) or more.

Additional private garages can be added to a Group U building, but they must be separated with fire walls. The 3,000-square-foot (279 m²) limit is a maximum. To reduce the risk of a fire from involving other adjacent garage spaces, fire walls are required to compartmentalize and further isolate the hazards. If the garages are located below another occupancy, such as Group R-2 apartments, the fire walls will be required to continue through to the roof of the residential portion of the building.

406.3.3 Garages and carports. Carports shall be open on no fewer than two sides. Carport floor surfaces shall be of approved noncombustible material. Carports not open on at least two sides shall be considered a garage and shall comply with the provisions of this section for garages.

Exception: Asphalt surfaces shall be permitted at ground level in carports.

The area of floor used for parking of automobiles or other vehicles shall be sloped to facilitate the movement of liquids to a drain or toward the main vehicle entry doorway.

Carports are covered structures, either free-standing or attached to the side of a building, for the purposes of providing shelter for motor vehicles. Carports must be open on at least two sides. This allows a fire condition to vent quickly to the outside. This further prevents a fire from going undetected and usually limits the amount of other incidental storage that may be included in a fully enclosed garage. Attached carports that are not open on at least two sides are considered a garage and must then be separated from the residence or other occupancy (see Section 406.3.4 for further details).

The use of a combustible floor finish that could absorb flammable and combustible liquids commonly used and stored within garages and carports presents a potential safety hazard to the occupants of an attached building. The floors of private garages must be sloped towards the main vehicle doors. Although not specified, the floor must be positively sloped at some rate, such as 1 in 48 (2-percent slope), to prevent the accumulation of any spilled flammable and combustible liquids and their vapors. This minimizes the risk of the vapors building up to a point where a fire condition could result.

406.3.4 Separation. Separations shall comply with the following:

1. The private garage shall be separated from the dwelling unit and its attic area by means of gypsum board, not less than 1/2 inch (12.7 mm) in thickness, applied to the garage side. Garages beneath habitable rooms shall be separated from all habitable rooms above by not less than a 1/8-inch (15.9 mm) Type X gypsum board or equivalent and 1/4-inch (12.7 mm) gypsum board applied to structures supporting the separation from habitable rooms above the garage. Door openings between a private garage and the dwelling unit shall be equipped with either solid wood doors or solid or honeycomb core steel doors not less than 1 3/4 inches (34.9 mm) in thickness, or doors in compliance with Section 716.5.3 with a fire protection rating of not less than 20 minutes. Openings from a private garage directly into a room used for sleeping purposes shall not be permitted. Doors shall be self-closing and self-latching.

2. Ducts in a private garage and ducts penetrating the walls or ceilings separating the dwelling unit, including its attic area, from the garage shall be constructed of sheet steel of not less than 0.019 inches (0.48 mm), in thickness, and shall have no openings into the garage.

3. A separation is not required between a Group R-3 and U carport, provided the carport is entirely open on two or more sides and there are not enclosed areas above.

As indicated in Item 1, when a private garage is attached to a residence, the adjacent areas (including attics) are to be separated to provide a minimum level of protection. This separation is to be constructed of at least 1/2-inch (12.7 mm) gypsum wallboard applied to the garage side. In a location where the garage is beneath any type of habitable space, the separation requirement is increased by requiring that 5/8-inch (15.9 mm) Type X gypsum board or some other material that would provide an equivalent level of protection be used. Bearing walls and other structural elements that support the horizontal separation shall be protected with minimum 1/2-inch (12.7 mm) gypsum board. Doors opening within the adjacent wall are required to be protected with a minimum 1/2-inch-thick (34 mm) solid core wood or 1/2-inch-thick (34 mm) solid or honeycomb steel door. Although the 1/2-inch-thick (34 mm) solid core wood and honeycomb steel doors are not listed as fire doors, they still provide adequate protection. Alternatively, doors with a 20-minute fire protection rating in accordance with
Section 716.5.3 may be used. All door openings from the garage, whether solid core wood, honeycomb steel or 20-minute rated, are prohibited from opening directly into a bedroom or any other room used for sleeping purposes. It is important to note that this separation requirement, including the protection and the limitation on the openings, is only applicable to garages and not to carports.

With regards to Item 2, ducts in the walls and ceilings that do not penetrate into the garage are already protected by the gypsum wallboard; therefore, additional separation is not necessary. If the ducts do penetrate through the separation, then the specified protection must be provided.

In accordance with Item 3, a roofed structure open on two or more sides without any enclosed uses above poses no special hazard to the occupants of the dwelling. If a fire were to start under the carport roof, the smoke, hot gases and flames would be able to escape out the open sides, providing the structure with an adequate amount of protection. See the commentary to Section 406.3.3 for additional related discussion.

Section 406.3.4 is silent regarding the separation of a private garage from other occupancies. Where a Group U private garage is attached to other occupancies, such mixed occupancy building needs to be designed in accordance with Section 508.3 for non-separated mixed occupancies or Section 508.4 for separated occupancies. Under separated occupancies, Table 508.4 would require a minimum 2-hour separation between a Group U and Group B occupancy in a building without sprinkler protection. It might also be possible to consider the private parking garage under the accessory occupancy provisions of Section 508.2.

406.3.5 Automatic garage door openers. Automatic garage door openers, if provided, shall be listed in accordance with UL 325.

- This section provides a requirement that automatic door openers comply with UL 325. This provision is also found in the International Residential Code® (IRC®).

406.4 Public parking garages. Parking garages other than private parking garages, shall be classified as public parking garages and shall comply with the provisions of Sections 406.4.2 through 406.4.8 and shall be classified as either an open parking garage or an enclosed parking garage. Open parking garages shall also comply with Section 406.5. Enclosed parking garages shall also comply with Section 406.6. See Section 510 for special provisions for parking garages.

- There are fundamentally two types of parking garages regulated by the IBC, private garages and public garages. Although there is no specific definition for either type of garage, the basis for both classifications is Section 406.3 addressing private garages and carports. Those structures that fall outside of the scope of Section 406.3 are considered as public parking garages. The primary difference between private and public parking garages is the size of the facility, rather than the use. Strictly limited in permissible height and area, private parking garages are typically not commercial in nature. They serve only a specific tenant or building and are not open for public use. It is important to note that there is no implication that public parking garages must be open to the public, as they are only considered public in comparison to private garages.

- Public parking garages are considered to be storage occupancies (Group S-2). In addition to the provisions of Sections 406.4, 406.5 and 406.6, public parking garages must also comply with the code provisions for Group S occupancies.

- The overall building fire loading in public parking garages is typically low because of the considerable amount of metal in vehicles, which absorbs heat and the average weight of combustibles per square foot being relatively low (approximately 2 pounds per square foot (9.8 kg/m² psf)). Still, a vehicle fire may be quite extensive.

- Public parking garages are divided into one of two categories. Those parking garages that contain sufficient clear openings in their exterior walls that meet the requirements of Section 406.5.2 can be classified as open parking garages. All other public parking garages must be considered as enclosed parking garages and must comply with Section 406.6. Special height and area provisions for parking garages located above or below other uses and occupancies are contained in Section 510.

406.4.1 Clear height. The clear height of each floor level in vehicle and pedestrian traffic areas shall be not less than 7 feet (2134 mm). Vehicle and pedestrian areas accommodating van-accessible parking shall comply with Section 1106.5.

- A clear height of 7 feet (2134 mm) is required for all parking garages. This is an exception to the 7 foot, 6 inch (2286 mm) minimum height required in Chapter 10 for the means of egress system. This minimum height permits free and unobstructed egress around the vehicles and exit access areas. Van-accessible parking areas and the vehicular route to them must comply with Section 1106.5.

406.4.2 Guards. Guards shall be provided in accordance with Section 1013. Guards serving as vehicle barriers shall comply with Sections 406.4.3 and 1013.

- For the same reasons as identified in the commentary to Section 1013, guards are required around all vertical openings in the floors and roofs of parking garages where the vertical distance between adjacent levels exceeds 30 inches (762 mm). As a separate requirement, vehicle barriers are required at specified locations where the vertical distance between adjacent levels exceeds 12 inches (305 mm). Guards that serve a dual purpose of guard and vehicle barrier systems must comply with both Section 1013 and Section 406.4.3.
406.4.3 Vehicle barriers. Vehicle barriers not less than 2 feet 9 inches (835 mm) in height shall be placed at the ends of drive lanes, and at the end of parking spaces where the vertical distance to the ground or surface directly below is greater than 1 foot (305 mm). Vehicle barriers shall comply with the loading requirements of Section 1607.8.3.

Exception: Vehicle barriers are not required in vehicle storage compartments in a mechanical access parking garage.

- This section requires vehicle barriers at locations where a 1-foot (305 mm) dropoff exists at the end of parking spaces or drive lanes. Vehicle barriers are to be designed in accordance with Section 1607.8.3. The vehicle barriers are required to resist a single load of 6,000 pounds (2722 kg). The minimum height of the barriers is 2 feet, 9 inches (835 mm), in recognition of the extensive number of vehicles with higher profiles on the road today. Barriers are not required in areas where the employees of the garage park the vehicles, such as mechanical access garages.

406.4.4 Ramps. Vehicle ramps shall not be considered as required exits unless pedestrian facilities are provided. Vehicle ramps that are utilized for vertical circulation as well as for parking shall not exceed a slope of 1:15 (6.67 percent).

- Since the vehicular ramps of parking garages are open to all levels, they are directly exposed to the effects of smoke and hot gases. In addition, the vehicle ramps are often sloped at a rate greater than 1:12 (8-percent slope). These ramps, therefore, cannot be counted as part of the required exits from each level or tier. Certainly occupants can travel from their vehicles on sloped parking levels to access the required exit stairways; however, occupants cannot continuously travel down the vehicle ramps to reach the exit discharge unless the slope is 1:15 or less and sidewalks or other protected walking surfaces are provided.

406.4.5 Floor surface. Parking surfaces shall be of concrete or similar noncombustible and nonabsorbent materials. The area of floor used for parking of automobiles or other vehicles shall be sloped to facilitate the movement of liquids to a drain or toward the main vehicle entry doorway.

Exceptions:
1. Asphalt parking surfaces shall be permitted at ground level.
2. Floors of Group S-2 parking garages shall not be required to have a sloped surface.

- To avoid acquiring a buildup of flammable liquids on the floor of parking garages, the floor finish is required to be noncombustible and nonabsorbent. Because of pollution concerns, however, garage floors are not automatically required to be drained into the building drainage system. This is consistent with requirements of the Environmental Protection Agency (EPA) for storm water drainage, as well as the philosophy of hazardous material handling (i.e., localize spills and treat them). If floor drains are provided, however, they must be installed in accordance with the IPC.

Exception 1 recognizes that many states have allowed the use of asphalt paving surfaces at grade levels of parking garages with no record of fire hazards. This exception does not allow asphalt paving to be used on stories above or below grade. Although not specified, the floor must be positively sloped at some rate, such as 1 in 48 (2-percent slope), to prevent the accumulation of any spilled flammable and combustible liquids and their vapors. This minimizes the risk of the vapors building up to a point where a fire condition could result.

Exception 2 was introduced into the code based on the recognition that many parking garages are constructed of prefabricated materials which prove difficult to achieve the required slope when assembled on site. The exception, however, waives the slope requirement for all Group S-2 parking facilities, not just those of prefabricated materials.

406.4.6 Mixed occupancy separation. Parking garages shall be separated from other occupancies in accordance with Section 508.1.

- If a building or structure consists not only of a Group S-2 parking garage but also other occupancies, then the building is treated as any other mixed occupancy. The building designer must choose one of the options available in Section 508 to address the mixed use and occupancy issues. Keep in mind that Sections 510.2, 510.3, 510.4, 510.7, 510.8 and 510.9 contain special provisions for mixed separations when the parking garages are located above or below other groups.

406.4.7 Special hazards. Connection of a parking garage with any room in which there is a fuel-fired appliance shall be by means of a vestibule providing a two-doorway separation.

Exception: A single door shall be allowed provided the sources of ignition in the appliance are not less than 18 inches (457 mm) above the floor.

- As part of the special use and occupancy requirements for parking garages, all possible ignition sources must be controlled and isolated. Specifically, all heating equipment must be located in rooms that are separated from the main areas where the vehicles are parked. Doors connecting the heating equipment rooms and the main parking area must be done with a vestibule or airlock arrangement such that one must pass through two doors prior to entering the other room. Again, this is done to minimize the possibility of any spilled flammable liquids and the resulting vapors from coming in contact with the ignition sources of the heating equipment.

An allowance is made if the heating equipment is located at least 18 inches (457 mm) above the floor of the separated room. In such a case, the vestibule/airlock arrangement with a double-door system is not required and access can be done with just a single
door. If this exception is used, it must be understood by the building and fire officials that these special stipulations and conditions are part of the certificate of occupancy. Please note that there are more specific standards regarding the installation of mechanical equipment in public and private garages in Section 304 of the IMC and Section 305 of the IFGC.

**406.4.8 Attached to rooms.** Openings from a parking garage directly into a room used for sleeping purposes shall not be permitted.

- Just as a private garage cannot have openings into bedrooms (see Section 406.3.4, Item 1), public parking garages are likewise limited. The risks of a fire and smoke quickly spreading into adjacent areas where occupants may be sleeping are too great.

**406.5 Open parking garages.** Open parking garages shall comply with Sections 406.5.1 through 406.5.11.

- The code establishes four types of garages: private, enclosed parking, repair garages and open parking. With the exception of private garages, all such structures are classified as Group S. Unlike other storage occupancies in which the fuel load is evenly distributed, garages represent a different fire hazard.

  Because of the generally fast-burning upholstery and the gasoline or diesel fuel content, fires in individual vehicles can be quite extensive. Because of both the overall combustible loading within a parking garage, which yields a low combustible fuel load ([approximately 2 pounds per square foot (psf) (9.8 kg/m²)], and the considerable amount of metal in vehicles, which absorbs heat, the overall fire hazards are low. Section 406.5 provides requirements that are unique to open parking garages, while Section 406.3 addresses private garages and Section 406.6 addresses enclosed parking garages. Because of the permanently open exterior walls of open parking garages, which permit the dissipation of heated gases, special provisions are made for heights and areas of such structures.

  Open parking garages are classified as Group S-2 and all of the provisions for this occupancy group are applicable except as modified herein.

**406.5.1 Construction.** Open parking garages shall be of Type I, II or IV construction. Open parking garages shall meet the design requirements of Chapter 16. For vehicle barriers, see Section 406.4.3.

- One of the basic premises of the provisions for open parking garages is that the overall fuel load is low and that the average fuel load per square foot is low. The construction of open parking garages, therefore, is restricted to Type I, II or IV, so that the combustible loading of cars is not exceeded by that of the structure.

**406.5.2 Openings.** For natural ventilation purposes, the exterior side of the structure shall have uniformly distributed openings on two or more sides. The area of such openings in exterior walls on a tier shall be not less than 20 percent of the total perimeter wall area of each tier. The aggregate length of the openings considered to be providing natural ventilation shall be not less than 40 percent of the perimeter of the tier. Interior walls shall be not less than 20 percent open with uniformly distributed openings.

  **Exception:** Openings are not required to be distributed over 40 percent of the building perimeter where the required openings are uniformly distributed over two opposing sides of the building.

- Key attributes of an open parking garage, based on the fire records of such facilities, include the exterior wall openings and ventilation of the structure. This section requires that 40 percent of the building perimeter has openings that are uniformly distributed on no less than two sides of the structure. In addition to providing for adequate distribution, the section also requires that a minimum of 20 percent of the total perimeter wall area at each level must be open. The openings in the exterior wall must be free so that natural ventilation will occur without interior wall obstructions.

  In instances where the open parking garage is provided with openings on two opposite sides of the structure, thereby providing cross ventilation, the 40 percent criterion does not apply; however, the openings must still meet the 20-percent criterion of the total perimeter wall area.

  In every case, interior walls are to have distributed openings totaling 20 percent of the wall area to allow ventilation of all spaces (see Figure 406.5.2).

**406.5.2.1 Openings below grade.** Where openings below grade provide required natural ventilation, the outside horizontal clear space shall be one and one-half times the depth of the opening. The width of the horizontal clear space shall be maintained from grade down to the bottom of the lowest required opening.

- Because permanently open exterior walls provide sufficient natural ventilation and permit the dissipation of heated gases, open parking garages are viewed as a relatively low hazard. However, there are situations where the required openings are located below the surrounding grade which makes it more difficult to provide the necessary openness required for good performance. A clear horizontal space as described by this section must be provided adjacent to the garage’s exterior openings to allow for adequate air movement through the opening. As the distance of the openings below the adjoining ground level increases, the minimum required exterior horizontal clear space also increases proportionally. The dimensional requirements are based on the provisions of Section 1203.4.1.2. The extent of the required clear space allows for adequate exterior open space to meet the intent and dynamics of natural ventilation requirements for open parking garages.
406.5.3 Uses. Mixed uses shall be allowed in the same building as an open parking garage subject to the provisions of Sections 402.4.2.3, 406.5.11, 508.1, 510.3, 510.4 and 510.7.

- Open parking garages can be constructed as part of a mixed-occupancy building. The building cannot be designed to take advantage of the height and area increases allowed by Sections 406.5.4.1 and 406.5.5. The code provides references to the placement of open parking garages as part of a covered or open mall building. It also provides specific references to three of the special building provisions in Section 510 where open parking garages may be located above or below other buildings. There is also a reference to the mixed-occupancy provisions of Section 508. There is also a reference to Section 406.5.11 where there are specific prohibitions for certain activities within an open parking garage.

406.5.4 Area and height. Area and height of open parking garages shall be limited as set forth in Chapter 5 for Group S-2 occupancies and as further provided for in Section 508.1.

- When an open parking garage is located within a building containing other occupancies, the code requires that the height and area limitations for the open parking garage be determined by using the normal provisions found in Chapter 5 for a Group S-2 occupancy. This essentially means that the garage would receive the same allowable areas of an enclosed parking garage or a storage building that was classified in the same occupancy.

406.5.4.1 Single use. Where the open parking garage is used exclusively for the parking or storage of private motor vehicles, with no other uses in the building, the area and height shall be permitted to comply with Table 406.5.4, along with increases allowed by Section 406.5.5.

Exception: The grade-level tier is permitted to contain an office, waiting and toilet rooms having a total combined area of not more than 1,000 square feet (93 m²). Such area need not be separated from the open parking garage.

In open parking garages having a spiral or sloping floor, the horizontal projection of the structure at any cross section shall not exceed the allowable area per parking tier. In the case of an open parking garage having a continuous spiral floor, each 9 feet 6 inches (2896 mm) of height, or portion thereof, shall be considered a tier.

The clear height of a parking tier shall be not less than 7 feet (2134 mm), except that a lower clear height is permitted in mechanical-access open parking garages where approved by the building official.

- When an open parking garage is located in a building that is only used as a parking garage, the type of hazard that is created by the occupancy is greatly reduced. Because of the openness requirements in Section 406.5.2 and the dissipation of heated gases, as well as the overall low fuel load, the height and area limitations for single-use open parking garages are not the same as for other buildings of Group S-2. The height requirements are based on actual fire experience and full-scale fire tests conducted in the United States, Great Britain, Japan and Switzerland. For these single-use buildings that comply with the other provisions of this section, Table 406.5.4 replaces Table 503 for the determination of heights and areas. Although these open parking garages are considered as being a single occupancy, the excep-

A1, A2 = AREA OF OPENINGS
L1, L2 = LENGTH OF OPENINGS
L1 + L2 > 40 PERCENT OF BUILDING PERIMETER
A1 + A2 > 20 PERCENT OF BUILDING PERIMETER WALL AREA
tion permits a limited amount of support-type spaces to be included in the structure.

TABLE 406.5.4. See below.

❖ Table 406.5.4 is used in the same manner as Table 503. For a given construction type, the height and area limitations can be determined from the table. For example, an open parking garage of Type IIB construction may be a maximum of eight tiers in height for a ramp access garage and the area would then be limited to 50,000 square feet (4545 m²) per tier.

The height restrictions in the table are measured as defined in Section 202. In this instance, parking may be permitted on the highest level of the structure, which also constitutes the roof of the structure. The areas provided are per tier.

406.5.5 Area and height increases. The allowable area and height of open parking garages shall be increased in accordance with the provisions of this section. Garages with sides open on three-fourths of the building’s perimeter are permitted to be increased by 25 percent in area and one tier in height. Garages with sides open on the entire building’s perimeter are permitted to be increased by 50 percent in area and one tier in height. For a side to be considered open under the above provisions, the total area of openings along the side shall not be less than 50 percent of the interior area of the side at each tier and such openings shall be equally distributed along the length of the tier. For purposes of calculating the interior area of the side, the height shall not exceed 7 feet (2134 mm).

Allowable tier areas in Table 406.5.4 shall be increased for open parking garages constructed to heights less than the table maximum. The gross tier area of the garage shall not exceed that permitted for the higher structure. No fewer than three sides of each such larger tier shall have continuous horizontal openings not less than 30 inches (762 mm) in clear height extending for not less than 80 percent of the length of the sides and no part of such larger tier shall be more than 200 feet (60 960 mm) horizontally from such an opening. In addition, each such opening shall face a street or yard accessible to a street with a width of not less than 30 feet (9144 mm) for the full length of the opening, and standpipes shall be provided in each such tier.

Open parking garages of Type II construction, with all sides open, shall be unlimited in allowable area where the building height does not exceed 75 feet (22 860 mm). For a side to be considered open, the total area of openings along the side shall not be less than 50 percent of the interior area of the side at each tier and such openings shall be equally distributed along the length of the tier. For purposes of calculating the interior area of the side, the height shall not exceed 7 feet (2134 mm). All portions of tiers shall be within 200 feet (60 960 mm) horizontally from such openings or other natural ventilation openings as defined in Section 406.5.2. These openings shall be permitted to be provided in courts with a minimum dimension of 20 feet (6096 mm) for the full width of the openings.

❖ The area modifications permitted by Section 406.5.5 for open building perimeters that are similar to Section 506.2 are also applicable to the area restrictions in Table 406.5.4. The section essentially provides three different ways to qualify as an open parking garage and use the increased heights and areas.

- Open parking garages of Type IA construction are unlimited in area and height. This is consistent with Type I construction in Table 503.
- Open parking garages of Type IB construction are also unlimited in area, but are limited in height to 12 tiers (or 18 tiers for a mechanical-access garage which is sprinkler protected). If a Type IB garage meets either of the open perimeter criteria below, it can be one tier higher than allowed in the table.
- Where the building is of Type II or IV construction and 75 percent of the perimeter is open, it is permitted to be increased 25 percent in area per tier (or from 50,000 square feet (4645 m²) to 62,500 square feet (5806 m²)) and one tier in height above the limits for the type of construction in Table 406.5.4.
- Where the building is of Type II or IV construction and is open for the entire perimeter, a 50-percent increase in area is permitted, as well as one tier in height. This results in the same number of tiers as the 75-percent open perimeter, but in this case the area of each tier can be as large as 75,000 square feet (6968 m²).

In addition to complying with the opening criteria found in Section 406.5.2, the openings for an increased area and/or height open parking garage

For SI: 1 square foot = 0.0929 m².
must be at least equal to 50 percent of the interior area of each tier and must be at least 30 inches (762 mm) in vertical dimension. They must be found on 50 percent of the perimeter sides considered open and each such opening shall front on a yard or public way with a minimum dimension of 30 feet (9144 mm). Each part of enlarged tiers needs to be within 200 feet (60 960 mm) of such openings.

For Type II garages there is a third design option. If all sides are open, the area per tier is unlimited provided the building height does not exceed 75 feet (22 860 mm) above grade plane. As in the other options, the openings must be at least 50 percent of the interior of each tier, but in this case the openings must be evenly distributed around the perimeter. All portions of each tier must be within 200 feet (60 960 mm) of such openings, and, where necessary, some of the openings needed for this ventilation may be located in courts, provided the courts have a least dimension of 20 feet (6096 mm).

When calculating the interior area of the side of a tier, the maximum height to be used in the calculation is 7 feet (2134 mm) as shown in Figure 406.5.2. This method allows for consistent application of the provision regardless of the wall height.

406.5.6 Fire separation distance. Exterior walls and openings in exterior walls shall comply with Tables 601 and 602. The distance to an adjacent lot line shall be determined in accordance with Table 602 and Section 705.

The required fire separation is intended to provide sufficient open space adjacent to the wall openings to allow for free ventilation and to reduce the probability for fire spread to adjacent structures. The exterior wall openings in an open parking garage are not subject to the opening limitations with a fire separation distance greater than 10 feet (3048 mm) (see Table 705.8, Note g).

406.5.7 Means of egress. Where persons other than parking attendants are permitted, open parking garages shall meet the means of egress requirements of Chapter 10. Where no persons other than parking attendants are permitted, there shall be no fewer than two exit stairways. Each exit stairway shall be not less than 36 inches (914 mm) in width. Lifts shall be permitted to be installed for use of employees only, provided they are completely enclosed by noncombustible materials.

Typical means of egress elements are required for open parking garages based on a design occupant load of one person per 200 square feet (19 m²) of gross floor area (see Table 1004.1.1). For mechanical-access open parking garages or for attendant-only ramp-access parking garages, the code would permit two exit stairs, each 36 inches (914 mm) wide.

406.5.8 Standpipe system. An open parking garage shall be equipped with a standpipe system as required by Section 905.3.

Depending on the height of an open parking garage, Section 905.3.1 may require a standpipe system. The standpipe system would aid the fire department in on-site fire-fighting operations, since Table 406.5.4 permits buildings that may not allow for conventional hoses and apparatus to be carried from ground operations to the fire floor.

406.5.9 Enclosure of vertical openings. Enclosure shall not be required for vertical openings except as specified in Section 406.5.7.

Based on the use of open parking garages requiring convenient and frequent access between floor levels, enclosure of most vertical openings is not required or desired due to the opening requirements of Section 406.5.2. This would include the exit access stairways as permitted by Section 1009.3. Exception 6. Where a designer chooses to provide an enclosure—for example, around an elevator hoistway—since the enclosure does not need to be rated, there is no requirement that a lobby be provided for the elevator (see IBC Interpretation No. 36-07).

406.5.10 Ventilation. Ventilation, other than the percentage of openings specified in Section 406.5.2, shall not be required.

Mechanical ventilation systems are not required in a structure that is inherently open to the exterior atmosphere.

406.5.11 Prohibitions. The following uses and alterations are not permitted:

1. Vehicle repair work.
2. Parking of buses, trucks and similar vehicles.
3. Partial or complete closing of required openings in exterior walls by tarps or any other means.
4. Dispensing of fuel.

This section reinforces the concepts and requirements of Section 406.5.2 and the definition of "open parking garage." Any other use or alteration of an open parking garage, which is designed to take advantage of the increased heights and areas, is specifically prohibited.

406.6 Enclosed parking garages. Enclosed parking garages shall comply with Sections 406.6.1 through 406.6.3.

Enclosed parking garages are considered to be storage occupancies. In addition to the provisions of Sections 406.4 and 406.6, enclosed parking garages must also comply with the code provisions for Group S-2 low-hazard storage occupancies.

The overall building fire load in enclosed parking garages is typically low because of the considerable amount of metal in vehicles that absorbs heat and the average weight of combustibles per square foot being relatively low [approximately 2 psf (9.8 kg/m²)]. Still, a vehicle fire may be quite extensive.

406.6.1 Heights and areas. Enclosed vehicle parking garages and portions thereof that do not meet the definition of open parking garages shall be limited to the allowable
SPECIAL DETAILED REQUIREMENTS BASED ON USE AND OCCUPANCY

heights and areas specified in Table 503 as modified by Sections 504, 506 and 507. Roof parking is permitted.

- Special height and area limitations allowed for open parking garages in Table 406.5.4 are not provided for enclosed parking garages. The typical allowable building heights and areas of Table 503 are to be used for these Group S-2 structures. It should be noted that Section 510 contains special provisions for enclosed parking garages located beneath other groups and occupancies. See that section for further discussion of these special building arrangements.

406.6.2 Ventilation. A mechanical ventilation system shall be provided in accordance with the International Mechanical Code.

- Enclosed parking garages are required to be ventilated in accordance with the provisions of the IMC. If motor vehicles will be operated for a period of time exceeding 10 seconds, the ventilation return air for the enclosed parking garage ventilation system must be exhausted (see Section 404 of the IMC).

[F] 406.6.3 Automatic sprinkler system. An enclosed parking garage shall be equipped with an automatic sprinkler system in accordance with Section 903.2.10.

- A building containing a Group S-2 enclosed parking garage is required to be sprinklered throughout where the fire area of the garage exceeds 12,000 square feet (1115 m²) or where the garage is located under occupancies other than Group R-3. A full discussion is provided in the commentary to Section 903.2.10.

406.7 Motor fuel-dispensing facilities. Motor fuel-dispensing facilities shall comply with the International Fuel Code and Sections 406.7.1 and 406.7.2.

- Motor fuel-dispensing facilities are those areas where motor fuels are stored, sold or otherwise dispensed to vehicles. These buildings and structures are classified as Group M. Motor fuel-dispensing facilities must be constructed in accordance with the applicable requirements of Chapter 23 of the IFC. Specific details are provided for the special hazards relative to fuel-dispensing systems and areas.

406.7.1 Vehicle fueling pad. The vehicle shall be fueled on noncoated concrete or other approved paving material having a resistance not exceeding 1 meegohm as determined by the methodology in EN 1081.

- The expansion of the use of hydrogen as a vehicle fuel necessitates that the code more clearly address the hazard of potential electrostatic discharge around fueling facilities. The preferred material for fueling pads is concrete, but the referenced standard provides alternative materials to achieve an antistatic performance of the pad.

406.7.2 Canopies. Canopies under which fuels are dispensed shall have a clear, unobstructed height of not less than 13 feet 6 inches (4115 mm) to the lowest projecting element in the vehicle drive-through area. Canopies and their supports over pumps shall be of noncombustible materials, fire-retardant-treated wood complying with Chapter 23, wood of Type IV sizes or of construction providing 1-hour fire resistance. Combustible materials used in or on a canopy shall comply with one of the following:

1. Shielded from the pumps by a noncombustible element of the canopy, or wood of Type IV sizes;

2. Plastics covered by aluminum facing having a thickness of not less than 0.010 inch (0.30 mm) or corrosion-resistant steel having a base metal thickness of not less than 0.016 inch (0.41 mm). The plastic shall have a flame spread index of 25 or less and a smoke-developed index of 450 or less when tested in the form intended for use in accordance with ASTM E 84 or UL 723 and a self-ignition temperature of 650°F (343°C) or greater when tested in accordance with ASTM D 1929; or

3. Panels constructed of light-transmitting plastic materials shall be permitted to be installed in canopies erected over motor vehicle fuel-dispensing station fuel dispensers, provided the panels are located not less than 10 feet (3048 mm) from any building on the same lot and face yards or streets not less than 40 feet (12 192 mm) in width on the other sides. The aggregate area of plastics shall be not greater than 1,000 square feet (93 m²). The maximum area of any individual panel shall be not greater than 100 square feet (9.3 m²).

- Almost all motor fuel-dispensing facilities are provided with a flat canopy-style roof structure that is column supported. Obviously these structures must be designed to meet the applicable wind and snow loads of Chapter 16 for life safety purposes. For fire safety purposes, the canopies must pose little fire risk and be located above any immediate fire hazards from the fuel-dispensing areas. Limitations are provided for all combustible materials used in the canopy construction.

406.7.2.1 Canopies used to support gaseous hydrogen systems. Canopies that are used to shelter dispensing operations where flammable compressed gases are located on the roof of the canopy shall be in accordance with the following:

1. The canopy shall meet or exceed Type I construction requirements.

2. Operations located under canopies shall be limited to refueling only.

3. The canopy shall be constructed in a manner that prevents the accumulation of hydrogen gas.

- This provision is part of the overall package of code requirements related to the gaseous hydrogen concept of fuel. These additional requirements are necessary to abate the inherent hazards while permitting the use of weather shelters. Not only must the canopies be of noncombustible materials but they must also have the fire-resistance ratings specified in Table 601 for either Type IA or IB construction.
406.8 Repair garages. Repair garages shall be constructed in accordance with the International Fire Code and Sections 406.8.1 through 406.8.6. This occupancy shall not include motor fuel-dispensing facilities, as regulated in Section 406.7.

- Repair garages are those in which provisions are made for the care, repair and painting of vehicles. Repair garages have an inherently higher fire hazard represented by numerous vehicles in some state of repair, with possible spray painting. As such, these buildings or structures are classified as Group S-1. Repair garages must also meet the applicable requirements of Chapter 23 of the IFC and Section 416 if there are paint-spraying operations.

- All motor vehicle work that involves repairs or reconstruction of damaged or nonfunctioning vehicles is considered a higher hazard. These types of facilities provide a variety of services, including tune-ups, oil changes, engine or transmission overhauls and body work, and are all considered as repair garages. Additional protection and detection systems are required to match the increased hazards.

406.8.1 Mixed uses. Mixed uses shall be allowed in the same building as a repair garage subject to the provisions of Section 508.1.

- Repair garages usually have integral office and administration areas or are part of an automobile dealership. To minimize the hazards and functions housed in the repair areas, the code reminds the user that these spaces are considered as different occupancies and must therefore comply with the general code requirements for mixed uses. The actual requirements will depend on the size of the spaces and how the designer chooses to deal with the different uses.

406.8.2 Ventilation. Repair garages shall be mechanically ventilated in accordance with the International Mechanical Code. The ventilation system shall be controlled at the entrance to the garage.

- Repair garages are required to be ventilated in accordance with the provisions of the IMC. If motor vehicles will be operated for a period of time exceeding 10 seconds, the ventilation return air for the repair garage ventilation system must be exhausted (see Sections 403 and 404 of the IMC).

406.8.3 Floor surface. Repair garage floors shall be of concrete or similar noncombustible and nonabsorbent materials.

Exception: Slip-resistant, nonabsorbent, interior floor finishes having a critical radiant flux not more than 0.45 W/cm², as determined by NFPA 253, shall be permitted.

- To avoid a buildup of flammable liquids on the floor of repair garages, the floor finish is in general required to be noncombustible and nonabsorbent. Because of pollution concerns, however, garage floors are not automatically required to be drained into the building drainage system. This is consistent with requirements of the EPA for storm water drainage, as well as the philosophy of hazardous material handling (i.e., localize spills and treat them). If floor drains are provided, however, they must be installed in accordance with the IPC.

406.8.4 Heating equipment. Heating equipment shall be installed in accordance with the International Mechanical Code.

- As part of the special use and occupancy requirements for repair garages, all possible ignition sources must be controlled and isolated. Specifically, all heating equipment must be installed in accordance with the IMC, which contains provisions that address items such as the elevation of the appliance above the floor and the use of overhead unit heaters.

[F] 406.8.5 Gas detection system. Repair garages used for the repair of vehicles fueled by nonodorized gases such as hydrogen and nonodorized LNG, shall be provided with a flammable gas detection system.

- Some gases contain additives, such as ethyl mercaptan, that produce pungent odors for easy sensory detection and recognition. If the repair garage repairs vehicles equipped with fuel systems that do not use these odorized gases, a gas detection system must be installed to replace the lost sensory detection capability.

[F] 406.8.5.1 System design. The flammable gas detection system shall be listed or approved and shall be calibrated to the types of fuels or gases used by vehicles to be repaired. The gas detection system shall be designed to activate when the level of flammable gas exceeds 25 percent of the lower flammable limit (LFL). Gas detection shall be provided in lubrication or chassis service pits of repair garages used for repairing nonodorized LNG-fueled vehicles.

- The flammable gas detection system is designed to produce an alarm or signal when exposed to different concentrations of gases or vapor and the gas detector or gas sensor is a critical part of the system for the detection of the different gases. Section 2311.7.2.1 of the IFC requires gas detection equipment to be listed in accordance with UL 2075 and include an indication of the different gases it will detect. Under UL 2075, a set of flammable gases and concentrations (PPM) is developed for each detector or sensor and the manufacturer is required to provide information as to what gases and the concentrations the device is designed to detect. Tests under the standard then verify the performance of each detector or sensor for each gas it is designed to detect. The gases that the equipment will detect may be shown in the manufacturer's instructions rather than on the product. This section will require quick-lube-type facilities that change oil and lubricate vehicles to install gas detection systems in the pit area if they service vehicles that are equipped with LNG fuel systems using nonodorized LNG.

[F] 406.8.5.1.1 Gas detection system components. Gas detection system control units shall be listed and labeled in accordance with UL 864 or UL 2017. Gas detectors shall be
listed and labeled in accordance with UL 2075 for use with the gases and vapors being detected.

- This section mandates that gas detection system components are listed in accordance with nationally recognized safety standards. These standards include a comprehensive set of construction and performance requirements that are used to evaluate and list gas detection system control units and gas detectors.

[F] 406.8.5.2 Operation. Activation of the gas detection system shall result in all of the following:

1. Initiation of distinct audible and visual alarm signals in the repair garage.
2. Deactivation of all heating systems located in the repair garage.
3. Activation of the mechanical ventilation system, where the system is interlocked with gas detection.

- Once the required flammable gas detection system identifies a gas level exceeding 25 percent of the lower explosive limit (LEL), it must do three things: alert the occupants of the emergency, cut power to all possible ignition sources and dilute the concentration level with additional ventilation air.

[F] 406.8.5.3 Failure of the gas detection system. Failure of the gas detection system shall result in the deactivation of the heating system, activation of the mechanical ventilation system where the system is inter-locked with the gas detection system and cause a trouble signal to sound in an approved location.

- The required flammable gas detection system must include a default mode of operation. If the system malfunctions or loses power, it must in effect do the same operational requirements referenced in Section 406.8.5.2. This redundancy will lessen the likelihood of an explosive fire risk for the specialized motor fuels.

[F] 406.8.6 Automatic sprinkler system. A repair garage shall be equipped with an automatic sprinkler system in accordance with Section 903.2.9.1.

- Section 903.2.9.1 requires buildings where repair garages are located to be provided with an automatic sprinkler system where any one of four listed conditions is present. The sprinkler threshold is reduced in those repair garages where work is performed on trucks or buses. See the commentary on Section 903.2.9.1 for further information.

SECTION 407
GROUP I-2

407.1 General. Occupancies in Group I-2 shall comply with the provisions of Sections 407.1 through 407.10 and other applicable provisions of this code.

- The provisions contained in Section 407 reflect previous requirements of the other former model codes, full-scale fire tests and historical fire experience. Features unique to health care facilities, such as a low fuel load, the presence of staff, operating practices and procedures and the regulatory process, were also included in developing the provisions. One of the concerns addressed by this section is the need to provide an acceptable level of protection without interfering with the operation of the facility.

Underlying the protection requirements for Group I-2 is a "defend-in-place" philosophy based on the difficulties associated with evacuating such facilities.

The first level of protection established is the individual room (typically a patient sleeping room). Horizontal evacuation to an adjacent smoke compartment provides the second level of protection. If necessary, the third level of protection involves evacuation of the floor or entire building.

This section has been created not only because of considerations unique to health care facilities, but also to facilitate the consideration of the entire package of protection features. The basic protection features include early detection, fire containment, horizontal evacuation and fire extinguishment. Additionally, a chapter of the International Fire Code® (IFC®) contains criteria for emergency planning and preparedness.

As previously noted, the provisions of this section are based in part on a relatively low fuel load. Certain areas within Group I-2, however, will have a higher concentration of combustibles. These areas, as well as other areas that represent a specific hazard within Group I-2, are addressed in Section 509 as incidental uses. Because of the nature of the activity, the incidental use area is required to be protected with an automatic sprinkler system, separated with a fire barrier and horizontal assembly, or both (see Table 509).

These provisions apply to all occupancies classified as Group I-2. The requirements of Section 407 are intended to be additional special use and occupancy provisions for facilities that provide care for more than five persons who are not capable of self-preservation. Other requirements for Group I-2 occupancies are provided throughout the code.

407.2 Corridors continuity and separation. Corridors in occupancies in Group I-2 shall be continuous to the exits and shall be separated from other areas in accordance with Section 407.3 except spaces conforming to Sections 407.2.1 through 407.2.4.

- Since the occupants of areas classified as Group I-2 may be incapable of self-preservation, the means of egress serving such areas must facilitate the evacuation of such persons, as well as other people with mobility impairments. Accordingly, corridors serving Group I-2 occupancies are required to be continuous to the exits and, except as provided for in Sections 407.2.1 through 407.2.4, separated from other use areas. As such, corridors in Group I-2 occupancies are intended to provide a protected path of travel that, once entered, leads directly and continuously to the exits (see also commentary, Sections 407.4.1 and 1018.6). Note that a door through a horizontal exit
constructed with a fire barrier or fire wall would constitute an exit (see Section 1025); however, moving through a smoke barrier into another smoke compartment is not a horizontal exit and therefore corridor continuity must be maintained on both sides of the smoke barrier.

To address the various operational requirements of occupancies classified as Group I-2, the code includes provisions that both permit various areas to be open to corridors and address suite arrangements of the exit access portions of the facilities. Standards for areas open to corridors are covered primarily in this chapter. The design of suites is regulated by provisions found in Section 407.4.3.

For the ease of operations of hospitals, it is often desirable to have certain areas open to exit access corridors. Recognizing these needs and that such areas are equipped throughout with an automatic sprinkler system, the code permits specific areas to be open to corridors, provided they are properly arranged and equipped with compensating protection features (e.g., automatic fire detection). Sections 407.2.1 through 407.2.4 identify those areas and the protection features required to maintain the safety of the corridor.

In addition to practical reasons, such as in the case of care providers’ stations, it is also desirable to designate certain areas being open to the corridor for treatment purposes. In many instances, the care recipient is encouraged to leave the sleeping room for both physical as well as social benefit. So that care recipients can be encouraged to socialize and benefit from group activities and social interaction, the areas need to be open to the corridor.

Such waiting areas also serve a useful purpose during a fire emergency. If evacuation becomes necessary, care recipients usually will be relocated to an adjacent smoke compartment in which the areas open to the corridor will serve as a refuge area. Section 407.5.1 contains provisions for the net area that must be available for the relocation of care recipients. Waiting areas provide a space in which care recipients can be relocated such that treatment can continue during a fire emergency.

407.2.1 Waiting and similar areas. Waiting areas and similar spaces constructed as required for corridors shall be permitted to be open to a corridor, only where all of the following criteria are met:

1. The spaces are not occupied as care recipient’s sleeping rooms, treatment rooms, incidental uses in accordance with Section 509, or hazardous uses.

2. The open space is protected by an automatic fire detection system installed in accordance with Section 907.

3. The corridors onto which the spaces open, in the same smoke compartment, are protected by an automatic fire detection system installed in accordance with Section 907, or the smoke compartment in which the spaces are located is equipped throughout with quick-response sprinklers in accordance with Section 903.3.2.

4. The space is arranged so as not to obstruct access to the required exits.

- In the design of health care facilities, it is desirable to have small waiting areas and similar spaces open to the corridor. Such seating areas or gathering spaces provide care recipients and others a place to sit outside of the sleeping rooms or to wait near special care areas for their turn in a treatment room. In consideration of the additional protection features specified, small waiting areas and similar spaces are permitted to be open to corridors in Group I-2 occupancies within each smoke compartment provided they are constructed to the corridor standards for Group I-2 occupancies, as specified in Section 407.3.

Care recipient sleeping rooms, treatment rooms, as well as hazardous and incidental use areas, cannot be open to the corridors under this section. This configuration is commonly found in a typical ward situation. The exception would be treatment areas for psychiatric wards addressed in Section 407.2.3 and the care suite provisions in Section 407.4.3. Areas similar to waiting rooms could include common visiting areas, reception or information stations and patient check-in stations. General hospital office areas or support spaces beyond those associated with waiting or reception areas must be separated from the corridor (see Figure 407.2.1).

To reduce the likelihood that a fire within such an open space could develop beyond the incipient stage, thereby jeopardizing the integrity of the corridor, the area is to be equipped with an automatic fire detection system (see Section 907). The detectors are to be located so as to provide the appropriate coverage to the space.

There is no size limit set by the code for these spaces. Due to the unlimited size of the space and consequently the potential for a significant number of people in the area, an automatic fire detection system is also required in all corridors open to the spaces within the smoke compartment, or the smoke compartment in which such spaces are located must be protected throughout with quick-response sprinklers.

Waiting areas and similar spaces open to corridors must be arranged so as to not obstruct access to exits. There must be a clear path of travel of the minimum required width for the corridor, which should be maintained at all times. As such, furniture layouts must be arranged in a manner that obstruction of the exits does not occur under normal use.

407.2.2 Care providers’ stations. Spaces for care providers’, supervisory staff, doctors’ and nurses’ charting, communications and related clerical areas shall be permitted to be open to the corridor, where such spaces are constructed as required for corridors.

- Stations for care providers need to be located to provide quick access to care recipients and to permit visual or audible monitoring of the sleeping rooms. For these and other practical reasons, care providers’ stations are permitted to be open to the corridor, provided the walls surrounding the area are constructed as required for corridor walls (see Figure 407.2.2).
Except as required in Section 407.8, the additional protection of automatic fire detection is not required because of the reduced risk to life safety and attendance by the staff (see Section 407.8). This section is not intended to apply to nurses' offices, administrative supply storage areas, drug distribution stations or similar areas with a higher fuel load and from which continual observation of the nursing unit is not essential.

**407.2.3 Psychiatric treatment areas.** Areas wherein psychiatric care recipients who are not capable of self-preservation are housed, or group meeting or multipurpose therapeutic spaces other than incidental uses in accordance with Section 509, under continuous supervision by facility staff, shall be

For SI: 1 square foot = 0.0929 m².

**Figure 407.2.1**
GROUP I-2: WAITING ROOMS AND SIMILAR AREAS

**Figure 407.2.2**
GROUP I-2: CARE PROVIDERS' STATION
permitted to be open to the corridor, where the following criteria are met:

1. Each area does not exceed 1,500 square feet (140 m²).
2. The area is located to permit supervision by the facility staff.
3. The area is arranged so as not to obstruct any access to the required exits.
4. The area is equipped with an automatic fire detection system installed in accordance with Section 907.2.
5. Not more than one such space is permitted in any one smoke compartment.
6. The walls and ceilings of the space are constructed as required for corridors.

This section applies to all areas of a building classified as Group I-2, including smoke compartments that contain patient sleeping rooms that house psychiatric care recipients who are not physically capable of self-preservation because the area is secured (see Section 1008.1.9.6).

To encourage care recipients of psychiatric facilities to participate in group meetings and therapeutic activities, treatment areas may be open to the corridor, provided that the area does not exceed 1,500 square feet (140 m²) and only one such area is provided within a smoke compartment. Other protection features that must be provided to permit the area to be open include: staff supervision, unobstructed access to exits and automatic fire detection in accordance with Section 907.2 within the area. The group meeting room, while not separated from the corridor, must be separated from other areas of the building with smoke partitions in accordance with Section 407.3.

407.2.4 Gift shops. Gift shops and associated storage that are less than 500 square feet (45 m²) in area shall be permitted to be open to the corridor where such spaces are constructed as required for corridors.

Gift shops are not permitted to be open to a corridor in occupancies classified as Group I-2 unless they are less than 500 square feet (46 m²) in area (see Figure 407.2.1). The section allows any associated storage to be included in the 500-square-foot (46.5 m²) limitation since the associated fire hazard in both areas would be the same. If the gift shop and associated storage were greater than 500 square feet (46.5 m²) combined, but the gift shop itself was less than 500 square feet (46.5 m²), an option would be to leave the gift shop open to the corridor and separate the storage from the gift shop and other areas of the building with smoke partitions in accordance with Section 407.3.

407.3 Corridor wall construction. Corridor walls shall be constructed as smoke partitions in accordance with Section 710.

Corridor walls are required to form a barrier to limit smoke transfer in accordance with provisions for smoke partitions in Section 710, thus providing protection for exit access routes, from separate areas containing combustible materials that could produce smoke and to provide adequate separation of the care recipient sleeping rooms. In a building protected throughout with an automatic sprinkler system, the probability that a fire will develop that is life threatening to persons outside the room of origin is reduced; therefore, corridor walls need only be able to resist the passage of smoke.

The corridor wall is not required to have a fire-resistance rating (Section 710.3), but the wall is to terminate at the underside of the floor or roof deck above or to the underside of the ceiling membrane if it is capable of resisting the passage of smoke (Section 710.4). The walls must be of materials consistent with the building’s type of construction classification.

Note that the provisions of Section 509 must be considered in determining the fire-resistance rating of any corridor walls that also enclose incidental uses where fire barriers are required (Section 509.4.1) or construction capable of resisting the passage of smoke (Section 509.4.2). Note that construction capable of resisting the passage of smoke does not have all the same requirements as smoke partitions as required in Section 710 (see Figure 407.3).

407.3.1 Corridor doors. Corridor doors, other than those in a wall required to be rated by Section 509.4 or for the enclosure of a vertical opening or an exit, shall not have a required fire protection rating and shall not be required to be equipped with self-closing or automatic-closing devices, but shall provide an effective barrier to limit the transfer of smoke and shall be equipped with positive latching. Roller latches are not permitted. Other doors shall conform to Section 716.5.

As with corridor wall construction (see commentary, Section 407.3), the door assemblies need only be capable of resisting the passage of smoke. Corridor doors in occupancies classified as Group I-2 are not required to be self-closing or automatic-closing except where required by other sections, such as for doors serving incidental uses as required in Section 509, or doors in shaft walls that enclose a vertical opening or exit stairway or ramp. This provision is primarily intended to apply to care recipient sleeping room corridor doors. Doors in walls that separate incidental uses in accordance with Section 509 are required to be self-closing to minimize the possibility that corridors will be affected by a fire originating in those adjacent areas. Self-closing or automatic-closing doors in the shaft walls of vertical openings and exit stairways and ramps are still required to avoid a breach in vertical opening protection that would enable rapid fire spread from story to story and for adequate protection of the exits. It is important to recognize that this section contains a specific set of requirements for the corridor doors in this occupancy and that the provisions of this section must be followed versus the provisions of Section 710.5.2 for doors in smoke partitions (see code and commentary, Section 102.1). Full-scale fire tests and historical
experience indicate that the automatic sprinkler system will provide adequate protection to persons outside of the room of origin. It is also expected that staff will be adequately trained and will close the doors to care recipient sleeping rooms within the affected areas, or will evacuate patients to an adjacent smoke compartment. The presence of the automatic sprinkler system, particularly one equipped with quick-response heads, increases the probability that staff will be able to close the door to the room of origin and thereby limit the size of the fire. Roller latches are not permitted on these doors, as they are not regarded as providing positive latching that will allow the door to act as a reliable smoke protective.

407.4.1 Direct access to a corridor. Habitable rooms in Group I-2 occupancies shall have an exit access door leading directly to a corridor.

Exceptions:

1. Rooms with exit doors opening directly to the outside at ground level.
2. Rooms arranged as care suites complying with Section 407.4.3

Direct access to the corridor system from a patient sleeping room or treatment room is a key component to staff access and patient movement. The term “habitable rooms” is not intended to include individual bathrooms, closets and similar spaces, as well as briefly occupied spaces, such as control rooms in radiology and small storage/supply rooms. Habitable areas would include staff areas within the patient treatment and sleeping areas (i.e., nutrition rooms, clean/dirty linen rooms, staff lounge, staff work areas).

The exceptions would allow direct access to the outside rather than needing to go back into the corridor; or access through a portion of a care suite before accessing the corridor.

407.4.1.1 Locking devices. Locking devices that restrict access to a care recipient’s room from the corridor and that are operable only by staff from the corridor side shall not restrict the means of egress from the care recipient’s room.

Exceptions:

1. This section shall not apply to rooms in psychiatric treatment and similar care areas.
2. Locking arrangements in accordance with Section 1008.1.9.6.

Locking devices are permitted on care recipient room doors, provided egress from the care recipient room is not restricted. Such locking devices enable care recipients in long-term care facilities to secure their rooms and staff to secure unoccupied rooms. In such cases, it is expected that the staff still has access, via key or other opening device.

The need to lock corridor doors to restrain care recipients in psychiatric facilities, however, is recognized. When such locking is necessary, provisions must be made for continuous supervision and prompt release. Additional guidance on locking arrangements can be found in Section 408.4, which applies to occupancies in Group I-3. A decision needs to be made to determine if the area being considered more closely represents an occupancy in Group I-2 or I-3 (i.e., a holding room in the emergency room of the hospital for patients who may be violent). In occupancies in Group I-3, it is generally assumed that the occupants are capable of self-preservation once the doors are unlocked. This may not be the case in some psychiatric facilities and, therefore, the provision applicable to occupancies in Group I-2 may be more appropriate.

Similar protection may also be necessary in certain
portions of other occupancies in Group I-2 where the movement of the care recipients must be controlled (i.e., care recipients with Alzheimer’s disease). For special locking arrangements for suites or floors where elopement may be an issue, see Section 1008.1.9.6.

407.4.2 Travel distance. The travel distance between any point in a Group I-2 occupancy sleeping room and an exit access door in that room shall be not greater than 50 feet (15 240 mm).

+ This section limits the overall travel distance within an individual patient sleeping room through the exit access door in that room. This is a separate concept from the travel distance within a suite (see Section 407.4.3.5.3) and should be considered for each patient sleeping room. To see how the travel distances work together, see Figure 407.4.3.5.3.

407.4.3 Group I-2 care suites. Care suites in Group I-2 shall comply with Section 407.4.3.1 through 407.4.3.4 and either Section 407.4.3.5 or 407.4.3.6.

+ Patient treatment and sleeping rooms are also permitted to be arranged as suites (see Figure 407.4.3 for an example plan of a patient suite). The figure illustrates a patient suite of more than 1,000 square feet (93 m²) where two remote egress doors are required. The criteria in this section recognizes the low patient-to-staff ratio of these facilities where the staff is directly responsible for the safety of the patients in the event of a fire.

Health care suites allow for the elimination of the smoke partition between the patient rooms and the staff areas. Curtains or glass partitions are often desirable to allow for a more efficient operation and/or direct and immediate supervision. By considering the connected space an intervening room rather than a corridor, these provisions can be applied.

Traditionally, suites are used when patients require direct observation and immediate access as a component of their medical care. Examples of this include post-anesthesia care units, critical care units, cardiac care areas, recovery rooms and surgical suites. While not prohibited in nursing homes, suite configurations are more commonly found in hospital situations. By the definition of the term “care suite” in Section 202, these can be groups of sleeping rooms or treatment rooms and their associated support/staff spaces. Maximum area, number of exit access doors, travel distance within the suite and allowances for intervening rooms between the suite and the corridor are addressed in Section 407.4.3.5 for patient sleeping rooms, and Section 407.4.3.6 for patient treatment areas. The use of the term “care suite” is not intended to prohibit other groups of rooms that are not patient care areas, such as records departments or the business offices found in hospitals.

407.4.3.1 Exit access through care suites. Exit access from all other portions of a building not classified as a care suite

---

For SI: 1 square foot = 0.0929 m².

Figure 407.4.3

GROUP I-2 EXAMPLE OF SUITE
shall not pass through a care suite. In a care suite required to have more than one exit, one exit access is permitted to pass through an adjacent care suite provided all of the other requirements of Sections 407.4 and 1014.2 are satisfied.

- Suites are intended to serve specific functions for patient treatment or sleeping. This section clarifies that the suite should not be used as part of the exit access of other areas within the building. It is intended to prevent corridors from discharging into a maze of intervening rooms prior to entering the exit. However, the second sentence would allow for a group of suites to work together as long as the overall exit access travel distance of 200 feet (60 960 mm) was met (see Table 1016.2); the next suite could meet the egress through intervening spaces as addressed in Section 1014.2; and both suites complied with the provisions in this section.

407.4.3.2 Separation. Care suites shall be separated from other portions of the building by a smoke partition complying with Section 710.

- This section clarifies the type of partition that should be used to separate the suite from the corridor, adjacent suite or any other portion of the building. This section requires separation by a smoke partition, similar to the construction of a corridor wall in Group I-2 (see Section 407.3).

407.4.3.3 One intervening room. For rooms other than sleeping rooms located within a care suite, exit access travel from the care suite shall be permitted through one intervening room where the travel distance to the exit access door from the care suite is not greater than 100 feet (30 480 mm).

- The term "intervening rooms" means a room serving as part of the required means of egress from another room. In a situation where the suite configuration would require exiting through a room adjacent to, but not part of the treatment room, such as the staff supervision area, patient preparation or waiting area, the travel distance is limited to 100 feet (30 480 mm) maximum. This would be measured from the most remote point in the patient treatment room, through the intervening room, to the exit access door to the corridor. Any travel distance within the suite is included in the overall exit access travel distance of 200 feet (60 960 mm) (see Table 1016.2). Many of the common suite layouts include a "long, skinny room" that resembles a corridor. If this room is not constructed to meet all of the corridor requirements, this is an intervening room. To see how the travel distances work together, see Figure 407.4.3.5.3. This could be applied to staff support areas or treatment areas within a care suite with sleeping rooms.

407.4.3.4 Two intervening rooms. For rooms other than sleeping rooms located within a care suite, exit access travel within the care suite shall be permitted through two intervening rooms where the travel distance to the exit access door from the care suite is not greater than 50 feet (15 240 mm).

- In a situation where the suite configuration would require exiting through two rooms adjacent to, but not part of the treatment room, the travel distance is limited to 50 feet (15 240 mm) maximum. This would be measured from the most remote point in the patient treatment room, through the intervening rooms, to the exit access door to the corridor. Any travel distance within the suite is included in the overall exit access travel distance of 200 feet (60 960 mm) (see Table 1016.2). An example of this might be an MRI suite where access to the treatment room was through both a waiting area and a patient prep/staff supervisory area. This could be applied to staff support areas or treatment areas within a care suite with sleeping rooms.

407.4.3.5 Care suites containing sleeping room areas. Sleeping rooms shall be permitted to be grouped into care suites with one intervening room if one of the following conditions is met:

1. The intervening room within the care suite is not used as an exit access for more than eight care recipient beds.

2. The arrangement of the care suite allows for direct and constant visual supervision by care providers.

- This group of sections deals with "care suites" that include patient sleeping rooms. Staff awareness is key to recognizing a dangerous condition and beginning evacuation procedures. In accordance with Section 407.4.1, "care suites" must lead directly to a corridor in order to allow for quick evacuation. The term "intervening rooms" means a room serving as part of the required means of egress from another room. Section 407.4.3.5 allows for there to be one room between the patient sleeping rooms and the corridor in two different scenarios.

1. Where patient rooms within suites do not have direct and constant visual supervision by staff, the suite is limited to eight patient beds if they want to allow for one intervening room.

For St.: 1 foot = 304.8 mm.

Figure 407.4.3.5.3
MEANS OF EGRESS TRAVEL IN SUITES WITH GROUP I-2 PATIENT SLEEPING ROOMS

2012 INTERNATIONAL BUILDING CODE® COMMENTARY
2. Where the suite can be arranged such that direct and constant supervision of patients can be provided, they can always have one intervening room.

To illustrate Option 1, consider a suite of rooms that serves for infant delivery. Birthing rooms are patient treatment rooms, but standard procedure is now for the patient to stay in that same room rather than being moved, so these rooms are also patient sleeping rooms. The rooms in the suite are typically divided by walls from a central nurse/doctor area so the staff has quick and direct access, but not direct and constant visual supervision; therefore, the suite is limited to eight patient beds. To illustrate Option 2, consider a critical care unit (CCU). Patient rooms are grouped around a central nursing station. These sleeping areas may be directly open to the nurse's station, or the intervening walls may have large windows or glass sliding doors that allow for direct and constant supervision. These patient sleeping rooms can also have one room between the sleeping room and each exit to the corridor, but the number of beds is not limited.

407.4.3.5.1 Area. Care suites containing sleeping rooms shall be not greater than 5,000 square feet (465 m²) in area.

- The combined area of the patient sleeping rooms, the staff areas and any associated spaces (i.e., clean room, nutrition centers, storage room) and any intervening rooms are permitted to have a total area of 5,000 square feet (465 m²). This suite must be separated from other areas by smoke partitions in accordance with Section 407.4.3.2.

407.4.3.5.2 Exit access. Any sleeping room, or any care suite that contains sleeping rooms, of more than 1,000 square feet (93 m²) shall have no fewer than two exit access doors from the care suite located in accordance with Section 1015.2.

- A suite that contains a patient sleeping room and an area of 1,000 square feet (93 m²) or less, can have only one exit access door to a corridor, provided that the 100-foot (30 480 mm) maximum travel distance (see Section 1014.4.3.5.3) is met. For suites that contain patient sleeping rooms and have an area of between 1,000 square feet and 5,000 square feet (93 m² and 465 m²), there must be at least two exit access doors to the corridor.

407.4.3.5.3 Travel distance. The travel distance between any point in a care suite containing sleeping rooms and an exit access door from that care suite shall be not greater than 100 feet (30 480 mm).

- The path of travel from the most remote corner of any patient sleeping room, through the suite, to the exit access door leading to the corridor, must not exceed 100 feet (30 480 mm). As a more specific provision, this would override the 75-foot (22 860 mm) common path of travel requirements in Section 1014.3 in a single-suite. In a two-exit suite, at least one of the exits must be within 100 feet (30 480 mm) of travel of every point in the suite. The path of travel measurement would include any travel through the intervening room permitted in Section 1014.4.3.5. Any travel distance within the suite is included in the overall exit travel distance of 200 feet (60 960 mm) (see Table 1016.2). The 50-foot (15 240 mm) maximum travel distance out of each patient sleeping room (Section 407.4.2) into the suite must also be met. To see how the travel distances work together, see Figure 407.4.3.5.3.

407.4.3.6 Care suites not containing sleeping rooms. Areas not containing sleeping rooms, but only treatment areas and the associated rooms, spaces or circulation space shall be permitted to be grouped into care suites and shall conform to the limitations in Section 407.4.3.6.1 and 407.4.3.6.2.

- According to the definition for "care suite" in Chapter 2, suites covered by these provisions are limited to areas that include patient sleeping rooms or patient treatment rooms. This group of sections deals with suites for patient treatment rooms. Common examples include diagnostic or therapy areas where the function of treatment requires adjacency. This could also include in-patient or outpatient surgery suites, emergency treatment area suites or areas such as recovery rooms or dialysis treatment centers. Patients may be anesthetized, but staff/patient ratios are high and staff is trained in proper evacuation procedures.

407.4.3.6.1 Area. Care suites of rooms, other than sleeping rooms, shall have an area not greater than 10,000 square feet (929 m²).

- The combined area of the patient treatment rooms, the staff areas and any associated spaces (i.e., clean room, nutrition centers and storage room) and any intervening rooms (in accordance with Sections 407.4.3.3 and 407.4.3.4) are permitted to have a total area of 10,000 square feet (929 m²). This suite must be separated from other areas by smoke partitions in accordance with Section 407.4.3.2.

407.4.3.6.2 Exit access. Care suites, other than sleeping rooms, with an area of more than 2,500 square feet (232 m²) shall have no fewer than two exit access doors from the care suite located in accordance with Section 1015.2.

- A suite that contains a patient treatment room and an area of 2,500 square feet (232 m²) or less can have only one exit access door to a corridor, provided that the maximum travel distance (see Sections 407.4.3.3 and 407.4.3.4) is met. As a more specific provision, this would override the 75-foot (22 860 mm) common path of travel requirements in Section 1014.3 in a single-exit suite. For suites that contain patient treatment rooms and have an area of more than 2,500 square feet and 10,000 square feet (232 m² and 929 m²), there must be at least two exit access doors to the corridor. These doors must meet the separation requirements in Section 1015.2. In a two-exit suite, at
SPECIAL DETAILED REQUIREMENTS BASED ON USE AND OCCUPANCY

least one of the exits must be within the travel distance of every point in the suite as specified in Sections 407.4.3.3 and 407.4.3.4.

407.5 Smoke barriers. Smoke barriers shall be provided to subdivide every story used by persons receiving care, treatment or sleeping and to divide other stories with an occupant load of 50 or more persons, into no fewer than two smoke compartments. Such stories shall be divided into smoke compartments with an area of not more than 22,500 square feet (2092 m²) and the travel distance from any point in a smoke compartment to a smoke barrier door shall not be greater than 200 feet (60 960 mm). The smoke barrier shall be in accordance with Section 709.

One of the basic premises of this section is that vertical evacuation of care recipients in Group I-2 occupancies is extremely difficult. It is essential, therefore, to provide a refuge area on every story used by care recipients for sleeping, care or treatment. The refuge area is intended to provide a protected area to which care recipients may be relocated if it becomes necessary to evacuate them from their original rooms. For this reason, each story used by care recipients for sleeping, care or treatment and all other stories with an occupant load of 50 or more must be divided into at least two smoke compartments. Each smoke compartment is limited to an area of no more than 22,500 square feet (2092 m²) (see the definition of "smoke compartment" in Section 202). The travel distance from any point in a smoke compartment to a smoke barrier door is limited to 200 feet (60 960 mm). This is distinct from the travel distance to exits. This distance is limiting the distance that care providers and care recipients must travel until reaching another smoke compartment and the refuge area it contains. Travel to an exit enclosure or exit door is not a substitute for travel to the smoke barrier and a separate compartment (see Figure 407.5). Every occupied space must be able to meet both exit access travel distance to an exit and to the entrance to an adjacent smoke compartment.

Smoke barriers used to divide one smoke compartment from the next are to be constructed in accordance with Section 709 and with horizontal assemblies as specified in Section 407.5.3. The smoke barrier is different from the smoke partitions required for corridor walls in Section 407.3. Among other things, a smoke barrier is required to have a fire-resistance rating of 1 hour and, except as otherwise provided for in the Exception 1 to Section 709.4, provide a continuous separation through all concealed spaces to resist the passage of fire and smoke (see Figure 407.5). The maximum area of the smoke compartment provides two protection features. First, the number of persons that are exposed to a fire will be restricted. Typical designs indicate that the number of persons exposed usually will be less than 100 and, more likely, 50 or less. Second, the overall dimensions of the smoke compartment must result in a maximum travel distance to the smoke barrier door of 200 feet (60 960 mm) for all design configurations.

407.5.1 Refuge area. Refuge areas shall be provided within each smoke compartment. The size of the refuge area shall accommodate the occupants and care recipients from the adjoining smoke compartment. Where a smoke compartment is adjoined by two or more smoke compartments, the minimum area of the refuge area shall accommodate the largest occupant load of the adjoining compartments. The size of the refuge area shall provide the following:

1. Not less than 30 net square feet (2.8 m²) for each care recipient confined to bed or litter.

2. Not less than 6 square feet (0.56 m²) for each ambulatory care recipient not confined to bed or litter and for other occupants.

Areas or spaces permitted to be included in the calculation of refuge area are corridors, sleeping areas, treatment rooms, lounge or dining areas and other low-hazard areas.

To provide adequate space for occupants who might be relocated to an adjacent smoke compartment, open space for refuge areas must be available. In the

![Diagram of smoke barrier and refuge area](image-url)

**Figure 407.5**

**GROUP I-2: SMOKE BARRIER**

For Sf: 1 foot = 304.8 mm, 1 inch = 25.4 mm, 1 square foot = 0.0929 m².
determination of the adequacy of the refuge areas, minimum net areas per occupant are required. In determining the area available, it should be noted that the facility may still need to function as a medical care facility even while the care recipients are relocated. On floors housing nonambulatory patients (i.e., care recipient sleeping floors), a minimum of 30 net square feet (2.8 m²) per patient is required to be provided in low-hazard areas, such as waiting areas, corridors or patient rooms. This is to permit the relocation of the care recipient on a bed or litter to an area of safety on the same floor. The 30 net square feet (2.8 m²) is intended only to apply to the number of care recipients and not the calculated occupant load as determined using Table 1004.1.1.

For floors classified as Group I-2, which are not used for care recipient sleeping rooms (i.e., treatment floors), the net area required is 6 square feet (0.56 m²) per occupant. In this instance, the area required is based on the calculated occupant load as determined by Table 1004.1.1. The 6-square-foot (0.56 m²) minimum is based on an assumption that some occupants will be using walkers, wheelchairs and possibly a few litters for care recipients who are being transported through the area at the time of the fire.

The refuge area must be able to accommodate all of the occupants and care recipients from the adjoining smoke compartment based upon the factors described above. If a smoke compartment containing a refuge area is adjoining by multiple smoke compartments, the minimum required size of the refuge area is to be based upon the largest of the occupant loads of the adjoining compartments. It is assumed that the refuge area will only need to serve one adjacent smoke compartment.

When there are multiple smoke compartments on the same level, each smoke compartment must have open space for the largest number of evacuees. Space for people already in the smoke compartment should be considered in the design, but do not have to be considered for determining the refuge area square footage requirements. Remember, the idea is for smoke compartments to be part of the "defend-in-place" scenario commonly used in hospitals and nursing homes (see commentary, Section 407.1).

Refuge areas required by this section are distinct from areas of refuge and exterior areas of assisted rescue required by Section 1007 for accessible means of egress.

407.5.2 Independent egress. A means of egress shall be provided from each smoke compartment created by smoke barriers without having to return through the smoke compartment from which means of egress originated.

- To prevent creation of a dead-end smoke compartment, exits are to be arranged so as to permit access without returning through a smoke compartment from which egress originated. This section does not require an exit from within each smoke compartment. See Figures 407.5.2(1) and 407.5.2(2) for acceptable and unacceptable egress arrangements.

407.5.3 Horizontal assemblies. Horizontal assemblies supporting smoke barriers required by this section shall be designed to resist the movement of smoke and shall comply with Section 711.9.

- In order to maintain the integrity of a smoke compartment, the horizontal assemblies supporting the smoke barrier walls must also be designed to resist the passage of smoke. With the combination of these horizontal assemblies and the fire barriers, a complete smoke-protected compartment is achieved. Provisions of Section 711.9 address openings and penetrations of each horizontal assembly providing a barrier to smoke. Elevators and other large openings will have to be in a shaft enclosure. A lobby complying with Section 713.14.1 will need to be provided for such elevators.

**SMOKE BARRIER (EXTENDED FROM OUTSIDE WALL TO OUTSIDE WALL)

**SMOKE COMPARTMENT

**ACCEPTABLE EGRESS ARRANGEMENT
[F] **407.6 Automatic sprinkler system.** Smoke compartments containing sleeping rooms shall be equipped throughout with an automatic fire sprinkler system in accordance with Sections 903.3.1.1 and 903.3.2.

- Recognizing the effectiveness of an automatic sprinkler system, the reference to Section 903.3.1.1 clarifies that the suppression system required by Section 903.2.6 must be a sprinkler system in accordance with the code and NFPA 13. Furthermore, in response to recent proven technology, smoke compartments containing patient rooms are required to be equipped throughout with quick-response or residential sprinklers as set forth in Item 1 in Section 903.3.2.

The majority of fire injuries in hospitals begin with the ignition of clothing on a person, a mattress, a pillow, bedding or linen. The Building and Fire Research Laboratory of NIST conducted fire tests in patient rooms using quick-response sprinklers and smoke detectors. The test results were published in a July 1993 report entitled, *Measurement of Room Conditions and Response of Sprinklers and Smoke Detectors During a Simulated Two-bed Hospital Patient Room Fire.* The report concluded that quick-response sprinklers actuated before any life would be threatened by a fire in a care recipient's (patient's) room.

Prior to the development of quick-response sprinkler technology, smoke detection in care recipient rooms classified as Group I-2 occupancies was typically required, due to the slower response time of standard sprinklers. While properly operating standard sprinklers are effective, the extent of fire growth and smoke production that can occur before sprinkler activation creates the need for early warning to enable faster response by the care providers and initiation of egress that is critical in occupancies containing persons incapable of self-preservation. With quick-response or residential sprinklers installed throughout the smoke compartment, and additional protection provided as indicated for spaces open to corridors, incidental uses and certain specific health care facilities, smoke detectors in care recipient sleeping rooms are not required in Group I-2 occupancies.

[F] **407.7 Fire alarm system.** A fire alarm system shall be provided in accordance with Section 907.2.6.

- Fire alarms are essential to this occupancy where many of those receiving care and treatment cannot leave a fire incident area without the assistance of staff. The alarm system is a key part of the safeguards to protect care recipients. Standards for this alarm system are found in Sections 907.2.6 and 907.2.6.2.

[F] **407.8 Automatic fire detection.** Corridors in nursing homes, long-term care facilities, detoxification facilities and spaces permitted to be open to the corridors by Section 407.2 shall be equipped with an automatic fire detection system. Hospitals shall be equipped with smoke detection as required in Section 407.2.

**Exceptions:**

1. Corridor smoke detection is not required where sleeping rooms are provided with smoke detectors that comply with UL 288. Such detectors shall provide a visual display on the corridor side of each sleeping room and an audible and visual alarm at the care provider’s station attending each unit.

2. Corridor smoke detection is not required where sleeping room doors are equipped with automatic door-closing devices with integral smoke detectors.

---

![Diagram of an unacceptable egress arrangement](image-url)
on the unit sides installed in accordance with their listing, provided that the integral detectors perform the required alerting function.

- Automatic fire detection is required in corridors and areas open to corridors in nursing homes, long-term care facilities and detoxification facilities. In recognition of quick-response sprinkler technology and the fact that the sprinkler system is electronically supervised and doors to sleeping rooms are supervised by staff on a continual basis when in the open position, it is now believed that sleeping room smoke detectors are not required for adequate fire safety in sleeping rooms. In nursing homes, long-term care facilities and detoxification facilities, however, some redundancy is appropriate because such facilities typically have less control over furnishings and personal items and, thereby, result in less predictable and usually higher fire hazard load than other Group I-2 occupancies. Also, there is generally less staff supervision in these facilities than in other health care facilities and, thus, less control over patient smoking and other fire causes. To provide additional protection against fires spreading from the room of origin, therefore, automatic fire detection is required in corridors of nursing homes, long-term care facilities and detoxification facilities. It should be noted that fire detection is not required in corridors of other Group I-2 occupancies except where otherwise specifically required in the code (see Sections 907.2.6 and 907.2.6.2). Similarly, since areas open to the corridor very often are the room of fire origin and because such areas are not required by the code to be under visual supervision by staff, some redundancy to protection by the sprinkler system is requested. Accordingly, all areas open to corridors must be protected by an automatic fire detection system. This requirement provides an additional level of protection against sprinkler system failures or lapses in staff supervision. There are two exceptions to the requirement for an automatic fire detection system in corridors of nursing homes, long-term care facilities and detoxification facilities. In both exceptions, the alternative methods of protection specifically provide an equivalent level of safety to what is required in care recipient sleeping rooms.

Exception 1 requires smoke detectors to be located in the care recipient's sleeping room, which activate both a visual display on the corridor side of the patient room and a visual and audible alarm at the care providers' station serving or attending the room. Detectors complying with UL 268 are intended for open area protection and for connection to a normal power supply or as part of a fire alarm system.

This exception, however, is specifically designed so as not to require the detectors to activate the building's fire alarm system where approved sleeping room smoke detectors are installed and where visual and audible alarms are provided. This is in response to the concern over unwanted alarms. It should be noted that the required alarm signals will not necessarily indicate to staff that a fire emergency exists. The nursing/care provider call system may typically be used to identify numerous conditions within the room.

Exception 2 addresses the situation where smoke detectors are incorporated within automatic door-closing devices. The units are acceptable as long as the required alarm functions are still provided. Such units are usually listed as combination door closer and hold-open devices.

407.9 Secured yards. Grounds are permitted to be fenced and gates therein are permitted to be equipped with locks, provided that safe dispersal areas having 30 net square feet (2.8 m²) for bed and litter care recipients and 6 net square feet (0.56 m²) for ambulatory care recipients and other occupants are located between the building and the fence. Such provided safe dispersal area shall be located not less than 50 feet (15 240 mm) from the building they serve.

- Group I-2 occupancies, particularly those specializing in the treatment of mental disabilities such as Alzheimer's, often provide a secured yard for care recipient use. During an emergency, it may be difficult to safeguard care recipients if they are allowed to have direct access to a public way. This section essentially creates a safe area where people may move from the building without having unrestricted access to the public way.

407.10 Hyperbaric facilities. Hyperbaric facilities in Group I-2 occupancies shall meet the requirements contained in Chapter 20 of NFPA 99.

- For these unique treatment facilities, Chapter 20 of NFPA 99 provides appropriate design criteria. This standard is only referenced where such facilities are installed in a Group I-2 occupancy.

SECTION 408
GROUP I-3

408.1 General. Occupancies in Group I-3 shall comply with the provisions of Sections 408.1 through 408.11 and other applicable provisions of this code (see Section 308.5).

- The provisions of Section 408 address the unique features of detention and correctional occupancies in Group I-3. The provisions are based on full-scale fire tests, fire experience (in particular several multi- death fires that occurred between 1974 and 1979) and the provisions for occupancies in Group I-2. With respect to evacuation, occupancies in Groups I-2 and I-3 are similar in that the occupants are typically not capable of self-preservation and, therefore, staff must assist in evacuation.

The general approach is a defend-in-place philosophy based on the difficulties associated with evacuation, especially in medium- and high-security facilities. The first level of protection is established as the room that is typically a sleeping room or cell. Horizontal evacuation to an adjacent smoke compartment provides the second level of protection, and vertical evacuation is the third level of protection. The evacuation difficulty associated with occupancies in Group I-3 is not occupant mobility; rather, it is the need to maintain security and, in some instances, to keep the residents segregated. There are also instances, such as protected witness facilities, in which the identity of the
occupant must not be revealed to other occupants or the public.

It is recognized that the broad classification of Group I-3 includes a variety of locking arrangements based on the various levels of security required. As such, Section 308.5 contains definitions for five different occupancy conditions that are intended to represent the various locking arrangements and different levels of security (see commentary, Section 308.5). Regardless of the security level, fire protection and life safety features must be provided in order to achieve an acceptable level of protection without interfering with the operation of the facility and the need to maintain security.

This section has been developed out of considerations unique to detention and correctional facilities and to facilitate the consideration of the entire package of protection features. The basic protection features provided include early detection, fire containment, evacuation and fire extinguishment. Section 408.7 of the IFC contains provisions for emergency preparedness, including staff training, staffing requirements and the need to be able to obtain and identify emergency keys. Additional consideration should be given to restricting the fuel load within resident housing areas. It should also be noted that Section 509 contains provisions for incidental uses within Group I-3. The incidental uses represent different degrees of hazard than are associated with the hazards of the primary building area—in this case, the housing of occupants under physical restraint. The different hazard is typically related to the basic nature of the contents or the quantity of combustibles.

The provisions of Section 408 apply to all occupancies in Group I-3 and those portions of occupancies that are considered Group I-3, except Condition 1 facilities (see Figure 408.1). As defined in Section 308.5.1, Condition 1 facilities permit free egress even to the exterior and, therefore, such occupancies are subject to the same provisions applicable to Group R.

The elimination of Condition 1 from the provisions of Section 408 may result in some interesting applications of the code. For example, the corridor separation requirements in Section 1018.1 for occupancies in
Group R are more restrictive than the corridor requirements for occupancies in Group I-3, Condition 2. This may result in a request to consider a facility as Condition 2 even though the building is really Condition 1. Such a request could be considered acceptable only if the additional requirements in the code and in the IFC for Condition 2 are met, including automatic fire suppression and staffing (see Section 408.7.2 of the IFC).

408.1.1 Definition. The following terms are defined in Chapter 2:

CELL.

CELL TIER.

HOUSING UNIT.

SALLYPORT.

This section lists terms that are specifically associated with the subject matter of Section 408. It is important to emphasize that these terms are not exclusively related to this chapter but may or may not also be applicable where the term is used elsewhere in the code.

Definitions of terms can help in the understanding and application of the code requirements. The purpose for including a list within this chapter is to provide more convenient access to terms which may have a specific or limited application within this chapter. For the complete definition and associated commentary, refer back to Chapter 2. Terms that are italicized provide a visual identification throughout the code that a definition exists for that term. The use and application of all defined terms are set forth in Section 201.

408.2 Other occupancies. Buildings or portions of buildings in Group I-3 occupancies where security operations necessitate the locking of required means of egress shall be permitted to be classified as a different occupancy. Occupancies classified as other than Group I-3 shall meet the applicable requirements of this code for that occupancy provided provisions are made for the release of occupants at all times.

Means of egress from detention and correctional occupancies that traverse other use areas shall, as a minimum, conform to requirements for detention and correctional occupancies.

Exception: It is permissible to exit through a horizontal exit into other contiguous occupancies that do not conform to detention and correctional occupancy egress provisions but that do comply with requirements set forth in the appropriate occupancy, as long as the occupancy is not a Group H use.

In accordance with the provisions of Section 508, portions of an occupancy in Group I-3 may be classified as a separate occupancy and meet the provisions of the code for that occupancy. Since the area may be used by the residents, however, a need may exist for the other occupancy to also contain security provisions, such as the locking of egress doors. This section specifically permits such a condition as long as arrangements have been made for release of the occupants within these areas at any time they are occupied. Acceptable methods include having either staff operate the locks or remote release of the locks, similar to that which is provided in the housing areas.

Although it is indicated that the section applies to portions of occupancies in Group I-3, consideration should be given to allow the necessary security to be provided in separate buildings that are part of a detention or correctional facility. Applications of this section should be restricted to the buildings that must be secure because they are occupied by residents, and arrangements for quick release of the locks must be provided at all times the building is occupied. If residents are to be permitted into an area or building without staff supervision, the residents should be able to initiate their own evacuation.

The means of egress provisions from this section and Chapter 10 that are applicable to Group I-3 are also applicable to the path through different occupancies. For example, if the means of egress from a cell block wing traverses through a Group A area, then the requirements of the code for the Group I-3 egress are also applicable to the path through the assembly occupancy.

The exception in the code permits egress through a different occupancy other than Group H, that is separated from the Group I-3 areas by either a fire wall or fire barrier. A horizontal exit complying with Section 1025 must be provided in this wall or barrier. This separation voids the requirements that Group I-3 egress provisions are also applicable to the different occupancies. The reason for this, of course, is that Group I-3 occupants have fled the immediate effects of the fire condition in the original detention or correctional areas and are now harbored in a refuge area.

408.3 Means of egress. Except as modified or as provided for in this section, the means of egress provisions of Chapter 10 shall apply.

Because of the need to provide security in occupancies in Group I-3, many of the means of egress requirements of Chapter 10 have been modified for Group I-3. Except as modified in Section 408, however, all other provisions of Chapter 10 are applicable.

408.3.1 Door width. Doors to resident sleeping units shall have a clear width of not less than 28 inches (711 mm).

Except for sleeping units that are provided to meet accessible unit provisions of Section 1107.5.5, sleeping unit doors may be a minimum of 28 inches (711 mm) in width. This section is not intended to negate the need to provide a 32-inch (813 mm) door if the room is intended to serve as part of an accessible route. In an occupancy in Group I-3, most sleeping units and even sections of the prison need not be accessible (see Sections 1103.2.14 and 1107.5.5).

408.3.2 Sliding doors. Where doors in a means of egress are of the horizontal-sliding type, the force to slide the door to its
fully open position shall be not greater than 50 pounds (220 N) with a perpendicular force against the door of 50 pounds (220 N).

Swinging doors in occupancies in Group I-3 may not be acceptable for security reasons. If the door swings into a room, the door can easily be blocked and staff access can be prevented. If the door swings out, staff does not have control of the door and the residents can use the door as a means to overcome a staff member; therefore, horizontal sliding doors are used quite extensively and are permitted in the means of egress. The doors must be capable of being opened with a force of 50 pounds (220 N) even if a 50-pound (220 N) force is being applied perpendicular to the door. The maximum force permitted to open the door exceeds the restrictions in Section 1008.1.3 in recognition of the physical capabilities of staff members.

408.3.3 Guard tower doors. A hatch or trap door not less than 16 square feet (610 m²) in area through the floor and having dimensions of not less than 2 feet (610 mm) in any direction shall be permitted to be used as a portion of the means of egress from guard towers.

This provision allows the use of trap doors in the floor of an observation point as both the access and the means of egress from the tower. In order to provide the 360-degree visibility necessary for guard observation stations, the size of the base of each such elevated station must be kept to a minimum. These towers are usually limited to prison/secure staff. The trap doors work in conjunction with the spiral stairway and ship ladder provisions of the next two sections.

408.3.4 Spiral stairways. Spiral stairways that conform to the requirements of Section 1009.12 are permitted for access to and between staff locations.

Recognizing the physical capabilities of the staff, spiral stairways are permitted for access to and between staff locations. In multiple story facilities, spiral stairways are often used between staff control areas on different levels. As such, staff can move between the areas without entering adjacent housing areas and without losing the space that would be required for a traditional stairway. Spiral stairways provide an option for vertical circulation in guard towers and similar observation areas where the floor area is limited and the desire is to have the least amount of obstruction of floor area possible.

408.3.5 Ship ladders. Ship ladders shall be permitted for egress from control rooms or elevated facility observation rooms in accordance with Section 1009.14.

Ship ladders are another alternative to spiral stairways for providing vertical paths of access and egress within a Group I-3 occupancy. These are intended for access to locations used by prison/secure staff. The design standard for ship ladders is found in Section 1009.14. In that section, the code limits any space accessed by a ship ladder to a maximum of 250 square feet (23 m²) and a maximum of three occupants (see commentary, Section 1009.14).

408.3.6 Exit discharge. Exits are permitted to discharge into a fenced or walled courtyard. Enclosed yards or courts shall be of a size to accommodate all occupants, be located not less than 50 feet (15 240 mm) from the building and have an area of not less than 15 square feet (1.4 m²) per person.

For security purposes, exits from areas in Group I-3, do not normally provide access to a public way. In some instances, the building is located in a complex that has perimeter walls preventing access to a public way but that permit occupants to move away from the building. In other instances or in complexes where the mixing of residents must be controlled, one or more yards or courts are provided for exit discharge. Such arrangements are acceptable, provided that the occupants have an area that is at least 15 square feet (1.4 m²) per person and is located at least 50 feet (15 240 mm) from the building.

This 50-foot (15 240 mm) distance enables residents to move away from the building and should have adequate spatial separation—especially since the building is required to be protected with an automatic fire suppression system in accordance with Section 903.2.6. The 15-square-foot (1.4 m²) measurement is provided so that the residents have adequate space in which to stand and to move around since they may need to remain in the yard or court for some time.

408.3.7 Sallyports. A sallyport shall be permitted in a means of egress where there are provisions for continuous and unobstructed passage through the sallyport during an emergency egress condition.

A sallyport is a compartment established for security purposes that restricts the movement of individuals. A sallyport consists of two or more security doors that do not normally operate simultaneously. One door will not normally open until the other doors are closed and locked. Sallyports are provided for security purposes to control movement and passage of residents from one area to another. The sallyport is to be arranged such that during an emergency, the doors may be opened simultaneously so as to permit free and unobstructed movement from the area. In many instances, the sallyport doors contain a manual release that can be operated by staff during an emergency to override the normal electric operation.

Although not addressed by this section, if the sallyport is in the path that the fire department or fire brigade will use to bring fire hoses, additional consideration may need to be given to permit the hose to go through the sallyport. An alternative would be to provide a standpipe connection on the housing-area side of the sallyport.

408.3.8 Interior exit stairway and ramp construction. One interior exit stairway or ramp in each building shall be permitted to have glazing installed in doors and interior walls at
each landing level providing access to the interior exit stairway or ramp, provided that the following conditions are met:

1. The interior exit stairway or ramp shall not serve more than four floor levels.

2. Exit doors shall be not less than 3/4-hour fire door assemblies complying with Section 716.5.

3. The total area of glazing at each floor level shall not exceed 5,000 square inches (3.2 m²) and individual panels of glazing shall not exceed 1,296 square inches (8.4 m²).

4. The glazing shall be protected on both sides by an automatic sprinkler system. The sprinkler system shall be designed to wet completely the entire surface of any glazing affected by fire when actuated.

5. The glazing shall be in a gasketed frame and installed in such a manner that the framing system will deflect without breaking (loading) the glass before the sprinkler system operates.

6. Obstructions, such as curtain rods, drapery traverse rods, curtains, drapes or similar materials shall not be installed between the automatic sprinklers and the glazing.

In addressing the security needs in Group I-3, the limitation on openings in the interior exit stairways given in Sections 1022.2, 1022.4 and 1022.5 is modified to facilitate visibility into the exit.

An interior exit stairway that is open to view in a correctional facility is useful and necessary for two reasons. First, the movement of the inmates is observable, thus reducing the potential for concealment, physical attacks on other inmates and other undesirable activities that could otherwise take place in enclosed spaces that are not observable.

Second, the movement of inmates who are under physical restraint is observable from the exterior, thus increasing the level of safety for correctional officers. The alternative of closed-circuit television within the interior exit stairway is not as desirable because the potential for malfunction of or intentional damage to the equipment makes this method a less reliable form of observation.

The conditions specified that permit glazing require full enclosure of the floor opening so that there is no direct communication between stories. These criteria provide a measure of fire integrity, if somewhat less than that otherwise required of an interior exit stairway.

408.4 Locks. Egress doors are permitted to be locked in accordance with the applicable use condition. Doors from a refuge area to the outside are permitted to be locked with a key in lieu of locking methods described in Section 408.4.1. The keys to unlock the exterior doors shall be available at all times and the locks shall be operable from both sides of the door.

The locking arrangements for egress doors depend on the occupancy condition (1, 2, 3, 4 or 5) given in Section 308.5. Except for Condition 1 buildings, the doors to the exterior from an occupancy in Group I-3 may be locked and need not be remotely controlled. The door locks are to be arranged so that they can be released from the exterior of the building, as well as the interior. This feature accomplishes two purposes. First, since the door can be unlocked from the outside, staff need not enter the housing area in which the fire may be located to release the locks. Second, many facilities do not permit staff members in the housing area to carry the keys for the exterior doors; therefore, there may be no benefit in requiring the door lock to be arranged to permit operation from the interior, although such an arrangement is not prohibited.

The provisions of Section 408.7.4 of the IFC concerning the marking of keys applies to both exterior and interior door locks. For this reason, it is usually desirable to minimize the number of keys required for an emergency; therefore, the exterior doors will most likely be keyed alike. Unfortunately, many facilities do not take this into consideration and the number of emergency keys becomes excessive to the extent that it is virtually impossible to identify each key by sight and touch.

408.4.1 Remote release. Remote release of locks on doors in a means of egress shall be provided with reliable means of operation, remote from the resident living areas, to release locks on all required doors. In Occupancy Conditions 3 or 4, the arrangement, accessibility and security of the release mechanisms required for egress shall be such that with the minimum available staff at any time, the lock mechanisms are capable of being released within 2 minutes.

Exception: Provisions for remote locking and unlocking of occupied rooms in Occupancy Condition 4 are not required provided that not more than 10 locks are necessary to be unlocked in order to move occupants from one smoke compartment to a refuge area within 3 minutes. The opening of necessary locks shall be accomplished with not more than two separate keys.

The provisions of this section do not mandate remote release locks; rather, the facility determines the level and manner in which security is to be provided. Door-locking arrangements fall into one of the conditions defined in Section 308.5. If remote release locks are provided, the means of operating them must be external to the resident housing area so that the staff is not required to enter the housing area to release the locks. Clearly, in Conditions 3 and 4, excessive delay in releasing locks puts the occupants at additional risk. Locks in Conditions 3 and 4 must be able to be released promptly (within 2 minutes) with the minimum staff that will be available. A control center is typically provided for two or more housing areas from which the locks are controlled. In evaluating the use and arrangement of the remote release, consideration must be given to the intended staffing levels at different times of the day, as well as the locations of the remote release.

The condition definitions of Section 308.5 are
intended to relate to the time necessary to evacuate the residents to a refuge area, such as a smoke compartment; therefore, in Condition 4, manual release locks may be used only when no more than 10 locks have to be unlocked in order to move all occupants from one smoke compartment to another and provided that this can be accomplished within 3 minutes. The time period of 3 minutes is presumed to be a reasonable staff response time to a fire emergency. So that the time to release the locks is kept to a minimum, it cannot take more than two separate keys to release the 10 locks. Again, the intended staff levels of the facility need to be considered (see Figure 408.4.1).

408.4.2 Power-operated doors and locks. Power-operated sliding doors or power-operated locks for swinging doors shall be operable by a manual release mechanism at the door, and either emergency power or a remote mechanical operating release shall be provided.

Exception: Emergency power is not required in facilities with 10 or fewer locks complying with the exception to Section 408.4.1.

To increase the likelihood that the doors in the means of egress can be operated even during a power failure, two alternative locking arrangements are required whenever the doors or locks are electrically operated. First, a manual release mechanism is to be provided at the door. Also, a remote backup (second) mechanical operating door release system must be provided or the electrical door control system must be provided with an emergency power source. If provided, the mechanical operating door release system must be capable of being operated from outside the residential housing area.

This section does not apply to manually operated doors and locks that meet the requirements of the exception to Section 408.4.1.

408.4.3 Redundant operation. Remote release, mechanically operated sliding doors or remote release, mechanically operated locks shall be provided with a mechanically operated release mechanism at each door, or shall be provided with a redundant remote release control.

- If a mechanically operated remote release mechanism is provided as the remote release system, either a second, redundant system is required or each remote release door or lock is to be provided with a mechanically operated device at the door. The redundant operation is essential to increase the likelihood that the doors will continue to operate in the event of failure of the primary locking system. If provided, the redundant mechanical operating door release system must also be operable from outside the residential housing area.

This provision does not apply to power-operated doors and locks that are required to have alternative systems in accordance with Section 408.4.2.

408.4.4 Relock capability. Doors remotely unlocked under emergency conditions shall not automatically relock when closed unless specific action is taken at the remote location to enable doors to relock.

- So as to maintain means of egress doors in an open position during an emergency condition, once a door in a means of egress is unlocked via an emergency unlocking system, the door must not automatically relock when closed unless a specific action is taken at the remote location. The normal operation of such doors and locks is typically arranged so that the door will automatically relock upon closure.

Many electronic-locking systems operate such that the door automatically relocks upon closure for secu-
rity reasons. To comply with the provisions of this section, however, a specific switch is usually provided that serves as an emergency control and does not permit the door to relock without operating it. This section does not require that doors automatically release upon activation of the fire alarm system.

408.5 Protection of vertical openings. Any vertical opening shall be protected by a shaft enclosure in accordance with Section 713, or shall be in accordance with Section 408.5.1.

- This section requires that vertical openings be protected in the manner established in Section 713. The section allows compliance with Section 408.5.1 as an alternative within a housing unit. If the provisions of Section 408.5.1 for floor openings are used, then Section 408.5.2 regarding plumbing chases is also available for use in the design.

408.5.1 Floor openings. Openings in floors within a housing unit are permitted without a shaft enclosure, provided all of the following conditions are met:

1. The entire normally occupied areas so interconnected are open and unobstructed so as to enable observation of the areas by supervisory personnel;
2. Means of egress capacity is sufficient for all occupants from all interconnected cell tiers and areas;
3. The height difference between the floor levels of the highest and lowest cell tiers shall not exceed 23 feet (7010 mm); and
4. Egress from any portion of the cell tier to an exit or exit access door shall not require travel on more than one additional floor level within the housing unit.

- This section is essentially an exception to the protection of vertical openings required by Section 712. It allows openings between the various floor levels and cell tiers within a single housing unit. This provision applies regardless of whether or not the communicat-

ifying floor levels are stories or mezzanines as long as they are within the same housing unit [see Figures 408.5(1) and (2)].

The following is a discussion of the conditions that must be met:

1. The areas must be sufficiently open and unobstructed so that a fire in one part will be immediately obvious to the occupants and supervisory personnel in the area. The intent of the provision is not to require open cell fronts; rather, it is to enable the staff to observe events occurring on all levels from one location. This arrangement is usually desirable from a security standpoint [see Figure 408.5(1)].

2. The exit capacity required is determined based on the occupant load of all floor levels exiting simultaneously. It is not unusual for most of the residents to be on the main level in the common space during periods when they are not required to be in the sleeping units (cells); therefore, this level must be able to handle the potential occupant load of all cell tier levels.

3. The height differential between the floor levels of highest and lowest cell tiers must not exceed 23 feet (7010 mm). The limitation of 23 feet (7010 mm) expands the general code limitations on unprotected floor openings beyond two stories, because in Group I-3 it is not uncommon to have more than two interconnected levels in this open arrangement; however, the effective limitation in number of cell tiers is three. As with atriums (see Section 404), an automatic sprinkler system is required to control the spread of smoke and fire through vertical openings. Beyond the specified dimension of 23 feet (7010 mm), effective unobstructed sight becomes less attainable [see Figure 408.5(2)].

---

For SI: 1 foot = 304.8 mm.

Figure 408.5(1)
GROUP I-3: VERTICAL OPENINGS
4. To minimize the potential that a fire in the day room would block access to all exits, the exits must be arranged such that it is possible to reach an exit on each level, or from the level next above or below. This would permit, for example, a three-tiered housing unit to have exits or exit access doors out of the housing unit, which are located on the lowest level and mid-level only; or on the lowest level and the top level only. In these two scenarios, the residents have access to an exit either from the level they are on or on the next level directly above or below.

408.5.2 Shaft openings in communicating floor levels. Where a floor opening is permitted between communicating floor levels of a housing unit in accordance with Section 408.5.1, plumbing chases serving vertically stacked individual cells contained with the housing unit shall be permitted without a shaft enclosure.

Where a housing unit is designed in compliance with Section 408.5.1, this section allows plumbing chases within the same housing unit to also be unprotected where they penetrate through the floors separating cell tiers. If opening protection is provided within a housing unit under the provisions of Section 712, the provisions of this section cannot be used in a building design.

408.6 Smoke barrier. Occupancies in Group I-3 shall have smoke barriers complying with Sections 408.8 and 709 to divide every story occupied by residents for sleeping, or any other story having an occupant load of 50 or more persons, into no fewer than two smoke compartments.

Exception: Spaces having a direct exit to one of the following, provided that the locking arrangement of the doors involved complies with the requirements for doors at the smoke barrier for the use condition involved:

1. A public way.

2. A building separated from the resident housing area by a 2-hour fire-resistance-rated assembly or 50 feet (15 240 mm) of open space.

3. A secured yard or court having a holding space 50 feet (15 240 mm) from the housing area that provides 6 square feet (0.56 m²) or more of refuge area per occupant, including residents, staff and visitors.

One of the basic premises of this section is that evacuation of a Group I-3 facility is impractical because of the need to maintain security. The security measures may also result in a delayed evacuation as compared to residential occupancies in which free egress is allowed; therefore, it is essential to provide a refuge area to which residents can be relocated when it becomes necessary to evacuate them from the housing units. For this reason, each cell tier and each floor with an occupant load of 50 or more is required to be divided into at least two smoke compartments using smoke barriers that comply with Sections 408.8 and 709 (see commentary, Section 709). It should be noted that Section 709 provides several exceptions to smoke barriers used in Group I-3 occupancies (e.g., construction, doors and opening protectives). A further exception allowing increased glazing is permitted by the provisions of Section 408.7.

The exception provides three alternatives that are common-sense options to movement into a smoke compartment. If the particular occupancy condition affords free, unobstructed access with no delay to the exterior, to a separate building or through a horizontal exit, then defend-in-place provisions are not needed.

408.6.1 Smoke compartments. The number of residents in any smoke compartment shall be not more than 200. The travel distance to a door in a smoke barrier from any room door required as exit access shall be not greater than 150 feet (45 720 mm). The travel distance to a door in a smoke barrier
from any point in a room shall be not greater than 200 feet (60 960 mm).

- This section defines the maximum allowable size of smoke compartments by limiting the number of residents in any single smoke compartment to 200, the maximum door-to-door distance within the compartment to 150 feet (45 720 mm) and the maximum total travel distance to 200 feet (60 960 mm). These limitations are intended to enable evacuation of a smoke compartment for all of the occupants (see Figure 408.6.1).

**408.6.2 Refuge area.** Not less than 6 net square feet (0.56 m²) per occupant shall be provided on each side of each smoke barrier for the total number of occupants in adjoining smoke compartments. This space shall be readily available wherever the occupants are moved across the smoke barrier in a fire emergency.

- To provide adequate space for the residents evacuated to an adjacent smoke compartment, an additional 6 square feet (0.56 m²) per person must be readily available for the total number of occupants in the adjoining smoke compartment (see Figure 408.6.2). The 6-square-foot (0.56 m²) criterion enables the occupants to be evacuated to the adjacent smoke compartment without delay from crowding.

In a fire emergency, any action that must be taken to unlock the space will result in a delay in moving occupants into the refuge area. As such, the code requires the refuge area to be readily available in order to preclude consideration (as a refuge area) of a space that may be normally locked and, therefore, not immediately usable.

**408.6.3 Independent egress.** A means of egress shall be provided from each smoke compartment created by smoke barriers without having to return through the smoke compartment from which means of egress originates.

- To prevent creating a dead-end smoke compartment, exits are to be arranged so as to permit access without returning through a compartment from which egress originated. An exit is not required from within each smoke compartment [see Figures 407.5.2(1) and (2) for acceptable and unacceptable exit arrangements].

**408.7 Security glazing.** In occupancies in Group I-3, windows and doors in 1-hour fire barriers constructed in accordance with Section 707, fire partitions constructed in accordance with Section 708 and smoke barriers constructed in accordance with Section 709 shall be permitted to have security glazing installed provided that the following conditions are met.

1. Individual panels of glazing shall not exceed 1,296 square inches (0.84 m²).

2. The glazing shall be protected on both sides by an automatic sprinkler system. The sprinkler system shall be designed to, when actuated, wet completely the entire surface of any glazing affected by fire.

3. The glazing shall be in a gasketed frame and installed in such a manner that the framing system will deflect without breaking (loading) the glass before the sprinkler system operates.

---

**Figure 408.6.1**

**GROUP I-3: SMOKE COMPARTMENTS**

*For SI: 1 foot = 304.8 mm, 1 inch = 25.4 mm, 1 square foot = 0.0929 m².*
4. Obstructions, such as curtain rods, drapery traverse rods, curtains, drapes or similar materials shall not be installed between the automatic sprinklers and the glazing.

* This section allows sprinkler protected glazing in walls in a Group I-3 facility provided the wall is rated for 1 hour or less. As with many provisions in Section 408, this enhances the security of a facility by providing more opportunities for staff to monitor the activities of residents.

**408.8 Subdivision of resident housing areas.** Sleeping areas and any contiguous day room, group activity space or other common spaces where residents are housed shall be separated from other spaces in accordance with Sections 408.8.1 through 408.8.4.

* Resident housing areas usually consist of sleeping areas and other contiguous common area spaces, such as day rooms or activity areas onto which sleeping areas open. The separation required by this section is intended to separate housing areas, where the occupants in those areas may be asleep, from other activity areas since people asleep are more vulnerable to a fire emergency. The separation requirements are based on the relative evacuation difficulty as determined by the occupancy condition. Sections 408.8.1 through 408.8.4 give the separation requirements for several occupancy conditions which separation is necessary.

**408.8.1 Occupancy Conditions 3 and 4.** Each sleeping area in Occupancy Conditions 3 and 4 shall be separated from the adjacent common spaces by a smoke-tight partition where the travel distance from the sleeping area through the common space to the corridor exceeds 50 feet (15 240 mm).

* A smoke-tight partition is required between the sleeping areas and common areas in Conditions 3 and 4 when travel distance from the sleeping area through the common area to an exit access corridor exceeds 50 feet (15 240 mm). This requirement recognizes the need to protect sleeping areas from nonsleeping areas due to the increased hazards associated with common areas, delayed recognition of fire hazards by sleeping persons and the restrictions on movement for these two occupancy conditions. Moreover, release from the sleeping area may be delayed and as such, evacuation with extended travel through a common space may not be safe. In such cases, the sleeping area will be a refuge area until the fire is controlled and the occupants in the sleeping area can be safely evacuated.

It should be noted that the provisions contained in Section 1014.2 are applicable to this circumstance, and as such, sleeping areas, including those in Group I-3 occupancies, are precluded from egressing through another sleeping area. Additionally, egress is not allowed from sleeping areas through toilet rooms.

**408.8.2 Occupancy Condition 5.** Each sleeping area in Occupancy Condition 5 shall be separated from adjacent sleeping areas, corridors and common spaces by a smoke-tight partition. Additionally, common spaces shall be separated from the corridor by a smoke-tight partition.

* Given that movement from an occupied space in Condition 5 is even more restricted than for the other conditions, smoke-tight partitions are required to be installed between areas, sleeping areas, common spaces and the exit access corridor. Protection is provided because the staff-controlled release from the sleeping area is not as immediate as in other conditions.

**408.8.3 Openings in room face.** The aggregate area of openings in a solid sleeping room face in Occupancy Conditions 2, 3, 4 and 5 shall not exceed 120 square inches (0.77 m²). The

![Figure 408.6.2](image)

**Figure 408.6.2**

**GROUP I-3: REFUGE AREA**

For SI: 1 square foot = 0.0929 m².
aggregate area shall include all openings including door undecuts, food passes and grilles. Openings shall be not more than 36 inches (914 mm) above the floor. In Occupancy Condition 5, the openings shall be closeable from the room side.

- Food pass-throughs, door undecuts and grilles are a functional necessity; therefore, openings are limited in size and close to the floor. The openings are required to be close to the floor to minimize the potential for the smoke to pass through the opening. By placing the opening close to the floor, the smoke will not pass through a smoke-tight barrier initially; rather, there will be some time delay as the smoke layer descends to 36 inches (914 mm) above the floor before smoke is transmitted through such openings.

**408.8.4 Smoke-tight doors.** Doors in openings in partitions required to be smoke tight by Section 408.8 shall be substantial doors, of construction that will resist the passage of smoke. Latches and door closures are not required on cell doors.

- If the partition is required to be capable of resisting the passage of smoke, door openings within the enclosure are also to be protected with an assembly that is capable of resisting the passage of smoke. As with other sections of the code that deal with doors and walls capable of resisting the passage of smoke, application of the section requires judgment by the building official. The intent is a solid door surface without louvered openings. Door closers and latches are not required. It is anticipated that the security lock will secure the door in the closed position. A door closer can interfere with the removal of the occupants not only in an emergency but also during normal operations.

**408.9 Windowless buildings.** For the purposes of this section, a windowless building or portion of a building is one with nonoperable windows, windows not readily breakable or without windows. Windowless buildings shall be provided with an engineered smoke control system to provide a tenable environment for exiting from the smoke compartment in the area of fire origin in accordance with Section 909 for each windowless smoke compartment.

- An engineered smoke control system is required for smoke compartments in which there are no openings through which the products of combustion can be vented. The intent of the system is to provide a tenable environment during the period it takes the occupants to egress from a smoke compartment that is the area of fire origin. As it often takes longer to evacuate a Group I-3 facility due to the locking and restricted egress paths, the maintenance of a tenable environment is essential. As defined for this section only, a windowless building is a building or portion thereof with only nonoperable windows, windows that are not readily breakable or without windows. The intent of this section is that staff must have some means to ventilate the products of combustion; there-fore, if the window cannot be broken by items readily available to the staff, the area is considered windowless.

**[F] 408.10 Fire alarm system.** A fire alarm system shall be provided in accordance with Section 907.2.6.3.

- Fire alarm systems are required in Group I-3 facilities. See the commentary to Section 907.2.6.3 for detailed requirements for this system.

**[F] 408.11 Automatic sprinkler system.** Group I-3 occupancies shall be equipped throughout with an automatic sprinkler system in accordance with Section 903.2.6.

- Automatic sprinkler systems are required in all Group I-3 facilities. See the commentary to Section 903.2.6 for detailed requirements for this system.

### SECTION 409

**MOTION PICTURE PROJECTION ROOMS**

**409.1 General.** The provisions of Sections 409.1 through 409.5 shall apply to rooms in which ribbon-type cellulose acetate or other safety film is utilized in conjunction with electric arc, xenon or other light-source projection equipment that develops hazardous gases, dust or radiation. Where cellulose nitrate film is utilized or stored, such rooms shall comply with NFPA 40.

- Cellulose acetate or other safety film used in the presence of potential ignition sources, including projectors or related equipment, creates a potential hazard. The provisions of this section are intended to minimize the potential for exposure of the audience and other occupants to the hazards associated with the presence of ignition sources in close proximity to the fuel load.

Provisions are established for projection rooms in recognition of the hazards attendant to the projection of ribbon-type cellulose acetate or other safety film in such spaces.

Safety film is typically made of cellulose acetate, polyester or triacetate film. In the early 1950s, safety film began to replace cellulose nitrate film. Although the use and manufacture of cellulose nitrate film has virtually ceased in the United States, large quantities of such film still exist, primarily for archival purposes. Cellulose nitrate film presents a serious hazard because degradation under external heat below ignition temperatures causes a chemical reaction. This reaction releases heat of sufficient quantity to raise the substance to ignition temperatures, resulting in spontaneous combustion. After ignition, rapid burning and the production of toxic and flammable gases takes place. If such film is used, the provisions of NFPA 40 are applicable as are the provisions of Section 306 of the IFC.

The provisions of this section apply only where the previously mentioned hazards exist. The use of ribbon-type cellulose acetate or other safety film in conjunction with electric arc, xenon or other light-source projection equipment that develops hazardous gases,
dust or radiation invokes these provisions. The provisions of this section do not apply where nonprofessional projection equipment is used, except that statements specific to cellulose nitrate film apply if such film is present regardless of the nature of the equipment. The safety film used by the motion picture industry since 1951 has fire hazard characteristics similar to ordinary paper of the same thickness and form.

If cellulose nitrate film is used, the provisions of NFPA 40 apply. NFPA 40 contains minimum requirements to provide a reasonable level of protection for the storage and handling of cellulose nitrate film. The standard does not contain provisions for the manufacture of cellulose nitrate film, since it has not been manufactured in the United States since 1951.

409.1.1 Projection room required. Every motion picture machine projecting film as mentioned within the scope of this section shall be enclosed in a projection room. Appurtenant electrical equipment, such as rheostats, transformers and generators, shall be within the projection room or in an adjacent room of equivalent construction.

- The projection room is to be enclosed in accordance with Section 409.2 to isolate the spaces housing the potential hazard. To minimize the potential for arcs or sparks to come in contact with the film, electrical equipment, such as rheostats, transformers and generators, should be located in a separate room. This section permits such equipment to be in the same room, but it should be arranged to minimize the potential for arcs or sparks to come in contact with the film, reducing the potential for ignition. Additional requirements for electrical equipment permitted in the projection room and requirements for nonprofessional equipment are given in NFPA 70.

409.2 Construction of projection rooms. Every projection room shall be of permanent construction consistent with the construction requirements for the type of building in which the projection room is located. Openings are not required to be protected.

The room shall have a floor area of not less than 80 square feet (7.44 m²) for a single machine and not less than 40 square feet (3.7 m²) for each additional machine. Each motion picture projector, floodlight, spotlight or similar piece of equipment shall have a clear working space of not less than 30 inches by 30 inches (762 mm by 762 mm) on each side and at the rear thereof, but only one such space shall be required between two adjacent projectors. The projection room and the rooms appurtenant thereto shall have a ceiling height of not less than 7 feet 6 inches (2286 mm). The aggregate of openings for projection equipment shall not exceed 25 percent of the area of the wall between the projection room and the auditorium. Openings shall be provided with glass or other approved material, so as to close completely the opening.

- The projection room is to be constructed as required by the construction type of the building. Since the room dimensions are small, ventilation is provided to reduce heat buildup and accumulation of dust particles. A minimum fire-resistance rating is not required unless by other provisions of the code. Limited openings are permitted and are not required to be protected so as to facilitate the intended function of projecting the image onto the auditorium screen. Openings to the auditorium must not exceed 25 percent of the area of the wall between the projection room and the auditorium. Glass or other approved material must be provided that will completely close the opening and prevent a sharing of atmospheres with the audience or seating area.

In order to minimize the buildup of heat in any area, adequate floor space must be available. The space is required to be at least 80 square feet (7.44 m²) in size for a single projector and an additional 40 square feet (3.7 m²) for each additional projector. The room must be of adequate size so that no less than 30 inches by 30 inches (762 mm by 762 mm) of clear working space is available on each side and behind the projectors, floodlights, spotlights and similar equipment. For adjacent equipment, a clear space of 30 inches (762 mm) is adequate.

Whereas the projection room is considered an occupiable room, the ceiling height must not be less than 7 feet, 6 inches (2286 mm) (see commentary, Section 1208.2).

409.3 Projection room and equipment ventilation. Ventilation shall be provided in accordance with the International Mechanical Code.

- All projection rooms and the equipment located within the rooms must be properly ventilated to abate the hazards of any hot gases and smoke generated by the equipment. Further, any intense heat given off by the equipment must be directly exhausted to the exterior rather than be absorbed by the building's ventilation system. Sections 502.11.1 and 502.11.2 of the IMC contain requirements for projectors provided with an exhaust discharge and those without an exhaust connection.

409.3.1 Supply air. Each projection room shall be provided with adequate air supply inlets so arranged as to provide well-distributed air throughout the room. Air inlet ducts shall provide an amount of air equivalent to the amount of air being exhausted by projection equipment. Air is permitted to be taken from the outside; from adjacent spaces within the building, provided the volume and infiltration rate is sufficient; or from the building air-conditioning system, provided it is so arranged as to provide sufficient air when other systems are not in operation.

- Separate supply (see Section 409.3.1) and exhaust (see Section 409.3.2) requirements are provided for projection rooms. Exhaust rates are specified in Section 502.11.2 of the IMC for projectors without exhaust connection.

Sufficient air must be introduced into each projection room to allow the effects of hot gases, smoke and heat to be diluted and to provide a makeup air source for the exhausted air. Although the code does
SPECIAL DETAILED REQUIREMENTS BASED ON USE AND OCCUPANCY

not prescriptively state where the air supply inlets are to be located, the intent is to create a well-ventilated room. Several air supply inlets should be provided so that the entire room has adequate air changes. The amount of air supplied to each projection room must be approximately equal to the volume of air that is exhausted according to the IMC. Makeup supply air can be obtained from any source as long as sufficient quantities are provided at all times that the exhaust system is operating.

409.3.2 Exhaust air. Projection rooms are permitted to be exhausted through the lamp exhaust system. The lamp exhaust system shall be positively interconnected with the lamp so that the lamp will not operate unless there is the required airflow. Exhaust air ducts shall terminate at the exterior of the building in such a location that the exhaust air cannot be readily recirculated into any air supply system. The projection room ventilation system is permitted to also serve appurtenant rooms, such as the generator and rewind rooms.

- Another method of providing exhaust is to exhaust the room itself. This method can only be used when the projectors do not have an integral lamp exhaust system. Exhaust rates for this type of system are specified in the IMC based on the type of projector. The exhaust ducts for the projection room must be terminated at the exterior of the building and cannot be combined with any other exhaust or return system present in the building. The intent of this requirement is so that the hot gases, smoke and heat will not be allowed to be disbursed elsewhere in the building.

409.3.3 Projection machines. Each projection machine shall be provided with an exhaust duct that will draw air from each lamp and exhaust it directly to the outside of the building. The lamp exhaust is permitted to serve to exhaust air from the projection room to provide room air circulation. Such ducts shall be of rigid materials, except for a flexible connector approved for the purpose. The projection lamp or projection room exhaust system, or both, is permitted to be combined but shall not be interconnected with any other exhaust or return system, or both, within the building.

- Projectors with an integral lamp exhaust system use air to cool the equipment during operation. The amount of air exhausted with these systems is part of the manufacturer's installation instructions. These integral exhaust systems must be directly connected to the mechanical exhaust systems. Further, the lamp exhaust system must be interconnected to the projector's power supply such that when the projector is operating, its exhaust system will be automatically activated.

409.4 Lighting control. Provisions shall be made for control of the auditorium lighting and the means of egress lighting systems of theaters from inside the projection room and from not less than one other convenient point in the building.

- The projection room is usually an attended location, but it is also a likely area for a fire to originate. Lighting controls that provide adequate normal and emergency auditorium lighting must be provided in the projection room. Upon detection of a fire anywhere in the building, the operator can immediately provide adequate illumination for the occupants exiting the auditorium. A second location for the lighting controls is also required somewhere else in the building, so that entry into the projection room is not required to provide the necessary illumination, as it could be the location of fire origin. This second control is required to be conveniently located for the staff yet inaccessible to unauthorized persons.

409.5 Miscellaneous equipment. Each projection room shall be provided with rewind and film storage facilities.

- In order to keep all operations related to projection activities in the protected enclosure, rewind and film storage facilities are to be located in the projection room or in an adjacent room in accordance with Section 409.1.1.

SECTION 410
STAGES, PLATFORMS AND TECHNICAL PRODUCTION AREAS

410.1 Applicability. The provisions of Sections 410.1 through 410.8 shall apply to all parts of buildings and structures that contain stages or platforms and similar appurtenances as herein defined.

- Historically, most significant theater fires originated on the stage. The 1903 Iroquois Theater fire in Chicago serves as a vivid example of a stage fire and its potentially tragic effects—602 people lost their lives. Hazards associated with stages include: combustible scenery and lighting suspended overhead; scenic elements, contents and acoustical treatment on the back and sides of the stage; and technical production areas including workshops, scene docks and dressing rooms located around the stage perimeter; and storage areas and property rooms located underneath the stage.

The protection requirements set forth in this section are intended to limit the threat from stage fires to an audience and reduce the likelihood of a large fire in the stage area. These provisions include construction restrictions, automatic sprinkler systems, ventilation, separation of the stage from the audience and compartmentalization of appurtenant rooms to the stage. Special allowances are provided for galleries, grid-irons, catwalks and other technical production areas.

Based on historical events and the expertise of a broad range of professionals with experience in theater design, operations and fire events, a set of principles guides the requirements for theaters. These principles are summarized as follows:

1. The fire hazards of stages are not necessarily a function of type (legitimate, regular or thrust) but rather area and height. Accordingly, a stage area in excess of 1,000 square feet (93 m²) or a
height in excess of 50 feet (15 240 mm) is the threshold that represents a significant potential for fuel load due to scenery and drops.

2. Stages that exceed 1,000 square feet (93 m²) or the 50-foot-height (15 240 mm) threshold require a means of emergency ventilation.

3. Stages that exceed 1,000 square feet (93 m²) and the 50-foot-height (15 240 mm) thresholds require automatic sprinkler protection.

4. Stages and platforms are similar to floor construction; therefore, the type of construction should be consistent with that of the floor construction in the building.

5. Separation of the stage from the seating area and dressing rooms, property rooms and similar spaces is critical in order to provide a degree of fire containment.

Section 410.3 contains provisions for the construction of the stage and gallery. Stage openings, decorations, equipment and scenery are addressed in Sections 410.3.3 through 410.3.6. Stage ventilation is required in accordance with Section 410.3.7. Platforms must be constructed in accordance with Section 410.4. The construction of auxiliary stage spaces is addressed in Section 410.5. Special means of egress requirements for stages, platforms and technical production areas are established in Section 410.6. Sections 410.7 and 410.8 contain the requirements for automatic sprinkler systems and standpipes, respectively.

All parts of a building or structure that contain a stage, platform or similar appurtenance are required to comply with the provisions of this section.

410.3 Stages. Stage construction shall comply with Sections 410.3.1 through 410.3.8.

- This section indicates the scope of the code provisions that apply to stage construction.

410.3.1 Stage construction. Stages shall be constructed of materials as required for floors for the type of construction of the building in which such stages are located.

**Exception:** Stages need not be constructed of the same materials as required for the type of construction provided the construction complies with one of the following:

1. Stages of Type IIB or IV construction with a nominal 2-inch (51 mm) wood deck, provided that the stage is separated from other areas in accordance with Section 410.3.4.

2. In buildings of Type IIA, IIIA and VA construction, a fire-resistance-rated floor is not required, provided the space below the stage is equipped with an automatic sprinkler system or fire-extinguishing system in accordance with Section 903 or 904.

3. In all types of construction, the finished floor shall be constructed of wood or approved noncombustible materials. Openings through stage floors shall be equipped with tight-fitting, solid wood trap doors with approved safety locks.

- Stages, most simply, are floor construction, and as such, must conform to the requirements for all other floors in the building so that the building's designated construction classification will be consistent throughout.

Since wood is the material of choice for stage floors because it allows for nailing of sets and props and provides the best acoustics for dance and other performances, the code allows three exceptions to the requirement for stage construction.

Exception 1 permits stages in buildings of any construction classification to be constructed with a nominal 2-inch (51 mm) wood deck supported by either unprotected noncombustible construction (Type IIB) or heavy timber construction (Type IV) where the stage is separated from the audience by a proscenium wall built in accordance with Section 410.3.4.

Under Exception 2, stage floors are not required to be fire-resistance rated in buildings of Types IIA, IIIA and VA where the space below the stage is equipped with an automatic sprinkler system or fire-extinguishing system installed in accordance with Section 903 or 904. In this case, the requirement for fire-resistance-rated floors is offset by the protection supported by the automatic fire-extinguishing system.

Exception 3 recognizes that stages are predominately constructed with a finished floor of wood and identifies wood as an acceptable finish material for all construction classifications. It also permits openings in stage floors to be protected with tight-fitting solid wood doors with safety locks to secure them. The normal operation of stage trap doors does not typically allow them to have a fire-resistance rating.
410.3.1.1 Stage height and area. Stage areas shall be measured to include the entire performance area and adjacent backstage and support areas not separated from the performance area by fire-resistance-rated construction. Stage height shall be measured from the lowest point on the stage floor to the highest point of the roof or floor deck above the stage.

- As previously stated, many of the code’s requirements for stages and platforms are triggered based on the volume of the stage or platform space. All of the wing areas and backstage areas are included as the stage area, unless they are separated with fire-resistance-rated construction. Stage height is not the height of the opening in the prosenium wall, but the height from the stage floor to the highest horizontal assembly that encloses the stage space. It will typically include the fly gallery and fly loft above the stage.

410.3.2 Technical production areas: galleries, gridirons and catwalks. Beams designed only for the attachment of portable or fixed theater equipment, gridirons, galleries and catwalks shall be constructed of approved materials consistent with the requirements for the type of construction of the building; and a fire-resistance rating shall not be required. These areas shall not be considered to be floors, stories, mezzanines or levels in applying this code.

Exception: Floors of fly galleries and catwalks shall be constructed of any approved material.

- This section identifies the components of the technical production areas located above the stage that are used to conceal movable scenery from the audience and where the operation of such scenery and other stage effects is controlled.

The normal use and operation of a stage requires that equipment, normally rigging, be installed and rearranged as production requirements vary. This equipment is normally installed by clamping or welding to the structural framing over and around the stage, making protecting the framing by encasement or membranes infeasible; hence, a fire-resistance rating is not required for these elements. In order to control the fuel load in this area, however, the code requires that all of the elements must be of approved materials consistent with the requirements of the building’s construction type. The exception to this requirement is that in all cases, the floors of fly galleries and catwalks may be constructed of any approved material regardless of the building’s construction type. Such spaces are generally limited in area, access is restricted to authorized personnel and they require floor materials that will deaden sound so as not to disrupt the performance below. These auxiliary areas do not have to meet the code’s requirements as another story, mezzanine level or equipment platforms.

410.3.3 Exterior stage doors. Where protection of openings is required, exterior exit doors shall be protected with fire door assemblies that comply with Section 716. Exterior openings that are located on the stage for means of egress or loading and unloading purposes, and that are likely to be open during occupancy of the theater, shall be constructed with vestibules to prevent air drafts into the auditorium.

- If exterior opening protective are required, exit discharge doors directly from the stage to the outside must be fire door assemblies in accordance with Section 716.

Since one of the major concerns is containing a stage fire to the stage area, any exterior opening from the stage that is likely to be opened during a performance is to be constructed with a vestibule to prevent air drafts into the auditorium. This vestibule requirement applies to all exterior openings that are likely to be open regardless of their intended use.

410.3.4 Proscenium wall. Where the stage height is greater than 50 feet (15 240 mm), all portions of the stage shall be completely separated from the seating area by a proscenium wall with not less than a 2-hour fire-resistance rating extending continuously from the foundation to the roof.

- The protection afforded by a 2-hour fire separation and opening protection (see Section 410.3.5) is required where the stage height is greater than 50 feet (15 240 mm). Stages with a height greater than 50 feet (15 240 mm) permit multiple settings and large amounts of scenery and scenic elements in dense configurations. The height may reduce the effectiveness of the suppression system and the multiple settings hung over the stage may further obstruct the suppression system and impede access to a fire originating high above the stage. Stages with a height less than 50 feet (15 240 mm) do not require separation from the audience since they represent a limited fuel load potential caused by scenery, drops and curtains.

410.3.5 Proscenium curtain. Where a proscenium wall is required to have a fire-resistance rating, the stage opening shall be provided with a fire curtain complying with NFPA 80 or an approved water curtain complying with Section 903.3.1.1 or, in facilities not utilizing the provisions of smoke-protected assembly seating in accordance with Section 1028.6.2, a smoke control system complying with Section 909 or natural ventilation designed to maintain the smoke level not less than 6 feet (1829 mm) above the floor of the means of egress.

- Fuel loads in a stage with a height greater than 50 feet (15 240 mm) most often are high and the resulting fire is severe. In such cases, to permit the audience to evacuate the seating area without being threatened directly or indirectly by a stage fire, this section requires the proscenium opening be protected with either a fire curtain (complying with NFPA 80) or an approved water curtain. Another available option is to provide a smoke control system or natural ventilation designed to prevent the accumulation of smoke within the first 6 feet (1829 mm) above the floor. This option is only permissible if a smoke-protected assembly seating design in accordance with Section 1028.6.2 is not utilized.
In accordance with NFPA 80, a fire curtain must be capable of preventing the passage of flame or smoke, thereby providing a certain level of protection for the audience when a stage fire occurs. It is notable that the fire curtain is not required to provide the same level of protection as is typically required for a fire door assembly. Also, since one of the goals is to protect against panic, flame and smoke must not be capable of passing through to the unexposed side of the fire curtain. The level of protection for the fire curtain is based upon evacuation time of the audience. Fire curtains are designed to provide 20 minutes of protection to allow the audience to evacuate.

NFPA 80 requirements for the fire curtain include, but are not limited to: testing of the fabric (NFPA 701, Test Method 2), a fire curtain sample assembly subjected to the standard fire test as specified in NFPA 251, activation (emergency and manual) and rate of closing speed. The speed of descent must be slowed for the last 8 feet (2438 mm) of travel in order to allow individuals on the stage to move away from the curtain and to avoid injury from being hit by the batten in the bottom pocket of the curtain. It should be noted that only stages with a height greater than 50 feet (15 240 mm) are required to have a proscenium wall and curtain.

Water curtains conforming with Section 903.3.1.1 are viewed as providing an equivalent degree of protection to that of a fire curtain. This, in part, recognizes that emergency ventilation is also required in accordance with Section 410.3.7, which will assist in controlling smoke movement. The duration of protection is, of course, continuous as long as the sprinkler system is in operation.

Lastly, today's assembly facilities, such as arenas and theaters in the round, make the use of a traditional fire curtain impractical. As such, a smoke control system or a natural ventilation system may be utilized in lieu of a fire curtain or approved water curtain, provided the special allowances for smoke-protected assembly seating are not being applied.

410.3.6 Scenery. Combustible materials used in sets and scenery shall meet the fire propagation performance criteria of NFPA 701, in accordance with Section 806 and the International Fire Code. Foam plastics and materials containing foam plastics shall comply with Section 2603 and the International Fire Code.

This section recognizes that scenery and sets are decorative materials. As such, combustible materials used in sets and scenery must meet the fire propagation performance criteria in accordance with the provisions of NFPA 701, Section 806 and the IFC. Section 806 references Section 2604 for specific requirements for foam plastics used as trim. It should also be noted that Section 2603 addresses the uses of foam plastics in insulation.

410.3.7 Stage ventilation. Emergency ventilation shall be provided for stages larger than 1,000 square feet (93 m²) in floor area, or with a stage height greater than 50 feet (15 240 mm). Such ventilation shall comply with Section 410.3.7.1 or 410.3.7.2.

In addition to an automatic sprinkler system, emergency ventilation is one of the key fire protection components for stages that contain large fuel loads. Stages with large areas or heights permit multiple settings and large amounts of scenery and scenic elements in dense configurations. Increased height also permits multiple settings to be hung over the stage that may reduce the effectiveness of the suppression system or impede access to a fire originating high above the stage. Based on these factors and the potential hazard presented by them, stages larger than 1,000 square feet (93 m²) in area or with a height greater than 50 feet (15 240 mm) are required to be equipped with emergency ventilation to control smoke movement and minimize the potential for fire and smoke to spread to the seating area.

410.3.7.1 Roof vents. Two or more vents constructed to open automatically by approved heat-activated devices and with an aggregate clear opening area of not less than 5 percent of the area of the stage shall be located near the center and above the highest part of the stage area. Supplemental means shall be provided for manual operation of the ventilator. Curbs shall be provided as required for skylights in Section 2610.2. Vents shall be labeled.

Where vents are used to ventilate a stage, the code requires that there be a minimum of two vents provided for redundancy. Those vents are to be located near the center and above the highest part of the stage, since this is the point at which smoke and hot gases are likely to accumulate. The minimum aggregate clear opening area of the vents is required to be 5 percent of the floor area of the stage. The vents must open automatically by approved heat-activated devices, often fusible links, and must also be operable by a supplemental manual means. The manual means serves as a backup to the automatic detectors and permits the vent to be opened as a precaution prior to achieving the heat required to activate the heat device. The vents are to be provided with curbs as required for skylights in Section 2610.2. In addition, the vents must be labeled by an approved agency (see Section 1703.5 for further labeling requirements).

[4] 410.3.7.2 Smoke control. Smoke control in accordance with Section 909 shall be provided to maintain the smoke layer interface not less than 6 feet (1829 mm) above the highest level of the assembly seating or above the top of the proscenium opening where a proscenium wall is provided in compliance with Section 410.3.4.

In addition to roof vents, another option for emergency ventilation of stages is provided in this section (i.e., smoke control). This section, in concert with the provisions contained in Section 909, provides the criteria for smoke control for stages larger than 1,000 square feet (93 m²) in floor area or with a stage height greater than 50 feet (15 240 mm). In such cases, the
smoke layer interface must be maintained 6 feet (1829 mm) above the highest level of the assembly seating or above the top of the proscenium opening when one is provided. The smoke layer is maintained 6 feet (1829 mm) above the proscenium opening in order to prevent smoke from entering into the audience area.

410.4 Platform construction. Permanent platforms shall be constructed of materials as required for the type of construction of the building in which the permanent platform is located. Permanent platforms are permitted to be constructed of fire-retardant-treated wood for Types I, II and IV construction where the platforms are not more than 30 inches (762 mm) above the main floor, and not more than one-third of the room floor area and not more than 3,000 square feet (279 m²) in area. Where the space beneath the permanent platform is used for storage or any purpose other than equipment, wiring or plumbing, the floor assembly shall not be less than 1-hour fire-resistance-rated construction. Where the space beneath the permanent platform is used only for equipment, wiring or plumbing, the underside of the permanent platform need not be protected.

This section establishes the scope of the code requirements for platform construction. A permanent platform is basically raised floor construction. As such, the construction must be consistent with that of all the floors in the building.

Permanent platforms can be of fire-retardant-treated wood in limited applications. In buildings of Type I, II or IV construction, platforms can be of fire-retardant-treated wood if they are no more than 30 inches (762 mm) in height, are no more than one-third of the floor area of the room and are 3,000 square feet (279 m²) or less in area. A platform that meets these three size limits poses a small fire risk relative to the normal fuel load in the room. As such, the platform deck and its supporting construction can be of fire-retardant-treated wood materials. If the platform exceeds any one of the three size limits, then it must be constructed of materials consistent with the building's type of construction classification. A basic premise of Section 410.4 is that the platform must not significantly increase the fire hazard of the space or building. As such, the space beneath platforms is regulated to appropriately abate the risk. Where the space beneath a permanent platform is utilized for any purpose other than electrical wiring or plumbing, the platform is to have a 1-hour fire-resistance rating. The purpose of the fire-resistance rating requirement is to provide some structural integrity to the platform should a fire occur in the concealed space. In the case of permanent platforms where the space beneath the platform is only used for plumbing or electrical wiring, no further protection is required since the fire risk will be minimal.

410.4.1 Temporary platforms. Platforms installed for a period of not more than 30 days are permitted to be constructed of any materials permitted by the code. The space between the floor and the platform above shall only be used for plumbing and electrical wiring to platform equipment.

Temporary platforms may be constructed of any material regardless of the building's construction classification due to their limited time of use and their normally limited size and fuel load. Because temporary platforms are permitted to be constructed of any approved material, the space beneath a temporary platform may never be used for any purpose other than electrical wiring or plumbing to the platform equipment. Such lines serving other areas may not be located beneath a temporary platform.

410.5 Dressing and appurtenant rooms. Dressing and appurtenant rooms shall comply with Sections 410.5.1 and 410.5.2.

Because stages are open to the viewing audience and typically contain a substantial fuel load, it is essential to contain fires in rooms around the stage to the room of origin; therefore, this section contains provisions for the separation of such areas from the stage and from one another.

410.5.1 Separation from stage. The stage shall be separated from dressing rooms, scene docks, property rooms, workshops, storerooms and compartments appurtenant to the stage and other parts of the building by fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both. The fire-resistance rating shall be not less than 2 hours for stage heights greater than 50 feet (15 240 mm) and not less than 1 hour for stage heights of 50 feet (15 240 mm) or less.

Separation of the stage from appurtenant rooms provides a significant level of fire containment. Such containment is fundamental to limiting the spread of fire from adjacent spaces to the stage area, as well as the growth of fires in the stage area itself. The 2-hour fire-resistance rating for stages with a height greater than 50 feet (15 240 mm), such as large theatrical stages, acknowledges the significant potential for a large fuel load and is consistent with the 2-hour rating of Section 410.3.4. Although stages with a height of 50 feet (15 240 mm) or less represent a limited potential fuel load, a 1-hour fire-resistance rating will provide an additional level of compartmentation in the event a fire originates at the stage (which may not be sprinklered if the stage complies with Section 410.7, Exception 2). Such stages are likely to be found in educational occupancies or meeting halls.

410.5.2 Separation from each other. Dressing rooms, scene docks, property rooms, workshops, storerooms and compartments appurtenant to the stage shall be separated from each other by not less than 1-hour fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both.

As an additional level of protection, rooms and compartments appurtenant to the stage must be separated from one another by an approved 1-hour fire-
resistance-rated fire barrier and horizontal assemblies. Rooms appurtenant to the stage often have very high fuel loads (i.e., property rooms and activities with a history of fire incidents, such as scenery workshops). This additional level of fire containment is intended to minimize fire growth and limit fires in these areas to the room of origin.

410.6 Means of egress. Except as modified or as provided for in this section, the provisions of Chapter 10 shall apply.

- The general means of egress requirements in Chapter 10 are applicable to stages, platforms and technical production areas except where modified by this section. The modifications provided in this section provide adjustments to the Chapter 10 general egress provisions because of the uniqueness of stage areas.

410.6.1 Arrangement. Where two or more exits or exit access doorways from the stage are required in accordance with Section 1015.1, no fewer than one exit or exit access doorway shall be provided on each side of a stage.

- Because of the relative fire hazards associated with stages, this section requires that a minimum of one approved means of egress be provided from each side of the stage if at least two means of egress are required based on the provisions of Section 1015.1. This is intended to provide the occupants of a stage ready access to evacuate the stage area in the event of a fire. Where the occupant load of the stage is such that only one means of egress is required by Section 1015.1, then it is not necessary to provide an exit or exit access doorway on both sides of the stage.

410.6.2 Stairway and ramp enclosure. Exit access stairways and ramps serving a stage or platform are not required to be enclosed. Exit access stairways serving technical production areas are not required to be enclosed.

- Exit access stairways that serve a stage, platform or technical production areas do not require enclosure due to the nature of the activities involved.

410.6.3 Technical production areas. Technical production areas shall be provided with means of egress and means of escape in accordance with Sections 410.6.3.1 through 410.6.3.5.

- A variety of special means of egress provisions are provided for technical production areas that take into account the unique characteristics of such areas. Defined in Section 202, technical production areas include all technical support areas regardless of their traditional name (fly gallery, gridiron). The provisions of Section 410.6.3 reflect the special allowances for minimum number of means of egress, maximum travel distance, allowable exit access components and minimum travel path width. It should be noted that these provisions are also applicable to those "technical production areas" that are not necessarily associated with a stage or platform, such as those that are present at a sports arena or stadium.

410.6.3.1 Means of egress. No fewer than one means of egress shall be provided from technical production areas.

- Fly galleries, gridirons and other technical production areas are ordinarily occupied by a few persons at any one time who are likely to be very familiar with the stage operations. As such, these areas need only be provided with one approved means of egress.

410.6.3.2 Travel distance. The length of exit access travel shall be not greater than 300 feet (91 440 mm) for buildings without a sprinkler system and 400 feet (121 900 mm) for buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1.

- The travel distance limitations reflect the limited hazard presented by technical production areas, the limited number of persons affected, and the necessary extent of such areas that would cause such distances to be reasonable.

410.6.3.3 Two means of egress. Where two means of egress are required, the common path of travel shall be not greater than 100 feet (30 480 mm).

Exception: A means of escape to a roof in place of a second means of egress is permitted.

- In those cases where a second means of egress from a technical production area is required, typically where the travel distance limits of Section 410.6.3.2 cannot be met, it is necessary to limit the common path of travel to 100 feet (30 480). This ensures that limited occupant travel will be necessary before the occupants have a choice of two paths that lead to the two required means of egress. The exception permits one of the means of egress to lead to the roof where at least two means of egress are provided.

410.6.3.4 Path of egress travel. The following exit access components are permitted where serving technical production areas:

1. Stairways.
2. Ramps.
3. Spiral stairways.
5. Alternating tread devices.
6. Permanent ladders.

- Due to the reduced hazards previously described, a variety of exit access components may be utilized throughout the means of egress serving technical production areas. In addition to stairways and ramps, the egress path may include spiral stairways as addressed in Section 1009.12, alternating tread devices as described in Section 1009.13, and permanent ladders.

410.6.3.5 Width. The path of egress travel within and from technical support areas shall be not less than 22 inches (559 mm).

- Since the means of egress from a technical production area will not be used by the public nor will it serve
a significant occupant load, it is considered acceptable that a reduced egress width be provided. The required minimum width of 22 inches (559 mm) is applicable to all of the exit access components serving only the technical production areas, including stairways, ramps, spiral stairways, alternating tread devices and permanent ladders, where provided.

[F] 410.7 Automatic sprinkler system. Stages shall be equipped with an automatic sprinkler system in accordance with Section 903.3.1.1. Sprinklers shall be installed under the roof and gridiron and under all catwalks and galleries over the stage. Sprinklers shall be installed in dressing rooms, performer lounges, shops and storerooms accessory to such stages.

Exceptions:

1. Sprinklers are not required under stage areas less than 4 feet (1219 mm) in clear height that are utilized exclusively for storage of tables and chairs, provided the concealed space is separated from the adjacent spaces by not Type X gypsum board not less than 1/2 inch (15.9 mm) in thickness.

2. Sprinklers are not required for stages 1,000 square feet (93 m²) or less in area and 50 feet (15 240 mm) or less in height where curtains, scenery or other combustible hangings are not retractable vertically. Combustible hangings shall be limited to a single main curtain, borders, legs and a single backdrop.

3. Sprinklers are not required within portable orchestra enclosures on stages.

Stages contain significant quantities of combustible materials stored in, around and above the stage that are located in close proximity to large quantities of lighting equipment (i.e., scenery and lighting above the stage). There also is scenery on the sides and rear of the stage; shops located along the back and sides of the stage, and storage, props, trap doors and lifts under the stage floor. This combination of fuel load and ignition sources increases the potential for a fire. As such, stages and technical production areas, such as dressing rooms, workshops and storerooms, are required to be protected with an automatic sprinkler system.

The references to Chapter 9 indicate that the sprinkler system may be designed in accordance with NFPA 13 and Section 903.3.1.1 or, if not more than 20 sprinklers are required on any single connection, a limited area sprinkler system may be used (see Section 903.3.5.1.1).

Exception 1 applies to areas less than 4 feet (1219 mm) in clear height under stages that are used only for the storage of tables and chairs. Because of the limited fuel load present, such areas are not required to be protected with sprinklers, provided that the concealed space is separated from all adjacent spaces by no less than 1/2 inch (15.9 mm) Type X gypsum board. This level of separation is intended to provide fire containment in the absence of sprinkler protection. This arrangement is often found in educational buildings where the room is used as a multipurpose room.

Exception 2 recognizes that stages 1,000 square feet (93 m²) or less in area and 50 feet (15 240 mm) or less in height represent a limited potential for combustibles that does not warrant the requirements for an automatic sprinkler system. The code further limits the amounts of combustible materials by not allowing any vertical retractable curtains, hangings and similar scenery elements. It should be noted, however, that although sprinkler protection is not required, the requirements of Section 410.5 still apply.

Exception 3 acknowledges the limited hazards associated with portable orchestra enclosures. These elements are temporary in nature and are intended to improve the acoustics of the stage performances. These temporary enclosures do not lend themselves to temporary sprinkler heads; therefore, none are required.

[F] 410.8 Standpipes. Standpipe systems shall be provided in accordance with Section 905.

Because of the potentially large fuel load and threedimensional aspect of the fire hazard associated with stages greater than 1,000 square feet (93 m²) in area, a Class III wet standpipe system is required on each side of such stages. The standpipes are required to be equipped with both a 1½-inch (38 mm) and 2½-inch (64 mm) hose connection. The required design criteria for the standpipe system, including hoses and cabinets, is specified in Section 903.3.4.

SECTION 411
SPECIAL AMUSEMENT BUILDINGS

411.1 General. Special amusement buildings having an occupant load of 50 or more shall comply with the requirements for the appropriate Group A occupancy and Sections 411.1 through 411.8. Amusement buildings having an occupant load of less than 50 shall comply with the requirements for a Group B occupancy and Sections 411.1 through 411.8.

Exception: Amusement buildings or portions thereof that are without walls or a roof and constructed to prevent the accumulation of smoke need not comply with this section.

For flammable decorative materials, see the International Fire Code.

A special amusement building is one in which the egress is not readily apparent, is intentionally confused or is not readily available (see Section 411.2). This section addresses the hazards associated with such use by requiring automatic fire detection (see Section 411.3), automatic sprinkler protection (see Section 411.4), alarm requirements (see Section 411.5), an emergency voice/alarm communication system (see Section 411.6) and specific means of egress lighting and marking (see Section 411.7). Additionally, only interior finish materials that
meet the most stringent flame spread classification, Class A, are permitted in special amusement buildings.

In addition to the provisions of this section, other applicable requirements, such as means of egress (i.e., occupant load and travel distance) and building construction (i.e., type of construction, and fire-resistance ratings), apply in accordance with the appropriate assembly group classification (see Section 303.1).

Special amusement buildings are considered assembly uses based on the definition in Section 303.1. This section further specifies that a Group A classification is only applicable when the building's design occupant load is 50 or more. The provisions of this section apply in addition to the other requirements for the appropriate assembly use, usually Group A-1 or A-3. Very small special amusement buildings are not required to be classified as Group A. If the design occupant load is less than 50, then the building is classified as Group B. This acknowledges the lesser hazards associated with smaller groups of people. Although smaller buildings are classified as Group B, they must still meet the requirements of this section as special amusement buildings.

Section 411 does not apply to a facility that is constructed to permit the free and immediate ventilation of the products of combustion to the outside. Such free and immediate ventilation addresses the hazard associated with many special amusement buildings relative to the rapid accumulation of smoke in a building in which the egress is not readily apparent, confounded or not readily available.

All flammable decorative materials used in special amusement buildings are required to follow the provisions of the IFC. The use of flammable and combustible materials in these types of buildings must be strictly regulated to limit the fire hazards to the building occupants (refer to Chapter 8 of the IFC for those restrictions).

411.2 Definition. The following term is defined in Chapter 2:

SPECIAL AMUSEMENT BUILDING.

❖ This section lists terms that are specifically associated with the subject matter of Section 411. It is important to emphasize that these terms are not exclusively related to this chapter but may or may not also be applicable where the term is used elsewhere in the code.

Definitions of terms can help in the understanding and application of the code requirements. The purpose for including a list within this chapter is to provide more convenient access to terms which may have a specific or limited application within this chapter. For the complete definition and associated commentary, refer back to Chapter 2. Terms that are italicized provide a visual identification throughout the code that a definition exists for that term. The use and application of all defined terms are set forth in Section 201.
shall be provided in accordance with Sections 907.2.12 and 907.5.2.2, which is also permitted to serve as a public address system and shall be audible throughout the entire special amusement building.

- An integral part of the fire protection systems required for special amusement buildings is an emergency voice/alarm communications system. This system can serve as a public address system to alert the building occupants of the fire emergency and provide them with the proper emergency instructions. The system must be installed in accordance with NFPA 72 and must be heard throughout the entire special amusement building. Upon activation, the system must sound an alert tone followed by the necessary voice instructions. These instructions can save valuable time in directing the building occupants to quickly and safely egress.

**411.7 Exit marking.** Exit signs shall be installed at the required exit or exit access doorways of amusement buildings in accordance with this section and Section 1011. Approved directional exit markings shall also be provided. Where mirrors, mazes or other designs are utilized that disguise the path of egress travel such that they are not apparent, approved and listed low-level exit signs that comply with Section 1011.5, and directional path markings listed in accordance with UL 1994, shall be provided and located not more than 8 inches (203 mm) above the walking surface and on or near the path of egress travel. Such markings shall become visible in an emergency. The directional exit marking shall be activated by the automatic fire detection system and the automatic sprinkler system in accordance with Section 907.2.12.2.

- During normal operation of a special amusement building, the illumination and marking of the egress path may not be adequate to allow for prompt egress from the building. This section clearly reminds the reader that exit signs must be provided at the required exit or exit access doors, and comply with the requirements of Section 1011. As special amusement spaces quite often consist of low-level lighting and/or spaces and features that can confuse a person’s orientation, exit signs are required regardless of the number of required means of egress. Where obstructions and confusion may still exist because of the nature of the facility, low-level exit signs and directional path markings (listed in accordance with UL 1994) must be provided and located not higher than 8 inches (203 mm) above the walking surface in order to direct the occupants toward the exits. In an emergency, activation of the automatic fire detection system or automatic sprinkler system must activate the directional exit markings to become visible.

**411.7.1 Photo luminescent exit signs.** Where photo luminescent exit signs are installed, activating light source and viewing distance shall be in accordance with the listing and markings of the signs.

- Photo luminescent exit signs operate due to exposure to specific sources of light as indicated in their listing and labeling. In some situations, not all types of photo luminescent exit signs can be used and, as such, the normal lighting levels in the area where such exit signs are to be installed must be assessed to verify compatibility.

**411.8 Interior finish.** The interior finish shall be Class A in accordance with Section 803.1.

- All interior finish materials must be tested for surface-burning performance in accordance with ASTM E 84 or UL 723. Due to the potential for fire to spread quickly in the relatively confined spaces in these structures, only Class A materials are permitted to be used as interior finish in a special amusement building. These special amusement buildings are not permitted the one classification reduction that would normally be allowed by Table 803.9 in a sprinklered building.

**SECTION 412
AIRCRAFT-RELATED OCCUPANCIES**

**412.1 General.** Aircraft-related occupancies shall comply with Sections 412.1 through 412.7 and the International Fire Code.

- Section 412 provides specific details for the construction of the full range of aircraft-related occupancies from residential aircraft hangars to those handling large commercial aircraft, as well as heliports and airports. This section contains code requirements for some very specialized occupancies dealing with aircraft. Aircraft pose some of the same hazards associated with motor vehicles; therefore, some of the same requirements are applicable for life and fire safety issues. The unique issues surrounding aircraft traffic control towers are addressed in Section 412.3.

Sections 412.4 and 412.5 are composed of code provisions that regulate both commercial and residential aircraft hangars. The overall building fire load for hangars is typically low because of the considerable amount of metal in the aircraft that can absorb heat and provide limited combustibility to sustain a fire. An aircraft fire, however, can be quite severe because of the flammability of the fuel contained in its tanks. Provisions for regulating the exterior walls, basements and floor surfaces of commercial aircraft hangars are specified along with separation and fire suppression requirements.

Section 412.6 addresses specialized hangars that are used for the painting of aircraft with flammable materials. Just as Section 416 contains limitations and requirements for the application of flammable finishes, so does Section 412.6 for aircraft paint hangars. Use and occupancy requirements commensurate with the hazards are provided, including construction, fire protection systems and necessary ventilation.

Lastly, Section 412.7 identifies those code requirements applicable to helicopter landing and service ports. Although the code relies heavily on the require-
ments of NFPA 418 for heliports and helistops located on the roofs of buildings and structures, there are provisions applicable for all locations. This section contains requirements for size limitations, design and means of egress.

There are additional requirements applicable to these occupancies in Chapter 11 of the IFC, Aviation Facilities, as well as other chapters of the IFC.

412.2 Definitions. The following terms are defined in Chapter 2:

**FIXED BASE OPERATOR (FBO).**

**HELISTOP.**

**RESIDENTIAL AIRCRAFT HANGAR.**

**TRANSIENT AIRCRAFT.**

- This section lists terms that are specifically associated with the subject matter of Section 412. It is important to emphasize that these terms are not exclusively related to this chapter but may or may not also be applicable where the term is used elsewhere in the code.

Definitions of terms can help in the understanding and application of the code requirements. The purpose for including a list within this chapter is to provide more convenient access to terms which may have a specific or limited application within this chapter. For the complete definition and associated commentary, refer back to Chapter 2. Terms that are italicized provide a visual identification throughout the code that a definition exists for that term. The use and application of all defined terms are set forth in Section 201.

412.3 Airport traffic control towers. The provisions of Sections 412.3.1 through 412.3.5 shall apply to airport traffic control towers not exceeding 1,500 square feet (140 m²) per floor occupied only for the following uses:

1. Air traffic control cab.
2. Electrical and mechanical equipment rooms.
3. Airport terminal radar and electronics rooms.
4. Office spaces incidental to the tower operation.
5. Lounges for employees, including sanitary facilities.

- Section 412.3 addresses airport traffic control towers. Although these structures do not house aircraft, they are included in this section for consistency. These structures pose unique hazards to occupants because of their extreme height and limited routes of escape. This section contains requirements governing the permitted types of construction and necessary egress along with the needed fire protection systems.

Airport traffic control towers are structures designed for highly specific functions. These functions include the housing of vital electronic equipment, providing an elevated structure for electronic communication, such as radar, and providing an observation area that allows an unobstructed view of the ground and airspace for air traffic controllers. This functional configuration creates special hazards, including limited means of egress, limited fire-fighting accessibility to upper floors and vulnerability to exposure fires. The code provisions are based on providing adequate fire protection and life safety to a small number of occupants within a limited area [1,500 square feet (139 m²) per floor maximum], while allowing a structure configuration that accommodates the intended function. The intent of the code is to restrict the fuel load by limiting the structure construction to mostly noncombustible materials; minimizing combustible contents and potential ignition sources by limiting the use of the structure; providing automatic fire detection systems, adequate and reliable egress and fire department access; and providing standby power in towers over 65 feet (19.812 m) in height. These measures result in prompt evacuation and fire department accessibility early in a fire event.

This section applies only to airport traffic control towers that do not exceed 1,500 square feet (139 m²) per floor and are limited to uses exclusively related to air traffic control purposes. Rooms and spaces related to the air traffic control function, such as equipment rooms, offices, lounges and restrooms, are permitted in the tower. The section does not apply to air traffic control towers containing other uses, including assembly areas, observation decks, restaurants and terminal operations. The 1,500-square-foot (139 m²) restriction is based, in part, on a survey of existing towers that would fall within the above restrictions. Regardless of the height of control towers, they are not considered high-rise buildings, and therefore they are exempt from Section 403.

412.3.1 Type of construction. Airport traffic control towers shall be constructed to comply with the height and area limitations of Table 412.3.2.

- The limited area per floor, low fuel load, adequate egress provisions and low occupant load present a relatively low potential fire hazard. The provisions of Table 503 are, therefore, modified by Table 412.3.1. The allowable height and area modifications permitted by Sections 504 and 506 do not apply to Table 412.3.1.

For SI: 1 foot = 304.8 mm, 1 square foot = 0.0929 m².

a. Height to be measured from grade plane to cab floor.

- Table 412.3.1 functions the same as Table 503, except that the height restriction is based on feet only.
and not on stories, and the actual height is measured from grade plane to the finished floor of the cab or the highest occupied level. The number of stories is not a criterion, since many of the towers do not have occupied stories for the entire height between the ground and the occupiable level at the top. If the type of construction is known, the allowable height is given by the corresponding figure in the second column. If the height is known, the permitted construction types are determined from the first column. The third column restates the area-per-floor restriction given in Section 412.3.

412.3.2 Egress. Not less than one exit stairway shall be permitted for airport traffic control towers of any height provided that the occupant load per floor is not greater than 15. The stairway shall conform to the requirements of Section 1009. The stairway shall be separated from elevators by a distance of not less than one-half of the diagonal of the area served measured in a straight line. The exit stairway and elevator hoistway are permitted to be located in the same shaft enclosure, provided they are separated from each other by a 4-hour fire barrier having no openings. Such stairway shall be pressurized to not less than 0.15 inch of water column (43 Pa) and not greater than 0.35 inch of water column (101 Pa) in the shaft relative to the building with stairway doors closed. Stairways need not extend to the roof as specified in Section 1009.16. The provisions of Section 403 do not apply.

Exception: Smokeproof enclosures as set forth in Section 1022.10 are not required where required stairways are pressurized.

- The benefit of a second exit in a tower-type structure is greatly reduced when the two exits would be in very close proximity. With the low fuel load, limited area per floor and limited number of occupants, only one exit is required per floor provided that the occupant load of each floor is 15 or less. The occupant load restriction of 15 persons is based on the calculated occupant load for a business use (1:100), with a maximum tower floor area of 1,500 square feet (139 m²) (see Table 1004.1.1).

Since only one exit stairway is provided, elevators must be remotely located from the stairway a distance of one-half of the diagonal of the area served, as if they were the second required exit. If conditions are such that the stairway is not usable but the elevators are, the elevators provide an alternative escape route from the tower and fire department access to each floor level. The elevators are to be considered an egress route only if the stairway is not usable.

The code does permit the required exit stairway and the normally provided elevator to be in the same shaft enclosure; however, to maintain their independence and usability, a 4-hour separation is required between the two building features. No intercommunicating openings are permitted between these two elements to increase the likelihood that one will remain operational during a fire situation. Additionally, an exit stairway located in the same shaft enclosure as the elevator hoistway must be pressurized in accordance with Section 909.20.5.

The exit stairway for an airport traffic control tower does not need to provide roof access. Because of the limited area of these buildings, the fire department most likely will not need access to the roof for firefighting operations. Roof access for repair and mechanical equipment maintenance is not mandated by the code. This section of the code also notes that the requirements for high-rise buildings in regards to stairway door operations and communication are also not applicable because of the limited occupant load.

Finally, an exception is provided for smokeproof enclosures. Assuming that the exit stairway is not in the same shaft enclosure as the elevator hoistway, the stairway must still be a smokeproof enclosure in accordance with Section 1022.10. Alternatively, the required exit stairway may be pressurized in accordance with Section 909.20.5. These provisions serve to maintain the required means of egress as the building occupants travel large vertical distances to the discharge doors and the public way.

[F] 412.3.3 Automatic fire detection systems. Airport traffic control towers shall be provided with an automatic fire detection system installed in accordance with Section 907.2.

- To ensure early fire detection and to alert the occupants to egress the building during the incipient stage of a fire event, an automatic smoke detection system is required in accordance with Section 907.2.22. The code does not require an automatic sprinkler system because of the limited fuel load, limited occupant load and protection afforded by early detection.

[F] 412.3.4 Standby power. A standby power system that conforms to Chapter 27 shall be provided in airport traffic control towers more than 65 feet (19 812 mm) in height. Power shall be provided to the following equipment:

1. Pressurization equipment, mechanical equipment and lighting.
2. Elevator operating equipment.
3. Fire alarm and smoke detection systems.

- To increase the reliability of the protection afforded by equipment provided for egress and fire department accessibility, a standby power system is required in airport traffic control towers that exceed 65 feet (19 812 mm) in height. The system must support the pressurization and mechanical equipment, egress illumination, elevator operation, fire alarm system and the automatic fire detection system. Height is measured in accordance with the definition found in Section 202. If the pressurized stairway alternatives in Section 412.3.2 are utilized, the mechanical equipment required to pressurize the stairway must be connected to the standby power system to provide the same degree of reliability required for the smokeproof enclosure. The reference to Chapter 27 incorporates some of the same standby power requirements contained under the high-rise provisions based on the premise that towers over 65 feet (19 812 mm)
in height represent similar hazards to those of high-rise buildings.

412.3.5 Accessibility. Airport traffic control towers need not be accessible as specified in the provisions of Chapter 11.

- Airport traffic control towers are not required to have an accessible route to the cab and the floor immediately below the cab (see Section 1104.4, Exception 3). Other areas of the control tower are typically employee work stations, which must be connected by an accessible route so that such stations can be approached, entered and exited (see Sections 1103.2.3 and 1104.3.1)

412.4 Aircraft hangars. Aircraft hangars shall be in accordance with Sections 412.4.1 through 412.4.6.

- The requirements of Section 412.4 address commercial (or nonresidential) aircraft hangars. It should be noted that most commercial aircraft hangars will not be limited in height in terms of feet (see Section 504.1) or in area (see Section 507) based on the presence of an automatic sprinkler system. All commercial aircraft hangars, however, must be regulated in regards to exterior wall fire-resistance ratings, basement limitations, floor surface construction requirements, heating equipment separation and finishing restrictions. All of these provisions serve to abate the hazards associated with large aircraft and their integral fuel tanks to acceptable fire safety levels.

412.4.1 Exterior walls. Exterior walls located less than 30 feet (9144 mm) from lot lines or a public way shall have a fire-resistance rating not less than 2 hours.

- To abate the hazards of a fire condition from spreading from a commercial aircraft hangar to adjacent buildings and structures, the code requires exterior walls that are located less than 30 feet (9144 mm) from lot lines or public ways to have fire-resistance-rated construction of not less than 2 hours. Fire-resistance-rated exterior walls permit the fire department additional time and protection as it attempts to take control of a fire situation in a hangar located less than 30 feet (9144 mm) from the lot lines or public ways.

412.4.2 Basements. Where hangars have basements, floors over basements shall be of Type IA construction and shall be made tight against seepage of water, oil or vapors. There shall be no opening or communication between basements and the hangar. Access to basements shall be from outside only.

- As part of the hangar requirements, the use and separation of any basement levels are rigidly controlled. A fire in the main level of a hangar could pose a severe hazard not only to the occupants of basements but also to the fire department itself. The floor/ceiling assembly located between the hangar and the first basement level below must be of Type IA construction. With a floor of 2-hour fire-resistance-rated construction along with the supporting construction, a fire on the main level should be contained. Not only is the floor construction required to be rated, but it must be properly sealed or otherwise made waterproof. This requirement prevents the chances of a fire or other liquids and vapors from seeping into the floor construction and leaking into the basement level. Further, the code prohibits any openings or access between the main level of the hangar and the basement level. This would include fire-resistance-rated shafts. Any opening into the basement has to be made from the exterior of the structure via area way construction.

412.4.3 Floor surface. Floors shall be graded and drained to prevent water or fuel from remaining on the floor. Floor drains shall discharge through an oil separator to the sewer or to an outside vented sump.

Exception: Aircraft hangars with individual lease spaces not exceeding 2,000 square feet (186 m²) each in which servicing, repairing or washing is not conducted and fuel is not dispensed shall have floors that are graded toward the door, but shall not require a separator.

- These provisions go hand in hand with the waterproof requirements of Section 412.4.2. The floors of all hangars must be positively sloped to prevent standing liquids. This requirement is not only for personnel safety but also to minimize the effects of any spilled flammable liquids. Floor drains, if provided, must discharge their contents into an oil separator or an outside sump. This prevents the flammable liquids from entering the jurisdiction's sewer system and causing additional hazards.

An exception has been included for those commercial aircraft hangars that are divided into individual tenant or lease spaces. Hangars with tenant or lease spaces of 2,000 square feet (186 m²) or less in area do not pose the same overall hazard. The likelihood of all the aircraft being used at the same time is remote; therefore, the hazard of ponding water or spilled fuel is remote. The floor surfaces of small aircraft hangar tenant or lease spaces only need to be sloped towards the main exterior wall openings. It is imperative that no other servicing, repair work or aircraft washing is done and that no fuel dispensing can occur in these small tenant lease spaces.

412.4.4 Heating equipment. Heating equipment shall be placed in another room separated by 2-hour fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both. Entrance shall be from the outside or by means of a vestibule providing a two-doorway separation.

Exceptions:

1. Unit heaters and vented infrared radiant heating equipment suspended not less than 10 feet (3048 mm) above the upper surface of wings or engine enclosures of the highest aircraft that are permitted to be housed in the hangar need not be located in a separate room provided they are mounted not less than 8 feet (2438 mm) above the floor in shops, offices and other sections of the hangar communicating with storage or service areas.
2. Entrance to the separated room shall be permitted by a single interior door provided the sources of ignition in the appliances are not less than 18 inches (457 mm) above the floor.

- As part of the special use and occupancy requirements for commercial aircraft hangars, all possible ignition sources must be controlled and isolated. Specifically, all heating equipment must be located in rooms that are separated from the main areas where the aircraft are parked. This separation (both fire barrier walls and horizontal assemblies) must be 2-hour fire-resistance-rated construction. Although not explicitly stated, all openings through the rated walls must be protected. Doors connecting the heating equipment rooms and the main hangar area must be done with a vestibule or airlock arrangement such that one must pass through two doors prior to entering the other room. Again, this is done to minimize the possibility of any spilled flammable liquids and the resulting vapors from coming in contact with the ignition sources of the heating equipment.

Two exceptions to the separation requirements are provided. Unit heaters or vented infrared radiant heating equipment that are carefully located high above not only the floor surfaces but also the fuel tanks and engine compartments of the aircraft pose little risk. An allowance is also made if the heating equipment is located at least 18 inches (457 mm) above the floor of the separated room. In such a case, the vestibule/airlock arrangement with a double door system is not required and can be done with just a single door. If either exception is used, care must be taken by the building and fire officials that these special stipulations and conditions are part of the certificate of occupancy.

412.4.5 Finishing. The process of "doping," involving use of a volatile flammable solvent, or of painting, shall be carried on in a separate detached building equipped with automatic fire-extinguishing equipment in accordance with Section 903.

- Any application of spraying or "doping" of flammable finishes or solvent treatments to aircraft is prohibited within the hangar. These types of operations must be done in a separate detached building that is provided with an automatic fire-extinguishing system. Although not specifically stated here, the intent of the code is to treat those types of buildings as an aircraft paint hangar in accordance with Section 412.6.

Doping is a type of lacquer used to protect, waterproof and make taut cloth surfaces of airplane wings. It is used on lighter-than-air, ultra-light and some light aircraft. It is essentially painting on fabric. Doping is not used on metallic surfaces; however, the use of flammable paints is also addressed in this section. When flammable finishes are applied, the process must occur in a separate building not attached to the hangar. Because the code text refers to Section 903, the intent is for an automatic sprinkler system to be installed, unless otherwise approved.

[F] 412.4.6 Fire suppression. Aircraft hangars shall be provided with a fire suppression system designed in accordance with NFPA 409, based upon the classification for the hangar given in Table 412.4.6.

Exception: Where a fixed base operator has separate repair facilities on site, Group II hangars operated by a fixed base operator used for storage of transient aircraft only shall have a fire suppression system, but the system is exempt from foam requirements.

- To minimize the fire hazards associated with aircraft hangars, most hangars are required to be protected with a fire suppression system. Where required, the fire suppression system must be designed and installed in accordance with NFPA 409, which requires fire suppression based on the type and construction, and the activities in a given hangar. In the standard, the suppression requirements are broken down based on three categories: Group I, Group II and Group III. Table 412.4.6 designates which group designation applies to various sizes of fire areas within a hangar and the type of construction. For example a hangar that is 28,000 square feet (2601 m²) in Type IIIB construction is a Group II hangar. Group I and II hangars are required to have fire suppression as specified in NFPA 409. In general, Group III hangars are exempt from providing fire suppression unless one or more of the hazardous operations listed in Section 412.4.6.1 occur within the hangar. In these situations fire suppression based on the appropriate portion of the standard for either Group I or II is required.

The exception would not require a foam system for Group II hangars if the hangar is essentially a parking garage for transient aircraft. The exception would likely only be applicable at a larger airport facility that has multiple hangars and separate hangars for repair operations.

TABLE 412.4.6. See page 4-88.

- As discussed Table 412.4.6 simply determines which hangar classification to which the fire suppression must be designed in accordance with NFPA 409. This is based upon the construction type of each building and its floor area. Table 412.4.6. Note a indicates that regardless of size or construction type, any hangar with a door opening greater than 28 feet high (8534 mm) requires that hangar to have fire suppression system required for a Group I. Note c provides a Group IV designation for any hangar located in a membrane structure.

[F] 412.4.6.1 Hazardous operations. Any Group III aircraft hangar according to Table 412.4.6 that contains hazardous operations including, but not limited to, the following shall be provided with a Group I or II fire suppression system in accordance with NFPA 409 as applicable:

1. Doping.
2. Hot work including, but not limited to, welding, torch cutting and torch soldering.
3. Fuel transfer.

4. Fuel tank repair or maintenance not including defueled tanks in accordance with NFPA 409, inerted tanks or tanks that have never been fueled.

5. Spray finishing operations.

6. Total fuel capacity of all aircraft within the unsprinklered single fire area in excess of 1,600 gallons (6057 L).

7. Total fuel capacity of all aircraft within the maximum single fire area in excess of 7,500 gallons (28,390 L) for a hangar with an automatic sprinkler system in accordance with Section 903.3.1.1.

- Any of the operations listed in Section 412.6.1 which are occurring in a Group III hangar will require, under NFPA 409, some level of fire suppression. The operations on the list are straightforward. Doping is clarified in Section 412.4.5.

[F] 412.4.6.2 Separation of maximum single fire areas. Maximum single fire areas established in accordance with hangar classification and construction type in Table 412.4.6 shall be separated by 2-hour fire walls constructed in accordance with Section 706. In determining the maximum single fire area as set forth in Table 412.4.6, ancillary uses which are separated from aircraft servicing areas by a fire barrier of not less than one hour, constructed in accordance with Section 707 shall not be included in the area.

- The classification of aircraft hangars for fire suppression purposes is based on the hangar's type of construction and fire area size. Fire area size is based on the aggregate floor area bounded by exterior walls and 2-hour fire walls where provided. For the purposes of hangar classification, ancillary uses located within the fire area are not required to be included in the fire area size provided they are separated from the aircraft servicing area by minimum 1-hour fire barriers.

Many times there are ancillary areas associated with an aircraft hangar, such as offices, maintenance shops and storage rooms. Since the fire suppression requirements of NFPA 409 are primarily for the protection of aircraft within the storage and servicing area, inclusion of the floor area of the ancillary spaces into the fire suppression criteria is considered unnecessary. The fire protection requirements in the ancillary areas are considered to be less extensive than those required for the aircraft servicing and storage areas. Therefore, their inclusion in the application of Table 412.4.6 for fire area size is not required where a limited degree of fire separation is provided.

In order to be exempted from the fire area calculation within the aircraft hangar, it is necessary that the ancillary areas be separated from the aircraft storage and servicing areas by minimum 1-hour fire barriers. The 1-hour requirement intends to provide an acceptable fire separation without the creation of additional fire areas that would require separation by 2-hour fire walls.

For SI: 1 foot = 304.8 mm, 1 square foot = 0.0929 m².

a. Aircraft hangars with a door height greater than 28 feet shall be provided with fire suppression for a Group I hangar regardless of maximum fire area.

b. Groups shall be classified in accordance with NFPA 409.

c. Membrane structures complying with Section 3102 shall be classified as a Group IV hangar.
412.5.1 Fire separation. A hangar shall not be attached to a dwelling unless separated by a fire barrier having a fire-resistance rating of not less than 1 hour. Such separation shall be continuous from the foundation to the underside of the roof and unpecked except for doors leading to the dwelling unit. Doors into the dwelling unit shall be equipped with self-closing devices and conform to the requirements of Section 716 with a noncombustible raised sill not less than 4 inches (102 mm) in height. Openings from a hanger directly into a room used for sleeping purposes shall not be permitted.

A residential aircraft hangar can either be a stand-alone detached structure or attached to the residential dwelling. If the hangar is in close proximity or attached to the dwelling, it must then be separated with 1-hour fire-resistance-rated fire barriers. This fire separation must be continuous from the floor slab up to the roof sheathing. The only openings permitted in the fire separation are normal access doors. Windows or other vent openings are prohibited as are any openings between the hangar and the bedrooms of the dwelling. The doors must have a 1/2-hour opening protective fire protection rating in accordance with Table 716.5. A 4-inch-high (102 mm) noncombustible step is required at the door along with a self-closing device. All of these fire separation requirements serve to isolate the fire hazards associated with the hangar from the occupants of the dwelling, similar to a private garage.

412.5.2 Egress. A hangar shall provide two means of egress. One of the doors into the dwelling shall be considered as meeting only one of the two means of egress.

The hangar must be provided with two separate and remotely located means of egress. This redundancy provides persons with an alternative means of escaping a fire in the hangar. One of the means of egress can be the access door into the adjacent dwelling unit. The other means of egress could be the aircraft entrance door subject to the requirements of Sections 1008.1.1 and 1008.1.2 regarding door size and swing.

[F] 412.5.3 Smoke alarms. Smoke alarms shall be provided within the hangar in accordance with Section 907.2.21.

A smoke alarm is required in the hangar space in accordance with Section 907.2.21. Similar to the smoke alarms required in each and every bedroom, in the immediate vicinity of the bedrooms and in each and every story of the dwelling, the hangar smoke alarm must be interconnected such that one alarm will activate all other alarms. An early detection and warning alert is essential to abate the hazards of an aircraft hangar located adjacent to a residence.

412.5.4 Independent systems. Electrical, mechanical and plumbing drain, waste and vent (DWV) systems installed within the hangar shall be independent of the systems installed within the dwelling. Building sewer lines shall be permitted to be connected outside the structures.

Exception: Smoke detector wiring and feed for electrical subpanels in the hangar.

To maintain the fire separation requirements of Section 412.5.1, the only openings permitted are normal access doors. Likewise, the mechanical and plumbing systems for the hangar must be independent of the systems within the residential house. The plumbing drain or waste line could discharge into its own building sewer line that then connects to the house's building sewer line. This connection must be done outside of both the house and the hangar. Electrical wiring serving as the feed for the subpanels in the hangar is permitted to penetrate the fire separation along with the wiring for the smoke alarm required by Section 412.5.3 and the necessary interconnection with the other interior alarms.

412.5.5 Height and area limits. Residential aircraft hangars shall be not greater than 2,000 square feet (186 m²) in area and 20 feet (6096 mm) in building height.

As stated in the definition in Section 202, the residential aircraft hangar is limited to 2,000 square feet (186 m²) in area and 20 feet (6096 mm) in building height. These limits control the fire hazard associated with such a use. The type and number of aircraft stored in the hangar are not limited. Since the hangar is considered part of the residential use, it can be constructed of any materials that are permitted for the house, including wood-frame construction.

[F] 412.6 Aircraft paint hangars. Aircraft painting operations where flammable liquids are used in excess of the maximum allowable quantities per control area listed in Table 307.1(1) shall be conducted in an aircraft paint hangar that complies with the provisions of Sections 412.6.1 through 412.6.8.

This section provides requirements for aircraft-related structures that exceed normal hangar storage purposes. The painting or cleaning of all aircraft with flammable liquids must be carefully controlled in an aircraft paint hangar. To determine the applicability of these requirements, the building owner must provide a complete list of all flammable liquids intended to be used in the building along with their anticipated quantities. If the amounts exceed the maximum allowable quantities per control area, then the building must be classified as an aircraft paint hangar. See Table 307.1(1) and Section 414.2 for further discussion of the maximum allowable quantities per control area of hazardous materials.

[F] 412.6.1 Occupancy group. Aircraft paint hangars shall be classified as Group H-2. Aircraft paint hangars shall com-
SPECIAL DETAILED REQUIREMENTS BASED ON USE AND OCCUPANCY

[412.6.2 Construction. The aircraft paint hangar shall be of Type I or II construction.

- All aircraft paint hangars must be constructed as a Type I or II building. Special height modifications are provided in Section 504.1 for aircraft paint hangars along with special area limitations in Section 507.9. If these modifications are not applicable, then the height and area limitations of Table 503 for a Group H-2 structure must be used. The requirement for non-combustible construction limits the fuel load that is added to the occupancy contents by the structure.

[F] 412.6.3 Operations. Only those flammable liquids necessary for painting operations shall be permitted in quantities less than the maximum allowable quantities per control area in Table 307.1.1(1). Spray equipment cleaning operations shall be conducted in a liquid use, dispensing and mixing room.

- To lessen the likelihood of a fire in the actual painting or aircraft cleaning areas, only flammable liquids necessary for those operations are permitted. The cleaning and maintenance of spray equipment is further limited to a liquid use, dispensing and mixing room. This requirement for separation and segregation of the different operations reduces the fire risks associated with the painting and cleaning services.

[F] 412.6.4 Storage. Storage of flammable liquids shall be in a liquid storage room.

- The storage of all flammable liquids must be limited to a liquid storage room, which is further defined in Section 202. The applicable requirements of Section 415 and the IFC must be followed for liquid storage rooms to reduce the fire risks to the rest of the hangar operation.

[F] 412.6.5 Fire suppression. Aircraft paint hangars shall be provided with fire suppression as required by NFPA 409.

- To minimize the fire hazards associated with aircraft paint hangars, all such buildings are required to be protected with a fire suppression system. This requirement is applicable regardless of the size of the hangar in terms of height or area or the types and quantities of aircraft that are being cleaned or painted. The fire suppression system must be designed and installed in accordance with referenced standard NFPA 409. This standard contains specific requirements for the suppression systems needed to properly protect paint hangars.

[F] 412.6.6 Ventilation. Aircraft paint hangars shall be provided with ventilation as required in the International Mechanical Code.

- Integral to the requirements for aircraft paint hangars are the ventilation provisions. Hazardous exhaust systems for controlling the overspray of painting and aircraft cleaning operations are required. These systems along with the necessary ventilation of the occupiable spaces must be in accordance with the IMC.

[F] 412.7 Heliports and heliostops. Heliports and heliostops shall be permitted to be erected on buildings or other locations where they are constructed in accordance with Sections 412.7.1 through 412.7.5.

- This section contains special use and occupancy requirements for a very unique and specialized aircraft occupancy—those related to helicopters. Because of the limited space requirements necessary for the landing and taking off of helicopters, these areas are more likely to be incorporated into other buildings and structures, such as hospitals or large office buildings than facilities for fixed-wing aircraft.

- Included in these requirements are provisions for minimum clearance sizes, structural use and design, means of egress and a referenced standard for rooftop locations. Heliports and heliostops pose less fire hazards than the storage of these aircraft in hangars, but increased life safety risks.

- Heliports and heliostops are permitted to be located anywhere as long as they meet the requirements of Section 412.7. Certainly federal, state and local governments may have restrictions on the locations of heliports and heliostops for general aviation purposes; however, the code only addresses those fire and life safety hazards associated with their locations to other buildings and structures and the means of egress from the same.

[F] 412.7.1 Size. The landing area for helicopters less than 3,500 pounds (1588 kg) shall be not less than 20 feet (6096 mm) in length and width. The landing area shall be surrounded on all sides by a clear area having a minimum average width at roof level of 15 feet (4572 mm) but with no width less than 5 feet (1524 mm).

- The landing pad for small helicopters [less than 3,500 pounds (1588 kg) in weight] must be a minimum 20-foot-diameter (6096 mm) circle. In addition, a concentric circle must be provided around the landing pad, which provides a clear area with an average width of 15 feet (4572 mm) but with the least dimension of not less than 5 feet (1524 mm). This additional clear space provides an increased landing area during windy conditions when pinpoint landing is not possible. Further, this clear area maintains the necessary separation between the rotating blades and all adjacent construction.

[F] 412.7.2 Design. Helicopter landing areas and the supports thereof on the roof of a building shall be noncombustible construction. Landing areas shall be designed to confine any
flammable liquid spillage to the landing area itself and provisions shall be made to drain such spillage away from any exit or stairway serving the helicopter landing area or from a structure housing such exit or stairway. For structural design requirements, see Section 1605.4.

- Landing areas (helistops) located on the roofs of buildings must be of noncombustible materials, including the supporting construction. This requirement is necessary to provide a structurally sound support for the additional weight of the helicopter and its loads. This section refers to Section 1607.6 for further structural design requirements. Section 1607.6 requires that the building designer must account for the increased roof loads, including impact loads in the structural design.

- Rooftop landing areas must be sloped or diked to prevent any spillage of flammable fuel from the helicopter from entering the building. This is most important since penthouse doors or exit stairways could allow spilled hazardous materials and vapors to enter the building, which would pose an unacceptable fire hazard.

[F] 412.7.3 Means of egress. The means of egress from heliports and helistops shall comply with the provisions of Chapter 10. Landing areas located on buildings or structures shall have two or more means of egress. For landing areas less than 60 feet (18 288 mm) in length or less than 2,000 square feet (186 m²) in area, the second means of egress is permitted to be a fire escape, alternating tread device or ladder leading to the floor below.

- As with all means of egress, the required egress paths from heliports and helistops must be in accordance with Chapter 10. Rooftop landing areas must be provided with at least two remotely located means of egress so that the helicopter occupants have redundant means to leave the landing area and enter the building. For very small landing areas, the code would permit one exit back into the building while the other could take the form of a fire escape, alternating tread device or ladder to the next lower floor level.

[F] 412.7.4 Rooftop heliports and helistops. Rooftop heliports and helistops shall comply with NFPA 418.

- In addition to the specific requirements of Section 412.7, rooftop heliports and helistops must comply with reference standard NFPA 418. That standard provides further life safety and fire safety requirements associated with rooftop landing areas.

[F] 412.7.5 Standpipe system. In buildings equipped with a standpipe system, the standpipe shall extend to the roof level in accordance with Section 905.3.6.

- In order to assist with fire suppression activities, a standpipe system is required in those buildings with a rooftop helistop or heliport. Section 905.3.6 requires that the standpipe system be extended to the roof level on which the helistop or heliport is located. Section 2007.5 of the IFC provides additional infor-
tant construction need not be rated, they must be self-closing and of either noncombustible construction or a minimum 1/4-inch (44 mm) thickness of solid wood core.

Exception 1 exempts the storage area from being separated by 1-hour fire-resistance-rated construction, provided the area is protected by an approved automatic sprinkler system. This exception only requires the sprinkler system in the attic, under-floor or concealed space. Complete sprinkler protection throughout the building is not required in order to be in compliance with the exception.

Exception 2 clarifies that storage in residential occupancies classified as Group R-3 and Group U utility structures are exempt from the separation requirement.

SECTION 414
Hazardous Materials

[F] 414.1 General. The provisions of Sections 414.1 through 414.7 shall apply to buildings and structures occupied for the manufacturing, processing, dispensing, use or storage of hazardous materials.

This section, along with Sections 307 (High-hazard Group H) and 415 (Groups H-1, H-2, H-3, H-4 and H-5) and the IFC, are intended to be companion provisions for the treatment of occupancies that contain hazardous materials. Any building or structure utilizing hazardous materials, regardless of quantity, is to comply with all of the applicable provisions of both this code and the IFC. This section also contains design alternatives for the use and storage of hazardous materials without classifying the building as a high-hazard Group H occupancy through the use of control areas (Section 414.2) or the mercantile display option (Section 414.2.5). While Section 414 contains general construction-related requirements for high-hazard occupancies, they are not indicative of a specific Group H occupancy classification but are dictated by hazardous material requirements in the IFC. Construction-related provisions for specific Group H occupancies are contained in Section 415.

The provisions of Section 414 apply to the use and storage of hazardous materials whether or not the building is classified as Group H. Requirements for specific materials are contained in the IFC.

[F] 414.1.1 Other provisions. Buildings and structures with an occupancy in Group H shall comply with this section and the applicable provisions of Section 415 and the International Fire Code.

Section 415 is referenced for specific provisions applicable to occupancies classified as Groups H-1, H-2, H-3, H-4 and H-5. Regardless of the actual quantity of hazardous materials present, the use and storage of all such materials are required to comply with the applicable provisions of the IFC.

[F] 414.1.2 Materials. The safe design of hazardous material occupancies is material dependent. Individual material requirements are also found in Sections 307 and 415, and in the International Mechanical Code and the International Fire Code.

This section emphasizes that high-hazard occupancies are different than other occupancies in that they are material dependent. This section alerts the code user to companion provisions in both the IMC and the IFC. Section 307 contains specific parameters for when a high-hazard occupancy classification is warranted. Section 415 contains specific building requirements dependent on the actual Group H occupancy classification for the building or area.

[F] 414.1.2.1 Aerosols. Level 2 and 3 aerosol products shall be stored and displayed in accordance with the International Fire Code. See Section 311.2 and the International Fire Code for occupancy group requirements.

When Level 2 and 3 aerosol products are stored or displayed in accordance with Chapter 51 of the IFC, they may be classified as a Group S-1 occupancy as stated in Section 311.2. Section 307.1. Exception 11 specifically exempts aerosol storage from being classified as a Group H occupancy when in compliance with the IFC. The protection required by the IFC is important so that the hazards created by these aerosols are addressed. The reference to the IFC will also address those locations where limited quantities of aerosol products are allowed in other occupancies.

[F] 414.1.3 Information required. A report shall be submitted to the building official identifying the maximum expected quantities of hazardous materials to be stored, used in a closed system and used in an open system, and subdivided to separately address hazardous material classification categories on Tables 307.1(1) and 307.1(2). The methods of protection from such hazards, including but not limited to control areas, fire protection systems and Group H occupancies shall be indicated in the report and on the construction documents. The opinion and report shall be prepared by a qualified person, firm or corporation approved by the building official and provided without charge to the enforcing agency.

For buildings and structures with an occupancy in Group H, separate floor plans shall be submitted identifying the locations of anticipated contents and processes so as to reflect the nature of each occupied portion of every building and structure.

A detailed plan addressing storage of hazardous materials, as well as their use in both closed and open systems must be prepared and submitted to the building official. Such plan is essential for assisting fire department and other emergency response personnel in hazardous materials situations. A report, such as a Hazardous Materials Management Plan (HMMTP), as indicated in the IFC, or other approved plan, should be submitted to aid fire department personnel in the building design preplanning phase.
414.2 Control areas. Control areas shall comply with Sections 414.2.1 through 414.2.5 and the International Fire Code.

As defined in Section 202, control areas are spaces within a building where quantities of hazardous materials not exceeding the maximum allowable quantities per control area are stored, dispensed, used or handled.

This section, in conjunction with the maximum allowable quantity tables in Section 307, utilizes a limited density concept for hazardous materials through the use of control areas. The intent of the control area concept is to provide an alternative method for the handling of hazardous materials without classifying the occupancy as Group H. In order to not be considered Group H, the amount of hazardous materials within any single control area bounded by fire barriers, horizontal assemblies, fire walls and exterior walls cannot exceed the maximum allowable quantity for a specific material listed in Table 307.1(1) or 307.1(2) (see Figure 414.2). A control area may be an entire building or a portion thereof. Note that when an entire building is the control area, the entire maximum allowable quantity of material from Table 307.1(1) or 307.1(2) located on any story is subject to the limitations of Table 414.2.2 (see IFC Interpretation Numbers 51-07 and 52-07).

414.2.1 Construction requirements. Control areas shall be separated from each other by fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both.

Control areas are compartments of a building surrounded by fire barrier walls and fire-resistance-rated horizontal assemblies. If there are no fire barriers or fire-resistance-rated horizontal assemblies, the entire building is a single control area, for the purpose of applying these code provisions. Therefore, if more than the permitted maximum allowable quantities of Table 307.1(1) or 307.1(2) are anticipated in the building, additional control areas with minimum 1-hour fire barrier wall construction (2 hours where more than three stories) must be provided in order to not warrant a high-hazard occupancy classification. The provisions for required fire barriers also minimize the possibility of simultaneous involvement of multiple control areas due to a single fire condition. A fire in a single control area would involve only the amount of hazardous materials as limited by the maximum allowable quantities.

414.2.2 Percentage of maximum allowable quantities. The percentage of maximum allowable quantities of hazardous materials per control area permitted at each floor level within a building shall be in accordance with Table 414.2.2.

Table 414.2.2 specifies the percentage of maximum allowable quantities of hazardous materials per control area dependent on the location of a given floor level with respect to grade. The noted percentages are a percentage of the maximum allowable quantities of hazardous materials permitted per control area in accordance with Tables 307.1(1) and 307.1(2).

For example, Table 307.1(1) would allow 240 gallons (908 L) of Class IB flammable liquid (in a storage condition) per control area in a fully sprinklered building [see Table 307.1(1), Note d]. Table 414.2.2, in turn, would allow 75 percent of the maximum allowable quantity per control area for control areas located on the second floor level above grade. As such, 180 gallons (681 L) of Class IB flammable liquids per control area could be stored on the second floor of a fully sprinklered building without classifying the building as a Group H-3 high-hazard occupancy.

TABLE 414.2.2. See page 4-94.

The purpose of Table 414.2.2 is to establish the maximum allowable quantity of hazardous materials permitted in a building without classifying the building as a high-hazard occupancy based on the use of control areas. The number of control areas and permitted quantities of hazardous materials per control area are reduced when stored or used above the first floor level. This table also sets forth the minimum vertical fire barrier assemblies between adjacent control areas on the same floor. For floor levels above the third floor, a minimum 2-hour fire barrier is required from adjacent areas to aid fire department response due to the additional time necessary for them to access the hazardous material storage areas on upper floors. The required fire-resistance rating of the horizontal assembly above the control area is dictated by the required fire-resistance rating of the enclosure walls of the control area in order to maintain continuity and integrity. Special attention needs to be given to the rating of the floor of the control area, especially for levels below the fourth level. Section 414.2.4 requires that the floor of the control area
and its supporting construction have a minimum 2-hour fire-resistance rating. In general, this will not affect floors above the third level since the continuity provisions of Section 707.5 when combined with the 2-hour separation requirement from Table 414.2.2 will ensure the floor that supports the fire barrier has an equivalent rating; however, in situations where Table 414.2.2 only requires the walls separating control areas to be of 1-hour fire-resistance-rated construction, Section 414.2.4 still would require a 2-hour fire-resistance-rated floor. This could greatly affect the design of a two-story building that was originally intended to be of Type IIIB construction (see commentary, Section 414.2.4).

The percentage of quantities of hazardous materials per control area per floor area is intended to be cumulative. A two-story building, therefore, could contain three control areas with each having 75 percent of the maximum allowable quantity on the second floor in addition to the four control areas containing 100 percent each of the maximum allowable quantity on the first floor. This condition would require that adequate fire-resistance-rated separation be provided.

Note a clarifies that the maximum allowable quantity of hazardous materials per control area is based on Tables 307.1(1) and 307.1(2). The maximum permitted amount includes the increases allowed by either an automatic sprinkler system in accordance with NFPA 13, approved hazardous material storage cabinets or both where applicable.

Note b clarifies the fire barrier separation needed to establish the boundaries of the control area that include not only the vertical wall assemblies but also the floor/ceiling assemblies in order to be adequately separated from all adjacent interior spaces.

Example: Determine the maximum amount of Class IB flammable liquids that can be stored within a single-story, 10,000-square-foot (929 m²) nonsprinklered Group F-1 occupancy (see Figure 414.2.2) of Type IIIB construction without classifying the storage area as Group H-2. Based on a maximum allowable quantity of 120 gallons (454 L) for Class IB flammable liquids from Table 307.1(1), a maximum of 120 gallons (454 L) can be stored in each of the four control areas; therefore, while the building may actually contain a total of 480 gallons (1817 L), a maximum of 120 gallons (454 L) is permitted in each control area that is separated from all adjacent control areas by minimum 1-hour fire barriers constructed in accordance with Section 707. The building, in this case, could still be classified as Group F-1. An automatic fire suppression system would not be required, since the 12,000-square-foot (1115 m²) threshold for suppression of Group F-1 fire areas is not exceeded (Section 903.2.4) and there are no control areas containing hazardous materials that exceed the maximum allowable quantities. Notes d and e of Table 307.1(1) would allow the base quantity of Class IB flammable liquids to be increased 100 percent in buildings protected with an automatic sprinkler system or when the material is stored in approved hazardous material storage cabinets. In this example, this would result in increasing the maximum allowable quantity of Class IB flammable liquids by a factor of two; therefore, the building could now contain a total of 960 gallons (3634 L) with a maximum of 240 gallons (908 L) in each of the four control areas, separated as required by the code, and still maintain a Group F-1 classification. If both an automatic sprinkler system and hazardous material storage cabinets are used to protect Class IB flammable liquids, then the base quantity of Table 307.1(1) could be increased by a factor of four. The building in this example, therefore, with both sprinkler protection and approved cabinets, could contain a total of 1920 gallons (7267 L) with a maximum of 480 gallons (1817 L) in each of the four control areas, separated as required by the code, and still maintain a Group F-1 classification. The allowable increase in the maximum allowable quantities is offset by the additional level or levels of protection. The use of control areas
provides a tradeoff based on building compartmentation. Fire protection (automatic sprinkler systems) and controlled storage through the use of approved hazardous material storage cabinets also adds a degree of protection, justifying the increased allowable quantities.

**[F] 414.2.3 Number.** The maximum number of control areas within a building shall be in accordance with Table 414.2.2.

- The maximum quantity of hazardous materials which is permitted in a building without classifying the building as a Group H, high-hazard occupancy, is regulated per control area and not per building area. The quantity limitation for the entire building would be established based on the number of permitted control areas on each floor of the building in accordance with Table 414.2.2. Based on the table, the first floor could contain four control areas with up to 100 percent of the maximum allowable quantity of hazardous materials per control area. For example, a single control area in a nonsprinklered building could contain up to 30 gallons (113 L) of Class IA flammable liquids, 125 pounds (57 kg) of Class II organic peroxides, 250 pounds (113 kg) of Class 2 oxidizers and 500 gallons (1893 L) of corrosive liquids based on the maximum allowable quantities of Tables 307.1(1) and 307.1(2). Those quantities could be contained in each of four different control areas, provided that all control areas are separated from each other with minimum 1-hour fire barriers and horizontal assemblies. Please note that in order to have more control areas per floor than indicated in Table 414.2.2, a fire wall in accordance with Section 706 would be required in order to create separate buildings within the total structure.

**[F] 414.2.4 Fire-resistance-rating requirements.** The required fire-resistance rating for fire barriers shall be in accordance with Table 414.2.2. The floor assembly of the control area and the construction supporting the floor of the control area shall have a fire-resistance rating of not less than 2 hours.

**Exception:** The floor assembly of the control area and the construction supporting the floor of the control area are allowed to be 1-hour fire-resistance rated in buildings of Types IIA, IIIA and VA construction, provided that both of the following conditions exist:

1. The building is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1; and
2. The building is three or fewer stories above grade plane.

- The fire separation requirements for control areas, both horizontal and vertical, are dependent on their location in a building in accordance with Table 414.2.2. The amount of hazardous materials per control area, as well as the number of control areas per floor, are reduced if stored or used above the first floor.

Where the control area is located above the first floor, the floor assembly and all supporting construction for the control area would require a minimum 2-hour fire-resistance rating. The required 2-hour fire-resistance rating of the floor construction only refers to the floor of the control area. The increased fire-resistance rating and reduced quantities are intended to aid fire department personnel. The use of control areas on upper floors provides an alternative method for multistory research and laboratory-type facilities that may need to use a limited amount of hazardous materials throughout various portions of the building. Without control areas, the maximum allowable quan-

* ASSUME CLASS IIB FLAMMABLE LIQUIDS

For SI: 1 square foot = 0.0929 m², 1 gallon = 3.785 L.
SPECIAL DETAILED REQUIREMENTS BASED ON USE AND OCCUPANCY

ty for a hazardous material would be limited to a single building area regardless of the overall size or height of the building. For example, if control areas are not utilized, a 50,000-square-foot (4645 m²) single-story building would be limited to the same quantity of hazardous materials as a two-story building with 5,000 square feet (464 m²) per floor.

Buildings of Type II A, II A and VA construction are required to have floor construction with a minimum fire-resistance rating of 1-hour as indicated in Table 601. The exception recognizes the combination of a 1-hour horizontal assembly in conjunction with sprinkler protection as a reasonable alternative for the noted construction types. The three-story limitation is consistent with the fire-resistant-rating requirements for fire barriers in Table 414.2.2.

[F] 414.2.5 Hazardous material in Group M display and storage areas and in Group S storage areas. The aggregate quantity of nonflammable solid and nonflammable or noncombustible liquid hazardous materials permitted within a single control area of a Group M display and storage area, a Group S storage area or an outdoor control area is permitted to exceed the maximum allowable quantities per control area specified in Tables 307.1(1) and 307.1(2) without classifying the building or use as a Group H occupancy, provided that the materials are displayed and stored in accordance with the International Fire Code and quantities do not exceed the maximum allowable specified in Table 414.2.5(1).

In Group M occupancy wholesale and retail sales uses, indoor storage of flammable and combustible liquids shall not exceed the maximum allowable quantities per control area as indicated in Table 414.2.5(2), provided that the materials are displayed and stored in accordance with the International Fire Code.

The maximum quantity of aerosol products in Group M occupancy retail display areas, storage areas adjacent to retail display areas and retail storage areas shall be in accordance with the International Fire Code.

This section addresses an option for control areas containing certain nonflammable or noncombustible hazardous materials that are stored in mercantile and storage occupancies, including outdoor control areas. This option would allow Group H-4 materials, which present a health hazard rather than a physical hazard, as well as limited Group H-2 and H-3 materials, such as oxidizers, to be stored in both retail display and stock areas of regulated mercantile occupancies and in storage-related occupancies in excess of the maximum allowable quantities of Tables 307.1(1) and 307.1(2) without classifying the building as Group H. Without this option, many mercantile and storage occupancies could be classified technically as Group H. The increased quantities of certain hazardous materials are based on the recognition that while there is limited risk in these occupancies, the packaging and storage arrangements can be controlled. For further information on the storage limitations required for these types of materials, see Section 5003.11.3 of the IFC.

This section, in conjunction with Table 414.2.5(1), establishes the maximum quantity of the indicated hazardous materials permitted within a single control area of a mercantile occupancy. As indicated in Table 414.2.5(1), this section only applies to certain nonflammable solids and nonflammable or noncombustible liquids. Please note that this option is not applicable to mercantile and storage occupancies containing hazardous materials other than those indicated in Table 414.2.5(1).

This section also addresses Group M occupancies utilized for the wholesale and retail sales of flammable and combustible liquids. Group M occupancies must be able to display flammable and combustible liquids for sale to the public. The maximum allowable quantities of flammable and combustible liquids per control area can exceed the limitations of Table 307.1(1), provided they are in compliance with the amounts in Table 414.2.5(2) and displayed and stored in accordance with Section 5704.3.6 of the IFC. Section 307.1, Exception 2 also addresses this design alternative to a Group H occupancy classification for flammable and combustible liquids in mercantile occupancies.

The retail sales of aerosol products requires compliance with Chapter 51 of the IFC and the applicable provisions of NFPA 30B.

TABLE 414.2.5(1). See page 4-97.

Table 414.2.5(1) lists the hazardous materials eligible for the mercantile and storage occupancy option and the corresponding maximum permitted quantities per control area depending on the extent of protection provided. The permitted quantities of each listed material are independent of each other, as well as the various classes or physical state of a specific material. For example, a given control area could contain up to the permitted maximum quantity of Class 2 solid oxidizers, Class 3 solid oxidizers and Class 2 liquid oxidizers, in addition to the permitted quantities of corrosive materials.

Notes b and c would allow the listed maximum quantity in Table 414.2.5(1) to be increased due to the use of sprinklers, approved hazardous materials storage cabinets or both. The notes are intended to be cumulative in that up to four times the listed amount may be allowed per control area, if the building is fully sprinkler protected and approved cabinets are utilized, without classifying the building as Group H.

Note d simply refers to Table 414.2.2 for the design and permitted number of control areas.

The 100-percent increase in maximum quantities for outdoor control areas permitted by Note f is based on the reduced exposure hazard to the building and its occupants. The increase encourages exterior storage applications without mandating sprinkler protection or approved hazardous material storage cabinets.

Notes g and h recognize that Class 2 and 3 solid
oxidizers include several disinfectants that are commonly used in recreational, potable and wastewater treatment. Without these exceptions, the tabular maximum allowable quantities allowed in Group M and S occupancies would not be sufficient to sustain trade demand during times of peak usage. Because small containers of these materials have not been involved in losses, the exceptions permit additional containers of 10 pounds (5 kg) or less. Note that Section 5003.11.3 of the IFC limits the tabular quantities to individual containers of 100 pounds (45 kg) or less, whereas these exceptions give the retailer/wholesaler the option of increasing quantities on the shelves when the packaging sizes are reduced and limited to 10 pounds (5 kg) or less.

Note i recognizes the inherently higher level of protection and safety afforded by a sprinkler system and that, by definition, the only hazard presented by Class 1 oxidizers is that they slightly increase the burning rate of combustible materials with which they may come into contact during a fire. Materials with such properties present nowhere near the level of hazard of many ordinary commodities that might be found in a Group M or S occupancy, such as foam plastics. To put this matter into perspective, Class 1 oxidizers are materials with a degree of hazard similar to that of toilet bowl cleaner crystals. Note i also correlates with Table 307.1(1), Note f.

Note j further recognizes the lesser hazard of Class 1 oxidizers and the inherent safety of storing hazardous materials outdoors by allowing quantities to be unlimited in outdoor control areas. Note j also correlates with Table 5003.1.1(3) of the IFC.

| A. Health-hazard materials—nonflammable and noncombustible solids and liquids |
|---|---|---|---|
| Material | Class | Solids pounds | Liquids gallons |
| 1. Corrosives | Not Applicable | 9,750 | 975 |
| 2. Highly toxic | Not Applicable | 20 | 2 |
| 3. Toxic | Not Applicable | 1,000 | 100 |

| B. Physical-hazard materials—nonflammable and noncombustible solids and liquids |
|---|---|---|---|
| 1. Oxidizers | 4 | Not Allowed | Not Allowed |
| | 3 | 1,150 | 115 |
| | 2 | 2,250 | 225 |
| | 1 | 18,000 | 1,800 |
| 2. Unstable (reactives) | 4 | Not Allowed | Not Allowed |
| | 3 | 550 | 55 |
| | 2 | 1,150 | 115 |
| | 1 | Not Limited | Not Limited |
| 3. Water reactives | 3 | 550 | 55 |
| | 2 | 1,150 | 115 |
| | 1 | Not Limited | Not Limited |

For SI: 1 pound = 0.454 kg, 1 gallon = 3.785 L.

a. Hazard categories are as specified in the International Fire Code.
b. Maximum allowable quantities shall be increased 100 percent in buildings that are sprinklered in accordance with Section 903.3.1.1. When Note c also applies, the increase for both notes shall be applied accumulatively.
c. Maximum allowable quantities shall be increased 100 percent when stored in approved storage cabinets, in accordance with the International Fire Code.
When Note b also applies, the increase for both notes shall be applied accumulatively.
d. See Table 414.2.2 for design and number of control areas.
e. Allowable quantities for other hazardous material categories shall be in accordance with Section 307.
f. Maximum quantities shall be increased 100 percent in outdoor control areas.
g. Maximum amounts are permitted to be increased to 2,250 pounds when individual packages are in the original sealed containers from the manufacturer or packager and do not exceed 10 pounds each.
h. Maximum amounts are permitted to be increased to 4,500 pounds when individual packages are in the original sealed containers from the manufacturer or packager and do not exceed 10 pounds each.
i. The permitted quantities shall not be limited in a building equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1.
j. Quantities are unlimited in an outdoor control area.
TABLE 414.2.5(2). See below.

- Table 414.2.5(2) provides the maximum allowable quantity of flammable and combustible liquids per control area in mercantile occupancies. The limitations are based on the type of flammable and combustible liquid in the control area, the type of storage (such as rack or palletized) and the level of sprinkler protection.

The easier the flammable or combustible liquid is to ignite, the more restrictive is the quantity of liquid allowed. As such, the table severely limits the quantity of Class IA liquids. Class IIIB liquids, on the other hand, with a flash point above 200°F (93°C) are unlimited in a building with an automatic sprinkler system.

The automatic sprinkler system must be designed in accordance with NFPA 13. Flammable and combustible liquids displayed on shelves of 6 feet (1829 mm) or less, are treated as an Ordinary Hazard Group 2 occupancy in accordance with NFPA 13, which would require a minimum sprinkler density of 0.20 gallon per minute (0.72 L/min) per square foot over the most remote 1,500-square-foot (140 m²) area.

Because the flammable and combustible liquid is more exposed in individual packaging, the sprinkler system can provide better fire control. If the flammable and combustible liquids are displayed or stored in cartons, pallets or racks, the minimum sprinkler density is 0.21 gallons per minute (0.79 L/min) per square foot over the most remote 1,500-square-foot (140 m²) area. This type of display or storage is limited to a maximum height of 4 feet, 6 inches (1372 mm). This type of packaging is more difficult for the fire sprinkler system to handle so a greater density is required.

To allow a larger quantity and increased storage height of flammable and combustible liquids, the mercantile occupancy would require an enhanced sprinkler system in accordance with the applicable provisions of the IFC and NFPA 30. These provisions would require the sprinkler system to have a greater design density and operating area to adequately protect most storage conditions. For additional guidance, see Section 5704.3.6 of the IFC.

[F] 414.3 Ventilation. Rooms, areas or spaces of Group H in which explosive, corrosive, combustible, flammable or highly toxic dusts, mists, fumes, vapors or gases are or may be emitted due to the processing, use, handling or storage of materials shall be mechanically ventilated as required by the International Fire Code and the International Mechanical Code.

Ducts conveying explosives or flammable vapors, fumes or dusts shall extend directly to the exterior of the building without entering other spaces. Exhaust ducts shall not extend into or through ducts and plenums.

Exception: Ducts conveying vapor or fumes having flammable constituents less than 25 percent of their lower flammable limit (LFL) are permitted to pass through other spaces.

Emissions generated at workstations shall be confined to the area in which they are generated as specified in the International Fire Code and the International Mechanical Code.

The location of supply and exhaust openings shall be in accordance with the International Mechanical Code. Exhaust air contaminated by highly toxic material shall be treated in accordance with the International Fire Code.

A manual shutoff control for ventilation equipment required by this section shall be provided outside the room adjacent to the principal access door to the room. The switch shall be of the break-glass type and shall be labeled: VENTILATION SYSTEM EMERGENCY SHUTOFF.

- This section requires mechanical ventilation for occupancies utilizing hazardous materials when required by the IFC. The specific ventilation requirements are

<table>

</tr>
</tbody>
</table>

For Sl: 1 foot = 304.8 mm, 1 square foot = 0.0929 m², 1 gallon = 3.785 L, 1 gallon per minute per square foot = 40.75 L/min/m².

- Control areas shall be separated from each other by not less than a 1-hour fire barrier wall.

- To be considered as sprinklered, a building shall be equipped throughout with an approved automatic sprinkler system with a design providing minimum densities as follows:
  1. For uncartonized commodities on shelves 6 feet or less in height where the ceiling height does not exceed 18 feet, quantities are those permitted with a minimum sprinkler design density of Ordinary Hazard Group 2.
  2. For cartoned, palletized or racked commodities where storage is 4 feet 6 inches or less in height and where the ceiling height does not exceed 18 feet, quantities are those permitted with a minimum sprinkler design density of 0.21 gallon per minute per square foot over the most remote 1,500-square-foot area.

- Where wholesale and retail sales or storage areas exceed 50,000 square feet in area, the maximum allowable quantities are allowed to be increased by 2 percent for each 1,000 square feet of area in excess of 50,000 square feet, up to a maximum of 100 percent of the table amounts. A control area separation is not required. The cumulative amounts, including amounts attained by having an additional control area, shall not exceed 30,000 gallons.
required to be in accordance with the applicable provisions in the IMC.

With regard to ducts conveying hazardous exhaust, the intent of this section is to minimize the potential for spreading hazardous exhaust to other parts of the building as a result of duct leakage or failure. In the event of a duct fire or explosion, other areas of the building could be jeopardized. Section 414.3 requires the exhaust flow to be maintained at concentrations below the lower flammability limit (LFL) of the contaminant. In all cases, ducts conveying hazardous exhaust must not extend into or through other ducts or plenum spaces, unless the flammable vapor-air mixtures are less than 25 percent of the LFL of the vapor being generated. The reference to work stations addresses spaces within a Group H-5 occupancy that utilize hazardous production materials within a fabrication area. The required control of emissions at work stations is intended to prevent exposure of the work station operator to hazardous fumes or vapors and to prevent hazardous concentrations of the materials used in the manufacturing process.

The exhaust system required by this section must be provided with an emergency manual shutoff control (kill switch) that will permit the exhaust system to be shut down without requiring personnel to enter the storage room. In the event of an emergency, it would be desirable to shut off an exhaust fan that is a source of ignition or is exhausting significant quantities of hazardous substances as a result of leaking storage containers. Under some circumstances, continued operation of an exhaust system could increase the level of hazard or cause the spread of fire. To prevent tampering and unauthorized use of the shutoff control, such controls must be of the type that requires a seal to be broken before they can be actuated. The control must be clearly identified as to its purpose.

[F] 414.4 Hazardous material systems. Systems involving hazardous materials shall be suitable for the intended application. Controls shall be designed to prevent materials from entering or leaving process or reaction systems at other than the intended time, rate or automatic controls, where provided, shall be designed to be fail safe.

- Process-type systems involving the use of hazardous materials generally involve many design variables. Many times, the building official may not be aware of the potentially dangerous chemical combination or use of incompatible materials that might be inherent in a given system. This section simply requires that all systems involving the use of hazardous materials should be designed to prevent an unwanted mixture of hazardous materials from occurring.

[F] 414.5 Inside storage, dispensing and use. The inside storage, dispensing and use of hazardous materials shall be in accordance with Sections 414.5.1 through 414.5.4 of this code and the International Fire Code.

- Sections 414.5.1 through 414.5.5 contain construction-related items for the inside storage and use of hazardous materials. The applicability of the provisions of Section 414.5 is dependent on the specific hazardous material requirements in the IFC. It is important to note that these provisions are not solely applicable to Group H occupancies.

[F] 414.5.1 Explosion control. Explosion control shall be provided in accordance with the International Fire Code as required by Table 414.5.1 where quantities of hazardous materials specified in that table exceed the maximum allowable quantities in Table 307.1(1) or where a structure, room or space is occupied for purposes involving explosion hazards as required by Section 415 or the International Fire Code.

- It is usually impractical to design a building to withstand the pressure created by an explosion; therefore, this section mandates an explosion relief system for all structures, rooms or spaces with uses involving explosion hazards. Explosions may result from the overpressurization of a containing structure, by physical/chemical means or by a chemical reaction. During an explosion, a sudden release of a high-pressure gas occurs and the energy is dissipated in the form of a shock wave.

All structures, rooms or spaces with those special uses listed in Table 414.5.1 involving explosion hazards must be equipped with some method of explosion control as required by Section 415 or the material-specific requirements in the IFC. Table 414.5.1 also specifies when explosion control is required based on certain materials where the quantities of hazardous materials involved exceed the maximum allowable quantities in Table 307.1(1). Similarly, Section 911 of the IFC recognizes explosion (deflagration) venting and explosion (deflagration) prevention systems as acceptable methods of explosion control, where appropriate. The use of barricades or other explosion protective devices, such as magazines, may be permitted as the means of explosion control where indicated in the IFC as an acceptable alternative and approved by the building official.

TABLE 414.5.1. See page 4-100.

- This table designates when some methods of explosion control are required for specific material or special use conditions. The applicability of this table assumes either the quantities of hazardous materials involved exceed the maximum allowable quantities in Table 307.1(1), listed in the table under "Hazard Category," or special explosion hazards exist as listed under "Special Uses." Section 911 of the IFC provides design criteria for explosion (deflagration) venting. Explosion prevention (suppression) systems, where utilized, must comply with NFPA 69. Barricade
construction must be designed and installed in accordance with NFPA 495. As indicated in Table 414.5.1, Note b, the IFC provides additional guidance as to the applicability and design criteria for explosion control methods.

[F] **414.5.2 Monitor control equipment.** Monitor control equipment shall be provided where required by the International Fire Code.

- Monitor control equipment consists of limit controls such as liquid level controls for atmospheric tanks, temperature level controls, controls for hazardous materials required to be stored at other than ambient temperature and pressure relief devices for stationary tanks. The provisions for limit controls are located in Sections 5004.8 and 5005.1.4 of the IFC. This section provides a correlative cross reference to limit control requirements that may be dictated by a specific hazardous material in the IFC.

[F] **414.5.3 Emergency or standby power.** Where mechanical ventilation, treatment systems, temperature control, alarm, detection or other electrically operated systems are required by the International Fire Code or this code, such systems shall be provided with an emergency or standby power system in accordance with Chapter 27.

**Exceptions:**

1. Emergency or standby power are not required for the following storage areas:

   1.1. Mechanical ventilation for storage of Class IB and Class IC flammable and combustible

- See Section 414.1.3.
- See the International Fire Code.
- As generated during manufacturing or processing.
- Storage or use.
- In open use or dispensing.
- Rooms containing dispensing and use of hazardous materials when an explosive environment can occur because of the characteristics or nature of the hazardous materials or as a result of the dispensing or use process.
- A method of explosion control shall be provided where Class 2 water-reactive materials can form potentially explosive mixtures.
liquids in closed containers not exceeding 6.5 gallons (25 L) capacity.

1.2. Storage areas for Class I and 2 oxidizers.

1.3. Storage areas for Class II, III, IV and V organic peroxides.

1.4. Storage, use and handling areas for asphyxiating, irritant and radioactive gases.

1.5. For storage, use and handling areas for highly toxic or toxic materials, see Sections 604.2.2.8 and 604.3.4.2 of the International Fire Code.

2. Standby power for mechanical ventilation, treatment systems and temperature control systems shall not be required where an approved fail-safe engineered system is installed.

- A backup emergency power source is considered essential for required systems monitoring hazardous materials; therefore, when limit controls, detection systems or mechanical ventilation is required for a specific hazardous material, an emergency electrical system or standby power system is required.

Exception 1 correlates with industry treatment of portable container storage. Notably, storage of small, closed containers does not pose a risk that warrants ventilation for these materials. FM Data Sheet 7-29, Flammable Liquid Storage in Portable Containers, does not require mechanical ventilation for flammable liquids in closed containers of not greater than 6.5 gallons (2290 L) individual capacity, with a flash point of not greater than 100°F (38°C) and a boiling point equal to or greater than 100°F (38°C). NFPA 30, Flammable and Combustible Liquids Code, also recognizes that closed container storage does not pose a risk that warrants ventilation (ventilation is required if there is open dispensing). These materials are in sealed containers in storage. Any loss of power would require an immediate cessation of operations, which would eliminate spill risk. By limiting the container size, the potential for accidental spills is significantly reduced.

Exceptions 2 and 3 address low-hazard oxidizers and organic peroxides that do not present a severe fire or reactivity hazard. Highly toxic and toxic materials (see Exception 5) must conform to applicable requirements of Chapter 60 of the IFC. For example, emergency power may be required for treatment systems utilized to process the accidental release of highly toxic or toxic compressed gases caused by a leak or rupture in storage cylinders or tanks. Without emergency power, all required monitoring systems, including the treatment system for neutralizing potential leaking gas, would be rendered inoperative if a power failure or other electrical system failure occurred.

Exception 4 exempts storage areas for asphyxiating, irritant or radioactive gases because, unlike the requirements for other hazard categories which use the Maximum Allowable Quantity (MAQ) per control area as a trigger threshold, the requirement for ventilation in storage areas containing asphyxiating, irritant and radioactive gases is not quantity based. The construction of compressed gas containers is robust compared to the containers used for other materials that may be of glass, plastic or paper. The integrity of the container alone represents a major safeguard against likely failure. While leakage from containers is a consideration, the need for the reestablishment of power to the ventilation system within a 60-second period is not warranted given the fact that the requirement could be imposed for insignificant quantities of the gas, and given the fact that occupancy of a storage area during power outage is not the norm.

Exception 6 recognizes the use of an engineered system that is designed to always fail in the appropriate design mode without human intervention in lieu of the emergency power system. The intent of the exception is to permit alternative systems that are not subject to power interruptions. The exception, as noted, does not apply to detection and alarm systems, but addresses those systems essential to the removal of hazardous fumes and vapors from potentially occupied areas.

[F] 414.5.4 Spill control, drainage and containment. Rooms, buildings or areas occupied for the storage of solid and liquid hazardous materials shall be provided with a means to control spillage and to contain or drain off spillage and fire protection water discharged in the storage area where required in the International Fire Code. The methods of spill control shall be in accordance with the International Fire Code.

- This section references the IFC for material-specific occupancies containing materials in excess of the maximum allowable quantities, which would require some method of spill control, drainage and containment. The specific provisions for providing adequate spill control, drainage and containment, when required, are located in Section 5004.2 of the IFC.

[F] 414.6 Outdoor storage, dispensing and use. The outdoor storage, dispensing and use of hazardous materials shall be in accordance with the International Fire Code.

- This section requires the outdoor storage, dispensing and use of hazardous materials to be in accordance with the provisions of the IFC, regardless of the quantity. Certain provisions in the IFC, however, are only applicable when the maximum allowable quantities are exceeded. In general, the permitted quantity per outdoor control area exceeds the permitted for the inside storage or use of the same material. The outdoor storage or use of hazardous materials in excess of the maximum allowable quantities does not result in a high-hazard occupancy classification but simply dictates the need for additional requirements.

[F] 414.6.1 Weather protection. Where weather protection is provided for sheltering outdoor hazardous material storage or use areas, such areas shall be considered outdoor storage or
use when the weather protection structure complies with Sections 414.6.1.1 through 414.6.1.3.

This section provides the minimum construction requirements for outdoor storage areas of hazardous materials that require protection from the elements. The need for weather protection is dependent on the specific material requirements in the IFC. For ready access to materials, many such structures are commonly constructed as an attached canopy. Depending on the hazardous material involved, additional protection, such as fire suppression of the outside storage area, fire-resistance-rated exterior wall construction or a limitation on exterior wall openings, may be necessary.

Structures not in compliance with the provisions of this section would be regulated as inside storage, and as such, would be considered a Group H, high-hazard, occupancy if the maximum allowable quantities of a specific hazardous material were exceeded.

[F] 414.6.1.1 Walls. Walls shall not obstruct more than one side of the structure.

Exception: Walls shall be permitted to obstruct portions of multiple sides of the structure, provided that the obstructed area is not greater than 25 percent of the structure’s perimeter.

The structure should be sufficiently open to allow for adequate cross ventilation. The intent of this section is to allow either one full side of a weather protection structure to be obstructed or, through the exception, to permit portions of multiple sides to be obstructed, provided the obstructed perimeter does not exceed 25 percent of the total perimeter.

[F] 414.6.1.2 Separation distance. The distance from the structure to buildings, lot lines, public ways or means of egress to a public way shall be not less than the distance required for an outside hazardous material storage or use area without weather protection.

The structure is required to be located with respect to lot lines, public ways or the means of egress to the public way as required for the specific hazardous material provisions in the IFC.

[F] 414.6.1.3 Noncombustible construction. The overhead structure shall be of approved noncombustible construction with a maximum area of 1,500 square feet (140 m²).

Exception: The maximum area is permitted to be increased as provided by Section 506.

The overhead structure is required to be of noncombustible construction to eliminate the possibility of adding to the fuel load in a fire condition. The exception permits the area of the overhead structure to exceed the 1,500-square-foot (139 m²) area limitation if either open building frontage (see Section 506.2) or an automatic sprinkler system (see Section 506.3) is provided.

[F] 414.7 Emergency alarms. Emergency alarms for the detection and notification of an emergency condition in Group H occupancies shall be provided as set forth herein.

An emergency alarm is required in all areas utilized for the storage, dispensing, use and handling of hazardous materials in accordance with Sections 414.7.1 through 414.7.3. This section assumes the area in question utilizes hazardous materials in excess of the maximum allowable quantities indicated in Tables 307.1(1) and 307.1(2) and, therefore, the building is classified as a Group H occupancy.

[F] 414.7.1 Storage. An approved manual emergency alarm system shall be provided in buildings, rooms or areas used for storage of hazardous materials. Emergency alarm-initiating devices shall be installed outside of each interior exit or exit access door of storage buildings, rooms or areas. Activation of an emergency alarm-initiating device shall sound a local alarm to alert occupants of an emergency situation involving hazardous materials.

A manual pull station or other emergency signal device approved by the building official must be provided outside of each egress door to hazardous material storage areas. Activation of the device is intended to warn the building occupants of a potential dangerous condition within the hazardous material storage area. The alarm signal required by this section is intended only to be a local alarm. A complete evacuation alarm system, excluding a local trouble alarm located within the immediate high-hazard area, is not required.

[F] 414.7.2 Dispensing, use and handling. Where hazardous materials having a hazard ranking of 3 or 4 in accordance with NFPA 704 are transported through corridors, interior exit stairways or ramps, or exit passageways there shall be an emergency telephone system, a local manual alarm station or an approved alarm-initiating device at not more than 150 foot (45 720 mm) intervals and at each exit and exit access doorway throughout the transport route. The signal shall be relayed to an approved central, proprietary or remote station service or constantly attended on-site location and shall initiate a local audible alarm.

This section requires access to an approved supervised signaling device along the transport route when hazardous materials must be transported through corridors, interior exit stairways or exit passageways. A spill or other incident involving hazardous materials within a corridor or exit may render it unusable for egress. A loud audible alarm, which relays a signal to a remote station, allows a quick response by emergency responders.

[F] 414.7.3 Supervision. Emergency alarm systems shall be supervised by an approved central, proprietary or remote station service or shall initiate an audible and visual signal at a constantly attended on-site location.

This section requires an approved method of electrical supervision for the emergency alarm systems for
the hazardous material storage and use areas required by Sections 414.7.1 and 414.7.2. The method of supervision should also be in compliance with the applicable provisions of NFPA 72.

SECTION 415
GROUPS H-1, H-2, H-3, H-4 AND H-5
Section 415 has been completely reorganized from the 2009 code; therefore, the * and ** margin indicators have not been included for clarity.

[F] 415.1 Scope. The provisions of Sections 415.1 through 415.10 shall apply to the storage and use of hazardous materials in excess of the maximum allowable quantities per control area listed in Section 307.1. Buildings and structures with an occupancy in Group H shall also comply with the applicable provisions of Section 414 and the International Fire Code.

This section establishes the application of Section 414 and references the International Fire Code (IFC) for additional specific hazardous material requirements. Section 415 is only applicable when the maximum allowable quantity of a hazardous material listed in either Table 307.1(1) or 307.1(2) is exceeded. The provisions of Section 414, however, are applicable wherever hazardous materials are stored or used, regardless of quantity.

[F] 415.2 Definitions. The following terms are defined in Chapter 2:
CONTINUOUS GAS DETECTION SYSTEM.
DETAILED BUILDING.
EMERGENCY CONTROL STATION.
EXHAUSTED ENCLOSURE.
FABRICATION AREA.
FLAMMABLE VAPORS OR FUMES.
GAS CABINET.
GASROOM.
HAZARDOUS PRODUCTION MATERIAL (HPM).
HPM FLAMMABLE LIQUID.
HPM ROOM.
IMMEDIATELY DANGEROUS TO LIFE AND HEALTH (IDLH).
LIQUID.
LIQUID STORAGE ROOM.
LIQUID USE, DISPENSING AND MIXING ROOM.
LOWER FLAMMABLE LIMIT (LFL).
NORMAL TEMPERATURE AND PRESSURE (NTP).
PHYSIOLOGICAL WARNING THRESHOLD LEVEL.
SERVICE CORRIDOR.
SOLID.
STORAGE, HAZARDOUS MATERIALS.

USE (MATERIAL).
WORKSTATION.

This section lists terms that are specifically associated with the subject matter of Section 415. It is important to emphasize that these terms are not exclusively related to this chapter but may or may not also be applicable where the term is used elsewhere in the code.

Definitions of terms can help in the understanding and application of the code requirements. The purpose for including a list within this chapter is to provide more convenient access to terms which may have a specific or limited application within this chapter. For the complete definition and associated commentary, refer back to Chapter 2. Terms that are italicized provide a visual identification throughout the code that a definition exists for that term. The use and application of all defined terms are set forth in Section 201.

[F] 415.3 Automatic fire detection systems. Group H occupancies shall be provided with an automatic fire detection system in accordance with Section 907.2.

This section references Section 907.2.5 regarding the installation of automatic fire detection systems in Group H occupancies. Specifically required are automatic smoke detection systems when highly toxic gases, organic peroxides and oxidizers are present. See also Chapters 60, 62 and 63 of the IFC commentary. Section 907.2.5 also requires a manual fire alarm system in Group H-5 occupancies. This system shall activate the occupant notification system as specified in Section 907.5.

[F] 415.4 Automatic sprinkler system. Group H occupancies shall be equipped throughout with an automatic sprinkler system in accordance with Section 903.2.5.

An automatic sprinkler system is required throughout buildings or portions of buildings classified as Group H occupancies as established in Section 903.2.5. In other than Group H-5 occupancies, the sprinkler system required by this section is only required in those areas that have the Group H classification. For example, in an 8,000-square-foot (743.2 m²) Group F-1 factory with a 600-square-foot (55.7 m²) Group H-3 storage room, only the storage room would require an automatic sprinkler system.

[F] 415.5 Fire separation distance. Group H occupancies shall be located on property in accordance with the other provisions of this chapter. In Groups H-2 and H-3, not less than 25 percent of the perimeter wall of the occupancy shall be an exterior wall.

Exceptions:

1. Liquid use, dispensing and mixing rooms having a floor area of not more than 500 square feet (46.5 m²) need not be located on the outer perimeter of the building where they are in accordance with the International Fire Code and NFPA 30.
2. Liquid storage rooms having a floor area of not more than 1,000 square feet (93 m²) need not be located on the outer perimeter where they are in accordance with the International Fire Code and NFPA 30.

3. Spray paint booths that comply with the International Fire Code need not be located on the outer perimeter.

- This section specifies the location of Group H storage areas within a building. In order to provide adequate access for fire-fighting operations and venting of the products of combustion, Group H-2 and H-3 storage areas within a building must be located along an exterior wall.

Exception 1 recognizes the use of inside storage rooms that are utilized for operations involving flammable and combustible liquids. These types of rooms, which have no perimeter access, are permitted by the IFC and NFPA 30. The size of the room as well as the quantity of liquids, however, are restricted due to the lack of perimeter access and ventilation options.

Exception 2 is similar to Exception 1 except that a larger room area is permitted since the flammable and combustible liquids are in a static storage condition.

Spray paint booths are typically power-ventilated structures within a building that have their own enclosure separate from the exterior wall construction. The location and fire separation requirements for the spray paint booth must be in accordance with Section 416 and NFPA 33.

[F] 415.5.1 Group H occupancy minimum fire separation distance. Regardless of any other provisions, buildings containing Group H occupancies shall be set back to the minimum fire separation distance as set forth in Sections 415.5.1.1 through 415.5.1.4. Distances shall be measured from the walls enclosing the occupancy to lot lines, including those on a public way. Distances to assumed lot lines established for the purpose of determining exterior wall and opening protection are not to be used to establish the minimum fire separation distance for buildings on sites where explosives are manufactured or used when separation is provided in accordance with the quantity distance tables specified for explosive materials in the International Fire Code.

- Due to the potentially volatile nature of hazardous materials, specific setback requirements are necessary for Group H occupancies. These provisions take precedence over provisions in the code that may specify a minimum fire separation distance based on building construction type and exposure (see Table 602). The listed conditions are dependent on the type of materials that are indicative of the specified Group H occupancies, the size of the hazardous material storage area and whether a detached building is required by Table 415.5.5.2.

When dealing with explosives, it is important to note that the base paragraph makes a distinction between the assumed lot lines (see Section 705.3) that are used for determining exterior wall and opening protection and those that are used for the separation of buildings, based on fire separation distance, where explosives are involved. Where explosives are involved, the separation distances are measured between structures and not to some imaginary lot line that is assumed to be between them. It is reasonable to make this distinction since the separation distances for explosives far exceed the normal exterior wall and opening separation requirements.

[F] 415.5.1.1 Group H-1. Group H-1 occupancies shall be set back not less than 75 feet (22 860 mm) and not less than required by the International Fire Code.

Exception: Fireworks manufacturing buildings separated in accordance with NFPA 1124.

- Unless a greater distance is required by the IFC, a minimum setback of 75 feet (22 860 mm) is required between the walls enclosing a Group H-1 occupancy and all lot lines. The exception recognizes that fireworks manufacturing buildings pose unique hazards due to the potential volume (net weight) of fireworks in any single building. NFPA 1124 specifies the minimum separation distances between all process buildings, public highways and other inhabited buildings.

[F] 415.5.1.2 Group H-2. Group H-2 occupancies shall be set back not less than 30 feet (9 144 mm) where the area of the occupancy is greater than 1,000 square feet (93 m²) and it is not required to be located in a detached building.

- Unless required to be in a detached building as regulated by Section 415.5.2, all Group H-2 occupancies that exceed 1000 square feet (93 m²) in floor area are to have at least 30 feet (9144 mm) between the walls enclosing the Group H-2 occupancy and the lot lines surrounding the site.

[F] 415.5.1.3 Groups H-2 and H-3. Group H-2 and H-3 occupancies shall be set back not less than 50 feet (15 240 mm) where a detached building is required (see Table 415.3.2).

- Where Table 415.5.2 requires a detached building due to the quantity of hazardous materials involved, the Group H-2 and H-3 occupancies must be set back at least 50 feet (15 240 mm) from surrounding lot lines.

[F] 415.5.1.4 Explosive materials. Group H-2 and H-3 occupancies containing materials with explosive characteristics shall be separated as required by the International Fire Code. Where separations are not specified, the distances required shall be determined by a technical report issued in accordance with Section 414.1.3.

- The physical separation requirements for Group H-2 and H-3 occupancies that contain explosive materials are not regulated by the IBC, but rather by Chapter 56 in the IFC. In those situations where the IFC does not provide minimum separation requirements, it is necessary to do a specific analysis of the conditions and develop a technical report as described in Section 414.1.3.
[F] 415.5.2 Detached buildings for Group H-1, H-2 or H-3 occupancy. The storage or use of hazardous materials in excess of those amounts listed in Table 415.5.2 shall be in accordance with the applicable provisions of Sections 415.6 and 415.7.

Table 415.5.2 requires detached buildings for some of the materials found in Groups H-2 and H-3 due to the large quantities involved. Even though these materials are less of a hazard when compared to those found in Group H-1, they do create a significant hazard in sufficiently large quantities.

**TABLE 415.5.2.** See below.

- Detached buildings are required to be adequately separated from lot lines and other important buildings. As such, additional exposure protection for exterior walls is not needed.

### [F] 415.5.2.1 Wall and opening protection.

Where a detached building is required by Table 415.5.2, there are no requirements for wall and opening protection based on fire separation distance.

- Detached buildings are required to be adequately separated from lot lines and other important buildings. As such, additional exposure protection for exterior walls is not needed.

### [F] 415.6 Special provisions for Group H-1 occupancies.

Group H-1 occupancies shall be in buildings used for no other purpose, shall not exceed one story in height and be without basements, crawl spaces or other under-floor spaces. Roofs shall be of lightweight construction with suitable thermal insulation to prevent sensitive material from reaching its decomposition temperature. Group H-1 occupancies containing materials that are in themselves both physical and health hazards in quantities exceeding the maximum allowable quantities per control area in Table 307.1(2) shall comply with requirements for both Group H-1 and H-4 occupancies.

- Due to the explosion hazard potential associated with Group H-1 materials, Group H-1 occupancies are required to be in separate detached structures. The limitation of one story is based on the need to exit a building with a detonation hazard as soon as possible. Exiting from a second story or basement, even within an interior exit stairway, may not offer sufficient protection where an explosion hazard exists. The one-story limitation is also intended to limit the volume of detonable materials that could be stored in any one structure.

Group H-1 occupancies that contain materials that present a health as well as a detonation hazard must also comply with the applicable requirements for a

For SI: 1 ton = 906 kg, 1 cubic foot = 0.02832 m³, 1 pound = 0.454 kg.

- For materials that are detonable, the distance to other buildings or lot lines shall be in accordance with Chapter 33 of the International Fire Code based on trinitrotoholene (TNT) equivalence of the material. For materials classified as explosives, see Chapter 56 of the International Fire Code.
- "Maximum Allowable Quantity" means the maximum allowable quantity per control area set forth in Table 307.1(1).
- Limited to Division 1.4 materials and articles, including articles packaged for shipment, that are not regulated as an explosive under Bureau of Alcohol, Tobacco, Firearms and Explosives (BATF) regulations or unpackaged articles used in process operations that do not propagate a detonation or deflagration between articles, provided the net explosive weight of individual articles does not exceed 1 pound.
Group H-4 occupancy (see commentary, Section 307.8).

[F] 415.6.1 Floors in storage rooms. Floors in storage areas for organic peroxides, pyrophoric materials and unstable (reactive) materials shall be of liquid-tight, noncombustible construction.

- Noncombustible floors are required to prevent the structure from contributing to a fire scenario. The floors are also required to be liquid tight to prevent the spread of hazardous materials to areas outside the storage room.

[F] 415.7 Special provisions for Group H-2 and H-3 occupancies. Group H-2 and H-3 occupancies containing quantities of hazardous materials in excess of those set forth in Table 415.5.2 shall be in detached buildings used for manufacturing, processing, dispensing, use or storage of hazardous materials. Materials listed for Group H-1 occupancies in Section 307.3 are permitted to be located within Group H-2 or H-3 detached buildings provided the amount of materials per control area do not exceed the maximum allowed quantity specified in Table 307.1(1).

- This section in conjunction with Table 415.5.2 specifies when a Group H-2 or H-3 occupancy must be in a detached structure. Detached structures used for the storage of hazardous materials are not intended to be mixed-use occupancies. In addition to the materials listed in Table 415.5.2, along with those addressed in Section 415.7.3, it is acceptable to locate materials listed in Section 307.3 in such detached structures provided they do not exceed the maximum allowable quantities per control area based on Table 307.1(1).

[F] 415.7.1 Detached buildings. Detached buildings shall not exceed one story in height and shall be without basements, crawl spaces or other under-floor spaces.

- Detached buildings of Group H-2 or H-3 occupancy are limited to a single story in height. Similar to Group H-1 concerns, the limitation of one story is based on the need to exit a building with a high physical hazard as soon as possible. Exiting from a second story or basement, even within a fire-resistance-rated interior stairway, may not offer sufficient protection where an explosion or accelerated burning hazard exists. The one-story limitation is also intended to limit the volume of detonable materials that could be stored in any one structure.

[F] 415.7.2 Multiple hazards. Group H-2 or H-3 occupancies containing materials which are in themselves both physical and health hazards in quantities exceeding the maximum allowable quantities per control area in Table 307.1(2) shall comply with requirements for Group H-2, H-3 or H-4 occupancies as applicable.

- Group H-2 and H-3 occupancies that contain materials that pose a health as well as a physical hazard must also comply with the applicable requirements for a Group H-4 occupancy (see commentary, Section 307.8).

[F] 415.7.3 Separation of incompatible materials. Hazardous materials other than those listed in Table 415.3.2 shall be allowed in manufacturing, processing, dispensing, use or storage areas when separated from incompatible materials in accordance with the provisions of the International Fire Code.

- In addition to those hazardous materials specifically listed in Table 415.5.2, it is acceptable to use or store other types of hazardous materials in a detached building provided the incompatible materials are isolated from each other in accordance with the IFC.

[F] 415.7.4 Water reagents. Group H-2 and H-3 occupancies containing water-reactive materials shall be resistant to water penetration. Piping for conveying liquids shall not be over or through areas containing water reagents, unless isolated by approved liquid-tight construction.

- Exception: Fire protection piping shall be permitted over or through areas containing water reagents without isolating it with liquid-tight construction.

- The design and construction of buildings used for storing water-reactive materials must be such that water will not be permitted to come in contact with the stored materials. The building materials should be designed to resist the passage of flowing water. Piping conveying liquids, other than sprinkler system piping, is prohibited in any area containing water-reactive materials.

[F] 415.7.5 Floors in storage rooms. Floors in storage areas for organic peroxides, oxidizers, pyrophoric materials, unstable (reactive) materials and water-reactive solids and liquids shall be of liquid-tight, noncombustible construction.

- Noncombustible floors are required to prevent the structure from contributing to a fire scenario. The floors are also required to be liquid tight to prevent the spread of hazardous materials to areas outside the storage room.

[F] 415.7.6 Waterproof room. Rooms or areas used for the storage of water-reactive solids and liquids shall be constructed in a manner that resists the penetration of water through the use of waterproof materials. Piping carrying water for other than approved automatic sprinkler systems shall not be within such rooms or areas.

- Similar to Section 415.7.6, storage rooms containing water-reactive materials must be waterproofed. Though water piping may not be run into or through such rooms, the code recognizes that automatic sprinkler systems are a more regulated type of water piping system and have a low leakage and failure rate when properly installed and maintained.

[F] 415.8 Group H-2. Occupancies in Group H-2 shall be constructed in accordance with Sections 415.8.1 through 415.8.4 and the International Fire Code.

- Sections 415.8.1 through 415.8.4 contain specific construction requirements for occupancies that contain Group H-2 materials in excess of the maximum
allowable quantities. Such occupancies are also required to comply with all material-specific related provisions in the IFC.

[F] 415.8.1 Combustible dusts, grain processing and storage. The provisions of Sections 415.8.1.1 through 415.8.1.6 shall apply to buildings in which materials that produce combustible dusts are stored or handled. Buildings that store or handle combustible dusts shall comply with the applicable provisions of NFPA 61, NFPA 85, NFPA 120, NFPA 484, NFPA 654, NFPA 655 and NFPA 684, and the International Fire Code.

- Combustible dusts can generate high-pressure gas by combustion in air. The pressure created can destroy process equipment and structures. While there is a minimum concentration of dust required, there is no reliable upper concentration limitation beyond which combustion will not occur. The ignition source is often the process equipment itself. The provisions of this section primarily address the construction of a building that contains this hazard. The construction requirements are primarily intended to reduce the exposure hazard should a fire or explosion occur. To minimize the impact of the explosion on the structure, explosion control in accordance with Section 414.5.1 and the IFC is required. The provisions of this section apply to all buildings in which combustible dusts and particles are of sufficient quantity to be readily ignited and subject to explosion. The concentration that would be required to constitute such a hazard is dependent on the particle size. Additional guidance on the relative fire risk associated with various combustible dusts can be found in the referenced standards. In addition to the provisions of this section, compliance with the provisions of the IFC and the referenced standards is essential to minimize the potential ignition and the fire and explosion hazards. Chapter 22 of the IFC contains specific safety precautions for combustible dust-producing operations and references additional standards for explosion protection based on the type of process involved. Essentially, each of the referenced standards prescribes reasonable requirements for safety to life and property from fire and explosion. The standards also minimize the resulting damage should a fire or explosion occur. More specifically, they contain provisions for construction, ventilation, explosion venting, equipment, heating devices, dust control, fire protection and supplemental requirements related to electrical wiring and equipment, provisions concerning protection from sparks, cutting and welding and smoking and signage regulations.

[F] 415.8.1.1 Type of construction and height exceptions. Buildings shall be constructed in compliance with the height and area limitations of Table 503 for Group H-2; except that where erected of Type I or II construction, the heights and areas of grain elevators and similar structures shall be unlimited, and where of Type IV construction, the maximum building height shall be 65 feet (19,812 mm) and except further that, in isolated areas, the maximum building height of Type IV structures shall be increased to 85 feet (25,908 mm).

- The construction of buildings in which combustible dusts can be readily ignitable and subject to an explosion hazard is restricted to the height and area limits in Table 503 for Group H-2. The limitation on construction is intended to reduce the available fuel source that could ignite and serve as the source of a dust explosion. Grain elevators and similar structures that require a height in excess of that permitted in Table 503 may be of unlimited height if the structures are of Type I or II construction; or such structures may be 65 feet (19,812 mm) if they are of Type IV construction. If the structure is of Type IV construction and located so as not to constitute an explosion hazard, the allowable height may be increased to 85 feet (25,908 mm). Although the buildings are required to have an automatic sprinkler system in accordance with Section 903.2.5, the speed at which the combustion process or explosion could occur may reduce the effectiveness of the sprinkler system. Additional guidance on methods to prevent explosions can be found in Section 911 of the IFC and applicable referenced standards, such as NFPA 69, for explosion prevention systems.

[F] 415.8.1.2 Grinding rooms. Every room or space occupied for grinding or other operations that produce combustible dusts shall be enclosed with fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both. The fire-resistance rating of the enclosure shall be not less than 2 hours where the area is not more than 3,000 square feet (279 m²), and not less than 4 hours where the area is greater than 3,000 square feet (279 m²).

- Grinding rooms are to be separated from remaining parts of the building by construction having a fire-resistance rating of at least 2 hours. If the area of the room is greater than 3,000 square feet (279 m²), the fire-resistance rating of the enclosure must be at least 4 hours. Not only is it the intent to protect the room from an explosion fire but also, assuming the explosion venting results in minimal structural damage, for the enclosure to contain the resulting fire, if any, to the room of origin. Without venting, it is doubtful whether the enclosure could withstand the forces exerted on the wall by an explosion.

[F] 415.8.1.3 Conveyors. Conveyors, chutes, piping and similar equipment passing through the enclosures of rooms or spaces shall be constructed dirt tight and vapor tight, and be of approved noncombustible materials complying with Chapter 30.

- The intent of this section is to restrict conveyors that pass through walls so that they do not serve as an ignition source or avenue of fire spread to adjacent areas. These conveyors and similar equipment must
be constructed of noncombustible materials and be
dirt and vapor tight.

[F] 415.8.1.4 Explosion control. Explosion control shall
equivalent mechanical ventilation complying with the International Mechanical Code.

- The pressure exerted by a combustible dust explo-
sion typically ranges from 13 to 89 psi (89 to 614
kPa). It is impractical to construct a building that will
withstand such pressures; therefore, either a means
of explosion control must be provided in accordance
with Section 911 of the IFC or an equivalent mechan-
cal ventilation system must be provided. The
mechanical ventilation system must be in accordance
with the IMC and must be designed to control the
dust concentration below hazardous levels. The
mechanical ventilation is dependent on the concen-
tration at which a dust explosion could occur. Addi-
tional guidance on the relative fire risk associated
with various combustible dusts can be found in the
referenced standards.

[F] 415.8.1.5 Grain elevators. Grain elevators, malt houses
and buildings for similar occupancies shall not be located
within 30 feet (9144 mm) of interior lot lines or structures on
the same lot, except where erected along a railroad right-of-
way.

- The 30-foot (9144 mm) separation between grain elev-
ators (or similar structures with regard to lot lines)
and other structures is intended to reduce the expo-
sure hazard. It is intended not only to reduce the
damage to the adjacent structure but also to minimize
the potential that a fire in the adjacent structure would
affect the grain elevator. Grain elevators are singled
out because of the additional height permitted in Sec-
tion 415.8.1.1 and the typical openness of the struc-
ture. The 30-foot (9144 mm) separation is not
required if the grain elevator is located along a rail-
road right-of-way. The railroad right-of-way will offer
some separation, except when a car is being loaded
from the grain elevator, in which case the 30-foot
(9144 mm) criterion may not be practical.

[F] 415.8.1.6 Coal pockets. Coal pockets located less than 30
feet (9144 mm) from interior lot lines or from structures on
the same lot shall be constructed of not less than Type IB
construction. Where more than 30 feet (9144 mm) from in-
terior lot lines, or where erected along a railroad right-of-way,
the minimum type of construction of such structures not more
than 65 feet (19812 mm) in building height shall be Type IV.

- Like grain elevators, coal pockets are typically open
structures and there is a need to provide separation
between the coal pocket and the adjacent structures
to reduce the exposure fire risk. Type IB construction
is the required minimum if a coal pocket is within 30
feet (9144 mm) of another structure or lot line. Like
grain elevators, if the separation is in excess of 30
feet (9144 mm), Type IV construction is permitted to
a maximum building height of 65 feet (19812 mm).

[F] 415.8.2 Flammable and combustible liquids. The stor-
age, handling, processing and transporting of flammable and
combustible liquids in Groups H-2 and H-3 occupancies shall
be in accordance with Sections 415.8.2.1 through 415.8.2.3,
the International Mechanical Code and the International Fire
Code.

- Although Section 415.8.2 and its subsections are part
of Section 415.8, these sections apply to both Group
H-2 and H-3 occupancies. The storage of flammable
and combustible liquids constitutes a special hazard
because of the potential fire severity and ease of igni-
tion related to such liquids. The flash point is the most
important criterion of the hazards associated with
flammable and combustible liquids because it repres-
ents the lowest temperature at which sufficient
vapor will be given off to form an ignitable or flamma-
ble mixture with air. Although it is the flammable
vapors that burn or explode, flammable liquids (by
definition) are normally stored above their flash point.
Since flammable and combustible liquids are found in
virtually every industrial plant and many other occupa-
cies, minimum requirements for the storage of
such liquids are set forth in the provisions of Chapter
57 of the IFC and NFPA 30.

Additionally, the provisions of Sections 415.8.2.1
through 415.8.2.9 permit the inside tank storage of
flammable and combustible liquids. It is intended that
all of these provisions, where applicable, be complied
with in order to allow the installation of large tanks of
flammable and combustible liquids within the build-
ing. These provisions were developed in part due to
the cost of complying with environmental consider-
ations regarding the installation of underground stor-
age tanks. In downtown areas, above-ground inside
storage tanks are commonly used in conjunction with
emergency power generators. While not specifically
defined, these provisions are intended for tanks pro-
posed for fixed installation as opposed to containers
and portable tanks, such as 55-gallon (208 L) drums.

[F] 415.8.2.1 Mixed occupancies. Where the storage tank
area is located in a building of two or more occupancies and
the quantity of liquid exceeds the maximum allowable quan-
ity for one control area, the use shall be completely sepa-
rated from adjacent occupancies in accordance with the
requirements of Section 508.4.

- This section requires mandatory fire-resistance-rated
separation of the Group H storage tank area from
adjacent areas containing other groups. By referencing
Section 508.4 for separated mixed occupancies,
the storage tank area would require a minimum fire
barrier construction, both horizontally and vertically,
whenever a mixed-occupancy condition occurs.

[F] 415.8.2.1.1 Height exception. Where storage tanks are
located within a building no more than one story above grade
plane, the height limitation of Section 503 shall not apply for
Group H.

- Group H storage tank areas may be located on an
upper floor in a multiple-story building subject to the

4-108

2012 INTERNATIONAL BUILDING CODE® COMMENTARY
limitations of Section 503. As long as the storage tank area is located within a building no more than one story, the height limitations of Table 503, with respect to both height in feet and number of stories, would not apply to the Group H fire area. The height limitation for the building would be dictated by the other occupancy groups in the building and the actual construction type. The height exception assumes the storage tank area complies with all of the applicable provisions of Section 415.8.2 and Chapter 57 of the IFC.

[F] 415.8.2.2 Tank protection. Storage tanks shall be noncombustible and protected from physical damage. Fire barriers or horizontal assemblies or both around the storage tanks shall be permitted as the method of protection from physical damage.

- Storage tanks shall be noncombustible and protected from physical damage. Fire barriers or horizontal assemblies or both around the storage tanks shall be permitted as the method of protection from physical damage.

The intent of this section is to reduce the potential for industrial accidents involving storage tanks by providing a physical barrier, such as a pipe bollard or barricade. This section would also allow the fire barrier or horizontal assembly that is enclosing the storage tank area to qualify as the means of protection from physical damage. Any method of physical protection, other than a fire barrier wall assembly, must be approved by the building official.

[F] 415.8.2.3 Tanks. Storage tanks shall be approved tanks conforming to the requirements of the International Fire Code.

- The design, construction and installation of all storage tanks for flammable and combustible liquids must comply with the applicable provisions of Chapter 57 of the IFC.

[F] 415.8.2.4 Leakage containment. A liquid-tight containment area compatible with the stored liquid shall be provided. The method of spill control, drainage control and secondary containment shall be in accordance with the International Fire Code.

**Exception:** Rooms where only double-wall storage tanks conforming to Section 415.8.2.3 are used to store Class I, II and IIIA flammable and combustible liquids shall not be required to have a leakage containment area.

- In order to prevent the spread of flammable and combustible liquids to adjacent nonstorage areas in the event of a leak in a storage tank, an adequately sized containment area is required. The sizing of the containment area should be designed to contain a spill from the largest vessel plus the fire protection water for the required duration. It is also important that the drainage system be sufficient to drain not only the flammable or combustible liquid but also the drainage water from the sprinkler system as well as hose streams. Since the outer wall of a double-walled storage tank acts as the secondary means of containment, the exception would allow the omission of the leakage containment area for all flammable and combustible liquids.

[F] 415.8.2.5 Leakage alarm. An approved automatic alarm shall be provided to indicate a leak in a storage tank and room. The alarm shall sound an audible signal, 15 dBA above the ambient sound level, at every point of entry into the room in which the leaking storage tank is located. An approved sign shall be posted on every entry door to the tank storage room indicating the potential hazard of the interior room environment, or the sign shall state: WARNING, WHEN ALARM SOUNDS, THE ENVIRONMENT WITHIN THE ROOM MAY BE HAZARDOUS. The leakage alarm shall also be supervised in accordance with Chapter 9 to transmit a trouble signal.

- This section requires an alarm system to indicate a leak in the storage tank. The alarm must be supervised, as well as sound a local signal. Automatic electrical supervision of the leakage alarm is required in accordance with Section 901.6.3

[F] 415.8.2.6 Tank vent. Storage tank vents for Class I, II or IIIA liquids shall terminate to the outdoor air in accordance with the International Fire Code.

- Section 5704.2.7.3.3 of the IFC specifies the proper location of the tank vent to enable flammable vapors to be released to the outside air and dissipate without creating a hazard. It also requires the tank vent to terminate a minimum of 12 feet (3658 mm) above grade and 5 feet (1524 mm) from building openings and lot lines to reduce the possibility of ignitable concentrations of the vapors collecting near the discharge end of the vent pipe, entering building openings or exposing adjoining property.

[F] 415.8.2.7 Room ventilation. Storage tank areas storing Class I, II or IIIA liquids shall be provided with mechanical ventilation. The mechanical ventilation system shall be in accordance with the International Mechanical Code and the International Fire Code.

- This section requires mechanical ventilation for storage tank areas in order to maintain any vapor buildup at safe levels until the hazard of a spill or leak can be abated. The ventilation requirements for flammable or combustible liquid storage tanks must be in accordance with the applicable provisions of the IMC and the IFC.

[F] 415.8.2.8 Explosion venting. Where Class I liquids are being stored, explosion venting shall be provided in accordance with the International Fire Code.

- Class I flammable liquids, when stored in sufficient quantities, can readily produce vapors within the explosive limitations. Explosion venting must be in accordance with the provisions of Sections 414.5.1 and 911 and Chapter 57 of the IFC.
[F] 415.8.2.9 Tank openings other than vents. Tank openings other than vents from tanks inside buildings shall be designed to ensure that liquids or vapor concentrations are not released inside the building.

- Additional provisions are necessary to minimize the possibility of an accidental release of flammable or combustible liquids or their vapors via any connection to the tank other than a vent. This includes requirements for liquid-tight openings below the liquid level in the tank, overflow protection and vapor recovery connections as indicated in Section 5004.2.7.5 of the IFC.

[F] 415.8.3 Liquefied petroleum gas facilities. The construction and installation of liquefied petroleum gas facilities shall be in accordance with the requirements of this code, the International Fire Code, the International Mechanical Code, the International Fuel Gas Code and NFPA 58.

- The key to this section is the reference to NFPA 58 for design and construction of liquefied petroleum gas facilities. NFPA 58 provides a comprehensive set of construction requirements for LP-gas distribution facilities, as well as bulk plants, and industrial plants in which LP-gas systems, storage systems, vaporizers, mixing systems and similar activities are involved.

[F] 415.8.4 Dry cleaning plants. The construction and installation of dry cleaning plants shall be in accordance with the requirements of this code, the International Mechanical Code, the International Plumbing Code and NFPA 32. Dry cleaning solvents and systems shall be classified in accordance with the International Fire Code.

- Dry cleaning plants that do not qualify for Exception 4 or 5 of Section 307.1 and in which the maximum allowable quantity per control area of dry cleaning solvents exceeds the values in Table 307.1(1) would be classified in Group H and would be required to comply with the applicable provisions of the IPC, the IMC and NFPA 32. It should be noted that Chapter 21 of the IFC also contains provisions for dry cleaning plants and references NFPA 32 for their maintenance. NFPA 32 contains provisions for the prevention and control of fire and explosion hazards associated with dry cleaning operations and for the protection of employees and the public. This standard addresses such issues as location, construction, building services, processes and equipment and fire control.

[F] 415.9 Groups H-3 and H-4. Groups H-3 and H-4 shall be constructed in accordance with the applicable provisions of this code and the International Fire Code.

- This section contains provisions that are applicable to all Group H-3 and H-4 occupancies in addition to material-specific requirements in the IFC. These requirements assume that the Group H-3 and H-4 occupancies contain more than the maximum allowable quantities of hazardous materials per control area permitted by Tables 307.1(1) and 307.1(2). Sections 307.5 and 307.6 contain a list of those materials that could be present in Group H-3 and H-4 occupancies.

[F] 415.9.1 Flammable and combustible liquids. The storage, handling, processing and transporting of flammable and combustible liquids in Group H-3 occupancies shall be in accordance with Section 415.8.2.

- This section refers back to Section 415.8.2, where the standards for the handling, storage and processing of these liquids are provided for both Group H-3 and H-2 occupancies.

[F] 415.9.2 Gas rooms. Where gas rooms are provided, such rooms shall be separated from other areas by not less than 1-hour fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both.

- In order to restrict the potential fire involvement of a storage room of hazardous gases within a Group H-3 or H-4 occupancy, a 1-hour fire-resistance-rated fire barrier or horizontal assemblies, or both, are required to separate gas rooms from other adjacent areas. The required fire-resistance-rated 1-hour barrier separation is not due to a mixed-occupancy condition but rather further compartmentation in a Group H-3 or H-4 occupancy.

[F] 415.9.3 Floors in storage rooms. Floors in storage areas for corrosive liquids and highly toxic or toxic materials shall be of liquid-tight, noncombustible construction.

- Storage rooms of corrosive liquids and highly toxic and toxic materials would be classified as a Group H-4 occupancy. Noncombustible floors are required to prevent the structure from contributing to a fire scenario. The floors are also required to be liquid tight to prevent the spread of liquids from a spill to areas outside the storage room.

[F] 415.9.4 Separation—highly toxic solids and liquids. Highly toxic solids and liquids not stored in approved hazardous materials storage cabinets shall be isolated from other hazardous materials storage by not less than 1-hour fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both.

- The potential involvement of materials that may be incompatible in storage situations with highly toxic solids and liquids must be addressed. The required degree of separation, either by approved cabinets or 1-hour fire-resistance-rated fire barrier and horizontal assembly construction, is also intended to restrict the highly toxic materials from other combustibles.

[F] 415.10 Group H-5. In addition to the requirements set forth elsewhere in this code, Group H-5 shall comply with the
provisions of Sections 415.10.1 through 415.10.11 and the 
*International Fire Code*.

- This section contains the requirements for Group H-5 
facilities that utilize HPM. Section 415.10 is intended 
to be a design option for buildings that utilize hazard-
ous materials in excess of the maximum allowable 
quantities permitted by Tables 307.1(1) and 307.1(2). 
HPM facilities are considered unique high-hazard 
occupancies. The HPM occupancy classification 
assumes that while the manufacturing process 
involves the use of hazardous materials, the end 
product by itself is not hazardous.

The provisions of Section 415.10 resulted from 
nonuniform regulation of semiconductor fabrication 
facilities and are based on code changes submitted 
by groups associated with the semiconductor industry. 
These industries include electronic high-tech 
industries, such as semiconductor microchip fabrica-
tion, as well as the floppy disk and telecommunication 
industries. Additionally, there are other comparable 
activities involving similar technology that also use 
high-hazard materials. HPM include flammable liq-
uids and gases, corrosives, oxidizers and, in many 
instances, highly toxic materials. The HPM may be a 
solid, liquid or gas with a degree of health rating in 
health, flammability or reactivity of Class 3 or 4 
in accordance with NFPA 704, which is used directly in 
research, laboratory or production processes.

Structures that contain HPM facilities are required 
to meet the provisions of Section 415.10 as well as 
any other code provisions for a Group H-5 occupancy 
classification unless specifically modified in Section 
415.10. Additionally, Chapter 27 of the IFC provides 
complementary fire safety controls that reduce the 
risks of hazard at an acceptable level in existing HPM 
buildings and fabrication areas.

**F** 415.10.1 Fabrication areas. Fabrication areas shall 
comply with Sections 415.10.1.1 through 415.10.1.8.

- The fabrication area of an HPM facility is where the 
hazardous materials are actively handled and pro-
cessed. The fabrication area includes accessory 
rooms and spaces such as workstations and em-
ployee dressing rooms.

**F** 415.10.1.1 Hazardous materials. Hazardous materials 
and hazardous production materials (HPM) shall comply 
with Sections 415.10.1.1.1 and 415.10.1.1.2.

- Sections 415.10.1.1.1 and 415.10.1.1.2 regulate the 
quantities and densities of HPM for each fabrication 
area of a Group H-5 facility.

**F** 415.10.1.1.1 Aggregate quantities. The aggregate quan-
tities of hazardous materials stored and used in a single fabrication area shall not exceed the quantities set forth in Table 415.10.1.1.1.

**Exception:** The quantity limitations for any hazard cate-
gory in Table 415.10.1.1.1 shall not apply where the fabrica-

tion area contains quantities of hazardous materials not 
exceeding the maximum allowable quantities per control area established by Tables 307.1(1) and 307.1(2).

- This section regulates the total amount of hazardous materials, whether in use or storage, within a single fabrication area based on the density/quantity of material specified in Table 415.10.1.1.1. The exception permits a fabrication area to have a total quantity of HPM of either the quantity specified in Table 415.10.1.1.1 or the maximum allowable quantities per control area specified in Table 307.1(1) or 307.1(2), whichever is greater. For example, a small fabrication area may have a quantity in accordance with Tables 307.1(1) and 307.1(2) even though it may exceed the quantities specified in Table 415.10.1.1.1. Conversely, a large fabrication area may have an aggregate quantity that exceeds those specified in Tables 307.1(1) and 307.1(2) if it does not exceed the quantities specified in Table 415.10.1.1.1.

It should be reiterated that this section refers to an aggregate quantity of hazardous materials that are in use and storage within a single fabrication area. Section 415.10.1.1.1 further limits the amount of HPM that is being stored within a fabrication area.

**Table 415.10.1.1.1.** See page 4-112.

- Table 415.10.1.1.1 controls the permitted densities/quantities of hazardous materials in a single fabrication area. In accordance with Section 415.10.1.1.1, the quantities permitted in Tables 307.1(1) and 307.1(2) may be exceeded, provided the quantities in Table 415.10.1.1.1 are maintained subject to the storage limitations of Section 415.10.1.1.2. Conversely, the maximum quantities of Table 415.10.1.1.1 may be exceeded, provided the maximum allowable quantities of Tables 307.1(1) and 307.1(2) are not exceeded.

In accordance with Note a, hazardous materials in pipping need not be included in evaluating the permitted quantity. Note b establishes that a specific quantity limitation, rather than a calculated density, is required for certain hazardous materials.

**F** 415.10.1.1.2 Hazardous production materials. The maximum quantities of hazardous production materials (HPM) stored in a single fabrication area shall not exceed the maximum allowable quantities per control area established by Tables 307.1(1) and 307.1(2).

- This section provides the overall limit of HPM that can be stored within a single fabrication area based on Tables 307.1(1) and 307.1(2). Any storage in excess of the permitted maximum allowable quantities would be required to be stored in an HPM storage room, liquid storage room or gas room. The aggregate quantities of hazardous materials in both a storage and use condition within a single fabrication area are regulated by Section 415.10.1.1.1.

</table>

For SI: 1 pound per square foot = 4.882 kg/m², 1 gallon per square foot = 0.097 L/m², 1 cubic foot @ NTP/square foot = 0.035 m³ @ NTP/m², 1 cubic foot = 0.02832 m³.

a. Hazardous materials within piping shall not be included in the calculated quantities.
b. Quantity of hazardous materials in a single fabrication shall not exceed the maximum allowable quantities per control area in Tables 307.1(1) and 307.1(2).

c. Densely packed baled cotton that complies with the packing requirements of ISO 8115 shall not be included in this material class.
d. The aggregate quantity of flammable, pyrophoric, toxic and highly toxic gases shall not exceed 9,000 cubic feet at NTP.
e. The aggregate quantity of pyrophoric gases in the building shall not exceed the amounts set forth in Table 415.5.2.
[F] 415.10.1.2 Separation. Fabrication areas, whose sizes are limited by the quantity of hazardous materials allowed by Table 415.10.1.1.1, shall be separated from each other, from corridors and from other parts of the building by not less than 1-hour fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both.

Exceptions:

1. Doors within such fire barrier walls, including doors to corridors, shall be only self-closing fire door assemblies having a fire protection rating of not less than \(\frac{1}{2}\) hour.

2. Windows between fabrication areas and corridors are permitted to be fixed glazing listed and labeled for a fire protection rating of not less than \(\frac{1}{2}\) hour in accordance with Section 716.

Fabrication areas must be separated from other parts of the building, egress corridors and other fabrication areas by fire barriers or horizontal assemblies, or both, having a fire-resistance rating of at least 1 hour. While the potential fire exposure could warrant a higher fire-resistance rating, the additional protection features indicative of a Group H-5 facility result in a 1-hour fire-resistance rating being acceptable. The fire barriers must be constructed in accordance with Section 707. The horizontal assemblies must be constructed in accordance with Section 711. One reason for separating one fabrication area from another is the limitation of HPM quantities in a single fabrication area. If the need exists for quantities in excess of those permitted by Section 415.10.1.1.1, the area can be divided into two fabrication areas with 1-hour fire barriers and horizontal assemblies.

Exception 1 clarifies that all doors within the fire barrier walls that comprise the fabrication area must be self-closing and have a fire protection rating of \(\frac{1}{2}\) hour; therefore, if a corridor wall was also part of the fabrication area, a \(\frac{1}{2}\)-hour opening protective would be required for the door opening. Openings in rated corridors that are not part of a fabrication area typically are required to only have a 20-minute fire protection rating. The doors are required to be self-closing since fabrication areas are "clean rooms" under positive pressure.

The \(\frac{1}{2}\)-hour requirement of Exception 2 will permit the use of fire protection-rated glazing or wired glass windows in accordance with Section 716.6. The use of windows is often desirable to facilitate the security of activities in the fabrication area as well as emergency response in the event of an accident.

[F] 415.10.1.3 Location of occupied levels. Occupied levels of fabrication areas shall be located at or above the first story above grade plane.

Due to the potential extensive use of hazardous materials, the occupiable levels of fabrication areas are not permitted in basements or other areas below grade. Maintaining fabrication areas at or above grade aids in the egress of the occupants and access for fire department operations.

[F] 415.10.1.4 Floors. Except for surfacing, floors within fabrication areas shall be of noncombustible construction.

Openings through floors of fabrication areas are permitted to be unprotected where the interconnected levels are used solely for mechanical equipment directly related to such fabrication areas (see also Section 415.10.1.5).

Floors forming a part of an occupancy separation shall be liquid tight.

Fabrication area floors are required to be noncombustible. The intent of the requirement for noncombustible floors is to prevent the structure from being involved in the fire from a liquid that may seep into the floor system. The requirement is not intended to apply to floor-covering material.

This section permits the interconnection of the operation floor and a mechanical floor, provided that the mechanical floor is essentially unoccupied. The intent is to prevent leakage past a required separation and to allow multiple-level fabrication areas where the space above or below the operation level is used for mechanical equipment, ducts and similar service equipment. Where a rated separation is required, the floors must be liquid tight. Whereas the hazards often involve liquids, floors are required to be liquid tight to prevent the spread of liquids from a spill to areas outside the fabrication area. "Liquid tight" requires that floors be sealed where they intersect with walls. This can be accomplished by a cove base of the same material as the floor.

[F] 415.10.1.5 Shafts and openings through floors. Elevator hoistways, vent shafts and other openings through floors shall be enclosed where required by Sections 712 and 713. Mechanical, duct and piping penetrations within a fabrication area shall not extend through more than two floors. The annular space around penetrations for cables, cable trays, tubing, piping, conduit or ducts shall be sealed at the floor level to restrict the movement of air. The fabrication area, including the areas through which the ductwork and piping extend, shall be considered a single conditioned environment.

Section 712 specifies the conditions when a shaft enclosure or some other application of addressing vertical openings in multi-story buildings is required. This section provides the requirements for specific opening penetrations through a floor within a fabrication area. The maximum number of stories that are allowed to be interconnected is three, since penetrations are limited to two floors. The penetrations for duct and piping are to have the annular space protected. When such penetrations exist, the fire separation required by Section 415.10.1.2 is to separate the entire interconnected volume.

[F] 415.10.1.6 Ventilation. Mechanical exhaust ventilation at the rate of not less than 1 cubic foot per minute per square foot \([0.0051 \text{ m}^3/(s \cdot \text{m}^2)]\) of floor area shall be provided throughout the portions of the fabrication area where HPM
are used or stored. The exhaust air duct system of one fabrication area shall not connect to another duct system outside that fabrication area within the building.

A ventilation system shall be provided to capture and exhaust gases, fumes and vapors at workstations.

Two or more operations at a workstation shall not be connected to the same exhaust system where either one or the combination of the substances removed could constitute a fire, explosion or hazardous chemical reaction within the exhaust duct system.

Exhaust ducts penetrating fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711 shall be contained in a shaft of equivalent fire-resistance-rated construction. Exhaust ducts shall not penetrate fire walls.

Fire dampers shall not be installed in exhaust ducts.

- A major design factor is the required minimum ventilation. The minimum rate is 1 cubic foot per minute (cfm) per square foot (0.0051 m²/s x m²), or about eight air changes per hour for an 8-foot-high (2438 mm) fabrication area. Typically, at least 24 air changes per hour are provided for operational needs and where unclassified electrical systems are to be used. In order to prevent the spread of gases or fumes, the exhaust air duct system of any fabrication area must not be connected to any other ventilation system. With regard to workstations, the required ventilation system is intended to prevent exposure of the work station operator to hazardous fumes or vapors and prevent hazardous concentrations of materials used in the manufacturing process. Additionally, ventilation systems must be designed to reduce the possibility of a chemical reaction occurring between two or more HPM or a material's and exhaust system's components. Where two or more chemicals may react dangerously if exhausted through a common duct, they must be removed separately. NFPA 491, which is included in the NFPA Fire Protection Guide on Hazardous Materials, is a good first reference when trying to determine if any two agents are reactive.

Ventilation should not be interrupted by a fire damper when a fire or other emergency occurs involving a workstation. This helps reduce the likelihood that hazardous combustion byproducts or hazardous concentrations of HPM are not forced back into the workstation or clean room. Continuous ventilation through a duct enclosed in a fire-resistance-rated shaft is required. Fire walls define separations between buildings. Ducts must never penetrate a barrier common to another building or occupancy. This reduces the likelihood of tampering with or interrupting the duct integrity.

[F] 415.10.1.7 Transporting hazardous production materials to fabrication areas. HPM shall be transported to fabrication areas through enclosed piping or tubing systems that comply with Section 415.10.6, through service corridors complying with Section 415.10.3, or in corridors as permitted in the exception to Section 415.10.2. The handling or transporting of HPM within service corridors shall comply with the International Fire Code.

- Except as permitted in the exception to Section 415.10.2 for existing facilities, all HPM must be transported to the fabrication area by service corridors or piping (see Sections 415.10.4 and 415.10.6). This reduces the chance that an egress route will be affected by an accidental leak or spill. Chapter 27 of the IFC contains additional requirements for the transport of HPM through all egress components as well as service corridors.

[F] 415.10.1.8 Electrical. Electrical equipment and devices within the fabrication area shall comply with NFPA 70. The requirements for hazardous locations need not be applied where the average air change is at least four times that set forth in Section 415.10.1.6 and where the number of air changes at any location is not less than three times that required by Section 415.10.1.6. The use of recirculated air shall be permitted.

- Consistent with Chapter 27, electrical installations are required to comply with NFPA 70. This section specifically permits the dilution of concentrations of hazardous areas such that the hazardous location provisions of NFPA 70 need not apply. This is because some of the equipment used in HPM facilities cannot comply with the hazardous location provisions of NFPA 70. The nature of the fabrication process also dictates the use of the dilution concept. Typically, such facilities have a ventilation system designed to provide at least 24 air changes per hour. At least 3 cfm per square foot (0.132 L/s/m²) or 24 air changes in an 8-foot-high (2438 mm) fabrication area is required at all locations in order to apply the hazardous location provisions of NFPA 70. Also, an average rate of 4 cfm per square foot (0.176 L/s/m²) or 32 air changes in an 8-foot-high (2438 mm) fabrication area are required if the hazardous location provisions of NFPA 70 are not applied.

[F] 415.10.1.8.1 Workstations. Workstations shall not be energized without adequate exhaust ventilation. See Section 415.10.1.6 for workstation exhaust ventilation requirements.

- Accidental exposure to flammable fumes or vapors can occur at workstations where hazardous materials are used. Either a mechanical or electrical interlock must be provided to engage the required exhaust ventilation system before HPM enters the workstation. This reduces the likelihood of gas or vapor exposure.

[F] 415.10.2 Corridors. Corridors shall comply with Chapter 10 and shall be separated from fabrication areas as specified in section 415.10.1.2. Corridors shall not contain HPM.
and shall not be used for transporting such materials except through closed piping systems as provided in Section 415.10.6.4

**Exception:** Where existing fabrication areas are altered or modified, HPM is allowed to be transported in existing corridors, subject to the following conditions:

1. Nonproduction HPM is allowed to be transported in corridors if utilized for maintenance, lab work and testing.

2. Where existing fabrication areas are altered or modified, HPM is allowed to be transported in existing corridors, subject to the following conditions:

   2.1. Corridors. Corridors adjacent to the fabrication area where the alteration work is to be done shall comply with Section 1018 for a length determined as follows:

   2.1.1. The length of the common wall of the corridor and the fabrication area; and

   2.1.2. For the distance along the corridor to the point of entry of HPM into the corridor serving that fabrication area.

2.2. *Emergency alarm system.* There shall be an emergency telephone system, a local manual alarm station or other approved alarm-initiating device within corridors at not more than 150-foot (45 720 mm) intervals and at each exit and doorway. The signal shall be relayed to an approved central, proprietary or remote station service or the emergency control station and shall also initiate a local audible alarm.

2.3. *Pass-throughs.* Self-closing doors having a fire protection rating of not less than 1 hour shall separate pass-throughs from existing corridors. Pass-throughs shall be constructed as required for the corridors and protected by an approved automatic sprinkler system.

- Corridors are required to comply with the requirements of Section 1018 and must be separated from fabrication areas in accordance with Section 415.10.1.2. Additionally, typical egress corridors in new buildings are not to be used for transporting HPM to the fabrication area. In accordance with Section 415.10.1.7, HPM must be transported by service corridors or piping (see Sections 415.10.3 and 415.10.6 and Figure 415.10.2).

Exception 1 allows corridors to be used for the movement of HPM that is only used for maintenance purposes, laboratory work and testing activities. The second exception addresses HPM facilities that existed before the adoption and enforcement of this section. It permits the transport of HPM in egress corridors in existing buildings under the conditions specified in Items 2.1, 2.2 and 2.3. When alterations are made to a fabrication area, such corridors must be upgraded. Chapter 27 of the IFC provides additional requirements for the storage, handling and transporting of HPM materials in existing HPM facilities. Item 2.1 of the exception requires that corridors be upgraded to a 1-hour fire-resistance rating for the entire length of the wall common to the fabrication area. Additionally, the entire length of the corridor that is used for transporting HPM to the fabrication area being renovated must also be upgraded to have a 1-hour fire-resistance rating. Item 2.2 requires a means to notify trained personnel of an emergency condition in an egress corridor. A local alarm is required to alert the occupants of a potential hazardous condition. The intent of Item 2.3 is to permit a "pass-through" for providing HPM to a fabrication area. A pass-through, such as a storage cabinet, is used to store and receive HPM for the fabrication area. The pass-through must be separated from the egress corridor by 1-hour fire-resistance-rated construction, including a 1-hour-rated self-closing fire door, and be protected by an automatic sprinkler system.

[F] 415.10.3 *Service corridors.* Service corridors within a Group H-5 occupancy shall comply with Sections 415.10.3.1 through 415.10.3.4.

- This section regulates the corridor that may be used for the transport of HPM in a Group H-5 facility of new construction. For the transport of HPM via piping systems, see Section 415.10.6.

   It is also clarified that a potential separation due to the mixed occupancy provisions of Section 508.4 does not apply, since service corridors are considered part of the Group H-5 occupancy.

[F] 415.10.3.1 *Use conditions.* Service corridors shall be separated from corridors as required by Section 415.10.1.2. Service corridors shall not be used as a required corridor.

- Service corridors are used for transporting HPM in lieu of piping. The separation between a service corridor and an egress corridor must be in accordance with Section 415.10.1.2. As such, a minimum 1-hour fire separation is required. Service corridors are also not intended to be used as a portion of the required means of egress.

[F] 415.10.3.2 *Mechanical ventilation.* Service corridors shall be mechanically ventilated as required by Section 415.10.1.6 or at not less than six air changes per hour, whichever is greater.

- Since the same HPM that may be present in the fabrication area may be transported in the service corridors, an adequate means of ventilation is required. This section requires a ventilation rate of either 1 cfm per square foot (0.044 L/s/m²) of floor area in accordance with Section 415.10.1.6 or six air changes per hour, whichever is greater depending on the size and volume of the service corridor.
**415.10.3.3 Means of egress.** The distance of travel from any point in a service corridor to an exit, exit access corridor or door into a fabrication area shall be not greater than 75 feet (22,860 mm). Dead ends shall be not greater than 4 feet (1,219 mm) in length. There shall be not less than two exits, and not more than one-half of the required means of egress shall require travel into a fabrication area. Doors from service corridors shall swing in the direction of egress travel and shall be self-closing.

- The exit access travel distance is limited to 75 feet (22,860 mm), except that the travel distance may be measured from a door to a fabrication area. In order to minimize the potential for an occupant to be trapped in a service corridor, dead ends must not exceed 4 feet (1,219 mm). As such, the occupant would most likely be intimate with the source of the problem or located in an adjacent fabrication area from which egress is provided via exit access, not service, corridors.

An occupant at any location in a service corridor is required to have access to at least two means of egress. No more than 50 percent of the means of egress may be through a fabrication area that, in most cases, will be one of the means of egress. This

---

**Figure 415.10.2**
ALLOWABLE HPM CORRIDOR ARRANGEMENTS
assumes that, should an incident or problem occur, it will be in either the service corridor or the fabrication area—not both. Because of the potential for a hazardous condition, all doors to service corridors must be self-closing and swing in the direction of egress travel. Smoke-detector-actuated hold-open devices are not acceptable because smoke detectors may not respond to hazardous conditions that do not involve products of combustion.

[F] 415.10.3.4 Minimum width. The clear width of a service corridor shall be not less than 5 feet (1524 mm), or 33 inches (838 mm) wider than the widest cart or truck used in the service corridor, whichever is greater.

- The minimum width requirement for the service corridor is to provide adequate clearance to get around the device used to transport the HPM in the event it is involved in an emergency incident in the service corridor. The size of the transport carts and trucks depends on the type and quantity of materials utilized in the facility.

[F] 415.10.3.5 Emergency alarm system. Emergency alarm systems shall be provided in accordance with this section and Sections 414.7.1 and 414.7.2. The maximum allowable quantity per control area provisions shall not apply to emergency alarm systems required for HPM.

- This section requires an emergency alarm system in all areas where HPM is transported or stored. The applicability of either Section 414.7.1 or 414.7.2 depends on whether the HPM material is in a storage or use condition. This section also clarifies that the requirement for an emergency alarm system in a Group H-5 facility in the locations identified in Sections 415.10.3.5.1 through 415.10.3.5.3 is not dependent on whether the maximum allowable quantities per control area of Tables 307.1(1) or 307.1(2) are exceeded.

[F] 415.10.3.5.1 Service corridors. An emergency alarm system shall be provided in service corridors, with no fewer than one alarm device in each service corridor.

- An emergency telephone system or manual alarm pull station is required in service corridors. Such devices must initiate an alarm at the emergency control station as well as activate a local audible device.

[F] 415.10.3.5.2 Corridors and interior exit stairways and ramps. Emergency alarms for corridors, interior exit stairways and ramps and exit passageways shall comply with Section 414.7.2.

- Since HPM materials would not be in exit access corridors or interior exit stairways unless they were being transported to another approved area, the emergency alarm requirements of Section 414.7.2 for dispensing, use and handling must be complied with.

[F] 415.10.3.5.3 Liquid storage rooms, HPM rooms and gas rooms. Emergency alarms for liquid storage rooms, HPM rooms and gas rooms shall comply with Section 414.7.1.

- This section requires compliance with the emergency alarm requirements of Section 414.7.1 for hazardous materials in a storage condition. This section addresses storage areas, which by their designation contain HPM in quantities greater than those listed in Table 307.1(1) or 307.1(2).

[F] 415.10.3.5.4 Alarm-initiating devices. An approved emergency telephone system, local alarm manual pull stations, or other approved alarm-initiating devices are allowed to be used as emergency alarm-initiating devices.

- This section classifies what constitutes an approved alarm-initiating device (see commentary, Section 414.7).

[F] 415.10.3.5.5 Alarm signals. Activation of the emergency alarm system shall sound a local alarm and transmit a signal to the emergency control station.

- The alarm signal is required to be transmitted to the emergency control station in order to notify trained personnel of an emergency condition. A local alarm is required to alert the occupants of a potentially hazardous condition.

[F] 415.10.4 Storage of hazardous production materials. Storage of hazardous production materials (HPM) in fabrication areas shall be within approved or listed storage cabinets or gas cabinets or within a workstation. The storage of HPM in quantities greater than those listed in Section 5004.2 of the International Fire Code shall be in liquid storage rooms, HPM rooms or gas rooms as appropriate for the materials stored. The storage of other hazardous materials shall be in accordance with other applicable provisions of this code and the International Fire Code.

- Section 415.10.4 addresses general storage provisions for HPM materials in a Group H-5 facility.

Even though the amount of HPM in a fabrication area is controlled, it still must be within approved cabinets or a workstation. This requirement is intended to limit the exposure to occupants of the fabrication area to only the material in use within that area. The larger amounts of HPM typically stored in separate areas present a hazard comparable to other Group H facilities; therefore, such storage rooms need to meet similar code requirements. Storage rooms containing HPM in quantities greater than permitted by Section 2704.2 of the IFC are required to comply with the applicable provisions of Sections 415.10.5.1 through 415.10.5.9, depending on the state of the material.

It should be noted that the HPM quantity limitations per fabrication area are essentially identical to the limitations of Section 415.10.1.1.2.

[F] 415.10.5 HPM rooms, gas rooms, liquid storage room construction. HPM rooms, gas rooms, liquid storage rooms,
constructed in accordance with Sections 415.10.5.1 through 415.10.5.9.

 Sections 415.10.5.1 through 415.10.5.9 selectively address construction requirements for two types of storage rooms: those classified as HPM rooms or gas rooms, and those utilized as liquid storage rooms. The size and separation of such rooms is dependent on the type of materials stored.

[F] 415.10.5.1 HPM rooms and gas rooms. HPM rooms and gas rooms shall be separated from other areas by fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both. The fire-resistance rating shall be not less than 2 hours where the area is 300 square feet (27.9 m²) or more and not less than 1 hour where the area is less than 300 square feet (27.9 m²).

 The amount of hazardous material in an HPM room or gas room is only limited by room size; therefore, since storage rooms in excess of 300 square feet (27.9 m²) are not limited by size or quantity of hazardous material, construction of fire barriers and horizontal assemblies of not less than 2-hour fire-resistance rating is required. It should be noted that this section assumes the storage areas have at least one exterior wall with a minimum 30-foot (9144 mm) fire separation distance (see Section 415.10.5.4). If the room has an area of less than 300 square feet (27.9 m²), the construction can be rated for 1 hour.

[F] 415.10.5.2 Liquid storage rooms. Liquid storage rooms shall be constructed in accordance with the following requirements:

1. Rooms greater than 500 square feet (46.5 m²) in area, shall have no fewer than one exterior door approved for fire department access.

2. Rooms shall be separated from other areas by fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both. The fire-resistance rating shall be not less than 1 hour for rooms up to 150 square feet (13.9 m²) in area and not less than 2 hours where the room is more than 150 square feet (13.9 m²) in area.

3. Shelving, racks and wainscoting in such areas shall be of noncombustible construction or wood of not less than 1-inch (25 mm) nominal thickness or fire-retardant-treated wood complying with Section 2303.2.

4. Rooms used for the storage of Class I flammable liquids shall not be located in a basement.

 This section assumes storage rooms are utilized for the storage of flammable and combustible liquids in closed containers. The size of the rooms is severely restricted when only 1-hour fire barriers and 1-hour horizontal assemblies are provided to limit the size of a potential fire. For rooms greater than 150 square feet (14 m²) in area, a minimum 2-hour-rated construction is required because the size of the room or quantity of hazardous materials is not limited. Due to the need for readily available access in a fire sce-

nario, all liquid storage rooms in excess of 500 square feet (46.5 m²) must have at least one exterior door that provides access to the room. In accordance with Section 415.10.5.4, all liquid storage rooms, regardless of size, must have at least one exterior wall.

 The construction limitations on the shelving racks and wainscoting are intended to limit their potential involvement in a fire scenario. Due to the volatile nature of Class I flammable liquids and the need for quick fire department access, they must be located in liquid storage rooms at or above grade.

[F] 415.10.5.3 Floors. Except for surfacing, floors of HPM rooms and liquid storage rooms shall be of noncombustible liquid-tight construction. Raised grating over floors shall be of noncombustible materials.

 Similar to the floor construction of fabrication areas, the floors of HPM rooms and liquid storage rooms are required to be noncombustible and liquid tight (see commentary, Section 415.10.1.4).

[F] 415.10.5.4 Location. Where HPM rooms, liquid storage rooms and gas rooms are provided, they shall have no fewer than one exterior wall and such wall shall be not less than 30 feet (9144 mm) from lot lines, including lot lines adjacent to public ways.

 Access from the exterior for fire-fighting operations is essential for storage rooms of hazardous materials. These rooms by their designation contain more than the maximum allowable quantities per control area listed in Tables 307.1(1) and 307.1(2). The 30-foot (9144 mm) limitation is based in part on the fact that the exterior wall need not have a fire-resistance rating depending on the construction type of the building (see Table 602). Such walls may also be used for explosion venting when such venting is required.

[F] 415.10.5.5 Explosion control. Explosion control shall be provided where required by Section 414.5.1.

 This section requires a method of explosion control only when an explosion hazard exists. Not all storage rooms are required to have explosion control. Section 414.5.1 requires a method of explosion control, such as explosion venting or barricade construction, depending on the specific hazardous material involved in accordance with the IFC. Table 414.5.1 provides guidance as to when explosion control is required for various hazardous materials.

[F] 415.10.5.6 Exits. Where two exits are required from HPM rooms, liquid storage rooms and gas rooms, one shall be directly to the outside of the building.

 Depending on the common path of egress travel available in accordance with Section 1014.3, two exits may be required from all HPM rooms, liquid storage rooms and gas rooms. For example, a liquid storage room containing Class IB flammable liquids in normally closed containers would be considered a Group H-3 occupancy. As such, a maximum common path of travel of 25 feet (7620 mm) would be permit-
ted before a second exit, one of which was directly to the exterior, is required. Storage rooms are required to be located along an exterior wall. In addition to the requirements of this section, all liquid storage rooms in excess of 500 square feet (46 m²) are required to have at least one exterior door regardless of travel distance.

[F] 415.10.5.7 Doors. Doors in a fire barrier wall, including doors to corridors, shall be self-closing fire door assemblies having a fire protection rating of not less than 1/2 hour.

- Doors that are in an interior wall that comprise part of the storage room enclosure are required to have a minimum 1/2-hour fire protection rating. The actual rating is dependent on the fire-resistance rating of the fire barrier separation required. While a 1-hour fire barrier would permit a door with a 1/2-hour fire protection rating, a 2-hour fire barrier would require a door to have a 1 1/2-hour fire protection rating in accordance with Table 716.5.

[F] 415.10.5.8 Ventilation. Mechanical exhaust ventilation shall be provided in liquid storage rooms, HPM rooms and gas rooms at the rate of not less than 1 cubic foot per minute per square foot (0.044 L/s/m²) of floor area or six air changes per hour, whichever is greater, for categories of material.

- Exhaust ventilation for gas rooms shall be designed to operate at a negative pressure in relation to the surrounding areas and direct the exhaust ventilation to an exhaust system.

- Similar to fabrication areas and service corridors, mechanical exhaust ventilation is required (see commentary, Sections 415.10.1.6 and 415.10.3.2).

[F] 415.10.5.9 Emergency alarm system. An approved emergency alarm system shall be provided for HPM rooms, liquid storage rooms and gas rooms.

- Emergency alarm-initiating devices shall be installed outside of each interior exit door of such rooms.

- Activation of an emergency alarm-initiating device shall sound a local alarm and transmit a signal to the emergency control station.

- An approved emergency telephone system, local alarm manual pull stations or other approved alarm-initiating devices are allowed to be used as emergency alarm-initiating devices.

- An emergency alarm system is required for all storage rooms containing hazardous materials in excess of the quantities permitted in Tables 307.1(1) and 307.1(2). See the commentary to Section 415.10.3.5 for similar emergency alarm requirements.

[F] 415.10.6 Piping and tubing. Hazardous production materials piping and tubing shall comply with this section and ASME B31.3.

- This section addresses the design requirements for all piping and tubing utilized to transport HPM throughout a Group H-5 facility, including where it can be located within the building.

- The nature of the HPM involved requires strict control of both the materials used in piping and the joint methods used to avoid leakage. ASME B31.3 provides criteria for piping installation applicable to HPM facilities.

[F] 415.10.6.1 HPM having a health-hazard ranking of 3 or 4. Systems supplying HPM liquids or gases having a health-hazard ranking of 3 or 4 shall be welded throughout, except for connections, to the systems that are within a ventilated enclosure if the material is a gas, or an approved method of drainage or containment is provided for the connections if the material is a liquid.

- The primary purpose of this section is to minimize the potential for a leak of HPM. The use of mechanical compression-type fittings or other nonwelded joints in areas of health hazard 3 or 4 must be limited to areas where any leaks will be vented and the materials exhausted. If the material is a liquid, then a method of drainage or containment is required to minimize the hazard.

[F] 415.10.6.2 Location in service corridors. Hazardous production materials supply piping or tubing in service corridors shall be exposed to view.

- Concealment of piping in service corridors must be avoided to provide a means of monitoring for leaks.

[F] 415.10.6.3 Excess flow control. Where HPM gases or liquids are carried in pressurized piping above 15 pounds per square inch gauge (psig) (103.4 kPa), excess flow control shall be provided. Where the piping originates from within a liquid storage room, HPM room or gas room, the excess flow control shall be located within the liquid storage room, HPM room or gas room. Where the piping originates from a bulk source, the excess flow control shall be located as close to the bulk source as practical.

- Excess flow control valves regulate the flow of hazardous materials within the piping system. The valves are designed to shut off in the event the predetermined flow is exceeded.

[F] 415.10.6.4 Installations in corridors and above other occupancies. The installation of HPM piping and tubing within the space defined by the walls of corridors and the floor or roof above, or in concealed spaces above other occupancies, shall be in accordance with Sections 415.10.6.1 through 415.10.6.3 and the following conditions:

1. Automatic sprinklers shall be installed within the space unless the space is less than 6 inches (152 mm) in the least dimension.

2. Ventilation not less than six air changes per hour shall be provided. The space shall not be used to convey air from any other area.

3. Where the piping or tubing is used to transport HPM liquids, a receptor shall be installed below such piping or tubing. The receptor shall be designed to collect any discharge or leakage and drain it to an approved location. The 1-hour enclosure shall not be used as part of the receptor.

4. HPM supply piping and tubing and nonmetallic waste lines shall be separated from the corridor and from
occupancies other than Group H-5 by fire barriers that have a fire-resistance rating of not less than 1 hour. Where gypsum wallboard is used, joints on the piping side of the enclosure are not required to be taped, provided the joints occur over framing members. Access openings into the enclosure shall be protected by approved fire protection-rated assemblies.

5. Readily accessible manual or automatic remotely activated fail-safe emergency shutoff valves shall be installed on piping and tubing other than waste lines at the following locations:

- At branch connections into the fabrication area.
- At entries into corridors.

**Exception:** Transverse crossings of the corridors by supply piping that is enclosed within a ferrous pipe or tube for the width of the corridor need not comply with Items 1 through 5.

- The installation of HPM piping in the space above an egress corridor or another occupancy, as well as the cavity of the egress corridor wall, present a potential source of hazard to the building’s occupants. The five requirements provided for such installations serve to mitigate the hazard by suppression, ventilation, containment and ignition control. In order to address the potential hazards, the containment must be a fire barrier with at least a 1-hour fire-resistance rating, drainage receptors, excess flow control and shutoff valves.

  - The elimination of the taping of the wallboard joints on the piping side of a rated assembly is in recognition of actual installation difficulties and the reduced likelihood of a fire on the interior of the wall cavity. To eliminate the taping of joints, however, the joints must occur over framing members.

  - When the piping traverses a corridor, the use of a coaxial enclosed pipe around the HPM piping is considered acceptable for providing the required separation and containment of a potential leak. The assumption is that the open ends of that pipe are in an HPM facility and, therefore, a leak into the outer casing can be monitored. If the adjacent areas that contain the open ends are not in an HPM facility, then the outer-jacket method cannot be used.

[F] 415.10.6.3 Identification. Piping, tubing and HPM waste lines shall be identified in accordance with ANSI A13.1 to indicate the material being transported.

- To facilitate monitoring, detecting and controlling any possible leaks, all piping, tubing and HPM waste lines must be identified in accordance with ANSI A13.1. This standard contains criteria for properly identifying the piping system, including labeling and frequency or distribution of the signs or labels.

[F] 415.10.7 Continuous gas detection systems. A continuous gas detection system shall be provided for HPM gases where the physiological warning threshold level of the gas is at a higher level than the accepted permissible exposure limit (PEL) for the gas and for flammable gases in accordance with Sections 415.10.7.1 and 415.10.7.2.

- A gas detection system in the room or area utilized for the storage or use of HPM gases provides early notification of a leak that is occurring before the escaping gas reaches hazardous concentration levels.

[F] 415.10.7.1 Where required. A continuous gas detection system shall be provided in the areas identified in Sections 415.10.7.1.1 through 415.10.7.1.4.

- Sections 415.10.7.1.1 through 415.10.7.1.4 prescribe the locations in a Group H-5 facility when a gas detection system is required.

[F] 415.10.7.1.1 Fabrication areas. A continuous gas detection system shall be provided in fabrication areas where gas is used in the fabrication area.

- All fabrication areas that utilize HPM gases must have a gas detection system. It should be noted that gas detection is often installed within workstations as a means of early detection of leaks. Such detection is generally not acceptable as an alternative to gas detection for the fabrication area, since a leak may occur remote from the workstation.

[F] 415.10.7.1.2 HPM rooms. A continuous gas detection system shall be provided in HPM rooms where gas is used in the room.

- HPM rooms, which by definition contain more than the quantities of hazardous materials per control area permitted by Tables 307.1(1) and 307.1(2), are required to have a gas detection system.

[F] 415.10.7.1.3 Gas cabinets, exhausted enclosures and gas rooms. A continuous gas detection system shall be provided in gas cabinets and exhausted enclosures. A continuous gas detection system shall be provided in gas rooms where gases are not located in gas cabinets or exhausted enclosures.

- In the potential event of a leaking cylinder of a hazardous gas, gas cabinets, exhausted enclosures and gas rooms must have a gas detection system.

[F] 415.10.7.1.4 Corridors. Where gases are transported in piping placed within the space defined by the walls of a corridor and the floor or roof above the corridor, a continuous gas detection system shall be provided where piping is located and in the corridor.

**Exception:** A continuous gas detection system is not required for occasional transverse crossings of the corridors by supply piping that is enclosed in a ferrous pipe or tube for the width of the corridor.

- In addition to the requirements of Section 415.10.6.4 for HPM piping and tubing in an egress corridor, a gas detection system is required for early notification of a potential leak of an HPM gas.

  The exception is similar to the exception in Section
415.10.6.4. In essence, the gas detection system required by this section as well as the additional provisions in Section 415.10.6.4 are not required if the exception is met (see commentary, Section 415.10.6.4).

[F] 415.10.7.2 Gas detection system operation. The continuous gas detection system shall be capable of monitoring the room, area or equipment in which the gas is located at or below all the following gas concentrations:

1. Immediately dangerous to life and health (IDLH) values where the monitoring point is within an exhausted enclosure, ventilated enclosure or gas cabinet.
2. Permissible exposure limit (PEL) levels where the monitoring point is in an area outside an exhausted enclosure, ventilated enclosure or gas cabinet.
3. For flammable gases, the monitoring detection threshold level shall be vapor concentrations in excess of 25 percent of the lower flammable limit (LFL) where the monitoring is within or outside an exhausted enclosure, ventilated enclosure or gas cabinet.
4. Except as noted in this section, monitoring for highly toxic and toxic gases shall also comply with Chapter 60 of the International Fire Code.

This section requires gas detection systems to be capable of sensing a leak at or below the permissible exposure limit (PEL). This exposure limit regulated by OSHA to prevent adverse health effects is the breathing zone exposure limit for employees over an 8-hour time weighted average. In most cases, gas detection in the semiconductor industry is conducted in an exhausted enclosure, ventilated enclosure or gas cabinet and not in the breathing zone of the employee, and is designed to detect and alert employees of leaks inside exhausted enclosures, ventilated enclosures or gas cabinets and is not intended to estimate potential employee breathing zone exposures. The semiconductor industry addressed this by codifying Section 10.9 of NFPA 318 to differentiate gas detection set points in exhausted enclosures (set at the IDLH) with gas detection when the monitoring point is in an area outside an exhausted enclosure, ventilated enclosure or gas cabinet. This section is consistent with the provisions of Section 10.9 of NFPA 318 guidelines that are much more relevant to the type of monitoring performed in semiconductor manufacturing (inside exhausted enclosures, ventilated enclosures or gas cabinets). Monitoring in the semiconductor industry is designed to detect and alert employees of leaks inside exhausted enclosures, ventilated enclosures and gas cabinets, and is not intended to estimate potential employee breathing zone exposures. Therefore, set points are not required or recommended to be set at occupational exposure limits (e.g., TLVs or PELs). Additionally, the 25 percent LFL is consistent with both Section 510.2 of the IMC and Section 10.9 of NFPA 318 Section 10.9. Chapter 60 of the IFC contains additional requirements for the monitoring of highly toxic and toxic compressed gases.

[F] 415.10.7.2.1 Alarms. The gas detection system shall initiate a local alarm and transmit a signal to the emergency control station when a short-term hazard condition is detected. The alarm shall be both visual and audible and shall provide warning both inside and outside the area where the gas is detected. The audible alarm shall be distinct from all other alarms.

The required local alarm is intended to alert occupants to a hazardous condition in the vicinity of where the HPM gases are being stored or used. The alarm is not intended to be an evacuation alarm; however, it is required to be monitored to hasten emergency personnel response.

[F] 415.10.7.2.2 Shutoff of gas supply. The gas detection system shall automatically close the shutoff valve at the source on gas supply piping and tubing related to the system being monitored for which gas is detected when a short-term hazard condition is detected. Automatic closure of shutoff valves shall comply with the following:

1. Where the gas detection sampling point initiating the gas detection system alarm is within a gas cabinet or exhausted enclosure, the shutoff valve in the gas cabinet or exhausted enclosure for the specific gas detected shall automatically close.
2. Where the gas detection sampling point initiating the gas detection system alarm is within a room and compressed gas containers are not in gas cabinets or an exhausted enclosure, the shutoff valves on all gas lines for the specific gas detected shall automatically close.
3. Where the gas detection sampling point initiating the gas detection system alarm is within a piping distribution manifold enclosure, the shutoff valve supplying the manifold for the compressed gas container of the specific gas detected shall automatically close.

Exception: Where the gas detection sampling point initiating the gas detection system alarm is at the use location or within a gas valve enclosure of a branch line downstream of a piping distribution manifold, the shutoff valve for the branch line located in the piping distribution manifold enclosure shall automatically close.

Where gas detection systems are required, automatic emergency shutoff valves are required to stop the flow of hazardous material from possibly deteriorating further in an emergency.

[F] 415.10.8 Manual fire alarm system. An approved manual fire alarm system shall be provided throughout buildings containing Group H-5. Activation of the alarm system shall initiate a local alarm and transmit a signal to the emergency control station. The fire alarm system shall be designed and installed in accordance with Section 907.

Due to the type and potential quantities of hazardous materials that could be present in a Group H-5 facility, a manual means of activating an evacuation alarm is essential for the safety of the occupants in an
emergency situation. The alarm signal must be transmitted to the emergency control station. The fire alarm must also be in accordance with the applicable provisions of Section 907 and NFPA 72.

[F] 415.10.9 Emergency control station. An emergency control station shall be provided in accordance with Sections 415.10.9.1 through 415.10.9.3.

- Due to the extent of hazardous materials permitted in an HPM facility, an approved on-site location is needed where the alarm signals from emergency equipment can be received.

[F] 415.10.9.1 Location. The emergency control station shall be located on the premises at an approved location outside the fabrication area.

- The emergency control station must be located on-site at a location approved by the building official. The emergency control station must not be located in an area where hazardous materials are stored, used or transported, such as a fabrication area.

[F] 415.10.9.2 Staffing. Trained personnel shall continuously staff the emergency control station.

- Appropriate response by trained personnel is essential to any emergency event involving HPM materials.

[F] 415.10.9.3 Signals. The emergency control station shall receive signals from emergency equipment and alarm and detection systems. Such emergency equipment and alarm and detection systems shall include, but not be limited to, the following where such equipment or systems are required to be provided either in this chapter or elsewhere in this code:

1. Automatic sprinkler system alarm and monitoring systems.
3. Emergency alarm systems.
4. Continuous gas detection systems.
5. Smoke detection systems.
6. Emergency power system.
7. Automatic detection and alarm systems for pyrophoric liquids and Class 3 water-reactive liquids required in Section 2705.2.3.4 of the International Fire Code.
8. Exhaust ventilation flow alarm devices for pyrophoric liquids and Class 3 water-reactive liquids cabinet exhaust ventilation systems required in Section 2705.2.3.4 of the International Fire Code.

- This section specifies the types of systems within a Group H-5 occupancy that are required to be connected to an approved emergency power system. As indicated in Section 2702, all emergency power systems must be installed in accordance with the applicable requirements of NFPA 70, 110 and 111.

[F] 415.10.10 Emergency power system. An emergency power system shall be provided in Group H-5 occupancies where required in Section 415.10.10.1. The emergency power system shall be designed to supply power automatically to required electrical systems when the normal electrical supply system is interrupted.

- A backup emergency power source is considered essential for systems that are monitoring and protecting hazardous materials in a Group H-5 occupancy. Without an emergency power system, all required electrical controls or equipment monitoring hazardous materials would be rendered ineffective if a power failure or other electrical system failure were to occur.

[F] 415.10.10.1 Required electrical systems. Emergency power shall be provided for electrically operated equipment and connected control circuits for the following systems:

1. HPM exhaust ventilation systems.
2. HPM gas cabinet ventilation systems.
3. HPM exhausted enclosure ventilation systems.
4. HPM gas room ventilation systems.
5. HPM gas detection systems.
6. Emergency alarm systems.
7. Manual fire alarm systems.
8. Automatic sprinkler system monitoring and alarm systems.
9. Automatic alarm and detection systems for pyrophoric liquids and Class 3 water-reactive liquids required in Section 2705.2.3.4 of the International Fire Code.
10. Flow alarm switches for pyrophoric liquids and Class 3 water-reactive liquids cabinet exhaust ventilation systems required in Section 2705.2.3.4 of the International Fire Code.
11. Electrically operated systems required elsewhere in this code or in the International Fire Code applicable to the use, storage or handling of HPM.

- This section specifies the types of systems within a Group H-5 occupancy that are required to be connected to an approved emergency power system. As indicated in Section 2702, all emergency power systems must be installed in accordance with the applicable requirements of NFPA 70, 110 and 111.

[F] 415.10.10.2 Exhaust ventilation systems. Exhaust ventilation systems are allowed to be designed to operate at not less than one-half the normal fan speed on the emergency power system where it is demonstrated that the level of exhaust will maintain a safe atmosphere.

- Emergency power for exhaust ventilation is required to prevent hazardous concentrations of HPM fumes or vapors in areas such as workstations or fabrication areas. Fans for exhaust ventilation draw a considerable amount of current when operating. Running exhaust fans at a reduced speed may be desirable when it will not endanger the operator or result in a hazardous condition; however, exhaust fans must not be run at a speed less than 50 percent of its rating, even if a slower speed will not produce a serious hazard.

[F] 415.10.11 Automatic sprinkler system protection in exhaust ducts for HPM. An approved automatic sprinkler system shall be provided in exhaust ducts conveying gases,
vapors, fumes, mists or dusts generated from HPM in accordance with Sections 415.10.11.1 through 415.10.11.3 and the International Mechanical Code.

- This section prescribes the sprinkler system requirements for exhaust ducts for HPM. The requirements depend on the construction materials of the exhaust duct.

An exhaust duct for HPM materials could convey flammable and combustible gases, fumes, vapors or ducts. To provide protection against the spread of fire within the exhaust system and to prevent a duct fire from involving the building, sprinkler protection is required in the exhaust duct. The use of an extinguishing agent other than water based on agent compatibility would be subject to local approval. Section 510 of the IMC contains additional requirements for protecting hazardous exhaust systems.

[F] **415.10.11.1 Metallic and noncombustible nonmetallic exhaust ducts.** An approved automatic sprinkler system shall be provided in metallic and noncombustible nonmetallic exhaust ducts where all of the following conditions apply:

1. Where the largest cross-sectional diameter is equal to or greater than 10 inches (254 mm).
2. The ducts are within the building.
3. The ducts are conveying flammable gases, vapors or fumes.
- Sprinklers are required within each individual duct when all three of the following conditions exist:

1. Cross-sectional diameter at the widest point is equal to or exceeds 10 inches (254 mm).
2. Ducts are located within the building.
3. Ducts convey gases or vapors within the flammable range.

Figure 415.10.11.1 illustrates how to measure the cross-sectional diameter of various duct shapes. Provisions of this section require the square and rounded ducts to be protected by automatic sprinklers. The round or elliptical ducts depicted on the right side of the diagram are not required to be protected.

**F 415.10.11.2 Combustible nonmetallic exhaust ducts.** Automatic sprinkler system protection shall be provided in combustible nonmetallic exhaust ducts where the largest cross-sectional diameter of the duct is equal to or greater than 10 inches (254 mm).

**Exception:** Duct need not be provided with automatic sprinkler protection as follows:

1. Ducts listed or approved for applications without automatic sprinkler system protection.
2. Ducts not more than 12 feet (3658 mm) in length installed below ceiling level.

- Galvanized steel is not an appropriate duct material for all substances handled in the broad category of hazardous exhaust systems. A duct material compatible with the exhaust must be selected, and factors such as corrosiveness, abrasion resistance, chemical resistance and operating temperatures must be taken into account. Section 510.8 of the IMC contains additional provisions for duct construction that is part of a hazardous exhaust system. As such, automatic sprinkler protection is also required for all combustible nonmetallic ducts with a cross-sectional diameter equal to or greater than 10 inches (254 mm).

**Exception** 1 states that automatic sprinklers are not

---

**Figure 415.10.11.1**

*CROSS-SECTIONAL DIAMETERS OF VARIOUS-SHAPED DUCTS*

For SI: 1 inch = 25.4 mm.
required where the risk to people or property is limited, such as when nonmetallic ducts approved for installation without sprinklers are used. Exception 2 states that when ducts do not exceed 12 feet (3658 mm) in length and are installed exposed below ceiling level, sprinklers may be omitted. The limited duct length and exposure reduces the potential of a concealed fire hazard.

[F] 415.10.11.3 Automatic sprinkler locations. Sprinkler systems shall be installed at 12-foot (3658 mm) intervals in horizontal ducts and at changes in direction. In vertical ducts, sprinklers shall be installed at the top and at alternate floor levels.

- Adequate sprinkler coverage needs to be maintained to prevent the spread of fire within the exhaust system. All sprinkler system components must also be in compliance with the applicable provisions of NFPA 13.

SECTION 416
APPLICATION OF FLAMMABLE FINISHES

[F] 416.1 General. The provisions of this section shall apply to the construction, installation and use of buildings and structures, or parts thereof, for the application of flammable finishes. Such construction and equipment shall comply with the International Fire Code.

- The principal hazards associated with paint spraying and spray booths originate from the presence of flammable liquids or powders and their vapors or mists. The purpose of this section is to provide requirements that address the hazards associated with spray applications and dipping or coating applications involving flammable paints, varnishes and lacquers. The requirements listed include such areas as ventilation, automatic sprinklers, control of ignition sources and proper operation of the equipment. In addition to the provisions of this section, the provisions of the IMC and Chapter 24 of the IFC also apply.

The provisions of this section apply to the indoor use of spray applications and dipping or coating applications involving flammable paints, varnishes and lacquers. Outdoor applications involving flammable paints, varnishes and lacquers are not covered, since overspray deposits are not likely to create hazardous conditions, and flammable vapor-air mixtures are minimized because of atmospheric dilution. Safeguards, such as ventilation, ignition control, material storage and waste disposal (see Chapter 24 of the IFC), should still apply. This reference to the IFC and its provisions regarding flammable finishes covers the application of flammable or combustible materials when applied as a spray by compressed air; "airless" or "hydraulic atomization" steam; electrostatically or by any other means in continuous or intermittent processes. They also cover the application of combustible powders when applied by powder spray guns, electrostatic powder spray guns, fluidized beds or electrostatic fluidized beds. The IFC and its referenced standards contain provisions relating to the location of spray areas; ignition sources; ventilation; liquid storage and handling; protection; operation; maintenance and training. The provisions found in Chapter 24 of the IFC also apply to processes in which articles or materials are passed through the contents of tanks, vats or containers of flammable or combustible liquids, including dipping; roll; flow and curtain coating; finishing; treating; cleaning and similar processes. Requirements for the location of dipping and coating processes; ventilation; equipment construction; liquid storage and handling; protection; operation; maintenance and training are also provided.

[F] 416.2 Spray rooms. Spray rooms shall be enclosed with not less than 1-hour fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both. Floors shall be waterproofed and drained in an approved manner.

- A spray room is a power-ventilated, fully enclosed room used exclusively for open spraying of flammable and combustible materials. The entire spray room is considered the spray area. The primary difference between a spray room and a spray booth is that spray booths are partially open. A spray room is to be enclosed with fire barriers and horizontal assemblies having a fire-resistance rating of at least 1 hour. Waterproof floors are to be arranged to drain either to the outside of the building, to internal drains or to other suitable places. Properly designed and guarded drains or scuppers of sufficient number and size to dispose of all surplus water likely to be discharged by automatic sprinklers must be provided.

[F] 416.2.1 Surfaces. The interior surfaces of spray rooms shall be smooth and shall be so constructed to permit the free passage of exhaust air from all parts of the interior and to facilitate washing and cleaning, and shall be so designed to confine residues within the room. Aluminum shall not be used.

- Rough, corrugated or uneven surfaces are difficult to clean. Periodic cleaning of interior surfaces reduces the fire hazard posed by the accumulation of flammable or combustible coatings. Due to the physical properties of aluminum, it is unsuitable for cleaning and scraping of overspray residue.

[F] 416.2.2 Ventilation. Mechanical ventilation and interlocks with the spraying operation shall be in accordance with the International Mechanical Code.

- The provisions addressing ventilation in spray rooms where flammable finishes are applied are found in Section 502.7 of the IMC. For effective ventilation, the system must run continuously during the spraying operation phase and the drying phase of the process when vapors are generated. The required interlock between the ventilation and spraying equipment is intended to reduce the likelihood that the operator will fail to activate the ventilation system prior to use of the spray equipment.
[F] 416.3 Spraying spaces. Spraying spaces shall be ventilated with an exhaust system to prevent the accumulation of flammable mist or vapors in accordance with the International Mechanical Code. Where such spaces are not separately enclosed, noncombustible spray curtains shall be provided to restrict the spread of flammable vapors.

- The objective of ventilation is to remove flammable vapors and mists so as to minimize the potential for a flash fire or explosion. The spray area is required to be ventilated in accordance with the provisions of the IMC. When the spray process is not separated from the other operations or areas, a noncombustible spray curtain must be provided to restrict the spread of flammable vapors. The IFC requires ventilation systems and enclosures to be interlocked with the spraying equipment to ensure that fans operate and doors remain closed when in use.

[F] 416.3.1 Surfaces. The interior surfaces of spraying spaces shall be smooth and continuous without edges; shall be so constructed to permit the free passage of exhaust air from all parts of the interior and to facilitate washing and cleaning; and shall be so designed to confine residues within the spraying space. Aluminum shall not be used.

- See commentary, Section 416.2.1.

[F] 416.4 Spray booths. Spray booths shall be designed, constructed and operated in accordance with the International Fire Code.

- Detailed requirements for the design and construction of spray booths are given in Section 2404.3.2 of the IFC. The IFC also addresses requirements for ventilation of adjacent areas, fire protection, fire extinguishers, control of ignition sources, housekeeping during operations, lighting and operation control through interlocks.

[F] 416.5 Fire protection. An automatic sprinkler system or fire-extinguishing system shall be provided in all spray, dip and immersing spaces and storage rooms and shall be installed in accordance with Chapter 9.

- Spray application operations are to be protected with an automatic sprinkler system or fire-extinguishing system. While an automatic sprinkler system is the most desirable type of suppression system, this section would allow the use of other effective extinguishing agents, such as dry chemical or foam. Because of the ease of ignition of flammable liquids, specifically spray paint applications of a flammable liquid, an automatic fire sprinkler system or fire-extinguishing system is required in rooms in which spray painting is conducted, as well as rooms in which flammable materials are used for painting, brushing, dipping or mixing on a regular basis. Dry sprinklers should not be used for the protection of spray operations, except possibly at the exhaust duct penetrations to the outside. Wet-pipe, preaction or deluge systems should be used so that water is placed on the fire in the shortest possible time. If the entire building is not protected with an automatic sprinkler system, then the system protecting the spray booth or room may be a limited area sprinkler system in accordance with Section 903.3.5.1.1. Locating sprinklers in paint spray booths presents an unusual problem, since the sprinkler may become clogged with paint. The most satisfactory solution is to locate the sprinklers in areas in a way that the paint spray will most likely not reach the sprinkler. Even in the most ideal locations, the sprinkler will need to be cleaned very frequently. A coating of grease with a low melting point, such as petroleum jelly, motor oil or a soft neutral soap, will facilitate cleaning of the sprinkler. Other alternatives that are commonly used include polyethylene or cellophane bags with a thickness of 0.003 inches (0.076 mm) or less or thin paper bags to protect the sprinklers.

Additional guidance on fire protection requirements for the application of flammable finishes can be found in Chapter 24 of the IFC.

SECTION 417 DRYING ROOMS

[F] 417.1 General. A drying room or dry kiln installed within a building shall be constructed entirely of approved noncombustible materials or assemblies of such materials regulated by the approved rules or as required in the general and specific sections of this chapter for special occupancies and where applicable to the general requirements of the International Mechanical Code.

- This section establishes specific safety requirements for drying rooms and dry kilns used in conjunction with the drying (accelerated seasoning) of lumber, and dryers or dehydrators used to reduce the moisture content of agricultural products. Included are drying operations for other combustible materials, such as certain building materials, textiles and fabrics. Drying operations associated with the application of flammable finishes are regulated by Section 416. The hazards associated with drying rooms and dry kilns relate to the volume of readily combustible materials being processed at temperatures conducive to their ignition in the event of a system malfunction.

The materials or assemblies used in the construction of drying rooms or dry kilns located within buildings must be noncombustible, regardless of the type of construction of the building itself (see commentary, Section 703.5 for a discussion of noncombustibility criteria) when required by Chapter 4 or the International Mechanical Code. The use of noncombustible materials of construction for drying rooms and dry kilns provides for a measure of confinement of a fire occurring within and prevents the room or kiln from contributing to the fuel load exposed to an unwanted fire.
SPECIAL DETAILED REQUIREMENTS BASED ON USE AND OCCUPANCY

[F] 417.2 Piping clearance. Overhead heating pipes shall have a clearance of not less than 2 inches (51 mm) from combustible contents in the dryer.

- Piped steam and hot-water indirect heating systems used in drying rooms or dry kilns can operate at temperatures of up to several hundred degrees Fahrenheit and are considered a safe and appropriate method of providing heat to the drying processes. A minimum clearance of 2 inches (51 mm) between hydronic piping and adjacent combustible contents in the drying room or dry kiln is required to reduce the likelihood of contact ignition of the combustible contents. Though hydronic piping is frequently installed overhead, the clearance is required regardless of the pipes' location within the drying room or kiln.

[F] 417.3 Insulation. Where the operating temperature of the dryer is 175°F (79°C) or more, metal enclosures shall be insulated from adjacent combustible materials by not less than 12 inches (305 mm) of airspace, or the metal walls shall be lined with 1/4-inch (6.35 mm) insulating mill board or other approved equivalent insulation.

- The insulation of metal drying room and kiln enclosures from adjacent combustible materials is required when the drying apparatus operates at or above 175°F (79°C). Insulation can be accomplished by the use of airspace or by lining the metal dryer walls with insulating material. The insulation will reduce the possibility that combustible materials in proximity to the drying room or dry kiln will be ignited by heat transfer from it. The temperature of 175°F (79°C) has been determined to be the highest allowable temperature without any clearance to combustibles.

[F] 417.4 Fire protection. Drying rooms designed for high-hazard materials and processes, including special occupancies as provided for in Chapter 4, shall be protected by an approved automatic fire-extinguishing system complying with the provisions of Chapter 9.

- The possibility of ignition increases in a drying room utilized in conjunction with hazardous materials, such as combustible fibers and other finely divided materials. The installation of an approved fire-extinguishing system in accordance with Chapter 9 will contain a fire within the drying room until the fire department (or industrial fire brigade) arrives. In sprinklered buildings, fire suppression can be easily and economically provided by installing sprinklers within the drying room or area. Wet-pipe, preaction or deluge systems should be used so that water is placed on the fire in the shortest possible time. Note that dryers used in conjunction with plywood, veneer and composite board mill operations are required by the IFC to be protected by an approved deluge water-spray system. See the commentary for Chapter 28 of the IFC for further information on lumber and woodworking facilities. In nonsprinklered or partially sprinklered buildings, the system protecting the drying room may be an approved, limited area sprinkler system in accordance with Section 903.3.5.1.1. An alternative fire-extinguishing system consisting of dry chemical, carbon dioxide, clean agent or other approved nonwater-based fire-extinguishing system in accordance with Section 904 can provide an equivalent level of protection, depending on the nature of the drying room contents. See the commentary to Section 904 for a discussion of the various alternative fire-extinguishing systems available.

SECTION 418
ORGANIC COATINGS

- The manufacture of organic coatings encompasses operations that produce decorative and protective coatings for architectural uses, industrial products and other specialized purposes. Requirements of this chapter address the hazards associated with the manufacture of solvent-based organic coatings. Water-based materials are exempt from these requirements. These provisions are consistent with Chapter 29 of the IFC, which contains more detailed requirements for the manufacture of organic coatings. NFPA 35 also provides additional guidance on the maintenance of facilities utilized for the manufacture of organic coatings.

[F] 418.1 Building features. Manufacturing of organic coatings shall be done only in buildings that do not have pits or basements.

- Basements, pits or depressed first-floor construction are prohibited because of the tendency for hazardous material vapors to accumulate in low areas and the difficulty in fighting fires in basements and pits in such occupancies.

[F] 418.2 Location. Organic coating manufacturing operations and operations incidental to or connected therewith shall not be located in buildings having other occupancies.

- Operations and activities closely related to the primary occupancy are necessary for the efficient, continuous and safe performance of the manufacture of organic coatings. Administration, storage, shipping and receiving, as well as other related but not indispensable operations, should be located in separate buildings.

[F] 418.3 Process mills. Mills operating with close clearances and that process flammable and heat-sensitive materials, such as nitrocellulose, shall be located in a detached building or noncombustible structure.

- Milling of heat-sensitive materials, such as nitrocellulose, is an extraordinary hazard. Such operations must be located in separate, single-purpose buildings away from other uses and high-hazard operations. Pebble mills pose a special vapor ignition hazard caused by static electricity. Both the grinding material
and inner lining of these mills are made of materials with good insulating characteristics. Because static electricity is produced during milling, it has nowhere to go. Generally, the inside of this type of mill is either partially or totally inerted using nitrogen or carbon dioxide gas to prevent ignition.

[F] 418.4 Tank storage. Storage areas for flammable and combustible liquid tanks inside of structures shall be located at or above grade and shall be separated from the processing area by not less than 2-hour fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both.

- Tank storage located below grade is prohibited. Basements located under grade-level storage areas should be discouraged. Below-grade flammable liquid fires are extremely difficult to fight. Similarly, above-grade spills will flow to lower floors, possibly resulting in spill fires on more than one building level. Tank storage of raw materials must be confined to locations at or above grade level. Tank storage rooms must be separated from process and other storage areas by fire barriers and horizontal assemblies that are a minimum of 2-hour fire-resistance rated. If possible, these rooms should be able to be accessed on at least one side from the outside. Cut-off rooms with access from two or even three sides are considered ideal.

[F] 418.5 Nitrocellulose storage. Nitrocellulose storage shall be located on a detached pad or in a separate structure or a room enclosed with not less than 2-hour fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both.

- Once ignited, nitrocellulose will continue to burn even in the absence of oxygen. Extra precautions must be used to prevent ignition and fire spread; therefore, nitrocellulose storage should be in either a separate detached structure, on a detached exterior pad or fully enclosed by a construction of minimum 2-hour fire-resistance rating complying with fire barrier and horizontal assembly requirements.

[F] 418.6 Finished products. Storage rooms for finished products that are flammable or combustible liquids shall be separated from the processing area by not less than 2-hour fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both.

- Finished products, which are also classified as flammable or combustible liquids, must also comply with the applicable provisions of Chapter 57 of the IFC and NFPA 30. As a minimum, a 2-hour fire-resistance-rated construction consisting of horizontal assemblies and fire barriers with approved opening protectives is required between the processing area and the storage area to eliminate mutual involvement in a single fire scenario. A higher degree of fire separation may be required depending on the building’s occupancy classification.

SECTION 419
LIVE/WORK UNITS

419.1 General. A live/work unit shall comply with Sections 419.1 through 419.9.

Exception: Dwelling or sleeping units that include an office that is less than 10 percent of the area of the dwelling unit are permitted to be classified as dwelling units with accessory occupancies in accordance with Section 508.2.

- These provisions allow a live/work unit that includes both living and working environments to be considered a single Group R-2 dwelling unit for application of the code. Several limitations and specific requirements are applied to both the living portion of the unit and the work portion of the unit. Prior to the adoption of these provisions, the code and the IRC did not allow residential live/work units in a form that is typically desirable for community development. This concept has become increasingly popular allowing design and construction of a public business, with employees working within a residence, allowing the public to enter the work area of the unit to acquire service. Examples of live/work commercial functions are artist’s studios, beauty parlors, nail salons and chiropractor’s offices. It is important to note that live/work is specifically not to apply to an in-home office. The exception to Section 419.1 is intended to address these small home offices which involve less than 10 percent of the dwelling’s floor area.

These concepts reflect an era of planning which created a community where residents could walk to all needed services such as the typical corner commercial store. Examples of this form of planning can be found in many older cities, as well as many “planned communities.” Live/work units began to re-emerge in the 1990s through a development style known as “Traditional Neighborhood Design” (TND). More recently, adaptive reuse in many older urban structures in city centers incorporated the same live/work tools to provide a variety of business offerings combined with residential unit types.

Historically, building codes did not have to deal with many live/work issues because zoning codes generally precluded a mixing of uses within a neighborhood, much less within a building. However, recent planning trends have been adopted in many jurisdictions, encouraging mixing of commercial and residential uses, not just in neighborhoods, but also in buildings, and even within unit types, such as the live/work unit commonly found in TND projects.

The provisions code for live/work units apply to the code criteria based on the Group R-2 provisions for construction. The occupant loads will be determined by the “function” of each space in accordance with Table 1004.1.1.

Section 419 allows mixed use within the dwelling unit or sleeping unit without classification as a mixed-occupancy condition as long as the unit meets the

2012 INTERNATIONAL BUILDING CODE® COMMENTARY

4-127
limits within this section. It is then to be classified as a Group R-2 occupancy. Special features that are common within a dwelling unit and are likely within the live/work unit are addressed in order to clearly delineate the means for designing a live/work unit.

419.1.1 Limitations. The following shall apply to all live/work areas:

1. The live/work unit is permitted to be not greater than 3,000 square feet (279 m²) in area;
2. The nonresidential area is permitted to be not more than 50 percent of the area of each live/work unit;
3. The nonresidential area function shall be limited to the first or main floor only of the live/work unit; and
4. Not more than five nonresidential workers or employees are allowed to occupy the nonresidential area at any one time.

These provisions were meant to apply strictly to small businesses associated with dwelling and sleeping units. In fact the intent is that the main occupancy of the building is residential with some business activity within the building. The code limits the nonresidential aspect to a maximum of 50 percent of the area of each unit. In addition, the total area of the live/work unit is limited to 3,000 square feet (279 m²). Therefore, the total area of the work unit would be a maximum of 1,500 square feet (139 m²). Since a nonresidential use is being located in a dwelling unit or sleeping unit, the nonresidential area is limited to the first or main floor. Therefore, those coming to the place of business do not need to enter the residential portion of the building. Finally, in keeping with the intent that these are small occupancies and that such occupancies could not create unnecessary life safety concerns, the number of nonresidential workers (employees) is limited to five. This limit of five is not the limit on the number of occupants that can be located within the work area, but simply the number of workers from outside the household that can be there on a regular basis. The 1,500 square-foot (139 m²) limit on area would limit the number of occupants based upon the occupant load factors.

419.2 Occupancies. Live/work units shall be classified as a Group R-2 occupancy. Separation requirements found in Sections 420 and 508 shall not apply within the live/work unit where the live/work unit is in compliance with Section 419. Nonresidential uses which would otherwise be classified as either a Group H or S occupancy shall not be permitted in a live/work unit.

Exception: Storage shall be permitted in the live/work unit provided the aggregate area of storage in the nonresidential portion of the live/work unit shall be limited to 10 percent of the space dedicated to nonresidential activities.

The entire live/work unit is to be classified as Group R-2 regardless of the types of business being conducted. This exempts such units from the requirements for separation in Sections 420 and 508 within the unit, but would still require the separation between each live/work unit.

The provisions that prohibit uses that would otherwise be classified as either Group H or S occupancies intend to avoid the accumulation of excessive and dangerous fire loads in residential related occupancies. This section would not prohibit the occupancy from containing the maximum allowable quantities of hazardous materials per control area within a building. Control areas are regulated in Section 414 (see the commentary for that section).

Storage is always a potential fire load with any business and to ensure that it does not become a large fire hazard it is limited to 10 percent of the nonresidential portion of the live/work unit. That would be a maximum of 150 square feet (14 m²); about the size of a large closet.

419.3 Means of egress. Except as modified by this section, the means of egress components for a live/work unit shall be designed in accordance with Chapter 10 for the function served.

This section requires compliance with Chapter 10 for means of egress unless the general requirements are modified by the following two subsections. The means of egress for the nonresidential portion of the live/work unit is regulated based upon the specific function of the space rather than the egress requirements for a Group R-2 occupancy. In many instances this will require an occupancy classification determination for the nonresidential portion for means of egress purposes without assigning such a classification to the function itself. For example, if the nonresidential portion of the live/work unit is a retail sales use, that portion of the unit would be regulated as a Group M occupancy for the means of egress provisions in Chapter 10.

419.3.1 Egress capacity. The egress capacity for each element of the live/work unit shall be based on the occupant load for the function served in accordance with Table 1004.1.1.

The egress capacity must be based upon the actual use of the space. Therefore if you had a mercantile type use in the live/work unit, the egress capacity must be based on 30 square feet (2.8 m²) per person of the gross area of the mercantile space. If a 3,000 square-foot (279 m²) unit is equally divided for mercantile and residential use, in such a case the calculated occupant load would be determined by dividing the area by the square feet per person: 1,500 square feet/ 30 square feet (18.5 m²) per person = 50 occupants. In addition, the capacity for residential use is 200 square feet per person (gross area), which would be 1,500 square feet/200 square feet per person = 8 occupants.

419.3.2 Spiral stairways. Spiral stairways that conform to the requirements of Section 1009.12 shall be permitted.

Spiral staircases are allowed in dwelling units and this section simply emphasizes this allowance with a specific reference back to the design criteria in Section 1009.12. There is no limit on the use of spiral
stairways regardless of the floor area of the non-residential uses in the live/work unit.

419.4 Vertical openings. Floor openings between floor levels of a live/work unit are permitted without enclosure.

[Fire] 419.5 Fire protection. The live/work unit shall be provided with a monitored fire alarm system where required by Section 907.2.9 and an automatic sprinkler system in accordance with Section 903.2.8.

[Fire] Since the unit is considered as Group R-2, the entire building would be required to be sprinklered in accordance with Section 903.3.1.1 (NFPA 13) or 903.3.1.2 (NFPA 13R).

This section requires the installation of a fire alarm system as required for a Group R-2 occupancy. Section 907.2.9 would only require a fire alarm system in certain cases. The requirements for a manual fire alarm are based on the location of the Group R-2 dwelling unit (three or more stories above the lowest level of exit discharge or one story below the highest level of exit discharge) and the number of units (more than 16). If a building has a sprinkler system and would require a manual system, the manual aspect is no longer required. Instead the sprinkler system is required to be tied to the notification appliances and activate the system upon water flow.

419.6 Structural. Floor loading for the areas within a live/work unit shall be designed to conform to Table 1607.1 based on the function within the space.

[Fire] Since live/work units may have structural loads not normally anticipated by Group R-2 occupancies, the code specifically requires structural design of floor loadings to be addressed in accordance with Table 1607.1, based on what is actually occurring in the space. For instance, if the nonresidential activity is a business, there may be equipment such as computers, files or a large copy machine which requires loading based on office loads of 100 psf (4788 Pa).

419.7 Accessibility. Accessibility shall be designed in accordance with Chapter 11 for the function served.

[Fire] Accessibility to and within the live/work unit must be designed and constructed in compliance with Chapter 11. The business/work area on the first floor must be fully accessible. In accordance with Section 1103.2.13, the dwelling unit portion must be evaluated separately. If the structure has four or more units, or the site has more than 20 units, Type A unit or Type B unit requirements may be applicable. The exceptions under Section 1107.7 are applicable. The most common application will typically be the multi-story dwelling unit (see Section 1107.7.2).

Section 1107.3 requires rooms and spaces available to the public be accessible. Accessible spaces that may be utilized by the public in accordance with Section 1107.3 include other spaces such as kitchens, living and dining areas and any exterior spaces including patios, terraces and balconies that may be on the same level as the entrance to the unit. These may not be “available to the public” unless they are part of the function of the nonresidential activity. Such spaces that are strictly part of the residential function of the live/work unit are only required to be accessible to the degree that such units are required to be made accessible.

419.8 Ventilation. The applicable ventilation requirements of the International Mechanical Code shall apply to each area within the live/work unit for the function within that space.

[Fire] Similar to the egress and structural requirements the use of the space must be looked at individually to ensure ventilation being provided fits the use. For instance, Table 403.3 of the IMC would require a florist to have 15 cubic feet (0.42 m³) per minute of outdoor air per person. With a possible floor area of 1,500 square feet (139 m²) for the work area and a minimum of 8 persons per 1,000 square feet (92.9 m²) as required by Table 403.3 the cfm required would be as follows:

- (8 occupants/1,000 square feet) x 1,500 square feet = 12 occupants

12 occupants x 15 cfm = 180 cfm of outside air ventilation

A two-bedroom dwelling unit would typically require 105 cfm (15 cfm per occupant x 7 occupants — 200 square feet per occupant in accordance with Table 1004.1.1). However, it is more typical that designs of residential dwelling units include the provision of fresh air by the natural ventilation option.

419.9 Plumbing facilities. The nonresidential area of the live/work unit shall be provided with minimum plumbing facilities as specified by Chapter 29, based on the function of the nonresidential area. Where the nonresidential area of the live/work unit is required to be accessible by Section 1103.2.13, the plumbing fixtures specified by Chapter 29 shall be accessible.

[Fire] In a manner consistent with the application of means of egress provisions to live/work units, plumbing facilities as specified by Chapter 29 are to be provided for the nonresidential use based on the function of the nonresidential area. Based on the example of a retail sales use as set forth in the commentary to Section 419.3, plumbing fixture requirements for the nonresidential retail sales area would be based on a Group M classification. However, the Group M classification would not be specifically assigned to the live/work unit. As previously stated in Section 419.7, the accessibility requirements for the nonresidential area would be based on the function of that area.
SECTION 420
GROUPS I-1, R-1, R-2, R-3

420.1 General. Occupancies in Groups I-1, R-1, R-2 and R-3 shall comply with the provisions of Sections 420.1 through 420.5 and other applicable provisions of this code.

- The nature of occupancies in Groups I-1, R-1, R-2 and R-3 is such that some level of protection against fire is needed for occupants in dwelling units and sleeping units. There remains a high frequency of fires where people live. These occupancies need to provide sprinkler protection. Requiring a minimum fire resistance to the construction separating both units and residential areas from nonresidential areas provides an extra level of protection in people’s homes from unfortunate occurrences in their neighbor’s homes. In accordance with Section 310.6, Group R-4 units are to be constructed to R-3 standards; therefore, these provisions also apply to sleeping units in a Group R-4. These separations are required between live/work units as provided in Section 419, but separations within each live/work unit between residential and nonresidential uses are not required.

420.2 Separation walls. Walls separating dwelling units in the same building, walls separating sleeping units in the same building and walls separating dwelling or sleeping units from other occupancies contiguous to them in the same building shall be constructed as fire partitions in accordance with Section 708.

- The sleeping units or dwelling units that are in a single building are required to be separated by fire partitions complying with Section 708, or horizontal fire-resistance-rated assemblies complying with Section 711. Fire partitions are the least robust of all fire-resistance-rated walls called out in the code. These occupancies all require smoke alarms in the sleeping areas of the units, and occupancies in Groups I-1 and R-1 also require general fire alarms. In addition, these occupancies are all required to be sprinklered. The reason for the nominal fire-resistant separation is to account for the fact that individuals asleep in these units could respond more slowly to a fire; therefore, some amount of fire resistance is deemed necessary to protect these occupants.

Section 708.3 requires fire partitions to be not less than 1-hour fire-resistance rated. If the building’s sprinkler protection is provided by a system complying with NFPA 13, the rating can be reduced to 30 minutes. Section 708.4 requires 1-hour-rated fire partitions to be supported by construction that has the same rating or better; however, this requirement is waived for these separation walls in buildings of Type II B, IIIB and VB construction.

This requirement also applies to walls that separate these Group R and I occupancies from other occupancies in the building. Even if those other areas are regulated under the accessory occupancies or nonseparated occupancies option of mixed occupancies contained in Sections 508.2 or 508.3 respectively, these partitions and horizontal assemblies are still required.

420.3 Horizontal separation. Floor assemblies separating dwelling units in the same buildings, floor assemblies separating sleeping units in the same building and floor assemblies separating dwelling or sleeping units from other occupancies contiguous to them in the same building shall be constructed as horizontal assemblies in accordance with Section 711.

- See the commentary to Section 420.2. Section 711.3 requires floor assemblies providing this separation to be not less than 1-hour fire-resistance rated. If the building’s sprinkler protection is provided by a system complying with NFPA 13, the rating can be reduced to 30 minutes. Section 708.4 requires 1-hour-rated fire partitions to be supported by construction that has the same rating or better; however, this requirement is waived for these floor assemblies in buildings of Type IIB, IIIB and VB construction.

[F] 420.4 Automatic sprinkler system. Group R occupancies shall be equipped throughout with an automatic sprinkler system in accordance with Section 903.2.8. Group I-1 occupancies shall be equipped throughout with an automatic sprinkler system in accordance with Section 903.2.8. Quick-response or residential automatic sprinklers shall be installed in accordance with Section 903.3.2.

- The provisions requiring automatic sprinkler protection for all buildings containing Group I or R occupancies are referenced here. In addition, reference is made to Section 903.3.2 regarding the required use of quick-response or residential automatic sprinklers.

[F] 420.5 Smoke detection and fire alarm systems. Fire alarm systems and smoke alarms shall be provided in Group I-1, R-1 and R-2 occupancies in accordance with Sections 907.2.6, 907.2.8 and 907.2.9, respectively. Single-or multiple-station smoke alarms shall be in accordance with Section 907.2.11.

- References to Sections 907.2.6, 907.2.8 and 907.2.9 are a reminder of the requirements for fire alarm systems and smoke alarms in Group I-1, R-1 and R-2 occupancies. It is also noted that Section 907.2.11 sets forth the requirements for single-station and multiple-station smoke alarms.

SECTION 421
HYDROGEN CUTOFF ROOMS

[F] 421.1 General. Where required by the International Fire Code, hydrogen cutoff rooms shall be designed and constructed in accordance with Sections 421.1 through 421.8.

- This section is simply stating that all hydrogen cutoff rooms are to be constructed in accordance with the provisions contained in Section 421. Hydrogen cutoff rooms were created to address the increasing and emerging concepts of fuel cells that use hydrogen and actually generate hydrogen onsite to run the fuel cells. The IFC requires in Section 2309.3.2.3 that
generation, compression, storage and dispensing equipment related to hydrogen be located in one of three places inside buildings. The first is a hydrogen cutoff room in accordance with this section. The second is outside a cutoff room where the gaseous hydrogen system is listed and labeled for indoor installation and installed in accordance with the manufacturer’s installation instructions. The third is in a dedicated hydrogen fuel dispensing area having an aggregate hydrogen delivery capacity no greater than 12 standard cubic feet (0.34 m³) per minute. The provisions of Section 421 address construction-related issues for hydrogen cutoff rooms such as location, fire-resistant separation, ventilation and safety features, such as gas detection and explosion control.

[F] 421.2 Definitions. The following terms are defined in Chapter 2:

GASEOUS HYDROGEN SYSTEM.

HYDROGEN CUTOFF ROOM.

- This section lists terms that are specifically associated with the subject matter of Section 421. It is important to emphasize that these terms are not exclusively related to this chapter but may or may not also be applicable where the term is used elsewhere in the code.

Definitions of terms can help in the understanding and application of the code requirements. The purpose for including a list within this chapter is to provide more convenient access to terms which may have a specific or limited application within this chapter. For the complete definition and associated commentary, refer back to Chapter 2. Terms that are italicized provide a visual identification throughout the code that a definition exists for that term. The use and application of all defined terms are set forth in Section 201.

[F] 421.3 Location. Hydrogen cutoff rooms shall not be located below grade.

- Restrictions against installation of cutoff rooms below grade are similar to those restricting the location of flammable and combustible liquids in basements. Explosion hazards are the primary concern, and placement of materials that have an ability to cause an explosion in below-grade spaces is not appropriate. Such spaces are more difficult to evacuate, create a fire explosion hazard to the structure above and are very difficult for the fire department to address.

[F] 421.4 Design and construction. Hydrogen cutoff rooms shall be classified with respect to occupancy in accordance with Section 302.1 and separated from other areas of the building by not less than 1-hour fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both; or as required by Section 508.2, 508.3 or 508.4, as applicable.

- Hydrogen cutoff rooms are required to be separated by not less than a 1-hour fire-resistance-rated fire barriers or horizontal assemblies, which is consistent with the requirements in Table 509 for incidental uses. In addition, the classification of the space will affect the separation requirements. Hydrogen cutoff rooms can contain any amount of hydrogen but if the maximum allowable quantities are exceeded, the cutoff room can no longer be considered an incidental use and instead must be classified as a Group H-2 occupancy. A Group H-2 could then must be addressed as a separated occupancy. In all cases, separation in accordance with Table 508.4 would apply in addition to the applicable occupancy-specific requirements.

[F] 421.4.1 Opening protective. Doors within the fire barriers, including doors to corridors, shall be self-closing in accordance with Section 716. Interior door openings shall be electronically interlocked to prevent operation of the hydrogen system when doors are open or ajar or the room shall be provided with a mechanical exhaust ventilation system designed in accordance with Section 421.4.1.1.

- To allow for broader applications (such as emergency generators using fuel cell technology), interior wall openings are allowed as necessary for easy access to the systems. In order to allow these openings, Section 716 is referenced for the proper rating and closure of doors. This section requires that the doors be self-closing and interlocked with the hydrogen generating equipment. This is necessary because the rest of the building may not be properly ventilated to address the presence of hydrogen. If the doors are not interlocked with the hydrogen generation system, then continuous ventilation is required in accordance with Section 421.4.1.1.

[F] 421.4.1.1 Ventilation alternative. Where an exhaust system is used in lieu of the interlock system required by Section 421.4.1, exhaust ventilation systems shall operate continuously and shall be designed to operate at a negative pressure in relation to the surrounding area. The average velocity of ventilation at the face of the door opening with the door in the fully open position shall not be less than 60 feet per minute (0.3048 m/s) and not less than 45 feet per minute (0.2287 m/s) at any point in the door opening.

- In applications where installation of interlocks is not practical, significant ventilation is required to ensure that a flammable mixture is not attained within the cutoff room and adjacent spaces. If exhaust ventilation is to be used as an alternative to an interlock, the exhaust system must be maintained in continuous operation so that a negative pressure with respect to spaces adjacent to the cutoff room is maintained.

[F] 421.4.2 Windows. Operable windows in interior walls shall not be permitted. Fixed windows shall be permitted where in accordance with Section 716.

- Operable windows are prohibited to further reduce the likelihood of allowing hydrogen from escaping into the room and entering other portions of the building that may not be properly ventilated. An operable window could inadvertently be left in the open or partially open position and go unnoticed. Fixed window open-
ings must meet the requirements of Section 716 to ensure that the requirements for opening protectives are met. More specifically, the proper fire protection ratings for openings in fire barriers are required.

[F] **421.5 Ventilation.** Cutoff rooms shall be provided with mechanical ventilation in accordance with the applicable provisions for repair garages in Chapter 5 of the *International Mechanical Code.*

- The purpose of this section is to prevent a dangerous accumulation of flammable gas in the room through the use of an exhaust ventilation system. The *Sourcebook for Hydrogen Applications* recommends ventilation at the rate of 1 cfm per square foot [0.00508 m³/(s x m²)] of floor area, which is consistent with the requirements in Chapter 5 of the IMC.

[F] **421.6 Gas detection system.** Hydrogen cutoff rooms shall be provided with an approved flammable gas detection system in accordance with Sections 421.6.1 through 421.6.3.

- Some gases contain additives that produce pungent odors for easy recognition. Systems using nonodorized gases, such as hydrogen and liquid natural gas, must utilize gas detection systems to detect leaks. This section specifically requires such detection due to the hazards associated with a build up of hydrogen at hazardous levels within a building.

[F] **421.6.1 System design.** The flammable gas detection system shall be listed for use with hydrogen and any other flammable gases used in the room. The gas detection system shall be designed to activate when the level of flammable gas exceeds 25 percent of the lower flammability limit (LFL) for the gas or mixtures present at their anticipated temperature and pressure.

- The detection system must initiate the operations specified in Section 421.6.2 at any time that the flammable gas concentration exceeds one-fourth of the concentration necessary to support combustion. Early detection of the presence of a flammable gas will allow adequate mitigation procedures to be taken. Hydrogen fires are not normally extinguished until the supply of hydrogen has been shut off because of the danger of reignition or explosion. A gas detection system in the room or space housing a gaseous hydrogen system results in early notification of a leak that is occurring before the escaping gas reaches a hazardous concentration.

[F] **421.6.2 Operation.** Activation of the gas detection system shall result in all of the following:

1. Initiation of distinct audible and visual alarm signals both inside and outside of the cutoff room.
2. Activation of the mechanical ventilation system.

- The detection system must activate the mechanical ventilation system that is required by Section 421.5, in addition to causing alarms to activate. Note that the mechanical ventilation alternative in Section 421.4.1.1 is continuously in operation.

The required local alarm is intended to alert the occupants to an emerging hazardous condition in the vicinity. The monitor control equipment must also initiate operation of the mechanical ventilation system in the event of a leak or rupture in the gaseous hydrogen system to prevent an accumulation of flammable gas.

[F] **421.6.3 Failure of the gas detection system.** Failure of the gas detection system shall result in activation of the mechanical ventilation system, cessation of hydrogen generation and the sounding of a trouble signal in an approved location.

- Systems must be designed to be self-monitoring and fail-safe in that all safety systems are activated to alert any occupants that a problem exists and to prevent more hydrogen from being generated by any appliances in the room when hazardous conditions cannot be monitored.

[F] **421.7 Explosion control.** Explosion control shall be provided in accordance with Chapter 9 of the *International Fire Code.*

- The requirements of this section are intended to address the circumstance resulting from a catastrophic failure of the cutoff room. These requirements are the final safeguard in case safety features such as interlocked doors, ventilation and gas detection systems should fail. An ignited hydrogen mixture produces large quantities of heat, causing a rapid expansion of the surrounding air. This can cause a pressure increase in a confined space and a catastrophic failure. Explosion control methods are identified in Section 911 of the IFC to prevent such a catastrophic failure. The explosion control requirements for hydrogen are consistent with the requirements in NFPA 50A and the Sourcebook for Hydrogen Applications.

[F] **421.8 Standby power.** Mechanical ventilation and gas detection systems shall be connected to a standby power system in accordance with Chapter 27.

- The ventilation system and gas detection system are life safety systems and, therefore, must be dependable. Both safety systems must remain active in the event of a power failure of the primary power supply. Hydrogen is a colorless, odorless gas; a release might go undetected if detection systems are not functioning. The accumulation of hydrogen in an unventilated area can lead to mixtures in the flammable range if safety systems and mechanical ventilation systems are not in operation. Chapter 50 of the IFC addresses emergency and standby power requirements for emergency systems. It also allows an exception to the requirement for systems that are fail-safe (see IFC Section 5004.7, Exception 4). This exception may be used in cutoff rooms where hydrogen is generated, but not stored. Any storage of hydrogen within the cutoff room would not qualify for the exception because in the event of a power failure, there will be no way to detect or ventilate a release from a storage vessel.
SECTION 422
AMBULATORY CARE FACILITIES

422.1 General. Occupancies classified as ambulatory care facilities shall comply with the provisions of Sections 422.1 through 422.7 and other applicable provisions of this code.

- Complex outpatient surgeries outside of the hospital are now commonplace. They are performed in facilities often called "day surgery centers" or "ambulatory surgical centers" because patients are able to walk in and walk out the same day. Procedures render patients temporarily incapable of self-preservation by application of nerve blocks, sedation or anesthesia. Patients in these facilities typically recover quickly. A definition of "Ambulatory care facility" is provided in Section 202.

The code identifies medical care Group I occupancies as having 24-hour stay. Without a 24-hour stay, these surgery centers are classified as Group B. Strictly regulating such occupancies as typical Group B occupancy is considered inappropriate, as this would allow the rendering of an unlimited number of people incapable of self-preservation with no more protection than a business office. These types of facilities contain distinctly different hazards to life and safety than other business occupancies, such as:

1. Patients incapable of self-preservation require rescue by other occupants or fire personnel.
2. Medical staff must stabilize the patient prior to evacuation; therefore, staff may require evacuation as well.
3. Use of oxidizing medical gases, such as oxygen and nitrous oxide.

In the past, there was a movement to classify ambulatory care facilities as Group I-2 occupancies. This was determined to be a poor fit, because these are not hospitals. Federal and state jurisdictions have recognized that there is a middle ground somewhere between Groups B and I-2. These requirements provide a scaled approach to protection. The occupancy classification is a Group B, but with some enhanced safety features focused on the concern with occupants being incapable of self-preservation on a temporary basis. The enhanced requirements are based on the concepts in the regulation of the Group I-2 occupancy requirements found in Section 407.

422.2 Separation. Ambulatory care facilities where the potential for four or more care recipients are to be incapable of self-preservation at any time, whether rendered incapable by staff or staff accepted responsibility for a care recipient already incapable, shall be separated from adjacent spaces, corridors or tenants with a fire partition installed in accordance with Section 708.

- In a multitenant or mixed-occupancy building where there are other uses present in addition to an ambulatory care facility, a degree of fire separation between the ambulatory care facility and those nonrelated spaces is required where the ambulatory care facility is intended to have at least four care recipients incapable of self-preservation at any one time. The minimum separation, a fire partition complying with Section 708, is viewed as an important tool in isolating the ambulatory care portion of building from fire hazards that may occur in other portions of the building. Where a building is considered wholly as an ambulatory care facility, or if the ambulatory care facility occupies the entire story of a multi-story building, there is no requirement for a fire partition to be constructed.

422.3 Smoke compartments. Where the aggregate area of one or more ambulatory care facilities is greater than 10,000 square feet (929 m²) on one story, the story shall be provided with a smoke barrier to subdivide the story into no fewer than two smoke compartments. The area of any one such smoke compartment shall be not greater than 22,500 square feet (2092 m²). The travel distance from any point in a smoke compartment to a smoke barrier door shall be not greater than 200 feet (60 960 mm). The smoke barrier shall be installed in accordance with Section 709 with the exception that smoke barriers shall be continuous from outside wall to an outside wall, a floor to a floor, or from a smoke barrier to a smoke barrier or a combination thereof.

- In larger facilities, the creation of smoke compartments is required to allow a protect-in-place environment. These compartments allow staff a safer environment to stabilize the patients before evacuation, and protection for fire personnel who may have to evacuate both patients and staff. The maximum size of a smoke compartment is limited to 22,500 square feet (2090 m²), consistent with the maximum size allowed for Group I-2 occupancies. It is important to note that each floor must be divided into at least two smoke compartments if the total floor area exceeds 10,000 square feet (929 m²) on each story. Conversely, smoke compartments are not required for ambulatory care facilities with a floor area that does not exceed 10,000 square feet (929 m²) on each story. The 10,000 square foot (929 m²) threshold is based on a story-by-story basis and is based on the aggregate floor areas where multiple ambulatory care facilities are present. The travel distance of 200 feet (60 960 mm) to a door providing egress from the smoke compartment is the same requirement as for Group I-2 occupancies.

422.4 Refuge area. Not less than 30 net square feet (2.8 m²) for each nonambulatory care recipient shall be provided within the aggregate area of corridors, care recipient rooms, treatment rooms, lounge or dining areas and other low-hazard areas within each smoke compartment. Each occupant of an ambulatory care facility shall be provided with access to a refuge area without passing through or utilizing adjacent tenant spaces.

- This requirement is very similar to that found in Section 407.5.1 for Group I-2 occupancies. The purpose is to provide adequate space for patients on beds who might be relocated to an adjacent smoke com-
partment. Since the facility may still be in operation during the fire, space must be provided in the corridors, patient rooms, treatment rooms, lounge or dining areas and other low-hazard areas for both the patients being relocated and accommodate the patients being treated in that smoke compartment. Section 407.5.1 acknowledges that there may be floors that do not house patients who are confined to beds or litter. It is also important that access to a refuge area be provided without requiring the occupant to travel through any other tenant space.

422.5 Independent egress. A means of egress shall be provided from each smoke compartment created by smoke barriers without having to return through the smoke compartment from which means of egress originated.

- This section is identical to Section 407.5.2 and requires that occupants should be able to exit the building without having to re-enter a smoke compartment from where they started. Although the strategy is to protect in place, occupants should not have to travel back through a smoke compartment to ultimately exit the building. This prevents the creation of a dead-end smoke compartment [see Figures 407.5, 407.5.2(1) and 407.5.2(2)].

[F] 422.6 Automatic sprinkler systems. Automatic sprinkler systems shall be provided for ambulatory care facilities in accordance with Section 903.2.2.

- Section 422.6 is part of the package of enhanced Group B requirements to accommodate the risk to occupants that is higher than the typical business occupancy but does not warrant classification as a Group I-2 occupancy. The actual sprinkler requirements are located in Section 903.2.2. The specific requirements apply when there are four or more care recipients incapable of self-preservation or if one or more care recipients are located on a story other than the level of exit discharge. The entire fire area meeting either one of the criteria must be sprinklered.

[F] 422.7 Fire alarm systems. A fire alarm system shall be provided for ambulatory care facilities in accordance with Section 907.2.2.1.

- As with the sprinkler requirements, the alarm requirements are actually located in Section 9. More specifically, Section 907.2.2.1 requires a manual fire alarm system in any fire area containing a Group B ambulatory care facility. Furthermore, an automatic smoke detection system is required within ambulatory care facility and public use spaces, such as lounges and corridors, except where all areas of the building are protected by an automatic sprinkler system. In addition, the sprinkler system is required to activate the occupant notification appliances upon sprinkler water flow (see commentary, Section 907.2.2.1). The scope of the smoke detection was purposely narrowed to limit the amount of retrofit measures that a building owner would be required to undertake if a new ambulatory care tenant was established in an existing building.

SECTION 423
STORM SHELTERS

423.1 General. In addition to other applicable requirements in this code, storm shelters shall be constructed in accordance with ICC-500.

- Standard ICC-500 provides requirements for the design and construction of shelters to protect people from the violent winds of hurricanes and tornadoes. The standard includes special requirements for structural design, including wind loads that are considerably higher than the wind loads required by Chapter 16 for all structures.

Wind loads for storm shelters will be based upon wind speed contour maps developed specially for this standard. The wind load design requirements are relatively severe when compared to the wind speed maps in Chapter 16. Contour maps for wind speeds in hurricane prone regions were determined based upon a 10,000-year mean return period. The map shows 200 mph wind speeds on the coast of Florida and the Carolinas, and wind speeds higher than 200 mph in some locations. These are wind speeds associated with a Category 5 hurricane. Shelter design wind speeds in the central part of the United States (a region called "tornado alley") are as high as 250 mph.

Such high wind speeds, of course, produce flying debris, turning construction materials into deadly missiles. The standard contains specific test methods and pass-fail criteria for window and doors protection from flying debris.

ICC-500 addresses nonstructural issues, as well. Storm shelters for hurricanes will be required to house people for 24 hours. Tornado shelters will be required to house people for 2 hours. The standard addresses minimum requirements for ventilation, sanitation, lighting, water supply and other minimal power needs.

It should be noted that the entrances and exits to storm shelters will be required to be accessible. In addition, the occupant load requirements are such that some wheelchair space will be required.

423.1.1 Scope. This section applies to the construction of storm shelters constructed as separate detached buildings or constructed as safe rooms within buildings for the purpose of providing safe refuge from storms that produce high winds, such as tornados and hurricanes. Such structures shall be designated to be hurricane shelters, tornado shelters, or combined hurricane and tornado shelters.

- Most storm shelters are safe rooms within a bigger facility. A common type of shelter doubles as a gymnasium or classroom in a school. The purpose of the storm shelter is to provide refuge for people during a storm. The standard does not address the use of the
shelter as a post-storm recovery facility, although it may well be used for that purpose.

423.2 Definitions. The following terms are defined in Chapter 2:

STORM SHELTER.

Community storm shelter.

Residential storm shelter.

- This section lists terms that are specifically associated with the subject matter of Section 423. It is important to emphasize that these terms are not exclusively related to this chapter but may or may not also be applicable where the term is used elsewhere in the code.

Definitions of terms can help in the understanding and application of the code requirements. The purpose for including a list within this chapter is to provide more convenient access to terms which may have a specific or limited application within this chapter. For the complete definition and associated commentary, refer back to Chapter 2. Terms that are italicized provide a visual identification throughout the code that a definition exists for that term. The use and application of all defined terms are set forth in Section 201.

SECTION 424

CHILDREN’S PLAY STRUCTURES

424.1 Children’s play structures. Children’s play structures installed inside all occupancies covered by this code that exceed 10 feet (3048 mm) in height and 150 square feet (14 m²) in area shall comply with Sections 424.2 through 424.5.

- Play structures for children’s activities have been regulated for some time by the code where such structures are located within covered mall buildings. The primary concern, consistent with other structures located within a covered mall building, is the combustibility of such play structures. Due to the potential fire hazards, the regulations are now applicable where such structures are located within any building regulated by this code, regardless of occupancy classification. The current provisions are essentially identical to those that historically regulated children’s play structures located within covered mall buildings. If these structures exceed 10 feet (3048 mm) in height and 150 square feet (14 m²) in area, then the provisions of Sections 424.2 through 424.5 must be followed.

424.2 Materials. Children’s play structures shall be constructed of noncombustible materials or of combustible materials that comply with the following:

1. Fire-retardant-treated wood complying with Section 2303.2.

2. Light-transmitting plastics complying with Section 2606.

3. Foam plastics (including the pipe foam used in soft-contained play equipment structures) having a maximum heat-release rate not greater than 100 kilowatts when tested in accordance with UL 1975 or when tested in accordance with NFPA 289, using the 20 kW ignition source.

4. Aluminum composite material (ACM) meeting the requirements of Class A interior finish in accordance with Chapter 8 when tested as an assembly in the maximum thickness intended for use.

5. Textiles and films complying with the flame propagation performance criteria contained in NFPA 701.

6. Plastic materials used to construct rigid components of soft-contained play equipment structures (such as tubes, windows, panels, junction boxes, pipes, slides and decks) exhibiting a peak rate of heat release not exceeding 400 kW/m² when tested in accordance with ASTM E 1354 at an incident heat flux of 50 kW/m² in the horizontal orientation at a thickness of 6 mm.

7. Ball pool balls, used in soft-contained play equipment structures, having a maximum heat-release rate not greater than 100 kilowatts when tested in accordance with UL 1975 or when tested in accordance with NFPA 289, using the 20 kW ignition source. The minimum specimen test size shall be 36 inches by 36 inches (914 mm by 914 mm) by an average of 21 inches (533 mm) deep, and the balls shall be held in a box constructed of galvanized steel poultry netting wire mesh.

8. Foam plastics shall be covered by a fabric, coating or film meeting the flame propagation performance criteria of NFPA 701.

9. The floor covering placed under the children’s play structure shall exhibit a Class I interior floor finish classification, as described in Section 804, when tested in accordance with NFPA 253.

- The amount of combustible materials associated with children’s play structures is rigidly limited. The provisions of Section 424.2 provide nine items of combustible materials that can be used to construct play equipment. These limitations are consistent with those previously applicable only to children’s play structures located in covered mall buildings.

[F] 424.3 Fire protection. Children’s play structures shall be provided with the same level of approved fire suppression and detection devices required for other structures in the same occupancy.

- Children’s play structures within a building must be provided with fire suppression and detection devices that provide an equal or better degree of fire protection than that required for the occupancy in which the play structures are located.

424.4 Separation. Children’s play structures shall have a horizontal separation from building walls, partitions and from elements of the means of egress of not less than 5 feet (1524 mm). Children’s playground structures shall have a horizon-
tal separation from other children's play structures of not less than 20 feet (6090 mm).

- Multiple children's play structures must be isolated from each other by a minimum distance of 20 feet (6090 mm). This separation reduces the concentration of combustible materials within a single area. A minimum separation of 5 feet (1524 mm) is also required between any play structure and portions of the building's construction, including means of egress elements, to allow for emergency personnel access and reduce fire spread potential.

424.5 Area limits. Children's play structures shall be not greater than 300 square feet (28 m²) in area, unless a special investigation, acceptable to the building official, has demonstrated adequate fire safety.

- Play structures are limited to a 300 square-foot (28 m²) area limitation unless adequate fire safety is proven to the building official by way of a special investigation.

Bibliography

The following resource materials are referenced in this chapter or are relevant to the subject matter addressed in this chapter.

NIST IR 5240-93, Measurement of Room Conditions and Response of Sprinklers and Smoke Detectors During a Simulated Two-bed Hospital Patient Room Fire. Gaithersburg, MD: National Institute of Standards and Technology, July 1993.

Chapter 5: General Building Heights and Areas

General Comments

Chapter 5 contains the provisions that regulate the minimum type of construction of a building, including allowable heights and areas, area modifications, height modifications, mezzanines, unlimited area structures, mixed occupancies and special provisions. The occupancy (or occupancies) and type of construction of a building is of key importance to the application of these provisions.

Section 501.1 gives the scope of Chapter 5. It specifies that the provisions of Chapter 5 apply not only to new construction, but also to existing building additions.

Section 502 lists terms that are related to the use and application of Chapter 5 and other provisions of the code related to height and area. The definitions are found in Chapter 2.

Section 503 addresses the general allowable height and area limitations of buildings. Table 503 establishes the limits for the height and area of a building as a function of the building’s occupancy classification and type of construction. It is a risk/safety table where the risk is based on the occupancy classification and the safety is related to the type of construction.

Section 504 describes the modifications to height limits in Table 503 that are allowed for buildings that have a sprinkler system installed in accordance with specified standards.

Section 505 provides the criteria and regulations for mezzanines and industrial equipment platforms.

Section 506 describes the allowable modifications to area limits given in Table 503 for buildings with automatic sprinkler systems and/or a sizable separation distance from adjacent lots or public ways.

Section 507 includes requirements for buildings with no area limitation. These provisions are commonly used for very large retail sales buildings, industrial warehouses and factories.

Section 508 provides requirements for buildings with multiple occupancies.

Section 509 addresses incidental uses such as waste and linen collection rooms, laundry rooms and incinerator rooms.

Section 510 contains special options for buildings that modify the general limitations of a building’s allowable height and/or area.

Chapter 5 is one of the most important chapters in the code because many other code requirements depend on the establishment of the minimum required type of construction for a building. A building has one minimum required construction type and must conform to those requirements, with certain exceptions for buildings conforming to the special provisions of Section 510. Without the correct determination of the minimum type of construction, misapplication of the code is probable.

Table 503 is the keystone in setting thresholds for building size based on the building’s use and the materials with which it is constructed. It is aimed at providing an acceptable level of hazard for building occupants by limiting fire load and fire hazards relating to height, area and occupancy. In accordance with Table 503, buildings of higher construction types [noncombustible materials and a higher degree of fire-resistance rating of elements (see Chapter 6)] can be larger and higher than buildings of lower construction types (combustible and unprotected with fire-resistance ratings).

The limits of Table 503 are modified by the text of the chapter, particularly the height and area modifications of Sections 504 and 506. Sections 507 and 510 give additional conditions under which the height and area limitations of Table 503 are modified, such as in the case of an unlimited area building.

Purpose

The main purpose of Chapter 5 is to regulate the size of structures based on the specific hazards associated with their occupancy and the materials of which they are constructed. Chapter 5 also provides for adjustments to the allowable area and height, based on the presence of fire protection systems for building occupants and fire service personnel in the event of a fire.

Following occupancy classification of uses based on Chapter 3, the code review for the design of any building continues with Chapter 5, with the determination of the minimum required type of construction based on the use and size of the building. Misapplication of Chapter 5 can result in a multitude of related errors in subsequent code application, since many code requirements depend on the type of construction that is required for the building.
SECTION 501
GENERAL

501.1 Scope. The provisions of this chapter control the height and area of structures hereafter erected and additions to existing structures.

- Chapter 5 is applicable to all new buildings as well as any existing structures that are to be enlarged. Allowable building height and building area are evaluated on the basis of occupancy classification, type of construction, location on the property relative to lot lines and other structures on the same lot, and the presence of an automatic sprinkler system in the building.

In the case of additions to existing buildings that are not separated by fire walls, the designer and plan reviewer must evaluate the entire building, including the addition, as if it were a new structure for purposes of determining allowable building area and height. For instance, if an existing Type IIB building is to have an addition, the aggregate area of the modified building (existing plus the addition) must be within the limits established by Table 503 for the allowable area and height of a Type IIB building, taking into account area and height modifications for open frontage and sprinklers.

If the aggregate area of the existing building and the addition exceeds the allowable area for Type IIB construction in Table 503, the addition is not permitted unless something is done to solve the allowable area problem. The solution could either be adding an automatic sprinkler system to the building to get an allowable area increase in accordance with Section 506.3; or by providing a fire wall between the addition and the existing building and, thereby creating two buildings in accordance with Section 503.1. If a fire wall is used, the designer must check the allowable area of the existing building again because the perimeter conditions have changed. Specifically, if the allowable area of the existing building resulted from an increase due to open frontage (see Section 506.2), then the following question must be answered: With the reduced open perimeter (there is no longer an open perimeter where the fire wall and adjacent building will be located), does the existing building exceed the building area limitations of Table 503 based on its use and construction type? If so, another solution must be found.

[F] 501.2 Address Identification. New and existing buildings shall be provided with approved address numbers or letters. Each character shall be not less than 4 inches (102 mm) in height and not less than 0.5 inch (12.7 mm) in width. They shall be installed on a contrasting background and be plainly visible from the street or road fronting the property. When required by the fire code official, address numbers shall be provided in additional approved locations to facilitate emergency response. Where access is by means of a private road and the building address cannot be viewed from the public way, a monument, pole or other approved sign or means shall be used to identify the structure. Address numbers shall be maintained.

- Identifying buildings, both new and existing, during an emergency (i.e., fire department, ambulances, medical, police) is greatly aided by the proper placement of address identification. In other than emergencies, the address identification serves as a convenience for people attempting to locate a building. The size and color criteria are intended to aid visibility from the street. When several structures are remotely located on a site or set back into a property, or at locations where multiple addresses are provided (e.g., strip malls) where the address is not readily visible from the public way, an approved method of identification will also be required, which will have characters posted in a location that will help in an emergency. The fire code official has the authority to require that address numbers be located in all locations deemed necessary to properly identify the building by street address. The primary concern is for emergency personnel to locate the building without going through a lengthy search procedure. In the case of a strip mall, identification would be provided for the backs of buildings that face alley or roads since the emergency response unit may often be directed to the back entrance. The address numbers must be maintained in a readily visible condition to provide for continuous identification. This would include the repainting of faded numbers or the trimming of trees or other vegetation that may be obscuring visibility of the address.

SECTION 502
DEFINITIONS

502.1 Definitions. The following terms are defined in Chapter 2:

AREA, BUILDING.
BASEMENT.
EQUIPMENT PLATFORM.
GRADE PLANE.
HEIGHT, BUILDING.
MEZZANINE.

- This section lists terms that are specifically associated with the subject matter of this chapter. It is important to emphasize that these terms are not exclusively related to this chapter but may or may not also be applicable where the term is used elsewhere in the code. For example, the defined term "basement" in most portions of the code applies to stories that do not meet the definition of a story above grade. However, for the application of flood plain regulations in Section 1612, a different definition of basement applies.

Definitions of terms can help in the understanding and application of the code requirements. The pur-
pose for including a list within this chapter is to provide more convenient access to terms which may have a specific or limited application within this chapter. For the complete definition and associated commentary, refer back to Chapter 2. Terms that are italicized provide a visual identification throughout the code that a definition exists for that term. The use and application of all defined terms are set forth in Section 201.

SECTION 503
GENERAL BUILDING HEIGHT AND AREA LIMITATIONS

503.1 General. The building height and area shall not exceed the limits specified in Table 503 based on the type of construction as determined by Section 602 and the occupancies as determined by Section 302 except as modified hereafter. Each portion of a building separated by one or more fire walls complying with Section 706 shall be considered to be a separate building.

The provisions for governing the height and area of buildings on the basis of occupancy classification and type of construction are established in this section. This section also establishes Table 503 as the primary tool for determining the minimum type of construction. All buildings are subject to these limitations unless more specific code requirements for a building type provide for different height or area limitations. For instance:

- Section 507 allows certain buildings to be unlimited in area due to lack of exposure, low hazard level, construction type, the presence of fire safety systems or a combination of these characteristics. Under these specific provisions, Table 503 does not apply unless referenced.

- Section 510 allows certain buildings with additional safeguards to adjust the heights and areas allowed by Table 503. Many of the provisions allow a mixture of construction types, and most involve a distinct portion of the structure being used for parking.

- Where more than one occupancy is present within one building, the provisions of Section 508 must be used in conjunction with Table 503 to determine the appropriate construction type for the occupancies involved.

Table 601 is used in conjunction with Table 503 to determine acceptable risk and fire safety levels for a building. Classification by occupancy, in accordance with the descriptions in Chapter 3, can be considered as establishing the level of “risk” associated with the use of a building. The various construction types, described in Chapter 6 and Table 601, can be thought of as various levels of safety in regard to fire resistance. Table 503 becomes a risk/safety matrix that sets a minimum level of safety (construction type) in accordance with the risk (the occupancy classification).

Fire walls are useful when a single building exceeds the allowable area limitation of Table 503. When fire walls (see Section 706) are used in a structure, multiple buildings are created. Each building created by the fire walls would be permitted to have its own occupancy classification and type of construction. Since multiple buildings would be created, each building would be evaluated separately in accordance with the height and area limitations of Table 503 (see commentary, Section 706).

The following is an example for the use of Table 503:

Example: Figure 503.1 shows a two-story office building of Type III B construction. Assuming the building is not sprinklered and does not qualify for any area or height increases, what is the maximum allowable area per story and height of the building? Given the size of the building, is Type III B construction adequate? What is the minimum required construction type?

Answer: From Table 503, the allowable area per story for a Group B occupancy of Type III B construction is 19,000 square feet (1765 m²). Since the actual
area is $130 \times 150 = 19,500$ square feet ($1812$ m$^2$). Type IIIB construction is not acceptable. The minimum required type of construction is Type I, IIA, IIB, IIIA or IV, depending on the desired materials for construction. All of these construction types for a Group B occupancy have allowable per-story areas greater than $19,500$ square feet ($1812$ m$^2$) in accordance with Table 503. The actual height in feet and stories is also within the table limits for these construction types.

503.1.1 Special industrial occupancies. Buildings and structures designed to house special industrial processes that require large areas and unusual building heights to accommodate cranes or special machinery and equipment, including, among others, rolling mills; structural metal fabrication shops and foundries; or the production and distribution of electric, gas or steam power, shall be exempt from the building height and area limitations of Table 503.

This section provides an exemption from the limits of Table 503. The occupancies that may use this exemption are quite limited. The exemption is only applicable when large areas or unusual heights beyond that permitted by Table 503 are necessary to accommodate the specific low-hazard or moderate-hazard manufacturing process.

It is the responsibility of the building official to determine when the application of this section is appropriate. The mere cost impact of the application of Table 503 does not dictate an exemption. The building official, in assessing the proposed construction, may wish to compare what protection features are being proposed to those features of other similar facilities.

TABLE 503. See page 5-5.

- Table 503 is the foremost code table used in establishing equivalent risk (offsetting a building's inherent fire hazard—represented by occupancy—with materials and construction features). Sections 504 and 506 give height and area increases to the limits of Table 503 for buildings with certain features. Section 507 contains provisions by which buildings can in fact be unlimited in area; however, the height limitations of Table 503 would still apply.

Table 503 has four components:

1. The left column represents all of the occupancy classifications defined in Chapter 3.

2. The top row lists all of the types of construction subclassifications explained in Chapter 6.

3. Each cell in this matrix contains the specific height (in stories above grade plane) and area (per story) limitations for the occupancy/type of construction combination in question.

4. Maximum building height in feet above grade plane is shown along a top row, just below the construction-type classifications. "Grade plane" is defined as an "averaged grade" around a building (see Section 202), and it may be different than finished grade.

In order to be considered in compliance with a type of construction, buildings must not exceed the maximum height based on number of stories shown in each cell of the table, nor exceed the maximum height in feet above grade plane shown along the upper row. Potential increases to the maximum allowable building height, in both stories and feet, are established elsewhere in Section 504.2.

Example 1: A proposed business building of Type IIIB construction is designed to be three stories above grade plane; however, the building height in feet above grade plane is 60 feet (18 288 mm). Since the height limitation for a Group B, Type IIIB building in Section 503 is 55 feet (16 764 mm), the proposed building could not be permitted as Type IIIB construction. If, however, the building is fully sprinklered in accordance with Section 504.2, an additional 20 feet (6096 mm) of height is allowed and Type IIIB would be acceptable.

Example 2: A mercantile building of Type IIB construction is proposed to be 50 feet (15 240 mm) and three stories above grade plane. It would not be permitted to be of Type IIIB construction unless protected by an automatic sprinkler system in accordance with Section 504.2, since it exceeds the number of stories permitted in Table 503 for a Group M building of Type IIB construction.

The area limitation appearing in each cell of the table represents the maximum square footage per story for each occupancy/type of construction combination before increases are made in accordance with Section 506. The definition of "Area, building" indicates the application of the tabular areas set in Table 503.

Unprotected combustible construction (Type VB) is not permitted for buildings of Group H-1 or 1-2. This type of construction—in particular, the fire hazard caused by the unprotected wood structure and the concealed spaces—does not provide the minimum protection required by the code to maintain equivalent risk in the presence of these occupancies.

For many groups in Type I.A or IB construction, both the height above grade and the area per story are not limited by the code because of the required fire-resistance ratings of these construction types. In addition, the story height and building area of Group A-5 buildings (outdoor assembly for viewing) are unlimited in any construction type; however, the overall height of a Group A-5 building is limited to the number of feet above grade plane specified in the first row of Table 503. For example, an open stadium of Type IIIA construction can be of unlimited area and an unlimited number of stories, but the structure cannot exceed 65 feet (19 812 mm) in height.

Simply put, the application of Table 503 is accomplished by identifying the occupancy classification of
the building in question along the left column, as well as identifying the cell in that row that matches the building's height (in stories and feet) and area per story. The resulting type of construction (at the top of the resulting column) represents the minimum required type of construction for the building before the application of increases are made in accordance with Sections 504 and 506.

Example 3: Assuming no area or height increases for a two-story Group S-1 building with a building height of 25 feet (7620 mm) above grade plane and a floor area of 11,500 square feet (1115 m²) per story, what is the minimum required construction type of the building in accordance with Table 503?

GENERAL BUILDING HEIGHTS AND AREAS

**Answer:** In accordance with the Group S-1 row of Table 503, the minimum required construction type is Type VA, which allows 14,000 square feet (1,301 m²) per story and limits the height to three stories and 50 feet (15 240 mm). The building cannot be Type VB construction, since it exceeds one story and 9,000 square feet (836 m²) per story. Type IIB construction (noncombustible, unprotected) is also acceptable, as are any of the other construction types except Type VB.

**503.1.2 Buildings on same lot.** Two or more buildings on the same lot shall be regulated as separate buildings or shall be considered as portions of one building if the building height of each building and the aggregate building area of the buildings are within the limitations of Table 503 as modified by Sections 504 and 506. The provisions of this code applicable to the aggregate building shall be applicable to each building.

Ordinarily, two buildings on the same lot are considered independently for compliance with the requirements of the code. Section 705.3 requires that when two buildings are on the same lot, an "imaginary" line is assumed between the buildings. This is used to determine the appropriate exterior wall fire-resistance ratings in Table 602, exterior wall requirements of Section 705, projection requirements of Section 705.2 and opening protective ratings and requirements set forth in Table 705.8 and Section 716 (also see the commentary for the definition of "Fire separation distance"). The primary purpose of Section 503.1.2 is to eliminate the application of the provisions of Section 705.3 when two small buildings can be regulated as one larger building on the lot. In other words, if the two buildings under consideration were actually connected (making one building) and could meet the area and height limitations for one building based on construction type, the connecting interior wall would not be required to have been rated; therefore, it is inconsistent to require the protection of the facing exterior walls simply because there is not a physical connection between two portions of the same building.

For example, in Figure 503.1.2(1), Buildings A and B are being constructed on the same lot at the same time. If they are considered to be separate buildings, then the code requirements for exterior wall and opening protection, as well as projections and roof coverings, would apply to each building on the basis of the placement of an imaginary lot line between the two buildings.

For SI: 1 foot = 0.3048 m, 1 square foot = 0.0929 m².

A = building area per story, S = stories above grade plane, UL = Unlimited, NP = Not permitted.

a. See the following sections for general exceptions to Table 503:
1. Section 504.2, Allowable building height and story increase due to automatic sprinkler system installation.
2. Section 506.2, Allowable building area increase due to street frontage.
3. Section 506.3, Allowable building area increase due to automatic sprinkler system installation.
4. Section 507, Unlimited area buildings.

b. See Chapter 4 for specific exceptions to the allowable height and areas in Chapter 5.

2012 INTERNATIONAL BUILDING CODE® COMMENTARY
Under this section, however, if they are considered to be one building (for minimum type of construction purposes), then there is no need for protection of the facing exterior walls and the code requirements for exterior wall and openings do not apply to the walls between the two buildings. These walls would have to meet exterior wall requirements for the type of construction specified in Table 601 for exterior bearing walls only. If they were nonbearing walls, then the required fire-resistance rating would be zero.

Although facing exterior walls between two buildings on the same lot are not subject to fire-resistance rating and opening size limitations by using this provision (except as previously indicated for bearing walls), the remainder of the exterior walls in both buildings must comply with any applicable exterior wall and opening provisions, including Tables 601, 602, 705.8, 716.5 and 716.6. Three of the walls in Building A and three of the walls in Building B, therefore, would still be required to meet the applicable requirements, and the exemption would only apply to the two walls (one from each building) that face each other.

A special circumstance occurs when a large structure is divided by fire walls into two or more buildings. In such a case, the exception provided by Section 503.1.2 would not be applicable because it is likely that a fire wall has been established because the overall structure exceeds the allowable area for a single building. If the configuration of the buildings results in a court, an imaginary line should be established between the two buildings in order to determine exterior wall and opening protection requirements [see Figure 503.1.2(2)].

**503.1.3 Type I construction.** Buildings of Type I construction permitted to be of unlimited tabular building heights and areas are not subject to the special requirements that allow unlimited area buildings in Section 507 or unlimited building height in Sections 503.1.1 and 504.3 or increased building heights and areas for other types of construction.

- Buildings of Type I construction permitted by Table 503 to be of unlimited height and area do not need to comply with the provisions of Section 504.2 or 506, which allow height and area increases. While most buildings of Type I construction are permitted to be unlimited in area, they are not required to comply with any of the provisions in Section 507 for unlimited area buildings. The requirements in Section 507 address special circumstances that permit a building to be unlimited in area. As there are no limitations to the size of these structures, the application of these sections would be superfluous. These buildings may be of unlimited size based on their type of construction alone. High-rise buildings are required to be sprinkler protected in accordance with Section 403.3. and this section should not be construed to be a release from that requirement if a building fits the definition of "High-rise building."

- A special industrial occupancy building, in accordance with Section 503.1.1, is permitted to be unlimited in height. However, this does not require the type of construction for the building to be Type I. Any type of construction is permitted for special industrial occupancy buildings. Similarly, noncombustible roof structures are permitted to be unlimited in height on buildings of all buildings, including those of Type I construction.

---

**Figure 503.1.2(1)**

BUILDINGS ON SAME LOT

For SI: 1 foot = 304.8 mm,
1 square foot = 0.0929 m².
SECTION 504
BUILDING HEIGHT

504.1 General. The building height permitted by Table 503 shall be increased in accordance with Sections 504.2 and 504.3.

Exception: The building height of one-story aircraft hangars, aircraft paint hangars and buildings used for the manufacturing of aircraft shall not be limited if the building is provided with an automatic sprinkler system or automatic fire-extinguishing system in accordance with Chapter 9 and is entirely surrounded by public ways or yards not less in width than one and one-half times the building height.

● Section 504 contains exceptions to the height limitations of Table 503 for certain buildings. These exceptions are made on the basis of the structure's proposed occupancy and of fire safety features included in the design of the structure. The principal exception given is the increase for buildings equipped throughout with an automatic sprinkler system (see Section 504.2). When a sprinkler system is installed either as an option or where required by other sections of the code, an increase in height may be applicable because of the increased protection provided by such a system. (See the exceptions to Section 504.2 that restrict this allowance.)

The exception permits fully suppressed aircraft hangars to exceed the height limits of Table 503 as long as they have the specified open area surrounding the building. The exception is necessary to accommodate the size of large aircraft within the building, and the hazard is mitigated by the requirement for suppression and the very large open space provided by the yards and public ways. While the code refers to fire-extinguishing requirements in Chapter 9, the detailed suppression requirements for aircraft hangars are specified in Section 412.4.6. Aircraft paint hangars may be unlimited in area as well, under certain conditions (see commentary, Section 507.9).

504.2 Automatic sprinkler system increase. Where a building is equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1, the value specified in Table 503 for maximum building height is increased by 20 feet (6096 mm) and the maximum number of stories is increased by one. These increases are permitted in addition to the building area increase in accordance with Sections 506.2 and 506.3. For Group R buildings equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.2, the value specified in Table 503 for maximum building height is increased by 20 feet (6096 mm) and the maximum number of stories is increased by one, but shall not exceed 60 feet (18 288 mm) or four stories, respectively.

Exception: The use of an automatic sprinkler system to increase building heights shall not be permitted for the following conditions:

1. Buildings, or portions of buildings, classified as a Group I-2 occupancy of Type IIB, III, IV or V construction.
2. Buildings, or portions of buildings, classified as a Group H-1, H-2, H-3 or H-5 occupancy.
3. Buildings where an automatic sprinkler system is substituted for fire-resistance rated construction in accordance with Table 601, Note d.

● This section permits the building height limitations of Table 503 to be increased one story and 20 feet (6096 mm) when the building is protected throughout
with an approved automatic sprinkler system. When used in this context, the phrase "equipped throughout" (see Section 903.3.1.1) means the entire structure is provided with sprinkler protection, and the only exceptions are the specific locations identified in Section 903.3.1.1 or in the applicable standard. If a building contains an area that meets the conditions of Section 903.3.1.1 or an exception in the applicable standard, then sprinklers may be omitted in that specific location of the building and the building is still considered protected throughout (see the commentary to Section 903.3.1.1.1 for application of the exceptions).

By referencing Section 903.3.1.1, the code requires a system in accordance with NFPA 13 (not NFPA 13R or NFPA 13D). There is an allowance where buildings of residential occupancies are permitted to receive an increase of one story and 20 feet (6096 mm) up to a maximum of four stories and 60 feet (18288 mm) if equipped with a sprinkler system that conforms to Section 903.3.1.2 (an NFPA 13R system). This alternative is intended to address the differences between application and protection provided by an NFPA 13 system versus an NFPA 13R system. Note that no increase is allowed for an NFPA 13D system, which is specifically scoped for one- and two-family residential buildings and townhouses. If a Group R building is protected throughout with an NFPA 13 system in accordance with Section 903.3.1.1, then the four-story, 60-foot (18288 mm) limitation would not apply. It should be noted that NFPA 13R systems are limited to buildings that are four stories or less in height above grade plane.

It should also be noted that the height increase is permitted even if the sprinkler system is required by Chapter 9 of the code, based on the use and size of the building. For instance, Section 903.2.8 requires all buildings containing Group R fire areas to be sprinklered. Even so, a Type VA, Group R-2 building protected throughout with an NFPA 13R system (in accordance with Section 903.3.1.2) is allowed up to four stories (one story more than the story limitation shown in Table 503 for Group R-2, Type VA construction) and up to 60 feet (18288 mm) in height.

Please note that the height increase can be combined with an area increase in accordance with Section 506.3.

On the other hand, an NFPA 13R sprinkler system would not yield a height-in-stories increase for a Type IIB building of Group R-2, since Table 503 already permits four stories. The height-in-feet threshold, however, would be 60 feet (18288 mm), a 5-foot (1524 mm) increase over what is allowed by Table 503 for Type IIB construction. If the Group R-2 building is protected throughout with a system in accordance with NFPA 13 (see Section 903.3.1.1), then the height thresholds would be five stories and 75 feet (22860 mm) [the permitted one-story, 20-foot (6096 mm) increase over the Table 503 limits].

The three exceptions to this section each describe circumstances where the height increases allowed by this section would not be permitted.

Exception 1 indicates several types of construction are eliminated from the height increase for buildings, or portions of buildings, containing a Group I-2 occupancy. Each of these types of construction either lacks the fire-resistance rating deemed necessary or includes combustible construction materials in a use where the occupants must rely on the fire sprinkler system for defend-in-place protection.

Exception 2 indicates buildings, or portions of buildings, containing a Group H-1, H-2, H-3 or H-5 occupancy are not eligible for the general height increase because of the higher hazards associated with these occupancies.

Exception 3 states that when an automatic sprinkler system is installed to address the allowed trade-off of sprinklers for 1-hour fire-resistance-rated construction given in Note d of Table 601, the height increase allowed in this section cannot be taken. For example, in a building constructed using Type IIIA construction, the required 1-hour fire-resistance rating of all structural members (with the exception of the exterior walls) could be reduced to zero if the building was equipped throughout with a sprinkler system in accordance with Section 903.3.1.1 (NFPA 13 system). However, the allowable height for the occupancy classification of, for example, Group B for Type IIA construction could not be increased by 20 feet (6096 mm) to 85 feet (25908 mm), as would otherwise be allowed in this section.

504.3 Roof structures. Towers, spires, steeples and other roof structures shall be constructed of materials consistent with the required type of construction of the building except where other construction is permitted by Section 1509.2.5. Such structures shall not be used for habitation or storage. The structures shall be unlimited in height if of noncombustible materials and shall not extend more than 20 feet (6096 mm) above the allowable building height if of combustible materials (see Chapter 15 for additional requirements).

Certain roof structures may exceed the height limitations of Table 503 in accordance with this section and Chapter 15. These roof structures on a noncombustible building (Type I or II) must be of noncombustible construction and, in some cases, must have ratings equivalent to those required for exterior walls (see Section 1509.5 for enclosed towers and spires). Section 1509.2.5 contains exceptions for exterior walls, mechanical equipment enclosures and screens when not in proximity to a property line. Structures that are used for habitation or storage must be considered an additional story. The height limitation for noncombustible roof structures in accordance with this section is unlimited. Please note that Section 1509.2 and its subsections contain additional restrictions for structures of a certain size or use. Combustible roof structures are permitted to extend up to 20 feet (6096 mm) above the allowable height set in Table 503 or as increased in accordance with Section 504.2.
SECTION 505
MEZZANINES AND EQUIPMENT PLATFORMS

505.1 General. Mezzanines shall comply with Section 505.2. Equipment platforms shall comply with Section 505.3.

- Special provisions are established for two types of elevated floor areas, mezzanines and equipment platforms. Each of the elements has its own unique characteristics, requirements and allowances. Section 505.2 addresses mezzanines and the special provisions for equipment platforms are located in Section 505.3.

505.2 Mezzanines. A mezzanine or mezzanines in compliance with Section 505.2 shall be considered a portion of the story below. Such mezzanines shall not contribute to either the building area or number of stories as regulated by Section 503.1. The area of the mezzanine shall be included in determining the fire area. The clear height above and below the mezzanine floor construction shall be not less than 7 feet (2134 mm).

- Although mezzanines provide an additional or intermediate usable floor level in a building, they are not considered an additional story as long as they comply with the requirements of Section 505. Building height area limitations are intended to offset the inherent fire hazard associated with specific occupancies and with materials and features of a specific construction type. Because of a mezzanine's restricted size and its required openness to the room or space in which it is located, a mezzanine does not contribute significantly to a building's inherent fire hazard; therefore, the area of a mezzanine is not considered when applying the provisions of Section 503.1 for building area limitations, and mezzanines are not considered in determining the height in stories of a building as regulated by Table 503. Please note that a mezzanine level is considered an occupied level that may affect the classification of a building as a high-rise (see commentary, Section 403). The occupant and fuel loads of the mezzanine should be taken into consideration, however, when determining the necessity for fire protection systems. As such, the area of the mezzanine is to be included in the calculation of the size of the fire area for sprinkler thresholds (see the commentary for the definition of "Fire area" in Section 202).

This section does not include any special requirements for the construction of a mezzanine or for fire-resistance ratings; therefore, the mezzanine is to be constructed of materials consistent with the construction type of the building. Required fire-resistance ratings are determined on the basis of Table 601 for the appropriate construction type.

Mezzanines are required to have a ceiling height of not less than 7 feet (2134 mm), and the ceiling height below the mezzanine must also be not less than 7 feet (2134 mm). Even habitable rooms located in mezzanines may have a ceiling height of 7 feet (2134 mm), in accordance with Exception 3 to Section 1208.2.

505.2.1 Area limitation. The aggregate area of a mezzanine or mezzanines within a room shall be not greater than one-third of the floor area of that room or space in which they are located. The enclosed portion of a room shall not be included in a determination of the floor area of the room in which the mezzanine is located. In determining the allowable mezzanine area, the area of the mezzanine shall not be included in the floor area of the room.

Where a room contains both a mezzanine and an equipment platform, the aggregate area of the two raised floor levels shall be not greater than two-thirds of the floor area of that room or space in which they are located.

Exceptions:

1. The aggregate area of mezzanines in buildings and structures of Type I or II construction for special industrial occupancies in accordance with Section 503.1.1 shall be not greater than two-thirds of the floor area of the room.

2. The aggregate area of mezzanines in buildings and structures of Type I or II construction shall be not greater than one-half of the floor area of the room in buildings and structures equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1 and an approved emergency voice/alarm communication system in accordance with Section 907.3.2.

- So as not to contribute significantly to a building's inherent fire hazard, a mezzanine is restricted to a maximum of one-third of the area of the room with which it shares a common atmosphere. The area may consist of multiple mezzanines at the same or different floor levels, provided that the aggregate area does not exceed the one-third limitation. (This determination is based on the gross floor area of the mezzanines.) If the area limitation is exceeded, the provisions of this section do not apply and the mezzanine level is considered an additional story.

In determining the allowable area of the mezzanine, the enclosed spaces of the room in which the mezzanine is contained are not to be included in calculating the room size. Although the mezzanine area is included in the calculation of fire area size, it is not included in the area of the room when computing the allowable mezzanine area. For example, a room contains 5,000 square feet (465 m²), 500 square feet (46 m²) of which are enclosed and not part of the common atmosphere with the mezzanine. A mezzanine may be provided in the room such that the area of the mezzanine is not more than 1,500 square feet (139 m²) (5,000 square feet - 500 square feet = 4,500 square feet (46 m²) = 1,500 square feet (139 m²)). The mezzanine level must be open, except that enclosed spaces are permitted for mezzanines in accordance with the exceptions to Section 505.2.3. Even if the mezzanine is enclosed, the allowable area of the mezzanine is always determined assuming the space is open to the room in which it is located.

By definition, in special industrial occupancies (see
commentary, Section 503.1.1) the inherent fire hazard is very low; therefore, mezzanines in such occupancies located in buildings of Type I or II construction are permitted to constitute up to two-thirds of the area of the room in which they are located, in accordance with Exception 1. The limitation on construction types further reduces the fire hazard associated with such occupancies.

Exception 2 provides additional allowable area for mezzanines in Type I or II construction in any occupancy, when sprinklers, as well as an approved emergency voice/alarm communication system are installed. The trade-off for additional area for installation of a sprinkler system recognizes the additional time that sprinklers provide for occupant evacuation. The emergency voice/alarm communication system is also seen as a necessary feature of this trade-off so that occupants of a building become aware of a fire that could start in a remote part of the mezzanine, in order to allow evacuation before smoke spread could cause a problem for occupants. Experience has shown that occupants react more readily when given voice instructions than when given a general alarm.

Equipment platforms, as defined in Section 202, are not considered mezzanines (see Section 505.3 for provisions addressing equipment platforms). Where one or more mezzanines and one or more equipment platforms are located within the same room, the aggregate area of such elevated spaces cannot exceed more than two-thirds of the floor area of the room in which they are located. In addition, the maximum floor area for any portion determined to be a mezzanine is limited based upon the provisions of this section.

505.2.2 Means of egress. The means of egress for mezzanines shall comply with the applicable provisions of Chapter 10.

A mezzanine can be likened to a single room when considering means of egress. The provisions of Chapter 10 are to be applied to mezzanines in the same manner as other portions of the means of egress. As with rooms, if the occupant load of the mezzanine exceeds the limitation of Table 1015.1 for the specific use of the space, at least two independent means of egress must be provided for the mezzanine. For example, if a mezzanine containing office areas (Group B) has an occupant load exceeding 49, a second means of egress from the mezzanine is required. Additionally, if a mezzanine has one means of egress and it is by means of an exit access stairway to the floor below, the travel distance from the most remote point on the mezzanine to the bottom of the stairway may not exceed 75 feet (22 860 mm) in accordance with Section 1014.3 for common path of travel [see the exceptions to Section 1014.3 that allow 100 feet (30 480 mm) in some circumstances]. If the travel distance to the bottom of the exit access stairway exceeds the limits of Section 1014.3, then a second means of egress must be provided from the mezzanine. This assumes that at the bottom of the stairway there are at least two separate travel paths available that lead to at least two exits.

Because mezzanines that comply with Section 505 are considered a portion of the story in which they are located in accordance with Section 505.2, the exit access stairway leading from it is not required to be enclosed. The enclosure provisions of Section 1009.3 do not apply to stairways that are contained within a single story.

This section does not require that an exit be provided directly from the mezzanine level. Exception 2 to Section 505.2.3, however, requires mezzanines that are not open to the room in which they are located to have access to an exit directly from the mezzanine level, if two means of egress are provided. When two means of egress are required, however, they are to be located remote from each other in accordance with Section 1015.2, as for any other space, so that if one means of egress is blocked by fire or smoke, then the other will be presumed available.

When exits are not located on the same level as the mezzanine, the occupant load of the mezzanine is added to the room or space below and the required means of egress width for that room is determined accordingly (see Section 1005). For example, if a room (Group B) has an occupant load of 45 and a mezzanine (also Group B) has an occupant load of 15, the total occupant load for the space served is 60; therefore, the room must have two exit access doors or exits in accordance with Table 1015.1. The mezzanine itself, however, needs only one means of egress provided the common path of travel provisions of Section 1014.3 are met.

The requirements for accessible means of egress are not in any way intended to be affected by these provisions. The requirements for accessibility relate only to the requirements for the occupancy and use of the space as provided in Chapters 10 and 11 of the code. If two means of egress are required from the mezzanine and an accessible route is required to the mezzanine, then two accessible means of egress must be provided from the mezzanine. If an accessible route is not required to the mezzanine or the mezzanine is not required to be accessible, then no accessible means of egress are required.

505.2.3 Openness. A mezzanine shall be open and unobstructed to the room in which such mezzanine is located except for walls not more than 42 inches (1067 mm) in height, columns and posts.

Exceptions:

1. Mezzanines or portions thereof are not required to be open to the room in which the mezzanines are located, provided that the occupant load of the aggregate area of the enclosed space is not greater than 10.

2. A mezzanine having two or more means of egress is not required to be open to the room in which the
mezzanine is located if at least one of the means of egress provides direct access to an exit from the mezzanine level.

3. Mezzanines or portions thereof are not required to be open to the room in which the mezzanines are located, provided that the aggregate floor area of the enclosed space is not greater than 10 percent of the mezzanine area.

4. In industrial facilities, mezzanines used for control equipment are permitted to be glazed on all sides.

5. In occupancies other than Groups H and I, that are no more than two stories above grade plane and equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1, a mezzanine having two or more means of egress shall not be required to be open to the room in which the mezzanine is located.

- A mezzanine presents a unique fire threat to the occupant. If a mezzanine is closed off from the larger room, an undetected fire could develop such that it would jeopardize or eliminate the opportunity for occupant escape.

The exceptions address situations where the hazard is reduced. A low occupant load, typical of small mezzanines, would permit a mezzanine to be enclosed in accordance with Exception 1. Occupant load is calculated in accordance with Section 1004.1 for the use or function of the mezzanine space. Similarly, Exception 3 permits the enclosure of a limited portion of a mezzanine.

Exception 2 permits enclosure of the mezzanine based on the availability of an exit at the mezzanine level, and the mezzanine has at least two means of egress. The definition of "Exit" is important for this exception. Based on the "exit" elements included as part of the definition in Section 202, the mezzanine must be served by at least one interior exit stairway or ramp (see Section 1022), a horizontal exit (see Section 1025), an exit passageway (see Section 1023), an exterior exit stairway or ramp (see Section 1026) or an exterior door discharging directly at grade. In addition, another means of egress is required, which may be an unenclosed exit access stairway to the room below.

Exception 4 addresses industrial facilities, where enclosure may be necessary for noise reduction or atmospheric control.

A fire in an enclosed mezzanine could easily go unrecognized for a longer period than in an open mezzanine. Therefore, Exception 5 permits enclosure of a mezzanine in a building that is fully protected by a sprinkler system and limited to two stories. Under this exception two means of egress must be provided for the mezzanine; however, direct access to an exit from the mezzanine is not necessary.

505.3 Equipment platforms. Equipment platforms in buildings shall not be considered as a portion of the floor below. Such equipment platforms shall not contribute to either the building area or the number of stories as regulated by Section 503.1. The area of the equipment platform shall not be included in determining the fire area in accordance with Section 903. Equipment platforms shall not be a part of any mezzanine and such platforms and the walkways, stairs, alternating tread devices and ladders providing access to an equipment platform shall not serve as a part of the means of egress from the building.

- "Equipment platform" is defined in Section 202 as an unoccupied, elevated platform used exclusively for supporting mechanical systems or industrial process equipment and providing access to them. If an elevated platform does not meet all of the conditions of this definition, then it must be considered either a mezzanine or another story.

Equipment platforms are treated as part of the equipment they support (within the limitations of the subsections to this section), and do not contribute in any way to the area of the building, the number of stories, the area of any mezzanine or any fire area. If equipment platforms are located in the same room as a mezzanine, however, the aggregate area of the platforms and mezzanines is limited by Section 505.2.1.

The definition of "equipment platform" includes the associated elevated walkways, stairs, alternating tread devices and ladders necessary to access the platform. Elements that serve an equipment platform are not permitted to serve as a means of egress for occupants of the building unless they meet all of the requirements for means of egress in Chapter 10. Because they are not used for means of egress, the elements used to access these platforms could be something other than a stairway or ramp. For example, a permanent ladder could be used to access an equipment platform. Since the code does not address ladder construction for this circumstance, other appropriate standards, such as Occupational Safety and Health Administration (OSHA) standards would need to be consulted for design.

505.3.1 Area limitation. The aggregate area of all equipment platforms within a room shall not be greater than two-thirds of the area of the room in which they are located. Where an equipment platform is located in the same room as a mezzanine, the area of the mezzanine shall be determined by Section 505.2.1 and the combined aggregate area of the equipment platforms and mezzanines shall not be greater than two-thirds of the room in which they are located.

- In determining the allowable area of an equipment platform, neither the enclosed spaces of the room in which the equipment platform is located nor the area of the equipment platform itself is to be included in calculating the room size. Whereas mezzanines are limited to one-third of the area of the room in which they are located, equipment platforms are permitted to be two-thirds of the area of the room. Whereas the area of mezzanines is included in the calculation of the fire area (see Section 505.1), the area of equipment platforms is not included as part of the fire area.

5-12
The area of mezzanines and equipment platforms, however, is summed when they are in the same room, and the aggregate area is limited to two-thirds of the area of the room. In addition, the total area of a mezzanine typically cannot exceed one-third of the area of the room.

505.3.2 Automatic sprinkler system. Where located in a building that is required to be protected by an automatic sprinkler system, equipment platforms shall be fully protected by sprinklers above and below the platform, where required by the standards referenced in Section 903.3.

- In buildings or spaces that are required to be protected with an automatic fire sprinkler system, sprinkler protection above and below the equipment platform is needed so the equipment platform will not obstruct sprinkler coverage or delay sprinkler activation if a fire develops below the platform. As stated in Section 903.3.1.1, sprinkler installation is to be in accordance with NFPA 13. This section should not be construed to require sprinkler protection for equipment platforms where such a system is not otherwise required.

505.3.3 Guards. Equipment platforms shall have guards where required by Section 1013.2.

- Guards are required for equipment platforms in the same manner that they are required at open walking surfaces in other parts of the building, and are subject to the same requirements for height, design load and configuration. Exception 3 to Section 1013.4 allows spacing of guard balusters in areas where electrical, mechanical and plumbing systems or equipment are accessed and used to only be close enough to prevent the passage of a 21-inch (533 mm) sphere.

SECTION 506
BUILDING AREA MODIFICATIONS

506.1 General. The building areas limited by Table 503 shall be permitted to be increased due to frontage (I) and automatic sprinkler system protection (I) in accordance with Equation 5-1:

\[ A_s = \{A_t + [A_t \times I_t] + [A_t \times I_s]\} \]  

(Equation 5-1)

where:

\[ A_s \] = Allowable building area per story (square feet).

\[ A_t \] = Tabular building area per story in accordance with Table 503 (square feet).

\[ I_t \] = Area increase factor due to frontage as calculated in accordance with Section 506.2.

\[ I_s \] = Area increase factor due to sprinkler protection as calculated in accordance with Section 506.3.

- Other than increasing the fire-resistance rating or using all noncombustible materials (going to a higher construction type) for the building structure, in general there are two circumstances that would decrease a building's fire hazard. These are: (1) isolating the building from other structures and (2) equipping it with a fire sprinkler system. Equation 5-1 takes these circumstances into account. The equation determines the largest area for any single story of a building, taking into account the permissible increases due to open frontage and the installation of an automatic sprinkler system. Equation 5-1 in conjunction with Sections 506.1 through 506.3 is used to determine the maximum allowable area for any individual story of a building. This information is then used in Sections 506.4 and 506.5 to establish the maximum allowed area in the total building.

The following examples demonstrate the determination of the maximum floor area per story:

**Example 1:** A single-story, Group B building of Type IIb construction does not have an automatic sprinkler system but is allowed a frontage increase of 50 percent in accordance with Section 506.2. In Equation 5-1, the following values would be given to the terms:

\[ A_t = 23,000 \text{ square feet (1765 m²)} \] (from Table 503)

\[ I_t = 0.5 \]

\[ I_s = 0 \]

The equation \[ A_s = \{A_t + [A_t \times I_t] + [A_t \times I_s]\} \]

becomes \[ A_s = 23,000 + [(23,000)(0.5)] + 0 \]

\[ = 23,000 + 11,500 \]

\[ = 34,500 \text{ square feet (3205 m²)} \].

The allowable area per story for the building is 34,500 square feet (3205 m²).

**Example 2:** A five-story, Group R-2 building of Type IIA construction has a frontage increase of 75 percent in accordance with Section 506.2. The building is fully sprinklered with an NFPA 13 system and the increase yielded by Section 506.3 is 200 percent. In Equation 5-1, the following values would be given to the terms:

\[ A_t = 24,000 \text{ square feet (2230 m²)} \] (from Table 503)

\[ I_t = 0.75 \]

\[ I_s = 2 \]

Equation 5-1 becomes:

\[ A_s = \{24,000 + [(24,000)(0.75)] + [(24,000)(2)]\} \]

\[ = 24,000 + 18,000 + 48,000 \]

\[ = 90,000 \text{ square feet (8361 m²) per story} \]

At this point, because the building is more than three stories in height, an additional calculation needs to be made in accordance with Section 506.4.1, which limits the aggregate area of all stories in the building. In accordance with that section, the total allowable area for the building may be no more than three times the maximum allowable area per story \( A_s \). Assuming all stories of the building have equal
area, the maximum allowable area of each story is calculated as follows:

\[(3)(A_0) = (3)(90,000) = 270,000 \text{ square feet} \]
\[(25 \text{,}083 \text{ m}^2) \text{ total allowable area in the building.}\]

Assuming the footprint of all five stories is the same size, 270,000/5 stories = 54,000 square feet (5017 m²) maximum per story.

Therefore, if the total allowable area is divided equally among the five stories, the allowable area per story for the building is 54,000 square feet (5017 m²). The code does not require that the total allowable building area be equally divided on the five stories. For example, a building with a 90,000-square-foot (8361 m²) first story, a 60,000-square-foot (5574 m²) second story and three stories of 40,000 square feet (3716 m²) each would also be within the 270,000-square-foot (25 083 m³) maximum size determined in Example 2, and each story is 90,000 square feet (8361 m²) or less.

Section 506.2 Frontage increase. Every building shall adjoin or have access to a public way to receive a building area increase for frontage. Where a building has more than 25 percent of its perimeter on a public way or open space having a width of not less than 20 feet (6096 mm), the frontage increase shall be determined in accordance with Equation 5-2:

\[I_f = (F/P - 0.25)W/30 \quad \text{(Equation 5-2)}\]

where:

\[I_f = \text{Area increase due to frontage.}\]

\[F = \text{Building perimeter that fronts on a public way or open space having 20 feet (6096 mm) open minimum width (feet).}\]

\[P = \text{Perimeter of entire building (feet).}\]

\[W = \text{Width of public way or open space (feet) in accordance with Section 506.2.1.}\]

The allowable area of a building is permitted to be increased when it has a certain amount of frontage on streets or open spaces since this provides access to the structure by fire service personnel, a temporary refuge area for occupants as they leave the building in a fire emergency and a reduced exposure to and from adjacent structures.

This section indicates how the frontage increase, or the term \"I_f\" in Equation 5-1, is calculated. There is no requirement in the code that buildings must have at least 25 percent of their perimeter on a public way or open space; however, in order to qualify for an area increase, a building must have more than 25 percent of its perimeter on a public way or open space having a minimum width of at least 20 feet (6096 mm). When the calculations are done, the maximum percent increase for a fully open perimeter (full frontage—the entire perimeter fronts on a public way or open space) is typically 75 percent. Width is measured at right angles to the perimeter walls as set forth in Section 506.2.1, but it is not the same as fire separation distance. The latter, as defined in Section 202, is measured to the centerline of public ways or to an imaginary line between buildings on the same lot. Open space can include the total width of the public way as well as the total open space between buildings on the same lot. "Public way" is also a defined term.

Section 506.2.2 requires that an open space that is not a public way be on the same lot or dedicated for public use, and it must have access from a street or an approved fire lane in order to contribute to the frontage increase (see commentary, Section 506.2.2).

If a structure is divided into two or more buildings by fire walls complying with Section 706, the area modifications allowed by Section 506 must be determined based on each separate building within the structure. This especially comes into play in determining increases allowable based on frontage. The fire wall is essentially the perimeter wall for that side of the building and must be included in determining the \(P\) in Equation 5-2. Since there is another building on the other side of the fire wall, this portion of the perimeter is not considered fronting on a public way or yard and, therefore, is not included in \(F\) [see Figure 506.2(1)].

The term \"W\" in Equation 5-2 represents the weighted average of the width of any open space for the portion of the perimeter that fronts on a public way or open space. The minimum width required is 20 feet (6096 mm). The maximum width allowed in this equation is 30 feet (9144 mm). The following example demonstrates this point:

Example: Refer to Figure 506.2(2). In Equation 5-2, the terms would have the following values:

\[F = 500 \text{ feet (15 240 mm), since all sides of the building front on a public way or open space having 20 feet (6096 mm) minimum open width.}\]

\[P = 500 \text{ feet (15 240 mm), the length of the entire perimeter.}\]

\[W = \text{The weighted average of the widths of the public way or open space } = [(20 \text{ ft.})(100 \text{ ft.)} + (30 \text{ ft.)} (150 \text{ ft.}) + (30 \text{ ft.)} (100 \text{ ft.}) + (30 \text{ ft.)} (150 \text{ ft.})]/500 \text{ ft.} = 28 \text{ feet (8534 mm).}\]

Note in the above computation for \(W\) that, where the actual width exceeds 30 feet (9144 mm), a value of 30 feet (9144 mm) is used as required by Section 506.2.1.

Equation 5-2, \(I_f = [(F/P) - 0.25](W/30)\), becomes:

\[I_f = [(500/500) - 0.25](28/30) = (.75)(.93) = 0.70\]

Therefore, the term \"I_f\" equals 0.70 when using Equation 5-1 for determining the allowable area per story (\(A_0\)).

Section 506.2.1 Width limits. To apply this section the value of \(W\) shall be not less than 20 feet (6096 mm). Where the value of \(W\) varies along the perimeter of the building, the calculation performed in accordance with Equation 5-2 shall be based on
the weighted average calculated in accordance with Equation 5-3 for portions of the exterior perimeter walls where the value of $W$ is greater than or equal to 20 feet (6096 mm). Where the value of $W$ is greater than 30 feet (9144 mm), a value of 30 feet (9144 mm) shall be used in calculating the weighted average, regardless of the actual width of the open space. $W$ shall be measured perpendicular from the face of the building to the closest interior lot line. Where the building fronts on a public way, the entire width of the public way shall be used. Where two or more buildings are on the same lot, $W$ shall be measured from the exterior face of each building to the opposing exterior face of each adjacent building, as applicable.

Weighted average $W = \frac{(L_1 \times w_1 + L_2 \times w_2 + L_3 \times w_3 \ldots)}{F}$.

(Equation 5-3)

where:

$L_o$ = Length of a portion of the exterior perimeter wall.

$w_o$ = Width of open space associated with that portion of the exterior perimeter wall.

$F$ = Building perimeter that fronts on a public way or open space having a width of 20 feet (6096 mm) or more.

**Exception:** Where the building meets the requirements of Section 507, as applicable, except for compliance with the 60-foot (18288 mm) public way or yard requirement, and the value of $W$ is greater than 30 feet (9144 mm), the value of $W$ divided by 30 shall be limited to a maximum of $2$.

- The amount of area increase (that is, the value of $\lambda$) will vary depending on the minimum width of the open space used in the frontage increase calculation. The general requirement is that the value of $W$ must equal at least 20 feet (6096 mm) and that the value of $W$ can not exceed 30 feet (9144 mm). The value of $W$ is the weighted average of the portions of the wall and each open space when the width of the open space is between 20 and 30 feet (6096 and 9144 mm). Except as provided in the exception, the width of open space used in this calculation cannot exceed 30 feet (9144 mm) even when part of the open space is wider than 30 feet (9144 mm). See the following two examples illustrating this requirement. Example 1 also illustrates the use of Equation 5-3 in the determination of the weighted average $W$.

**Example 1:** In Figure 506.2.1(1), the value $W = [(200$ feet x 25 feet) + (100 feet x 20 feet) + (200 feet x 30 feet)]/500 feet = 26 feet (7925 mm).

**Example 2:** In Figure 506.2.1(2), the value of $W$ would be 30 feet (9144 mm), since the minimum width of the open space that qualifies as open frontage is greater than 30 feet (9144 mm) on all sides of this building. The reason the value of $W$ must be taken at 30 feet (9144 mm) and not 50 feet (15 240 mm) is that this section sets an upper limit on the value of the $W/30$ term in Equation 5-2.

Typically, when multiple buildings are located on the same lot, an imaginary lot line must be established somewhere between the buildings in order to determine the fire separation distance. However, the value of $W$ is defined as the width of the public way or open space, and is not dependent upon the fire separation distance. Therefore, for purposes of determining the value of $W$ between buildings on the same lot, the entire distance between the buildings is permitted to be used, not solely the fire separation distance. Similarly, the entire width of a public way is used and not just the distance to the centerline of the public way. Such measurements are to be taken at right angles from the building.
The exception to Section 506.2.1 states that for certain buildings, the value of \( W \) divided by 30 is permitted to have a maximum value of 2.0. This exception applies to buildings that would be allowed to be unlimited in area in accordance with Section 507, save for the fact that the open area of 60 feet (18 288 mm) required by Section 507 is not met. Therefore, the weighted average of \( W \) would be calculated between 20 feet (6096 mm) and 60 feet (18 288 mm).

506.2.2 Open space limits. Such open space shall be either on the same lot or dedicated for public use and shall be accessed from a street or approved fire lane.

- The requirement that the open space be on the same lot is so that the owner or the jurisdiction can control the space that is assumed to be open for purposes of the area increase. One cannot encumber a neighbor’s property with a requirement that the space will always remain unoccupied.

Any part of the perimeter that is not accessible to the fire department by means of a street or fire lane cannot be considered open for the purposes of Section 506.2. For instance, if the back side of a building on a narrow lot cannot be reached by means of a fire lane on one side of the building (and there is no alley or street at the back), that portion of the perimeter is not considered open for purposes of frontage increase, even if there is actual open space exceeding 20 feet (6096 mm) in width. See Figure 506.2.2(1) as an illustration of this limitation.

This section does not require that a fire lane or street extend immediately adjacent to every portion of the perimeter that is considered open for purposes of the increase. Rather, access by a fire lane must be provided up to the open side such that fire department personnel can approach the side and pull hoses across the open area to fight a fire, and no corner of the building will impede the use of hoses and equipment on that side of the building. The following examples demonstrate this point.

**Example 1:** In Figure 506.2.2(1), the south and east side of the building facing the street can be considered open perimeter (frontage). The north side of the building cannot be considered open perimeter for purposes of the increase, since it is not accessible from the street or a fire lane. Even though the 20-foot-wide yard can be included in open frontage because it does not provide a fire lane to the rear of the building, the 100-foot yard cannot be included.

**Example 2:** In Figure 506.2.2(2), all sides of the building are considered open perimeter (frontage) for purposes of the increase. Access up to each side of the building is provided by means of a fire lane or street.

Section 503 of the International Fire Code® (IFC®) specifies that access roads extend to within 150 feet (45 720 mm) of all portions of the exterior walls of a building; however, there are exceptions that would permit the omission of such roads under certain circumstances. One such exception is for buildings equipped throughout with an automatic sprinkler system where the fire code official is permitted to extend the 150-foot (45 720 mm) limit.

The IFC also stipulates that the access roads must be at least 20 feet (6096 mm) in unobstructed width, although it also gives the building official authority to
require greater widths if necessary for effective firefighting operations. The type of surface necessary for the approved fire lane is determined by the local building official with input from the fire department, but the road must be capable of supporting the imposed loads of fire apparatus and be surfaced so as to provide all-weather driving capabilities.

506.3 Automatic sprinkler system increase. Where a building is equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1, the building area limitation in Table 503 is permitted to be increased by an additional 200 percent \((I_2 = 2)\) for buildings with more than one story above grade plane and an additional 300 percent \((I_3 = 3)\) for buildings with no more than one story above grade plane. These increases are permitted in addition to the height and story increases in accordance with Section 504.2.

**Exception:** The use of an automatic sprinkler system to increase the building area limitation shall not be permitted for the following conditions:

1. Buildings classified as a Group H-1 occupancy.
2. Buildings, or portions of buildings, classified as either a Group H-2 or H-3 occupancy. For buildings containing such occupancies, the allowable area shall be determined in accordance with Section 508.4.2, with the sprinkler system increase applicable only to the portions of the building not classified as Group H-2 or H-3.

3. Buildings where an automatic sprinkler system is substituted for fire-resistance rated construction in accordance with Table 601, Note d.

- This section permits an increase of the allowable building areas established in Table 503 for each type of construction if the building in question is equipped throughout with an automatic sprinkler system. This section provides for two levels of increase: 200 percent for multistory buildings and 300 percent for single-story buildings.

The scope of the phrase "protected throughout with an automatic sprinkler system" means that the entire structure is to be provided with sprinkler protection designed and installed in accordance with NFPA 13, as stipulated in Section 903.3.1.1. It is intended that only buildings protected throughout the entire structure with a system designed in accordance with NFPA 13 be eligible for the sprinkler increase permitted by this section, except as specifically modified by the exceptions in Section 903.3.1.1. Those exceptions permit the omission of sprinklers in certain locations within buildings because of conditions that exist in those locations. Even if an exception is utilized in the sprinkler design, the building is still eligible for the area increase because the exempted locations either have a negligible impact on the fire load of the building or it is likely that other requirements will abate the hazard associated with these rooms. This section

![Figure 506.2.2(1) ACCESS TO OPEN SPACE](image1)

![Figure 506.2.2(2) ACCESS TO OPEN SPACE](image2)
also clarifies that these area increases are cumulative with the height/story increases in Section 504. Please note that under Section 504.2 Group R-2 occupancy buildings are allowed a height increase when an NFPA 13R sprinkler system, as stipulated in Section 903.3.1.2, is provided. However, such a system will not allow an area increase under the requirements of this section. To achieve both height and area increases in a Group R occupancy building, an NFPA 13 system must be installed.

The three exceptions to this section address circumstances under which the area increases described in this section would not be allowed.

Exception 1 does not permit the area increase for buildings with Group H-1 occupancy areas because of the higher level of hazard that this group represents.

Exception 2 allows Group H-2 and H-3 occupancies to be placed in a building where the automatic increase would be taken, but with the limitation that the increase for automatic sprinklers would not apply to the Group H-2 or H-3 areas. These Group H-2 or H-3 areas would be required to be separated from the other uses, given that Sections 508.2.4, 508.3.3 and 508.4.4 specifically require separation of these occupancies from other occupancies. The required separation would be as given for separated occupancies in Section 508.4.4 and the allowable area would be based upon the sum of the ratios of the actual area of each occupancy to the allowable area per story (see commentary, Section 508.4.2). In the case of the Group H-2 or H-3 areas, the allowable area per story could not include the increase of 200 percent or 300 percent. This would have the effect of limiting the allowable areas of the entire building when a Group H-2 or H-3 area is being included.

Example: It is desired to construct a single-story Group F-1 factory using Type IIIIB construction, with a 3,500-square-foot (325 m²) Group H-2 area. An automatic sprinkler system will be used throughout the building. The building does not qualify for any frontage increase.

Allowable area of the Group F-1 area with an automatic sprinkler system = 12,000 square feet (1115 m²) plus 3[12,000 square feet (1115 m²)] = 48,000 square feet (4459 m²). So, without a Group H-2 area, the building could be 48,000 square feet (4459 m²) in area.

However, with the Group H-2 area present:

Actual area of F-1 = 3,500 square feet < 1
Allowable area of F-1 = 36,000 square feet

Actual area of H-2 = 7,000 square feet

Solving this equation for the actual area of Group F-1, it is determined that the maximum area of Group F-1 that could be allowed would now be 18,000 square feet (1672 m²). Thus, while the high hazard is allowed, it does restrict the size of the host occupancy.

Exception 3 states that when an automatic sprinkler system is installed to address the allowed tradeoff of sprinklers for 1-hour fire-resistance-rated construction given in Note d of Table 601, the area increases allowed in this section cannot be taken. For example, in a Group B building constructed using Type IIA construction, the required 1-hour fire-resistance rating of all structural members (with the exception of the exterior walls) could be reduced to zero if the building were fully equipped with a sprinkler system in accordance with Section 903.3.1.1 (NFPA 13); however, the allowable area will not be increased by the percentages that would otherwise be allowed in this section.

506.4 Single occupancy buildings with more than one story. The total allowable building area of a single occupancy building with more than one story above grade plane shall be determined in accordance with this section. The actual aggregate building area at all stories in the building shall not exceed the total allowable building area.

Exception: A single basement need not be included in the total allowable building area, provided such basement does not exceed the area permitted for a building with no more than one story above grade plane.

The total allowable area of a single occupancy building (the aggregate area of all stories) is determined in accordance with Section 506.4.1. This limit is based on determining the maximum allowable building area per story under the provisions of Sections 506.1 through 506.3. For buildings with two or more stories above grade plane, the total allowable area must be shared by all stories (see commentary, Section 506.4.1) and must be equal to or greater than the aggregate of the actual area of all stories. The area of a single basement, however, is not required to be counted as part of the total building area when evaluating total allowable area in accordance with Section 506.4.1. Therefore, if the total allowable area of a single occupancy building is 50,000 square feet (4645 m²) in accordance with Section 506.4.1, the total aggregate area of all stories above grade plane must not exceed 50,000 square feet (4645 m²). The presence of a single basement, however, is permitted to make the actual total area of the building larger than 50,000 square feet (4645 m²). If more than one basement is present, the extra basement levels must be counted as contributing to the total allowable area for the building.

Where a proposed building exceeds the total allowable building area determined under this section, the structure must either be built of a higher construction type that allows greater area, or it must be divided by fire walls into two or more buildings. The maximum allowable building area is determined for each building established by fire walls independently from the
determinations for buildings on the other side of a fire wall. For fire walls, see Section 706.

506.4.1 Area determination. The total allowable building area of a single occupancy building with more than one story above grade plane shall be determined by multiplying the allowable building area per story \(A_s\), as determined in Section 506.1, by the number of stories above grade plane as listed below:

1. For buildings with two stories above grade plane, multiply by 2;
2. For buildings with three or more stories above grade plane, multiply by 3; and
3. No story shall exceed the allowable building area per story \(A_s\), as determined in Section 506.1, for the occupancies on that story.

Exceptions:

1. Unlimited area buildings in accordance with Section 507.
2. The maximum area of a building equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.2 shall be determined by multiplying the allowable area per story \(A_s\), as determined in Section 506.1, by the number of stories above grade plane.

This section establishes a total allowable building area for a single occupancy building. The aggregate area of all stories, excluding a single basement, located within the building must not exceed the allowable building area established in this section. The determination of total allowable building area starts with the determination of the allowable building area per story. The per-story allowable area is established in Table 503 and may be increased under the provisions of Sections 506.1 through 506.3. The maximum allowable building area for the total building can be distributed on the various stories of the building provided any one story does not exceed the maximum allowable area per story.

The following examples demonstrate the determination of total building area as a function of allowable area per story:

Two-story building: A single occupancy building has an allowable area per story \(A_s\), determined in accordance with Section 506.1, of 10,000 square feet (929 m²). The total allowable area of the building is 10,000 square feet (929 m²) \(\times 2\) (number of stories) = 20,000 square feet (1858 m²). Each story above grade, therefore, may be 10,000 square feet (929 m²). In addition, the building may have one basement of no more than 10,000 square feet (929 m²) in accordance with the exception to Section 506.4.

Four-story building: A single occupancy building has an allowable area per story \(A_s\), determined in accordance with Section 506.1, of 10,000 square feet (929 m²). The total allowable area of the building is 10,000 square feet (929 m²) \(\times 3\) (the maximum multiplier) = 30,000 square feet (2787 m²). If each story is of uniform size, each story above grade may be 7,500 square feet (697 m²) (30,000 square feet (2787 m²)/4 stories). In addition, the building may have one basement of no more than 10,000 square feet (929 m²) in accordance with the exception to Section 506.4.

If the allowable area per story is not exceeded for any single story, but the total allowable area is exceeded, a higher construction type must be used or the conditions of an area increase must be met. The following example demonstrates this point:

Building exceeds total allowable area: A four-story Group S-2 building of Type VA construction is proposed. The actual area per story is 34,000 square feet (3159 m²), with a total building area of 136,000 square feet (12 636 m²). The building has a fully open perimeter, but does not have a fire suppression system.

Section 506.2 yields an increase of 75 percent for full open frontage for this building, resulting in an allowable area per story \(A_s\) of 36,750 square feet (3414 m²) (21,000 square feet [1951 m²] \(\times 1.75\); see Section 506.2 for frontage increase calculation). The allowable area per story is limited to 36,750 square feet (3414 m²), while the total allowable area of the building (aggregate of all stories above grade) is 36,750 square feet (3414 m²) \(\times 3\) (the maximum multiplier) = 110,250 square feet (10 242 m²). If each story is of uniform size, each story above grade may be 27,562 square feet (2560 m²) [110,250 square feet (10 242 m²)/4 stories]; therefore, the building does not comply. Two possible solutions for this problem are:

1. Change construction type to Type IIIA: Instead of Type VA construction, Type IIIA construction could be utilized. The allowable area per story \(A_s\) for Type IIIA construction is 39,000 square feet (3623 m²) \(\times 1.75\) = 68,250 square feet (6340 m²). The total allowable area of the building (aggregate area of all stories above grade) is 68,250 square feet (6340 m²) \(\times 3\) (the maximum multiplier) = 204,750 square feet (19 021 m²). If each story is of uniform size, each story above grade may be 51,187 square feet (4755 m²) [204,750 square feet (19 021 m²)/4 stories]. Since the actual area per story is 34,000 square feet (3159 m²), the building complies.

2. Provide sprinklers: Alternatively, if the building is equipped throughout with an automatic fire suppression system, the allowable area per story \(A_s\) for Type VA construction would be 1,000 square feet (1951 m²) \(\times 3.75\) = 78,750 square feet (7316 m²) [represents a 200-percent increase for sprinklers in accordance with Section 506.3, plus a 75-percent increase for frontage in accordance with Section 506.2 (see commentary, Sections 506.2 and 506.3)]. The total allowable area of the building (aggregate
area of all stories above grade) is 78,750 square feet (7316 m²) x 3 (the maximum multiplier) = 236,250 square feet (21 948 m²). If each story is of uniform size, each story above grade may be 59,062 square feet (5487 m²) [236,250 square feet (21 948 m²)/4 stories]. Since the actual area per story is 34,000 square feet (3159 m²), the building complies.

This section does not require that the total allowable area of the building be equally distributed among the stories of a building, as long as no single story exceeds the allowable area per story (A) determined in accordance with Section 506.1. The following example demonstrates this point:

Building with stories of unequal area: Suppose the allowable area per story (A) for a single occupancy building is calculated in accordance with Section 506.1 to be 40,250 square feet (3739 m²) and the building has four stories. The total allowable area of the building (aggregate area of all stories above grade) is 40,250 square feet (3739 m²) x 3 (the maximum multiplier) = 120,750 square feet (11 218 m²). As long as no single story exceeds 40,250 square feet (3739 m²), the maximum allowable area could be divided among the stories unequally. For instance, the first story could have an area of 40,250 square feet (3739 m²) and the three upper stories could each have an area of (120,750 square feet (11 218 m²) - 40,250 square feet (3739 m²))/3 = 26,833 square feet (2493 m²).

Exception 1 is necessary to establish that the use of the unlimited area provisions in Section 507 would obviate the need for compliance with Section 504. The unlimited area provisions apply to one- or two-story buildings, depending upon the occupancies and sprinkler provisions utilized.

Exception 2 is an increase allowed for residential sprinkler systems installed in accordance with NFPA 13R. The area increases allowed by Section 506.3 are only applicable when the building is to be equipped with a sprinkler system in accordance with NFPA 13—not NFPA 13R. The three-story multiplier limit or “three-story cap” was initially evaluated based upon use of area increases resulting from the installation of an NFPA 13 system. Since buildings equipped with an NFPA 13R system are not allowed an area increase, it was determined that the “three-story cap” had an unintentional detrimental impact on residential buildings. Specifically, for a four-story residential building with an NFPA 13R sprinkler system, the provisions of Section 506.4.1 would reduce the area per story and the total building area. Given that the maximum height of buildings with NFPA 13R systems is four stories, this application of an increase in allowable area was determined to be warranted.

506.5 Mixed occupancy area determination. The total allowable building area for buildings containing mixed occupancies shall be determined in accordance with the applicable provisions of this section. A single basement need not be included in the total allowable building area, provided such basement does not exceed the area permitted for a building with no more than one story above grade plane.

- As with single occupancy buildings regulated by Section 506.4, mixed occupancy buildings are limited to a maximum area for an entire building. The maximum building area is a factor of the maximum area allowed per story as established under Sections 506.1 through 506.3. Mixed occupancies present a different mathematical problem with regard to the maximum total area allowed for the building. The total allowable area of a mixed occupancy building is determined in accordance with Section 506.5.1 or 506.5.2 depending on the number of stories above grade plane. All three of the mixed occupancy design options (accessory occupancies, nonseparated occupancies and separated occupancies) are acknowledged by this section and the sum of the ratio concept is maintained. For one-story mixed occupancy buildings, Section 506.5.1 defaults to Section 508.1. (In Section 508.1, the code user is directed to provisions for accessory occupancies, nonseparated occupancies and separated occupancies, each of which prescribes allowable area determination procedures for each mixed occupancy contingency.) For multistory buildings, Section 506.5.2 also defaults to Section 508.1, which limits the allowable area of a given story based on the applicable design method. Similar to single occupancy buildings, the area of a single basement in mixed occupancy buildings is not required to be counted as part of the total building area when evaluating total allowable area. If more than one basement is present, the extra basement levels must be counted as contributing to the total area for the building. Similar to single occupancy, multistory buildings, these mixed occupancy, multistory provisions only apply to buildings not permitted to be of unlimited area.

Where a proposed building exceeds the total allowable building area determined under this section and the referenced provisions of Section 508, the structure must either be built of a higher construction type that allows greater area, or it must be divided by fire walls into two or more buildings. The maximum allowable building area is determined for each building established by fire walls independently from the determination of the buildings on the other side of a fire wall. For fire walls, see Section 706.

506.5.1 No more than one story above grade plane. For buildings with no more than one story above grade plane and containing mixed occupancies, the total building area shall be determined in accordance with the applicable provisions of Section 508.1.

- Mixed occupancy, one story above grade buildings are required to comply with the applicable provisions of Section 508.1. The code provides three basic options for mixed occupancies: (1) accessory occupancies, (2) nonseparated occupancies and (3) separated occupancies. The availability of the options
depends upon the area of each story desired for each different occupancy and the relationship of one occupancy to the other.

**Example:** A single-story business office of 23,000 square feet (2137 m²) contains a lunch room that is 2,000 square feet (186 m²) in area. The main occupancy is Group B and the accessory occupancy is Group A-2. Since the Group A-2 occupancy has a floor area of less than 10 percent of the overall floor area of the single story, this can be viewed as an accessory occupancy and there is no fire separation requirement between the Group A-2 and B occupancies. For purposes of evaluating the area limitation of Table 503, the building is evaluated solely as Group B.

In contrast to the accessory occupancy provisions illustrated above, the fundamental concept for non-separated occupancies is that the allowable building areas are based upon the most restrictive requirements of each of the occupancies in the mixed occupancy building.

**Example:** A single-story Type IIB building contains both Group B and M occupancies and is being evaluated under the "non-separated occupancies" provisions of Section 508.3. The Group B portion is 1,000 square feet (93 m²) in area while the Group M portion is 10,000 square feet (929 m²) in area. The building does not have a sprinkler system and does not qualify for any frontage increase. With the exception of Type I construction, the area limitation of Table 503 is more restrictive for Group M than for Group B. Therefore, for purposes of evaluating the area limitation of Table 503, the building is evaluated solely as Group M.

- Actual area (Group M)/Allowable area (Group M) < 1.0
- 11,000/12,500 = 0.88 which is < 1.0 :: OK

- The separated occupancies concept requires the different occupancies to be separated in accordance with Table 508.4. The sum of the ratios of the actual floor area of each separated occupancy contained herein, as compared to the area allowed per story by Table 503 and as modified by Section 506 for each respective occupancy, must not exceed one.

**Example:** A single-story Type IIB building contains separated Group B and M occupancies. The Group B portion is 1,000 square feet (93 m²) in area while the Group M portion is 10,000 square feet (929 m²) in area. The building does not have a sprinkler system and does not qualify for any frontage increase.

\[
\frac{\text{Actual area (B)}}{\text{Allowable area (B)}} + \frac{\text{Actual area of (M)}}{\text{Allowable area of (M)}} < 1.0
\]

\[
\frac{1,000}{23,000} + \frac{10,000}{12,500} = 0.04 + 0.8 = 0.84 < 1.0 :: \text{OK}
\]

506.5.2 More than one story above grade plane. For buildings with more than one story above grade plane and containing mixed occupancies, each story shall individually comply with the applicable requirements of Section 508.1. For buildings with more than three stories above grade plane, the total building area shall be such that the aggregate sum of the ratios of the actual area of each story divided by the allowable area of such stories based on the applicable provisions of Section 508.1 shall not exceed 3.

- When buildings containing mixed occupancies are two or more stories above grade plane, the same concept applied to Section 506.5.1 is applied to each story of the building. Once a mixed occupancy building exceeds three stories in height, the maximum allowed area for the total building is set at three times the sum of the ratios. The following examples illustrate the application of the total area limitations for each building as well as showing the variety of ways in which the provisions of Section 508, Mixed Use and Occupancy, can be used in the design of the building.

**Example:** Sprinklered, two-story Type IIA building.

- **First story:**
  - Group B occupancy—3,000 square feet (278 m²)
  - Group S-2 occupancy—23,000 square feet (2137 m²)

- **Second story:**
  - Group A-3 occupancy—2,000 square feet (186 m²)
  - Group B occupancy—24,000 square feet (2230 m²)

  The first story qualifies for the nonseparated occupancy design method since the total square footage [26,000 square feet (2415 m²)] is less than that permitted for the most restrictive occupancy [Group B-37,500 square feet (3484 m²)].

  The second story is larger than that permitted for a Group A-3 occupancy; however, since the Group A-3 occupancy is less than 10 percent of the area of the second story, it qualifies as an accessory occupancy if subsidiary to the Group B occupancy.

  In this instance, each story individually qualifies based on the applicable mixed-occupancy provision.

**Example:** Sprinklered, four-story Type IIB building, no frontage increase.

- **First story:**
  - Group B occupancy—20,000 square feet (1858 m²)
  - Group M occupancy—25,000 square feet (3159 m²)

- **Second story:**
  - Group A-3 occupancy—4,000 square feet (372 m²)
  - Group B occupancy—41,000 square feet (3809 m²)

- **Third story:**
  - Group B occupancy—15,000 square feet (1394 m²)
  - Group S-1 occupancy—
GENERAL BUILDING HEIGHTS AND AREAS

15,000 square feet (1394 m²)
Group F-1 occupancy—
15,000 square feet (1394 m²)

Fourth story:
Group B occupancy—
10,000 square feet (929 m²)
Group S-2 occupancy—
35,000 square feet (3252 m²)

The first story does not qualify as an accessory or nonseparated occupancy. As separated occupancies, the ratio on the story is 0.96 [(20,000/69,000) + (25,000/37,500)].

The second story is larger than that permitted for a Group A-3 occupancy; however, since the Group A-3 occupancy is less than 10 percent of the area of the second story, it qualifies as an accessory occupancy if subsidiary to the Group B occupancy. The ratio on the story is 0.65 (45,000/69,000).

The third story qualifies as a nonseparated occupancy since the allowable area per story for the most restrictive occupancy (Group F-1; 46,500 square feet) is larger than the actual area on any individual story. The ratio of the floor is 0.97 (45,000/46,500).

The fourth floor qualifies as a nonseparated occupancy since the allowable area per floor for the most restrictive occupancy (Group B; 69,000 square feet) is larger than the actual area on any individual story. The ratio of the story is 0.65 (45,000/69,000).

The aggregate sum of the ratios is 3.23 (0.96 + 0.65 + 0.97 + 0.65). Since the aggregate sum of the ratios exceeds three, Type IIIB construction would not be permitted without further modification.

SECTION 507
UNLIMITED AREA BUILDINGS

507.1 General. The area of buildings of the occupancies and configurations specified in Sections 507.1 through 507.12 shall not be limited.

Exception: Other occupancies shall be permitted in unlimited area buildings in accordance with the provisions of Section 508.2.

Where Sections 507.2 through 507.12 require buildings to be surrounded and adjoined by public ways and yards, those open spaces shall be determined as follows:

1. Yards shall be measured from the building perimeter in all directions to the closest interior lot lines or to the exterior face of an opposing building located on the same lot, as applicable.

2. Where the building fronts on a public way, the entire width of the public way shall be used.

This section addresses circumstances under which a building would be allowed to be constructed unlimited in building area. Depending upon the height (in stories) of the structure and the occupancy classification, the code presents different circumstances that would allow an unlimited area building. There is a common thread among the requirements for these facilities:

1. Except for the option in Section 507.2, the building is equipped throughout with an automatic sprinkler system.

2. The building is surrounded by increased open space, usually 60 feet (18 288 mm) in width.

3. The buildings are limited to one or two stories above grade plane.

4. The building only houses low-hazard or moderate-hazard occupancies.

In all cases the open space can occur either within public ways surrounding the site, or by yards provided on the lot between the building and the lot lines, or a combination of yards and public ways. Where a yard is used to achieve the open space, it must be on the same lot as the building receiving the benefit. With respect to the 60 feet (18 288 mm), the code specifies that the entire width of the public way can be included. (Fire separation distance, which is a different requirement, requires measurement to the centerline of the public way). The open space must be provided in all directions around the perimeter of the building, not just measured at right angles to the building (see Figure 507.1). Two unlimited area buildings on the same lot must be separated by 60 feet (18 288 mm) or 40 feet (12 192 mm) if Section 507.5 is used unless they are treated as a single building under the provisions of Section 503.1.2.

The open space located on the private property does not need to be dedicated to the public or publicly owned, but can be the location of parking, landscaping, roadways and other minor accessory features (tanks, generators, trash dumpster enclosures) (see IBC Interpretation No. 20-03). However, the yard cannot be occupied by any exterior use that is essentially a continuation of use of the building. For example, many big box retailers will have an adjoining lawn and garden merchandise area; or a lumber supply area that is only partially enclosed by walls, fencing and roof covering. This type of use would need to be considered part of the unlimited area building, and the 60 feet (18 288 mm) of open space provided beyond this area (see IBC Interpretation No. 03-05).

The open areas serve two key roles: separation of these buildings from other buildings and ample space on all sides for fire-fighting operations.

Please note that Section 507.5 permits a reduction in the open space in exchange for increased wall and opening protection for those unlimited area buildings allowed by Sections 507.2, 507.3, 507.4, 507.6 and 507.11.

Historically, structures constructed under the provisions for unlimited area buildings have performed quite well in regard to fire and life safety. In general, only those occupancies and configurations that are specifically identified in Section 507 are subject to the unlimited area allowance.

5-22 2012 INTERNATIONAL BUILDING CODE® COMMENTARY
The exception clarifies that the accessory use provisions of Section 508.2 can also be applied to unlimited area buildings. This allows uses not specifically addressed in Sections 507.2 through 507.12 to be located in any of these buildings, provided they meet the requirements of accessory occupancies according to Section 508.2. The exception is distinct from Section 507.3.1, which addresses Group A-1 and A-2 occupancies in unlimited area buildings under Section 507.3. The provisions of Section 507.3.1 are for additional primary uses in these unlimited area buildings. A large office building could have an employee cafeteria, which is a Group A-2 occupancy, as an accessory, provided it was less than 10 percent of the floor area and didn't exceed the values of Table 503. Such accessory space would not need to be separated as required for the larger spaces allowed under Section 507.3.1.

507.2 Nonsprinklered, one story. The area of a Group F-2 or S-2 building no more than one story in height shall not be limited where the building is surrounded and adjoined by public ways or yards not less than 60 feet (18 288 mm) in width.

By definition, occupancies of Groups F-2 and S-2 are not permitted to contain significant amounts of combustible materials (see Sections 306.3 and 311.3); therefore, because the fire load of the contents is low, the hazard is low. The type of construction is not restricted, and sprinklers are not required for unlimited area buildings containing Group F-2 and S-2 occupancies, provided the building is no more than one story above grade plane. See the commentary in Section 507.1 regarding the required open space. Section 507.5 can be applied to buildings built under Section 507.2.

507.3 Sprinklered, one story. The area of a Group B, F, M or S building no more than one story above grade plane of any construction type, or the area of a Group A-4 building not more than one story above grade plane of other than Type V construction, shall not be limited where the building is provided with an automatic sprinkler system throughout in accordance with Section 903.3.1.1 and is surrounded and adjoined by public ways or yards not less than 60 feet (18 288 mm) in width.

Exceptions:

1. Buildings and structures of Types I and II construction for rack storage facilities that do not have access by the public shall not be limited in height; provided that such buildings conform to the requirements of Sections 507.3 and 903.3.1.1 and Chapter 32 of the International Fire Code.

2. The automatic sprinkler system shall not be required in areas occupied for indoor participant sports, such as tennis, skating, swimming and equestrian activities in occupancies in Group A-4, provided that:

   2.1. Exit doors directly to the outside are provided for occupants of the participant sports areas; and

   2.2. The building is equipped with a fire alarm system with manual fire alarm boxes installed in accordance with Section 907.

Because of their excellent record in controlling and preventing fires, the installation of a sprinkler system throughout single-story buildings of the listed groups, individually or in combination, permits them to be unlimited in area (IBC Interpretation No. 44-06). This also applies to two-story above-grade-plane buildings of these groups, with the exception of Group A-4 (see Figure 507.1).
GENERAL BUILDING HEIGHTS AND AREAS

Section 507.4). See the commentary in Section 507.1 regarding the required open space. Section 507.5 can be applied to buildings built under Section 507.3.

The life-safety hazards in buildings of these occupancies, because of the typical activities of the occupants and their level of awareness, are considered low enough that larger building areas and increased fire loads can be tolerated. For Groups B, F, M and S, this section may be applied to buildings of all construction types; it is not limited to noncombustible construction only. For indoor arenas and other Group A-4 buildings, the unlimited area provision can be applied to buildings of Type I, II, III and IV construction only. This reflects the size of the occupant load in these types of facilities. The sprinkler system is required to be designed and installed in accordance with NFPA 13 (see Section 903.3.1.1). The height of the unlimited area building cannot exceed the limits established in Table 503 and Section 504.2 for the occupancy and type of construction.

Exception 1 specifically permits Type I and II buildings with rack storage to be unlimited in height if they are surrounded by 60 feet (18 288 mm) of open space, do not permit access by the public and comply with NFPA 13 and Chapter 32 of the International Fire Code® (IFC®). These standards contain provisions for storage configuration, in-rack sprinkler coverage and system requirements that offset the hazard introduced by increased height.

Exception 2 eliminates providing a sprinkler system in certain areas of unlimited area Group A-4 occupancies where a lack of fuel loading and excessive ceiling heights would reduce the need for, and effectiveness of, the system. Group A-4 occupancies frequently have indoor participant sports areas, such as tennis courts, skating rinks, swimming pools, baseball fields, basketball courts and equestrian activities, with spectator seating usually situated around the perimeter of the sports field or area. These types of indoor recreation areas often require very large, open areas with such high ceilings that the installation of an automatic sprinkler system in the immediate participant sport area would be ineffective. The potential for significant fire involvement in such an area is generally quite low because of the low fuel load; therefore, sprinkler coverage is unnecessary for the playing field in most of these buildings. These areas are, therefore, exempt from the suppression requirement of this section, provided the conditions regarding exiting and the required fire alarm system are met. The use of the sports area for other uses such as a weekend crafts fair or other activity not specifically listed would be in violation of the exception and should not be permitted. When an indoor arena or sports facility is built without suppression in the participant sport area, occupants of the playing field or participant sport area must be able to exit the building directly from the playing area, without having to pass through other parts of the building. This eliminates the hazard of having to pass through higher fuel load areas such as locker rooms or concession areas. The building must also be equipped with a manual alarm system that complies with Section 907. This manual alarm system provides an additional and acceptable level of life safety in spite of the omission of sprinklers over the playing field area. This exception only applies to Group A-4 occupancies that are contained within an unlimited area building.

Omission of sprinkler coverage is permitted in the unlimited area building for the participant sport area only. All other areas are required to be equipped with an automatic sprinkler system. This includes all other rooms and spaces in the building, such as the spectator seating areas, locker rooms, restaurants, lounges, shops, arcades, skyboxes and storage areas.

507.3.1 Mixed occupancy buildings with Groups A-1 and A-2. Group A-1 and A-2 occupancies of other than Type V construction shall be permitted within mixed occupancy buildings of unlimited area complying with Section 507.3, provided:

1. Group A-1 and A-2 occupancies are separated from other occupancies as required for separated occupancies in Section 508.4.4 with no reduction allowed in the fire-resistance rating of the separation based upon the installation of an automatic sprinkler system.

2. Each area of the portions of the building used for Group A-1 or A-2 occupancies shall not exceed the maximum allowable area permitted for such occupancies in Section 503.1; and

3. Exit doors from Group A-1 and A-2 occupancies shall discharge directly to the exterior of the building.

This section allows Group A-1 and A-2 occupancies in mixed occupancy, single-story unlimited area buildings under limited conditions. These are considered as additional primary use occupancies allowed in buildings regulated by Section 507.3. For accessory uses, see the commentary for Section 507.1. A typical example of a practical application of this would be the construction of a strip mall that is mainly for retail stores, but might contain a restaurant or a movie theater, or both. Group A-1 or A-2 buildings would not be permitted as stand-alone unlimited area buildings. Similar to the requirement in Section 507.3 for Group A-4 buildings, unlimited area buildings that contain a Group A-1 or A-2 occupancy are not permitted to be built of Type V construction.

The restrictions on the use of Group A-1 or A-2 occupancies in mixed occupancy, unlimited area buildings include: (1) required separation; (2) limited area of each Group A occupancy to the area allowed in Section 503.1; and (3) all required exits discharging to the exterior.

Item 1 states that the Group A-1 or A-2 occupancy is required to be separated from the rest of the unlimited area building by fire barriers in accordance with Section 508.4.4. For example, if a strip mall contains mercantile facilities next to a theater (Group A-1), the theater would need to be separated from the mercan-
tile facilities by a 2-hour fire barrier, as determined from Table 508.4. Although the unlimited area building is required to be sprinklered, the required fire-resistance rating for the Group A-1 or A-2 occupancy separation must be based on the nonsprinklered entry in Table 508.4 (i.e., no reduction is permitted in the fire-resistance rating of the separation due to the presence of the sprinkler system).

Item 2 requires each Group A-1 or A-2 area to be limited to that allowed by Section 503.1. For example, if the strip mall mentioned above were Type IIIB construction, the allowable area of the theater would be 34,000 square feet (3159 m²) [tabular value of 8,500 square feet (790 m²) x 4]. Note that the allowable area is increased by 300 percent as permitted by Section 506.3 for single-story buildings equipped with fire sprinklers. The allowable area could also be increased for frontage in accordance with Section 506.2, depending upon the amount of frontage that the Group A portion has, relative to its own perimeter. The important point is that the area limits for each Group A-1 or A-2 occupancy are based on Section 503.1, not the tabular values of Table 503. Thus, because Section 503.1 states that the allowable area is limited to the values in Table 503.1 except as modified hereafter, the allowable increases given in Section 506 would be applicable. Also note that each Group A-1 or A-2 occupancy is evaluated on its own and not as an aggregate (i.e., the area of the Group A-1 and A-2 occupancies would not have to be added together).

Item 3 states that all exits from the Group A-1 or A-2 occupancy must discharge directly to the exterior. While other paths of travel available to the occupants are permitted to discharge into other portions of the building, the required exits must discharge directly to the exterior such that an occupant in the Group A-1 or A-2 portion can exit the space without having to pass through other parts of the building. This eliminates the hazard of having to pass through higher fuel load areas.

507.4 Two story. The area of a Group B, F, M or S building no more than two stories above grade plane shall not be limited where the building is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1, and is surrounded and adjoined by public ways or yards not less than 60 feet (18 288 mm) in width.

The rationale for allowing unlimited area two-story buildings in these four occupancy groups is the same as for one-story structures of these uses. The type of construction is not restricted. The number of stories are those above grade plane. Group A is not included in the occupancies that can be located within a two-story, unlimited area building because of the hazards associated with higher occupant loads. Even though limited Group A occupancies can be located in one-story unlimited area buildings, such occupancies cannot be located on either story of a two-story, unlimited area building unless they are accessory occupancies (see Section 507.1). The provisions of Section 507.3.1 do not apply to two-story buildings. See the commentary in Section 507.1 regarding the required open space. Section 507.5 can be applied to buildings built under Section 507.4.

507.5 Reduced open space. The public ways or yards of 60 feet (18 288 mm) in width required in Sections 507.2, 507.3, 507.4, 507.6 and 507.11 shall be permitted to be reduced to not less than 40 feet (12 192 mm) in width provided all of the following requirements are met:

1. The reduced width shall not be allowed for more than 75 percent of the perimeter of the building.
2. The exterior walls facing the reduced width shall have a fire-resistance rating of not less than 3 hours.
3. Openings in the exterior walls facing the reduced width shall have opening protective with a fire protection rating of not less than 3 hours.

The minimum width of the open space surrounding those unlimited area buildings specified in Sections 507.2, 507.3, 507.4, 507.6 and 507.11, may be reduced if the exterior walls are protected with minimum 3-hour fire-resistance-rated construction and the openings are protected with 3-hour rated assemblies. All three conditions of this section must be met in order to reduce the open space to a minimum of 40 feet (12 192 mm). The criteria and standards for wall assemblies and opening protection are contained in Chapter 1. The rated walls and protected openings are required only for those portions of the walls that do not face at least 60 feet (18 288 mm) of unoccupied space or public way.

507.6 Group A-3 buildings of Type II construction. The area of a Group A-3 building no more than one story above grade plane, used as a place of religious worship, community hall, dance hall, exhibition hall, gymnasium, lecture hall, indoor swimming pool or tennis court of Type II construction, shall not be limited provided all of the following criteria are met:

1. The building shall not have a stage other than a platform.
2. The building shall be equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1.
3. The building shall be surrounded and adjoined by public ways or yards not less than 60 feet (18 288 mm) in width.

Assembly buildings pose a greater risk in general, primarily because of their relatively large occupant loads and the density of such loads; therefore, the unlimited area provisions are more restrictive for assembly occupancies. Limited types of Group A-3 buildings are allowed as unlimited area buildings provided each is limited to one story above grade plane. In the case of the Group A-3 occupancies listed, the construction classifications allowed to be unlimited area include Type II, which are noncombustible structures, and Type III and IV (see Section 507.7), which are combustible structures. The types of Group A-3
occupancies listed—churches, dance halls, community halls, exhibition halls, gymnasiums, lecture halls, indoor swimming pools and tennis courts—are typically well-lit, open spaces, containing a low fuel load. Libraries and museums are excluded, as they generally have a higher fuel load, as are bowling alleys and pool halls that are often poorly lit and have higher levels of activity. The dance halls included in Group A-3 are not to be confused with nightclubs, which are Group A-2 occupancies.

The Group A-3 buildings listed in this section must have 60 feet (18288 mm) of open space surrounding the structure. Similar to the occupancies referenced in Sections 507.3 and 507.4, a sprinkler system must be provided and is required to be designed and installed in accordance with NFPA 13. Group A-3 buildings are further restricted, however, in that the building must not have a stage (other than a platform). These requirements aid in the exiting of the building in an emergency. See the commentary to Section 507.1 regarding the required open space. Section 507.5 can be applied to buildings built under Section 507.6.

507.7 Group A-3 buildings of Types III and IV construction. The area of a Group A-3 building of Type III or IV construction, with no more than one story above grade plane, and used as a place of religious worship, community hall, dance hall, exhibition hall, gymnasium, lecture hall, indoor swimming pool or tennis court, shall not be limited provided all of the following criteria are met:

1. The building shall not have a stage other than a platform.
2. The building shall be equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1.
3. The assembly floor shall be located at or within 21 inches (533 mm) of street or grade level and all exits are provided with ramps complying with Section 1010.1 to the street or grade level.
4. The building shall be surrounded and adjoined by public ways or yards not less than 60 feet (18288 mm) in width.

The requirements for Group A-3 buildings of Type III or IV construction are similar to the provisions for buildings of Type II construction. Due to the permitted use of combustible materials in Group A-3 buildings of Type III and IV construction, these buildings are further restricted in that the assembly floor level of the building must not be higher than 21 inches (533 mm) above street or grade level. These requirements aid in the exiting of the building occupants in an emergency. In order to further assist in the evacuation of the building in an emergency, assembly floors which are not at grade level must be provided with ramps (i.e., no stairs) which lead to grade level. Note that the 21-inch (533 mm) height limitation for the assembly floor would prohibit the installation of a mezzanine, balcony or most raised floor surfaces in the building. See the commentary to Section 507.1 regarding the required open space. Please note that Section 507.5 can not be applied to buildings built under Section 507.7.

507.8 Group H occupancies. Group H-2, H-3 and H-4 occupancies shall be permitted in unlimited area buildings containing Group F and S occupancies in accordance with Sections 507.3 and 507.4 and the provisions of Sections 507.8.1 through 507.8.4.

This section sets forth provisions for limited areas of Group H-2, H-3 and H-4 occupancies in unlimited area buildings. Group F facilities often inherently contain a certain amount of Group H-2, H-3 and H-4 occupancies when hazardous materials are needed for the industrial processes. Similarly, it is reasonable to provide for limited quantities of hazardous material storage in a storage (Group S) occupancy.

507.8.1 Allowable area. The aggregate floor area of Group H occupancies located in an unlimited area building shall not exceed 10 percent of the area of the building nor the area limitations for the Group H occupancies as specified in Table 503 as modified by Section 506.2 based upon the perimeter of each Group H floor area that fronts on a public way or open space.

Multiple high-hazard (Group H-2, H-3 and H-4) occupancies are permitted within a manufacturing or storage building constructed under the unlimited area building provisions; however, the aggregate floor area of all such occupancies cannot be more than 10 percent of the floor area of the entire building. It is important that the higher hazards be limited in amount in order to maintain the high degree of fire and life safety anticipated in an unlimited area building. In addition, the aggregate floor area of the Group H occupancies cannot exceed the area limitations established by Table 503 with any permitted frontage increases as calculated by Section 506.2. Where the Group H occupancies are not located at the building's perimeter or where they have no more than 25 percent of their perimeter at the exterior walls, no increase beyond that established in Table 503 is permitted.

507.8.1.1 Located within the building. The aggregate floor area of Group H occupancies not located at the perimeter of the building shall not exceed 25 percent of the area limitations for the Group H occupancies as specified in Table 503.

For those Group H occupancies that are not located at the perimeter of the building, an additional limitation is placed on their allowable area. If the high-hazard occupancy is surrounded on all sides by an unlimited area building, it is difficult for fire department personnel to locate and access that area; therefore, Group H-2, H-3 and H-4 occupancies that are not located at the perimeter of the building are limited to 25 percent of the area limitation specified in Table 503 for the building type of construction and occupancy classification, as shown in Figure 507.8.1.1.
507.8.1.1 Liquid use, dispensing and mixing rooms. Liquid use, dispensing and mixing rooms having a floor area of not more than 500 square feet (46.5 m²) need not be located on the outer perimeter of the building where they are in accordance with the International Fire Code and NFPA 30.

- Identical language is found in Exception 1 to Section 415.5 allowing small liquid use, dispensing and mixing rooms to be located within the building's interior rather than at its perimeter.

507.8.1.2 Liquid storage rooms. Liquid storage rooms having a floor area of not more than 1,000 square feet (93 m²) need not be located on the outer perimeter where they are in accordance with the International Fire Code and NFPA 30.

- Liquid storage rooms no more than 1,000 square feet (93 m²) are permitted to be located within the building. This allowance is also reflected in Section 415.5, Exception 2.

507.8.1.3 Spray paint booths. Spray paint booths that comply with the International Fire Code need not be located on the outer perimeter.

- Spray paint booths are regulated independently by the IFC and NFPA 33. There is no requirement that they be located on a building's perimeter. This language is also provided in Exception 3 of Section 415.5. It should be noted that an approved spray booth is not typically classified as a Group H occupancy, but rather simply regulated as an appliance (see definition of spray booth in Section 202) located within the general building occupancy. Therefore, the allowable floor area for one or more spray booths in an unlimited area building would be regulated by the provisions of IFC Section 1504.3.2.6, not by this section. In addition, the floor area of the spray booths would not be included in the aggregate floor area of the Group H occupancies in the unlimited area building for the purposes of applying the allowable area limitations of Sections 507.8.1 and 507.8.1.1.

507.8.2 Located on building perimeter. Except as provided for in Section 507.8.1.1, Group H occupancies shall be located on the perimeter of the building. In Group H-2 and H-3 occupancies, not less than 75 percent of the perimeter of such occupancies shall be an exterior wall.

- Unless in compliance with Section 507.8.1.1, Group H occupancies are to be located on the building's perimeter. More ready access to the high-hazard occupancy from the exterior of the building provides the fire department with an opportunity to respond more effectively to an incident. As set forth in Section 507.8.1, Group H-2, H-3 and H-4 occupancies that are located on the perimeter of an unlimited area building are permitted to be a maximum of 10 percent of the total building area, or the maximum area permitted by Table 503 as modified by Section 506.2 for the Group H occupancy, whichever is less.

The increase permitted in Section 506.2 is to be based on the open frontage of Group H-2, H-3 and H-4 floor areas. In Figure 507.8.2(1), the Group H-2 floor area is located in the corner of the Group F-1 building, so that two walls of the perimeter of the Group H-2 floor area front an unoccupied open space. In accordance with Section 506.2, the area increase due to frontage (F) is calculated to be 25 percent, in accordance with the figure. Applying this increase to the area from Table 503, the allowable area for the Group H-2 occupancy is [7,000 square feet (650 m²) x (1.25)] = 8,750 square feet (813 m²). This is less than 10 percent of the total area per story [i.e., 15,000 square feet (1394 m²)], so 8,750 square feet (813 m²) is the maximum allowable area for the

---

**Figure 507.8.1.1**

USE GROUP H-2 NOT LOCATED AT THE PERIMETER OF AN UNLIMITED AREA BUILDING
GENERAL BUILDING HEIGHTS AND AREAS

Group H-2 occupancy.

Locating the Group H-2 floor area further away from the perimeter of the Group F-1 building, as occurs in Figure 507.8.2(2), qualifies the Group H-2 floor area for an even greater allowable area increase [see Figure 507.8.2(2)].

The mandate that Group H-2 and H-3 occupancies have a minimum of 25 percent of their perimeter as an exterior wall is based on the provisions of Section 415.5. Additionally, the three exceptions to Section 415.5 are the basis for those of Sections 507.8.1.1.1, 507.8.1.1.2 and 507.8.1.1.3. Please refer to the commentary to Section 415.5 for further information.

507.8.3 Occupancy separations. Group H occupancies shall be separated from the remainder of the unlimited area building and from each other in accordance with Table 508.4.

In order to maintain the necessary fire resistance between the high-hazard areas and the remainder of the unlimited area building, the required occupancy

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm,
1 square foot = 0.0929 m².

Figure 507.8.2(1)
GROUP H-2 AT THE CORNER OF AN UNLIMITED AREA BUILDING

For SI: 1 foot = 304.8 mm, 1 square foot = 0.0929 m².

Figure 507.8.2(2)
GROUP H-2 AT THE CORNER OF AN UNLIMITED AREA BUILDING

2012 INTERNATIONAL BUILDING CODE® COMMENTARY
separations established in Table 508.4 for separated occupancies must be provided.

507.8.4 Height limitations. For two-story unlimited area buildings, Group H occupancies shall not be located more than one story above grade plane unless permitted based on the allowable height in stories and feet as set forth in Table 503 for the type of construction of the unlimited area building.

- This section notes that the Group H occupancy must be on the first story above grade unless Table 503 allows for such occupancies on the second story above grade. This will depend on the type of construction. All the other size limitations still apply.

507.9 Aircraft paint hangar. The area of a Group H-2 aircraft paint hangar no more than one story above grade plane shall not be limited where such aircraft paint hangar complies with the provisions of Section 412.6 and is surrounded and adjoined by public ways or yards not less than in width than one and one-half times the building height.

- Because of their specialized nature and the required size of these facilities, one-story Group H-2 aircraft paint hangars are not limited in area if they meet all of the requirements of Section 412.6. This section requires that the building be of Type I or II construction and have a fire suppression system in accordance with NFPA 409. This standard requires a foam-water suppression system in the paint areas and water sprinklers in all accessory areas. The criteria for the foam-water system depends on the size (and classification in accordance with NFPA 409) of the hangar. Other requirements of Section 412.6 include compartmentalized storage and use of flammable liquids, compliance with the IFC for spray application of flammable liquids and compliance with the International Mechanical Code® (IMC®) for ventilation of flammable-finish application areas (see commentary, Section 412.6.6).

In addition to compliance with Section 412.6, the hangar must be surrounded by open space. However, instead of the 60-foot (18 288 mm) width required for other buildings (see Sections 507.2, 507.3, 507.4, 507.6, 507.7, 507.10 and 507.11), the open space surrounding the hangar must be at least one and one-half times the height of the building. Therefore, if the hangar was 30 feet [9144 mm] high, there would need to be at least 45 feet [13 716 mm] [30 feet [9144 mm] x 1.5] of open space surrounding the building.

Note that one-story paint hangars would also be permitted to exceed the height limit (in feet) of Table 503 if the exception to Section 504.1 is satisfied. Note, further, that Section 507.5 cannot be applied to buildings built under Section 507.9.

507.10 Group E buildings. The area of a Group E building no more than one story above grade plane, of Type II, IIIA or IV construction, shall not be limited provided all of the following criteria are met:

1. Each classroom shall have not less than two means of egress, with one of the means of egress being a direct exit to the outside of the building complying with Section 1020.
2. The building is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1.
3. The building is surrounded and adjoined by public ways or yards not less than 60 feet (18 288 mm) in width.

- This section permits Group E structures to be built as an unlimited area building. A direct exit to the outside from each classroom must be provided in addition to another means of egress. It is clear in the wording that to fulfill this requirement, students must be able to egress the classroom directly to the outside without intervening corridors, exit passageways or exit enclosures. The unlimited area school building must also be fully sprinklered in accordance with NFPA 13, have open space on all sides of at least 60 feet (18 288 mm) and be no more than one story above grade plane. See the commentary to Section 507.1 regarding the required open space. Please note that Section 507.5 cannot be applied to buildings built under Section 507.10.

Where associated assembly spaces are included as part of the Group E occupancy classification in accordance with Exception 4 to Section 303.1.3, they would also be allowed to be unlimited in area under this section. The type of construction is limited to Type II, IIIA or IV.

507.11 Motion picture theaters. In buildings of Type II construction, the area of a motion picture theater located on the first story above grade plane shall not be limited provided the building is provided with an automatic sprinkler system throughout in accordance with Section 903.3.1.1 and is surrounded and adjoined by public ways or yards not less than 60 feet (18 288 mm) in width.

- Motion picture theaters located in buildings of Type II construction that are no more than one story above grade plane may be unlimited in area by virtue of being of noncombustible construction, and having low fire loading and sprinkler protection in accordance with NFPA 13. The building must also be surrounded by at least 60 feet (18 288 mm) of open space. See the commentary to Section 507.1 regarding the required open space. Section 507.5 can be applied to buildings built under Section 507.11.

507.12 Covered and open mall buildings and anchor buildings. The area of covered and open mall buildings and anchor buildings not exceeding three stories in height that comply with Section 402 shall not be limited.

- This section is simply included as a reference to Section 402 for covered malls. The definition of "Cov-
GENERAL BUILDING HEIGHTS AND AREAS

ered mall" includes open malls as well. An open mall is very similar to a covered mall but the central pedestrian mall area is open to the sky. If an open mall complies with the provisions for covered malls under Section 402, it is allowed to be of unlimited area. See the commentary to Section 507.1 regarding the required open space. While Section 507.5 does not include Section 507.12, Section 402.1.1 permits a similar reduction in open space.

SECTION 508
MIXED USE AND OCCUPANCY

508.1 General. Each portion of a building shall be individually classified in accordance with Section 302.1. Where a building contains more than one occupancy group, the building or portion thereof shall comply with the applicable provisions of Section 508.2, 508.3 or 508.4, or a combination of these sections.

Exceptions:

1. Occupancies separated in accordance with Section 510.
2. Where required by Table 415.5.2, areas of Group H-1, H-2 and H-3 occupancies shall be located in a detached building or structure.
3. Uses within live/work units, complying with Section 419, are not considered separate occupancies.

Very frequently, buildings are designed for multiple uses, and invariably that will result in the building having more than one occupancy classification. This section describes the provisions governing the condition when a building contains more than one of the occupancies identified in Sections 303 through 312. For example, a facility that appears to be used solely for storage often has a small office area for bookkeeping and other purposes. Because the office would be classified as a business occupancy, the building would be identified as a mixed occupancy, storage (Group S-1) and business (Group B).

The section contains three major parts:

1. Accessory occupancies (see Section 508.2). This portion of the section addresses situations where a building contains a main occupancy with minor areas of a building classified as one or more different occupancies that can be treated for allowable area purposes as part of the main occupancy.
2. Mixed occupancies that are not separated from each other (see Section 508.3) since the building is regulated for several of the worst-case conditions of each occupancy involved. This section addresses circumstances where the building contains more than one different occupancy classification in which certain requirements for each occupancy are addressed on a building-wide basis.
3. Mixed occupancies where occupancies of different hazard levels are separated (see Section 508.4). This section addresses circumstances where the building contains more than one occupancy classification but in which occupancies with different hazard levels are separated from each other by fire-resistance-rated construction.

The final sentence of this section reemphasizes the choice for the designer to use just the provisions of one of the three parts, or options, and not to use the other options. But the code also allows a mixture of the options in different portions of a building. For example, a building could be designed to comply with only Section 508.3 for nonseparated mixed occupancies and not comply with any of the provisions of either Section 508.2 or 508.4. A different example could be to use the provisions of Section 508.3 on the first story of a building which perhaps had three or four different occupancies, but then separate the upper stories of the building from the first story and treat the upper stories under Section 508.4 for separated occupancies. A final example would be a building that was predominately one use but had small accessory areas on various stories. For this building the best option might be Section 508.2 regarding accessory occupancies.

These options depend on the limitations of their use, as stated in the respective sections of the code. Basically, the availability of the options depend on the size of the areas desired for each different occupancy, and the relationship of one occupancy to the other.

Exception 1 provides a fourth set of options for mixed occupancies by referring to Section 510, which describes various special circumstances, including where parking garages are located above or below other uses.

Exception 2 reminds the user that including Group H-1, H-2 or H-3 in the same building with other occupancies when quantities exceed certain amounts is prohibited by Section 415.5.2 because of the nature of the hazard for high quantities of flammable, combustible and explosive materials.

Exception 3 exempts uses within a live/work unit from needing to comply with Section 508 provided the uses are within the limitations of Section 419. Live/work units provide the option for as much as 50 percent of nonresidential uses within what is classified as a Group R-2 dwelling unit.

Note that Section 509 regulates incidental uses that, when they occur as part of an occupancy, require additional protection or separation from the balance of the building. Incidental uses are part of the occupancy and the presence of an incidental use in a building does establish a mixed occupancy condition and as such is not required to comply with Section 508.
508.2 Accessory occupancies. Accessory occupancies are those occupancies that are ancillary to the main occupancy of the building or portion thereof. Accessory occupancies shall comply with the provisions of Sections 508.2.1 through 508.2.4.

- Buildings often have rooms or spaces with an occupancy classification that is different from, but accessory to, the principal occupancy classification of the building. When such accessory areas are limited in size, they will not ordinarily represent a significantly different life safety hazard. This principle does not apply where otherwise indicated in Section 508.2.4 for areas classified as Group H.

The occupancy must be ancillary to the principal purpose for which the structure is occupied. This means that the purpose and function of the area is subordinate and secondary to the structure's primary function. As such, the activities that occur in accessory use areas are necessary for the principal occupancy to properly function and would not otherwise reasonably exist apart from the principal occupancy.

508.2.1 Area limitations. Aggregate accessory occupancies shall not occupy more than 10 percent of the building area of the story in which they are located and shall not exceed the tabular values in Table 503, without building area increases in accordance with Section 506 for such accessory occupancies.

- The aggregate area within a story devoted to the occupancies that are designated as accessory occupancies must not be greater than 10 percent of the area of that story [see Figure 508.2.1(1)].

The area of the portion of the building devoted to an accessory occupancy must also be less than the tabular building area permitted by Table 503, based on the group classification that most nearly resembles the accessory occupancy under consideration. Area increases for street frontage and automatic sprinkler protection based on the provisions of Sections 504 and 506 are not allowed [see Figure 508.2.1(2)].

508.2.2 Occupancy classification. Accessory occupancies shall be individually classified in accordance with Section 302.1. The requirements of this code shall apply to each portion of the building based on the occupancy classification of that space.

- Under Section 508.2, each accessory use is to be classified in accordance with Section 302 in the appropriate occupancy classification. Code requirements such as means of egress, the provision of sprinkler protection and structural load are to be determined for this occupancy as if it were a main occupancy of the building. For example, an accessory lunchroom located in a business office regulated as an accessory occupancy would need to be protected with an automatic sprinkler system if the lunchroom's occupant load exceeds 100. In addition, any means of egress doors serving the lunchroom, from the lunchroom to the exterior exit doors, would need to be provided with panic hardware. The lunchroom would need to comply with all other code requirements applicable to a Group A-2 use.

Figure 508.2.1(1) ACCESSORY USES LIMITED BY FLOOR AREA

Figure 508.2.1(2) ACCESSORY USES LIMITED BY TABULAR AREA

For SI: 1 square foot = 0.0929 m².
Please note that Section 508.2.3 states that height and area of the building are based on the main occupancy; therefore, for determining the construction type for the total building, the building's floor area and height should be compared to the limits of Table 503 to determine the appropriate construction type. See Section 508.2.1 regarding the area of the accessory occupancy itself and see Section 508.2.3 regarding the height of the accessory occupancy itself.

When applying Chapter 9, many of the requirements for automatic sprinkler systems are based on the size of the fire area in which the occupancy is located. For instance, a Group A-2 occupancy requires a sprinkler system when the fire area is greater than 5,000 square feet (465 m²) or when the fire area has an occupant load of 100 or more. By understanding the definition of a "Fire area," if there is no rated separation of the accessory occupancy from the main occupancy, the fire area will be everything between fire barriers, fire walls or exterior walls, and therefore could, and most likely will, contain both the accessory occupancy area as well as the main occupancy.

Continuing with this example, suppose that a single-story business office of 23,000 square feet (2137 m²) contains a lunchroom that is 2,000 square feet (186 m²) and an occupant load of 134. The main occupancy is a Group B, and the accessory occupancy is a Group A-2. Because the Group A-2 occupancy has a floor area of less than 10 percent of the overall floor area of the single story, it could be regulated as an accessory occupancy, and there is no fire separation requirement between the Group A-2 and Group B. A Group A-2 occupancy is required to be provided with an automatic sprinkler system when it is either in excess of 5,000 square feet (465 m²) or 100 occupants. Since this fire area is 23,000 square feet (2137 m²) and contains a Group A-2 occupancy with an occupant load of over 100 and is located within a fire area of greater than 5,000 square feet (465 m²) this fire area would need to be provided with an automatic sprinkler system throughout based on either of the two thresholds.

508.2.3 Allowable building area and height. The allowable building area and height of the building shall be based on the allowable building area and height for the main occupancy in accordance with Section 503.1. The height of each accessory occupancy shall not exceed the tabular values in Table 503, without increases in accordance with Section 504 for such accessory occupancies. The building area of the accessory occupancies shall be in accordance with Section 508.2.1.

For accessory occupancies, the area of the building containing the accessory occupancy is based on the area of the main occupancy because accessory occupancies must be limited in size and pose a limited increased degree of hazard. The accessory occupancies' height is further limited in that it cannot exceed the tabular height given by Table 503. For this determination, the height increase for sprinklers cannot be applied to the accessory occupancies. Therefore, the construction type for the total building will be based on the total area of the main and accessory occupancies, but the result may be to limit an accessory occupancy to certain stories of a building. Continuing with the Group A-2 accessory lunchroom in the Group B occupancy building: If the building is two stories of Type VB construction, the accessory Group A-2 lunchroom would be limited to a first-story location under the limits set in Table 503 even if the building is fully sprinklered.

508.2.4 Separation of occupancies. No separation is required between accessory occupancies and the main occupancy.

Exceptions:

1. Group H-2, H-3, H-4 and H-5 occupancies shall be separated from all other occupancies in accordance with Section 508.4.

2. Group I-1, R-1, R-2 and R-3 dwelling units and sleeping units shall be separated from other dwelling or sleeping units and from accessory occupancies contiguous to them in accordance with the requirements of Section 420.

When a designer is using Section 508.2, most accessory occupancies need not be separated from the main occupancy, unless that accessory occupancy is a Group H-2, H-3, H-4 or H-5 high-hazard occupancy. Please note that even where an accessory occupancy is not separated from the main occupancy under the provisions of Section 508.2.4, there may be other provisions of the code that might require a fire-resistance-rated separation. For instance, if it was desired not to provide a sprinkler system in the fire area discussed in the commentary example in Section 508.2.2, then a fire barrier would need to be installed to make the fire area containing the Group A-2 occupancy smaller than the threshold amount of 5,000 square feet (465 m²) and below the 100-occupant threshold. Or, another example is, in some cases there could be a wall between two different occupancies that is required by another section of the code to be fire-resistance rated (e.g., a separation wall is provided that also serves as a corridor wall that is required to be fire-resistance rated).

Exception 1 addresses the need to separate Group H-2, H-3, H-4 or H-5 occupancies because of the higher risk posed by these high-hazard occupancies. Please notice that Group H-1 occupancies are not mentioned because these occupancies are always required to be located in a separate building (see Section 415.6).

Exception 2 states that the separation between dwelling units and sleeping units and any accessory occupancies must still comply with Section 420. For example, a common lounge or manager's office that otherwise might qualify as an accessory occupancy
within an apartment building must still be separated from adjoining dwelling units.

Those rooms and spaces listed in Table 509 are incidental uses and are not to be considered as accessory occupancies, but rather must be separated or protected as specified in the table.

**508.3 Nonseparated occupancies.** Buildings or portions of buildings that comply with the provisions of this section shall be considered as nonseparated occupancies.

- This section describes the second option a designer may choose to apply to a building that contains more than one occupancy classification. Except with respect to occupancies classified in Group H, this option is similar to the accessory occupancy option (see Section 508.2) in that there is no requirement for various occupancies to be physically separated by any type of fire-resistance-rated assembly (see Figure 508.3).

The principle behind nonseparated occupancies is that the different occupancies within the same building do not have to be separated by fire-resistance-rated assemblies if the building complies throughout with the more restrictive code requirements for minimum construction type and fire protection systems (Chapter 9) applicable to the occupancies in the building. If the building is also a high-rise building, the most restrictive provisions of Section 403 applicable to the specific occupancies in the building will also apply. Although each occupancy is separately classified as to its group, a fire-resistance-rated assembly is not required by the nonseparated occupancies option. A designer may choose to physically separate the occupancies; however, a fire-resistance rating of these separations would not be required by this section.

There are four basic steps to follow when applying the nonseparated occupancies concept:

**Step 1:** Determine which occupancy group classifications are present in the building.

**Step 2:** Determine the minimum type of construction based on the height and area of the building for each occupancy in accordance with this chapter and Table 503 as if each occupancy occurred throughout the building. Compare the requirements for each occupancy and then apply the requirement for the highest type of construction to the entire building (see Section 508.3.2).

**Step 3:** Apply the most restrictive provisions found in Chapter 9 throughout the building containing nonseparated occupancies. For example, if the two occupancies in a 6,000-square-foot (557 m²) building are Group B and Group A-2, even though Section 903 does not require an automatic sprinkler system is non-high-rise Group B buildings, it does require sprinklers in a Group R-2 building of this size. For this example, the building with these nonseparated occupancies would need to be fully sprinklered.

For a high-rise building, also apply the most restrictive provisions contained in Section 403 related to the occupancies present (see Section 508.3.1).

**Step 4:** Apply all other requirements of the code, except for Section 403 and Chapter 9, to each occupancy individually based on the specific occupancy of each space (e.g., means of egress) (see commentary, Chapter 10) (see Section 508.3).

**508.3.1 Occupancy classification.** Nonseparated occupancies shall be individually classified in accordance with Section 302.1. The requirements of this code shall apply to each
portion of the building based on the occupancy classification of that space. In addition, the most restrictive provisions of Chapter 9 which apply to the nonseparated occupancies shall apply to the total nonseparated occupancy area. Where nonseparated occupancies occur in a high-rise building, the most restrictive requirements of Section 403 which apply to the nonseparated occupancies shall apply throughout the high-rise building.

- The nonseparated occupancies option requires that each occupancy area be considered a different occupancy for purposes of application of code requirements and therefore requires that all code issues related to that occupancy be considered separately for the areas of the building where the occupancy is located. The exception to this is for the provisions of Chapter 9 and Section 403, which must be applied to the whole building containing the nonseparated occupancies.

  The principle behind the nonseparated occupancies concept is that the different occupancies within the same building do not have to be separated by fire-resistance-rated assemblies if the building complies throughout with the more restrictive code requirements for construction, fire protection systems and, where applicable, requirements for high-rise buildings. Although each occupancy group is separately classified as to its group, a fire-resistance-rated assembly is not required under the nonseparated occupancies option. A designer may choose to physically separate the occupancies; however, a fire-resistance rating of these separations would not be required by this section, as stated in Section 508.3.3.

  For example, if a building contains both Groups B and M, each portion of the building must comply with the code requirements for its respective group classification located in that portion. The occupant load for the area classified as Group B is based on the code requirements applicable to the business occupancy. Similarly, the occupant load for the Group M area is based on requirements applicable to the mercantile occupancy. Live loads for the Group B area are applied to the area of business occupancy. Group M live loads are applied to the area of mercantile occupancy. Exterior wall ratings based on fire separation distance (see Table 602) apply to exterior walls of the business occupancy for Group B buildings; the same is true for walls in Group M occupancies.

  It is important to note the threshold requirements for fire protection systems are contained in Chapter 9. In some cases, they are simply based on the occupancy and in other cases they are based on height or area criteria. Also, the requirements to be met in some cases only apply to the fire area in which a given occupancy is contained, while in others they apply to the entire building.

  For example, if the business occupancy as described in Figure 508.3 required a fire alarm system with manual fire alarm boxes, then one would be required for the entire building—even though Chapter 9 does not require a fire alarm system for a storage occupancy. Note that when determining if a fire alarm system is required and the threshold for the requirement is based on occupant load, it is based on the occupant load of the individual occupancy and not for all the occupancies in the nonseparated building (see commentary, Section 907.2).

508.3.2 Allowable building area and height. The allowable building area and height of the building of portion thereof shall be based on the most restrictive allowances for the occupancy groups under consideration for the type of construction of the building in accordance with Section 503.1.

- The fundamental concept underlying the nonseparated occupancies option is that the allowable building heights and allowable building areas are based on the most restrictive requirements of Table 503 applicable to each of the occupancy groups in the mixed occupancy building.

  For example, the tabular area for Group S-1 in Table 503 is less than the corresponding tabular area for Group B; therefore, Group S-1 results in a requirement for a higher type of construction for buildings of equal size and will, therefore, determine the minimum construction type of the building. If the building were, say, Type II B construction, then the allowable area for the building would be 17,500 square feet (1626 m²), based on the allowable area of Group S-1 occupancies for Type II B construction in Table 503. Area increases for sprinklers and frontage could be applied. The same methodology of applying the most restrictive criteria of Table 503 (with any permitted sprinkler increase) is used to evaluate the maximum permitted height in stories above grade plane.

508.3.3 Separation. No separation is required between nonseparated occupancies.

*Exceptions:*

1. Group H-2, H-3, H-4 and H-5 occupancies shall be separated from all other occupancies in accordance with Section 508.4.

2. Group I-1, R-1, R-2 and R-3 dwelling units and sleeping units shall be separated from other dwelling or sleeping units and from other occupancies contiguous to them in accordance with the requirements of Section 420.

- As is indicated by the name of this mixed occupancy option, "nonseparated occupancies," the occupancy groups within the building need not be separated from each other by fire-resistance-rated construction. It must be noted that other portions of the code might require fire separation assemblies, and where the separations are required by other provisions, they must be provided even in a building designed under the nonseparated mixed occupancy option. For instance, if it was desired not to provide a sprinkler system in the fire area discussed in the commentary...
example in Section 508.2.2, then a fire barrier would need to be installed to make the fire area containing the Group A-2 occupancy smaller than the threshold amount of 5,000 square feet (465 m²) and the occupant load less than 100. Another example is, in some cases it could be a wall between two different occupancies that is required by another section of the code to be fire-resistance rated (e.g., a separation wall is provided that also serves as a corridor wall that is required to be fire-resistance rated).

When one or more of the occupancies is a Group H-2, H-3, H-4 or H-5 high-hazard occupancy, the nonseparated occupancies option could not be applied for the Group H portions of the building (Exception 1). Any Group H occupancies would need to be separated as required by Section 508.4 for separated occupancies.

Exception 2 states that the horizontal assemblies and walls required to separate dwelling units and sleeping units from each other and from other occupancies need to comply with Section 420 even if the nonseparated occupancies provisions are applied.

**Example:** A building contains a 46,200-square-foot (4292 m²) general warehouse and an accompanying 30,000-square-foot (2787 m²) regional dispatch office for a total area of 76,200 square feet (7079 m²). The building is a one-story, metal building. Assume that there is no allowable area increase for frontage. In applying the four-step procedure for nonseparated uses, the following holds true:

**Step 1:** The warehouse is classified in Group S-1 and the offices are classified in Group B.

**Step 2:** The minimum type of construction is based on the lesser allowable area of the building for each occupancy classification. First, determine if any increases can be obtained (no frontage increase—check for installation of a sprinkler system). In Step 3, the building is shown to be sprinkled throughout; therefore, a 300-percent increase can be applied to the tabular areas set in Table 503 (see Section 506.3). For the purpose of analysis, assume the building is of Type IIB construction. The Group B requirements would allow the building to be 92,000 square feet (8547 m²) (23,000 square feet + 300 percent of 23,000 square feet). The Group S-1 requirements, however, only allow a building of Type IIB construction to be 70,000 square feet (6503 m²) (17,500 square feet + 300 percent of 17,500 square feet). The most restrictive is the Group S-1 requirement; therefore, it governs. Hence, Type IIB construction would not allow adequate area for the S-1 occupancy. Since the most restrictive allowable area is required to be consid-
ered, a higher construction type would be required. The minimum type of construction needs to be Type IIA.

**Step 3:** The fire area containing the occupancy classified in Group S-1 is more than 12,000 square feet (1115 m²); thus, in accordance with Section 903.2.10, this area must be sprinklered. The area classified as Group B ordinarily is not required to be equipped with sprinklers by Section 903; however, since the Group S-1 provision does require sprinkler protection, it is more restrictive than the requirement for Group B under Chapter 9. Therefore, the entire building must be sprinklered.

**Step 4:** The occupant load of each area should be calculated separately (based on the occupancy of that area) using Section 1004.1 and Table 1004.1.1.

**Business:** = 30,000 square feet (2787 m²) divided by 100 square feet (9 m²) per person = 300 people.

**Storage:** = 46,200 square feet (4292 m²) divided by 500 (warehouses) square feet (46 m²) per person = 93 people.

**Total occupant load:** 393 people

The evaluation of means of egress in accordance with Chapter 10 is then based on these occupant loads.

The load-bearing members in the north, east and west exterior walls of the building must provide a minimum 1-hour fire-resistance rating as required for Type IIA construction in Table 601. The nonload-bearing walls are also required to have a 1-hour fire-resistance rating because of the 15-foot (4572 mm) fire separation distance (see Table 602).

The fire separation distance on the south side of the mixed occupancy building is 8 feet (2438 mm). Table 602 requires the Group S-1 and B portions of this wall to have a 1-hour fire-resistance rating. The ratings required by this table apply to both load-bearing and nonload-bearing exterior walls. The substitution of an automatic sprinkler system in lieu of 1-hour fire-resistance-rated construction (as indicated in Note d of Table 602) does not apply to exterior walls; therefore, all exterior walls (whether load-bearing or nonload-bearing) in this building are required to have a 1-hour fire-resistance rating.

This analysis must be continued for other aspects of code compliance for each respective occupancy. Once all four steps have been satisfied, the building is deemed to have an equivalent level of safety as a building with only one occupancy. Any future changes in the occupancy, or the areas used by each occupancy, would require review and approval by the local jurisdiction in accordance with the provisions contained in Sections 105.1 and 3408.
508.4 Separated occupancies. Buildings or portions of buildings that comply with the provisions of this section shall be considered as separated occupancies.

This section describes the third option, separated occupancies, that a designer may choose to apply when constructing a building that contains more than one occupancy classification. This third option differs from the first two alternatives (i.e., accessory occupancies and nonseparated occupancies) (see Sections 508.2 and 508.3) in four ways:

1. Occupancies that are to be evaluated as separated occupancies must be separated in accordance with Table 508.4. When the table requires a separation, the occupancies must be separated completely, both horizontally and vertically, by the provision of fire-resistance-rated fire barriers and horizontal assemblies (see Sections 707 and 711). It should be noted that Table 508.4 indicates "N" at the intersection of some occupancies. The "N" indicates that no rated separation is required. This is allowed where the adjacent occupancies pose similar levels of risk. Separations, where provided, do not necessarily create separate fire areas. Table 508.4 is not intended to be used for determining the required fire-resistance rating for creating multiple fire areas. The minimum separations for fire area purposes are established in Table 707.3.9.

2. The determination of the minimum type of construction is based on both the height of each occupancy relative to the grade plane and the areas of each occupancy relative to the total area per story.

3. Allowable building area is determined based on the occupancies on each story through a comparison of the allowed area for each occupancy category and the actual floor area proposed for each occupancy.

4. In comparison to the nonseparated occupancies provisions in Section 508.3 where the most restrictive of the requirements of Chapter 9 apply throughout the building, under separated occupancies, requirements for such systems as sprinkler systems, alarms and standpipes are determined based on the areas containing each occupancy. It must be noted that the determination of sprinkler requirements in Section 903 is based on the occupancies present. The threshold for providing a sprinkler system is often based on the size of a fire area. In the cases where Table 508.4 does not require a separation, the result is that certain fire areas will contain more than one occupancy. Therefore when determining when sprinklers are required, the total size of the fire area needs to be considered, not just the portion containing each occupancy. For example, a proposed building is 16,000 square feet (1486 m²), there is 8,000 square feet (743 m²) of Group M occupancy and 8,000 square feet (743 m²) of Group B. According to Table 508.4, there does not need to be a separation between these two occupancies. Individually neither is large enough to require a sprinkler system. However, if no separation is provided, the fire area is 16,000 square feet (1486 m²), and in accordance with Section 903.2.7 a fire area containing a Group M occupancy and exceeding 12,000 square feet (1115 m²) must be sprinkler protected. [Fire areas (defined in Section 202) are used in Section 903.2 to determine if sprinklers are required. Fire areas are a distinct requirement from separation of occupancies and the separation of occupancies by a fire-resistance-rated wall may not always create a separate fire area. Fire areas can be delineated by fire walls and fire barriers per Chapter 7.]

There are four basic steps to follow when using the separated occupancies option:

**Step 1:** Determine which occupancies are present in the building (see Section 508.4.1).

**Step 2:** Separate the occupancies in accordance with Table 508.4 with fire barrier walls and horizontal assemblies in accordance with Sections 707 and 711 (see Section 508.4.4).

**Step 3:** Apply all code requirements for each separated space individually based on the occupancy or occupancies present (i.e., design occupant load, means of egress elements, exterior wall requirements and fire protection). For the application of code provisions, each separated space is taken into consideration individually. Again, it must be remembered that Table 508.4 may not require a separation and, therefore, code requirements based on fire area must be addressed for the total fire area even though it contains more than one occupancy.

**Step 4:** Determine the minimum type of construction of a building based on the building height limitations of Sections 503 and 504 and the building area limitations of Sections 503 and 506 (see Sections 508.4.3 and 508.4.2, respectively).

**Part A:** Determine the minimum type of construction required based on the height of each occupancy relative to the grade plane (see Section 508.4.3). This needs to be evaluated for both height in feet and stories above grade plane.

**Part B:** Determine the minimum type of construction based on a weighted average of areas occupied by the various occupancies (see Section 508.4.2).

508.4.1 Occupancy classification. Separated occupancies shall be individually classified in accordance with Section 302.1. Each separated space shall comply with this code.
based on the occupancy classification of that portion of the building.

- In the separated occupancies option, occupancies that are to be evaluated as separated occupancies must be separated in accordance with Table 508.4. When a separation is required they must be separated completely, both horizontally and vertically, with fire barriers and horizontal assemblies (see Sections 707 and 711).

Except for certain occupancies, it is the designer's prerogative to use the accessory occupancies option, nonseparated occupancies option or the separated occupancies option when establishing a mixed occupancy building. It is also possible to apply both or all three options within different portions or different stories of a building. Where a mixture of options is used, the design documentation needs to clearly show how the requirements of each option are applied in each portion of the building.

**508.4.2 Allowable building area.** In each story, the building area shall be such that the sum of the ratios of the actual building area of each separated occupancy divided by the allowable building area of each separated occupancy shall not exceed 1.

- For each story, it must be determined that the sum of the ratios of the actual floor area of each separated occupancy, respective to the most restrictive occupancy contained therein as compared to the areas per story allowed by Table 503 and as modified by Section 506 for each respective occupancy, does not exceed one. In the evaluation of allowable area, intervening fire barriers between different fire areas containing the same occupancy are not a consideration. In determining the floor area per occupancy, all areas of the same occupancy are added together irrespective of the presence of multiple fire areas.

In determining the allowable areas for each occupancy, the tabular areas from Table 503 are permitted to be modified in accordance with the provisions of Section 506; thus, the allowable areas are intended to include the increases permitted for sprinklers and open perimeter. For determination of the allowable perimeter increase, use the entire building perimeter—not the occupancy perimeters. If considering the sprinkler increase, the entire building must be sprinklered, not just particular occupancies.

**508.4.3 Allowable height.** Each separated occupancy shall comply with the building height limitations based on the type of construction of the building in accordance with Section 503.1.

**Exception:** Special provisions permitted by Section 510 shall permit occupancies at building heights other than provided in Section 503.1.

- The allowable height is occupancy dependant. As long as individual occupancies meet the height limitations based upon a measurement from grade plane then the building complies. For example, a building of Type III B construction with no increases for sprinklers containing a Group B occupancy and a Group F-1 occupancy could be three stories. The only limitation in this case, in terms of building height, would be that the Group F-1 occupancy could not be located any higher than the second story.

**508.4.4 Separation.** Individual occupancies shall be separated from adjacent occupancies in accordance with Table 508.4.

- Table 508.4 provides the required separation between areas containing the separated occupancies. Separations must be of fire-resistance-rated construction for 1, 2 or 3 hours as specified in the cells of the table. Generally the required rating will be higher if a building is not fully protected by an automatic sprinkler system. The table states “NP” in certain cells. These occur where occupancies are not permitted to be in a mixed occupancy building, or where one or both occupancies cannot be in a non-sprinklered building. Other cells contain the letter “N.” For the adjoining occupancies represented by each such cell, no separation is required. Although certain adjacent occupancies are not required to be physically separated, they are still evaluated under the separated option, but note that, where code requirements are based on established fire areas, occupancies not separated must be considered as sharing the same fire area.

For example, a completely sprinklered building of Type VB construction contains areas devoted to business and assembly occupancies. The designer has chosen the separated occupancies option and has completely separated the areas containing the two different occupancies by fire barriers (complying with Section 707) and horizontal assemblies (complying with Section 711) having a minimum 1-hour fire-resistance rating in accordance with Table 508.4. This is found by consulting the box that intersects with “A, E” in the first column with “B, F-1, M, S-1” in the first row and, because the entire building is sprinklered, the fire-resistance rating of the fire barrier walls and horizontal assemblies is required to be 1 hour, as indicated in the column designated “S.” Had the building not been sprinklered, the required rating would have been 2 hours, as indicated in the column designated “NS.”

Please note that Table 508.4 contains groupings of some of the occupancies, including:

- A, E
- 1-1, 1-3, 1-4
- R
- F-2, S-2, U
- B, F-1, M, S-1
- H-3, H-4

These are occupancies that share the same level of hazard with respect to fire safety. It is possible,
therefore, to have two occupancies that comply with these separated use provisions that require no separation between them. For instance, a mixed occupancy of Groups B and M would not be required to have a separation between them, but the provisions for calculation of the sum of the ratios of actual areas to allowable areas would still be applied to this circumstance.

**TABLE 508.4.** See below.

- The purpose of Table 508.4 is to set forth the fire-resistance rating required for fire barrier walls and horizontal assemblies used to separate occupancies. The fire-resistance rating of the separation between different occupancies is based on the relative anticipated fire severity of the occupancies.

**Note a:** A reference is made to Section 420 for provisions requiring the separation of dwelling units and sleeping units in Group I-1, R-1, R-2 and R-3 occupancies. See the commentary to Section 420.

**Note b:** The fire-resistance rating of spaces used solely for private or pleasure vehicles may be reduced by 1 hour but never less than 1 hour.

**Note c:** See the commentary to Section 406.3.4.

**Note d:** Occupancies in the same classification do not need to be separated. For example, a Group A-2 restaurant is not required to have a rated separation from a Group A-3 museum.

**508.4.1 Construction.** Required separations shall be fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both, so as to completely separate adjacent occupancies.

- This section is merely a reference to the appropriate provisions in Chapter 7 for fire-resistance-rated assemblies that are required to meet the provisions for adequate separation of occupancies.

The following three examples illustrate the application of the separated occupancies option.

**Example 1:** A four-story building contains a retail store on the first story, a lecture hall with fixed seats on the second story and offices on the top two stories. Each story is 10,500 square feet (975 m²). A sprinkler system is not provided throughout the building. Assume that there is no open perimeter increase [see Figure 508.4(1)]. In applying the four-step procedure for separated uses, the following holds true:

- **Step 1:** First story is Group M for the entire story. Second story is Group A-3 for the entire story. Third and fourth stories are Group B for both stories.

- **Step 2:** The separation requirements in accordance with Table 508.4 require a 2-hour fire-resistance rating for the horizontal assembly between the Group M occupancy and the Group A-3 occupancy. Likewise, a 2-hour fire-resistance-rated horizontal assembly is required between the Group A-3 occupancy and the Group B occupancy. Each occupancy is separated horizontally with an approved fire-resistance-rated assembly. There is no rating required for the horizontal assembly between the third and fourth stories because they are in the same occupancy.

S = Buildings equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1.
NS = Buildings not equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1.
N = No separation requirement.
NP = Not permitted.
a See Section 420.
b The required separation from areas used only for private or pleasure vehicles shall be reduced by 1 hour but to not less than 1 hour.
c See Section 406.3.4.
d Separation is not required between occupancies of the same classification.
**Step 3:** The occupancy-specific requirements need to be addressed. The building is essentially broken into the following three areas based on the separations provided to achieve the separated occupancy requirements:

- **Group M area = 10,500 square feet (975 m²).**
- **Group A-3 area = 10,500 square feet (975 m²).**
- **Group B area = 21,000 square feet (1951 m²) [combined area for two stories, each 10,500 square feet (975 m²)].**

Because of the construction required for each separation, these occupancy areas may also be separate fire areas as determined by Table 707.3.10.

Since the story containing the Group M occupancy is also a fire area that is less than 12,000 square feet (1115 m²) and is located below the fourth story, sprinklers are not required for the Group M occupancy.

The story containing the Group A-3 occupancy is also a fire area that is less than 12,000 square feet (1115 m²), but it is located on the second story and above the level of exit discharge. According to Section 903.2.1.3, a Group A-3 occupancy fire area in this location must be provided with a sprinkler system. In addition, this would mean that the Group M occupancy would be required to be sprinklered in accordance with Section 903.2.1 which requires that all stories between the Group A-3 occupancy and the level of exit discharge be sprinklered.

The third and fourth stories containing the Group B occupancy do not require sprinklers because neither the size nor height of these stories triggers any threshold in Section 903.

Additionally, provisions in other parts of the code for each occupancy area (e.g., means of egress, exterior wall requirements, interior finishes) should be used based on the occupancy located on each story. For example, the design occupant load of the area containing the Group M occupancy is based on the mercantile occupant load factor found in Table 1004.1.1 while the area containing the Group A-3 occupancy is based upon the number of fixed seats in the lecture hall in accordance with Section 1004.7.

**Step 4:**

**Part A:** Review for the minimum types of construction based on the height limitations for each of the three occupancies as follows (see Figure 508.4(2)):

1. **Group M**, one story in height; the minimum type of construction is Type VB [one story and 40 feet (12 192 mm) in accordance with Table 503].
2. **Group A-3**, two stories in height; the minimum type of construction is Type VA [two stories and 50 feet (15 240 mm) in accordance with Table 503].
3. **Group B**, four stories in height; the minimum type of construction is Type III A [five stories and 65 feet (19 812 mm) in accordance with Table 503].

The highest type of construction for any one of the occupancies governs for the entire building; thus, the minimum allowable type of construction permitted for the building based on height is Type IIIA. The designer is permitted to choose any one of the construction types other than Types IIB, IIIB, VA and VB for the design of the building. The separated occupancy option presumes that each occupancy is restricted to the story (or stories) for

![Diagram](image-url)
which it is designated. For this example, the first story is separated and designated for the Group M occupancy, and the Group M occupancy can only occur on that story. In comparison, the nonseparated option would assume that the Group M occupancy could occur on any of the four stories. If the building were completely sprinklered, Section 504.2 would permit a height increase. Accordingly, under Table 503, the minimum type of construction allowed for the building would be Type VA. In addition, the minimum fire-resistance rating of each floor/ceiling assembly would need to be only 1 hour, in accordance with Table 508.4.

Part B: Since each story has only one occupancy, the maximum allowable area for a story of the building is derived directly from Table 503. Based on the allowable construction type determined, Type IIB construction is acceptable for Groups B and M; however, it is not acceptable for Group A-3. Based on the given area of 10,500 square feet (975 m²) and without any area increases, the allowable types of construction permitted for Group A-3 based on area are Types IA, IB, IIA, IIIA, IV and VA. Although the Group A-3 story, as well as the story below, will be required to be sprinkler protected, because the whole building is not protected, area increases for sprinklers are not allowed in this example.

From Part A it was determined that Type VA construction is not permitted for the height of the building due to Group B; therefore, the allowable types of construction for the building based on height and area are Types IA, IB, IIA, IIIA and IV.

Example 2: Consider a 76,200-square-foot (7079 m²) building with a fire barrier wall separating a 46,200-square-foot (4292 m²) warehouse from a 30,000-square-foot (2787 m²) office space [see Figure 508.4(3)].

Step 1: The warehouse occupancy (which is also a fire area) is classified in Group S-2. The office occupancy (which is also a fire area) is classified in Group B.

Step 2: A 2-hour fire barrier is required in accordance with Table 508.4 for nonsprinklered buildings (1 hour for sprinklered buildings) between the two occupancies and extends continuously through all concealed spaces to the underside of the roof deck in accordance with Section 707.

Step 3: The separation required by Table 508.4 also creates two fire areas since it requires the same level of fire separation as Table 707.3.10 which is used to determine the minimum required fire area separation. The Group B area is one story and 30,000 square feet (2787 m²). A sprinkler system is not required by the code for a one-story Group B fire area (unless it is an ambulatory care center). The Group S-2 fire area is 46,200 square feet (4292 m²), which is also not required to have a sprinkler system. However, the designer wants to be able to utilize Type IIB construction. Table 503 restricts Group S-2 occupancies within a Type IIB building to 26,000 feet (2416 m²); therefore, a sprinkler system will need to be provided under Section 506.3 to allow an increase in allowable area. For a single-story building, the increase is 300 percent; the allowable area for a Group S-2 building in Type IIB would then be 104,000 square feet (9662 m²). To allow this increase the entire building including both occupancies would need to be sprinkler protected.

Further, evaluate each occupancy area in the same manner for compliance with all provisions of the code.

Step 4:

Part A: The proposed building is only one story in height. Based on height, any type of

---

**Figure 508.4(2)**

SEPARATED OCCUPANCIES—EXAMPLE 1: LOCATION ON STORIES
construction is acceptable for the occupancies under consideration.

**Part B:** Make a trial evaluation of the building assuming it to be Type IIIB construction:

Actual area of Group S-2 = 46,200 square feet (4292 m²) and actual area of Group B = 30,000 square feet (2787 m²).

Group S-2 maximum allowable area, including allowable increases (allowable tabular area plus sprinkler increase) = 26,000 + (26,000)(3.0) = 104,000 square feet (9662 m²).

The maximum allowable area for Group B including allowable increases (allowable tabular area plus sprinkler increase) = 23,000 + (23,000)(3.0) = 92,000 square feet (8547 m²).

Using the sum of the ratios approach, 46,200/104,000 + 30,000/92,000 = 0.77 which does not exceed 1.0.

Therefore, Type IIIB construction is an acceptable minimum type of construction. When the factor arrived at is substantially below 1.0, it indicates that the building might qualify as a lower type of construction or as nonseparated occupancies.

The building is deemed to comply with the code after each of the code requirements, as determined by Steps 1 through 4, is satisfied.

In the case of multistory buildings, an evaluation of the allowable area must be performed for every story of the building that contains separated uses.

**Example 3:** Consider a 76,200-square-foot (7079 m²) building identical to that used in Example 2, except that the warehouse is classified in Group S-1. The Group S-1 warehouse is 46,000 square feet (4292 m²) and the Group B office space is 30,000-square-foot (2787 m²) [see Figure 508.4(4)].

**Step 1:** The warehouse is classified as Group S-1. The office is classified as Group B.

**Step 2:** Table 508.4 indicates that there is no separation requirement between Groups B and S-1, since they are in the same grouping of occupancies in the table.

**Step 3:** As there is no separation between the occupancies, there is only one fire area including both occupancies. The fire area for the occupancy of Groups B and S-1 is the entire area of the one-story building, or 76,200 square feet (7079 m²). In accordance with Section 903.2.9, since the fire area containing Group S-1 is greater than 12,000 square feet (1115 m²) the entire building is required to be sprinklered. Note that even if the uses were separated, Section 903.2.9 requires sprinklers throughout all buildings containing a Group S-1 fire area greater than 12,000 square feet (1115 m²).

---

**Figure 508.4(3)**
SEPARETED OCCUPANCIES—EXAMPLE 2

---

For SI: 1 foot = 304.8 mm, 1 square foot = 0.0929 m².
Step 4:

Part A: Based on the one-story height, any type of construction is acceptable for the occupancies under consideration.

Part B: Make a trial evaluation of the building assuming it to be Type IIB construction.

Actual area of Group S-1 = 46,200 square feet (4292 m²) and actual area of Group B = 30,000 square feet (2787 m²).

Group S-1 maximum allowable area, including allowable increases (allowable tabular area plus sprinkler increase) = 17,500 + (17,500)(3.0) = 70,000 square feet (6503 m²).

The maximum allowable area for Group B including allowable increases (allowable tabular area plus sprinkler increase) = 23,000 + (23,000)(3.0) = 92,000 square feet (8547 m²).

Using the sum of the ratios approach, 46,200/70,000 + 30,000/92,000 = 0.99 which does not exceed 1.0.

Note that, in this case, the separated use option requires no separation between these particular uses, and the Type IIB classification is acceptable. Comparing this to the example for nonseparated uses, with the same dimensions of each occupancy, the Type IIB construction classification is not acceptable, and a Type IIA construction classification is required.

Since Section 508.3 (nonseparated occupancies) makes a reference to applying the most restrictive requirements of Section 403 and Chapter 9, there may be the assumption that under the separated occupancies option, requirements can be applied separately to each occupancy in all cases. This is not completely true. There are sections of Chapter 9, such as Section 903.2.6, 903.2.8 or 903.2.9, that require sprinklers throughout the entire building when a particular occupancy is present. Some sections in Chapter 9, however, do permit separate application of requirements, even though the term “fire area” is not used. For example, a warehouse building with an office would be categorized as Groups B (office) and S-1 (warehouse). If the separated occupancies option is selected and the office has an occupant load of at least 500 people, then a fire alarm system is only required in the Group B area and not the Group S-1 area (see Section 907.2). It should be noted that alarm requirements must address the path of egress for occupants and may require notification appliances along those paths.

With respect to the high-rise provisions of Section 403, the requirements generally apply throughout the building and are not specific to fire areas. There are limited provisions in Section 403 that are specific to one occupancy or another. Regardless of the option selection in a mixed occupancy building, requirements in Section 403 that are based on occupancy will need to be applied throughout the building.

Another approach available to the designer of

---

**Figure 508.4(4)**
SEPARATED OCCUPANCIES—EXAMPLE 3

---

For SI: 1 foot = 304.8 mm, 1 square foot = 0.0929 m².
structures that contain more than one occupancy requires that the occupancies are completely separated by fire walls (see Section 706), thus creating separate buildings for each use. This is the simplest option to apply and analyze. When a fire wall is utilized, for code application purposes, two or more separate and independent buildings (see the definition of “Building” in Section 202) are created, and each building is reviewed individually.

SECTION 509
INCIDENTAL USES

509.1 General Incidental uses located within single occupancy or mixed occupancy buildings shall comply with the provisions of this section. Incidental uses are ancillary functions associated with a given occupancy that generally pose a greater level of risk to that occupancy and are limited to those uses listed in Table 509.

Exception: Incidental uses within and serving a dwelling unit are not required to comply with this section.

Incidental uses are rooms or areas that constitute special hazards or risks to life safety. Such spaces often pose risks that are not typically addressed by the provisions for the general occupancy groups under consideration. However, such rooms or areas may functionally be an extension of the primary use. Only those rooms or areas found in Table 509 are to be regulated as incidental uses. Incidental uses can be located within both single-occupancy and mixed-occupancy buildings. The concern is that those areas designated as incidental uses pose a risk to the remainder of the building, and as such, some degree of protection is required. The protection requirements, however, are not applicable to incidental uses that are located within and serve a dwelling unit. Incidental uses are not required to also comply with the accessory use provisions of Section 508.2.

TABLE 509. See page 5-44.

Table 509 identifies accessory uses and the required separation or other protection to be provided. Where a fire-resistance-rated separation is required, the incidental use must be separated from other portions of the building with fire barriers that comply with Section 707 and/or horizontal assemblies complying with Section 711. Where Table 509 permits protection by an automatic sprinkler system without fire barriers, the walls enclosing the incidental use must comply with Section 509.4.2.

509.2 Occupancy classification. Incidental uses shall not be individually classified in accordance with Section 302.1. Incidental uses shall be included in the building occupancies within which they are located.

This provision expressly states that incidental uses are not considered as separate and distinct occupancy classifications, but rather are classified the same as the building occupancies in which they are located. As an example, a 200 square-foot (18.5 m²) laundry room in an apartment building would simply be classified as a part of the Group R-2 occupancy. Similarly, a waste and linen collection room in a nursing home would be classified as a portion of the Group I-2 occupancy.

509.3 Area limitations. Incidental uses shall not occupy more than 10 percent of the building area of the story in which they are located.

The floor area limitation of 10 percent for incidental uses emphasizes the ancillary nature of such rooms and areas. Each incidental use is limited to a maximum floor area of 10 percent of the floor area of the story in which it is located. Where there are two or more tenants located on the same story, the 10 percent limitation is presumably based upon the floor area of each individual tenant space rather than that of the entire story. The application of the limit on a tenant-by-tenant basis is consistent with the concept of incidental uses typically being ancillary only to a portion of the building, the specific tenant occupancy.

509.4 Separation and protection. The incidental uses listed in Table 509 shall be separated from the remainder of the building or equipped with an automatic sprinkler system, or both, in accordance with the provisions of that table.

In addition to identifying those rooms or areas that warrant regulation as incidental uses, Table 509 also indicates the required degree of protection or separation. The requirements identified in Table 509 vary depending on the incidental use. In some cases, a specific type of separation and/or protection is required, while in others there is an option. As indicated by Section 509.4.2.1, the requirement for an automatic sprinkler system for the majority of those listed applies only to the incidental use room or area, not the entire building. If a building is required to be provided with a sprinkler system for other reasons, then any sprinkler requirement for an incidental use is also met.

509.4.1 Separation. Where Table 509 specifies a fire-resistance-rated separation, the incidental uses shall be separated from the remainder of the building by a fire barrier constructed in accordance with Section 707 or a horizontal assembly constructed in accordance with Section 711, or both. Construction supporting 1-hour fire barriers or horizontal assemblies used for incidental use separations in buildings of Type IIB, IIC and VB construction is not required to be fire-resistance rated unless required by other sections of this code.

Where a fire-resistance rated separation is required, the incidental use must be separated from other portions of the building with fire barriers that comply with Section 707 or horizontal assemblies complying with Section 711, or both. Where Table 509 permits protection by an automatic sprinkler system without fire barriers, the construction enclosing the incidental use must resist the passage of smoke in accordance with Section 509.4.2. Where the construction surrounding an incidental use is only required to be 1 hour, and
the building is of nonrated construction (Type IIb, IIIb or VB), the rated construction does not need to be supported by 1-hour fire-resistance-rated construction. In all other instances, the construction supporting incidental occupancy separations must be supported by construction with at least the same rating as the separations.

509.4.2 Protection. Where Table 509 permits an automatic sprinkler system without a fire barrier, the incidental uses shall be separated from the remainder of the building by construction capable of resisting the passage of smoke. The walls shall extend from the top of the foundation or floor assembly below to the underside of the ceiling that is a component of a fire-resistance-rated floor assembly or roof assembly above or to the underside of the floor or roof sheathing, deck or slab above. Doors shall be self- or automatic-closing upon detection of smoke in accordance with Section 716.5.9.3. Doors shall not have air transfer openings and shall not be undercut in excess of the clearance permitted in accordance with NFPA 80. Walls surrounding the incidental use shall not have air transfer openings unless provided with smoke dampers in accordance with Section 710.7.

Where Table 509 permits protection by an automatic sprinkler system without fire barriers, the construction enclosing the incidental use must resist the passage of smoke. While this section can be viewed as a performance standard, construction details for resisting the passage of smoke are provided in this section. Although the section specifically states that air transfer openings must be provided with smoke dampers, it is silent with respect to ducts. If ducts are penetrating this separation, the arrangement of the duct system should be analyzed to determine if it will allow smoke to pass through the wall and not restrict it to the incidental use.

The wall construction described here is required to be neither a smoke barrier conforming to Section 709 nor a smoke partition conforming to Section 710.

509.4.2.1 Protection limitation. Except as specified in Table 509 for certain incidental uses, where an automatic sprinkler system is provided in accordance with Table 509, only the space occupied by the incidental use need be equipped with such a system.

The point of this section is that the sprinkler system stipulated in Table 509 is required for the incidental use only. In general, the nature of these incidental uses is such that they are small areas that are not frequented by the building occupants very often in which a fire could get underway and go unnoticed for a longer time than a part of the building that is constantly occupied.

SECTION 510
SPECIAL PROVISIONS

510.1 General. The provisions in Sections 510.2 through 510.9 shall permit the use of special conditions that are exempt from, or modify, the specific requirements of this chapter regarding the allowable building heights and areas of buildings based on the occupancy classification and type of

For SI: 1 square foot = 0.0929 m², 1 pound per square inch (psi) = 6.9 kPa, 1 British thermal unit (Btu) per hour = 0.293 watts, 1 horsepower = 746 watts, 1 gallon = 3.785 L.
construction, provided the special condition complies with
the provisions specified in this section for such condition and
other applicable requirements of this code. The provisions of
Sections 510.2 through 510.8 are to be considered independ-
ent and separate from each other.

The subsections of Section 510 are exceptions to the
general height and area limitations of Chapter 5. Most
of the subsections address attached parking struc-
tures and contain conditions by which these can be
attached to buildings without creating hardship in
regard to allowable area and height for the building.
These allowances are not always related to buildings
containing parking below but can involve other uses
and occupancies. Also many of these scenarios will
be applied such that there may be multiple buildings
above the parking garage.

510.2 Horizontal building separation allowance. A building
shall be considered as separate and distinct buildings for
the purpose of determining area limitations, continuity of fire
walls, limitation of number of stories and type of construction
where all of the following conditions are met:

1. The buildings are separated with a horizontal assembly
   having a fire-resistance rating of not less than 3 hours.

2. The building below the horizontal assembly is not
   greater than one story above grade plane.

3. The building below the horizontal assembly is of Type IA construction.

4. Shaft, stairwell, ramp and escalator enclosures through
   the horizontal assembly shall have not less than a 2-hour
   fire-resistance rating with opening protective in
   accordance with Section 716.5.

Exception: Where the enclosure walls below the
horizontal assembly have not less than a 3-hour fire-
resistance rating with opening protective in accord-
ance with Section 716.5, the enclosure walls
extending above the horizontal assembly shall be
permitted to have a 1-hour fire-resistance rating,
provided:

1. The building above the horizontal assembly is
   not required to be of Type I construction;

2. The enclosure connects fewer than four stories;

3. The enclosure opening protective above the
   horizontal assembly have a fire protection rat-
   ing of not less than 1 hour.

5. The building or buildings above the horizontal assembly
   shall be permitted to have multiple Group A occup-
   ancy uses, each with an occupant load of less 300, or
   Group B, M, R or S occupancies.

6. The building below the horizontal assembly shall be
   protected throughout by an approved automatic sprinkler system
   in accordance with Section 903.3.1.1, and
   shall be permitted to be any of the following occupancies:

   6.1. Group S-2 parking garage used for the parking
   and storage of private motor vehicles;

   6.2. Multiple Group A, each with an occupant load
   of less than 300;

   6.3. Group B;

   6.4. Group M;

   6.5. Group R; and

   6.6. Uses incidental to the operation of the building
   (including entry lobbies, mechanical rooms, storage areas and similar uses).

7. The maximum building height in feet (m) shall not
   exceed the limits set forth in Section 503 for the build-
   ing having the smaller allowable height as measured
   from the grade plane.

Section 510.2 essentially allows a 3-hour fire-resis-
tance-rated horizontal assembly to create separate
buildings similar to the concept used for fire walls
(see Figure 510.2), however consideration as sepa-
rated buildings by this method is only applicable to a
limited number of specified conditions. This allow-
ance provides an extensive benefit for height and
area in these structures. Buildings constructed under
this section are frequently referred to as "pedestal," "podium" or "platform" buildings. It should be noted
that multiple buildings may be located above the hori-
zontal assembly. Structures built under this section
are considered to be distinct buildings above and
below the 3-hour fire-resistance-rated horizontal
assembly. As distinct buildings, they are individually
evaluated with respect to allowable building area, the
number of stories and the type of construction. In
addition, if a fire wall is needed to address building
area issues in the upper building or buildings, the fire
wall construction can stop at the 3-hour fire-resis-
tance-rated horizontal assembly and does not need
to extend to the foundation. However, other building
systems and requirements must be evaluated using
the total structure. For example, if the upper building
is apartments and the lower building an open parking
garage, both buildings will need to be protected by an
automatic sprinkler system because of the require-
ment for buildings occupied by Group R occupancies
(see Section 903.2.8).

There are seven conditions that set the limits of this
design:

1. Separation of upper and lower buildings by a 3-
   hour fire-resistance-rated horizontal assembly.

2. The building area below the horizontal assem-
   bly is limited to having no more than one story
   above grade plane. There is no limit on the
   number of basement levels included below the
   single story above grade plane.

3. The building below the horizontal assembly is
   of Type IA construction. As such it is allowed to
   be of unlimited area in accordance with Table
   503.

4. All openings through the 3-hour fire-resistance-
   rated horizontal assembly are to be protected by
a 2-hour shaft (the shaft openings having 1½-hour protective screens; see Table 715.5).

5. The uses in the upper building or buildings are limited to Group A occupancy uses where each Group A area has an occupant load of less than 300, or Group B, M, R or S occupancies.

6. The building below is allowed to be used exclusively for any of the occupancies listed in Items 6.1 through 6.6 or any combination of those occupancies. While historic versions of Section 510.2 limited the use of the lower building to parking, the provision has evolved to reflect a mixed occupancy setting of urban neighborhoods. The limit of the 300 occupants in Group A occupancies is also reflective of the history of these provisions from the legacy codes, and it reflects the intent of restricting the assembly spaces to smaller businesses so that the assembly use does not dominate the building.

7. The height of the combined buildings above and below the horizontal assembly is limited to the number of feet above grade plane allowed by Section 503 for the type of construction of the upper building. However, the charging language of Section 510.2 does not restrict the number of stories to the entire structure but only to that which is above the horizontal assembly. Thus, a Type VA building, protected by a NFPA 13R sprinkler system and containing a Group R-2 occupancy, can have four stories above the horizontal assembly, provided the overall height of both buildings does not exceed 60 feet (18.288 mm) above grade plane.

This is one of the rare circumstances where there could be two different construction types in a single structure without being separated by a fire wall. It is possible that following the conventional provisions for mixed occupancies in Sections 508.3 and 508.4 would be less restrictive than the conditions of this section. Compliance with the general provisions of Section 508.3 or 508.4 is permissible, and this section should be viewed as an alternative means of compliance with Section 508.3 or 508.4.

There is one exception within the seven items: the exception to Item 4 indicates the conditions by which the shaft construction protecting openings in the horizontal separation may be 1-hour rated above the horizontal separation. This allowance is only for openings connecting a maximum four stories. This would include the connection to the area below the horizontal assembly (see Figure 510.2). A common example of a building constructed under the provisions of Section 510.2 is a Type IA building that contains parking at grade level and below, with up to four stories of Group R-2 apartments in a Type VA, wood frame constructed building above the separation (see Figure 510.2). In many city neighborhoods where zoning laws encourage a mixture of uses, the first story is often occupied with retail shops, service businesses, and small restaurants. The height of this structure measured in feet is limited by the Type VA upper structure to maximum of 70 feet (21.336 mm) above grade plane. But the number of stories of the Type VA portion of the building is determined by starting at the horizontal separation between the construction types.

510.3 Group S-2 enclosed parking garage with Group S-2 open parking garage above. A Group S-2 enclosed parking garage
garage with not more than one story above grade plane and located below a Group S-2 open parking garage shall be classified as a separate and distinct building for the purpose of determining the type of construction where all of the following conditions are met:

1. The allowable area of the building shall be such that the sum of the ratios of the actual area divided by the allowable area for each separate occupancy shall not exceed 1.

2. The Group S-2 enclosed parking garage is of Type I or II construction and is at least equal to the fire-resistance requirements of the Group S-2 open parking garage.

3. The height and the number of tiers of the Group S-2 open parking garage shall be limited as specified in Table 406.5.4.

4. The floor assembly separating the Group S-2 enclosed parking garage and Group S-2 open parking garage shall be protected as required for the floor assembly of the Group S-2 enclosed parking garage. Openings between the Group S-2 enclosed parking garage and Group S-2 open parking garage, except exit openings, shall not be required to be protected.

5. The Group S-2 enclosed parking garage is used exclusively for the parking or storage of private motor vehicles, but shall be permitted to contain an office, waiting room and toilet room having a total area of not more than 1,000 square feet (93 m²), and mechanical equipment rooms incidental to the operation of the building.

Parking garages of both types, enclosed and open, are addressed in Section 406. Special height and area allowances are given in Section 406.5.4 for open parking structures; however, these special height and area provisions are not applicable if any level of the parking garage does not meet the definition of “Open parking garage” by not having the requisite clear open area to the exterior. This would normally preclude having parking levels below grade in an open parking garage.

Section 509.3 contains provisions that would allow an open parking structure to take advantage of the special height and area limits for open parking structures in Section 406.5.4 while incorporating, in the same building, enclosed parking levels below grade. This is an alternative to treating the whole building as an enclosed parking garage.

There are five conditions listed that must be met in order to use this alternative:

1. Appropriate increases in accordance with Section 506 are to be considered for each portion, and for purposes of frontage increase the same measurement of open perimeter may apply to both the upper and lower garages.

2. The enclosed parking structure below must meet or exceed the fire resistance of the open-parking structure above. At a minimum, the enclosed parking structure must be of Type II-B construction (all noncombustible materials, without fire-resistance-rated protection); however, if the open parking structure above is Type VA, II-A, IIA or I-A, the enclosed parking structure would also have to meet or exceed the required ratings of the building elements from Table 601 for the construction type of the open parking structure.

3. Both the entire height of the building and the number of tiers are limited by Table 406.5.4; therefore, even if the first story above grade is part of the enclosed parking garage portion of the building, the height of the structure above grade plane could not exceed what would be permitted by Table 406.5.4 if the entire structure above grade plane were part of the open parking garage portion.

4. Protection of the floor assembly of the Group S-2 building depends on the construction type and Table 601 for the S-2 enclosed parking garage.

5. Certain accessory uses are permitted to be present when taking advantage of these alternative provisions, such as a small office and waiting area.

510.4 Parking beneath Group R. Where a maximum one story above grade plane Group S-2 parking garage, enclosed or open, or combination thereof, of Type I construction or open of Type IV construction, with grade entrance, is provided under a building of Group R, the number of stories to be used in determining the minimum type of construction shall be measured from the floor above such a parking area. The floor assembly between the parking garage and the Group R above shall comply with the type of construction required for the parking garage and shall also provide a fire-resistance rating not less than the mixed occupancy separation required in Section 508.4.

This section permits an extra story (above the limits of Table 503), based on construction type, for Group R buildings with parking on the first story (see Figure 510.4). There are several conditions that must be met: the parking must be limited to one story above grade; must be Type IV (if open) or I (open or enclosed) construction; the entrance to the garage must be at grade; and a 1-hour horizontal assembly must be provided between the parking and the Group R occupancy in accordance with Table 508.4. The limitation of Table 503 for height above grade plane (in feet) is not changed under this circumstance. It should be noted that all buildings containing Group R occupancies are required to be sprinklered in the code. Therefore, the separation required would only be 1 hour, but the parking area must also be sprinklered.

For instance, a fully sprinklered Group R-2 building of Type VB construction would normally be permitted to be three stories above grade (Table 503 limit of two stories plus the additional story increase for
sprinklers in Section 504.2). If it meets the conditions of this section for parking on the first story above grade, then it could actually be four stories above grade; however, the building height in feet cannot exceed 60 feet (18 288 mm) above grade plane in accordance with Table 503 for Type VB construction and Section 504.2, which allows a height increase for sprinklers. Figure 510.4 provides an example of a Group R-1 building over enclosed parking.

510.5 Group R-1 and R-2 buildings of Type IIIA construction. The height limitation for buildings of Type IIIA construction in Groups R-1 and R-2 shall be increased to six stories and 75 feet (22 860 mm) where the first floor assembly above the basement has a fire-resistance rating of not less than 3 hours and the floor area is subdivided by 2-hour fire-resistance-rated fire walls into areas of not more than 3,000 square feet (279 m²).

- This section contains special provisions for increasing the height of Type IIIA Group R-1 and R-2 buildings based upon increases in fire resistance and compartmentation. More specifically, the higher rating would apply to the floor structure of the first story above grade (3 hours), and the fire walls (2 hours) subdividing the building into floor areas of not more than 3,000 square feet (279 m²). The fire walls must extend from foundation to roof. In addition, the fire walls must comply with the requirements in Section 706.

It should be noted that this section is independent of the fire area requirements of Section 901.7 but such separations could certainly be considered as creating fire areas or separate buildings. In either case all buildings containing a Group R-1 or R-2 fire area would require sprinklers in accordance with Section 903.2.8.

This section constitutes a trade-off of building area for extra height, and depends on the materials and rating requirements for Type IIIA construction, as well as the extra fire resistance of the first story.

See Figure 510.5 for an example of a Type IIIA building height increase for a Group R-2 occupancy.

510.6 Group R-1 and R-2 buildings of Type IIA construction. The height limitation for buildings of Type IIA construction in Groups R-1 and R-2 shall be increased to nine stories and 100 feet (30 480 mm) where the building is separated by not less than 50 feet (15 240 mm) from any other building on the lot and from lot lines, the exits are segregated in an area enclosed by a 2-hour fire-resistance-rated fire wall and the first floor assembly has a fire-resistance rating of not less than 1 1/2 hours.

- This section contains special provisions for increasing the height of Type IIA, Group R-1 and R-2 buildings. The higher 1 1/2-hour rating would apply to the floor assembly of the first story above grade, and the exits are required to be enclosed with fire walls extending from foundation to roof, otherwise meeting all the requirements of Section 706. Such fire walls would create separate fire areas or buildings for the purposes of the application of the rest of the code.

A separation distance of at least 50 feet (15 240 mm) from other buildings on the same lot or property lines is also required to use this alternative. This section constitutes a trade-off of extra protection for exits for extra building height, and depends also on the materials and rating requirements for Type IIA construction, as well as the extra fire-resistance rating protecting the first story from the basement. The entire building must be sprinklered in accordance with Section 903.2.8. See Figure 510.6 for an example of a Type IIA building height increase for a Group R-1.
R-2 occupancy.

Note that such buildings will likely be considered high-rise buildings and, as such, also must comply with Section 403.

510.7 Open parking garage beneath Groups A, I, B, M and R. Open parking garages constructed under Groups A, I, B, M and R shall not exceed the height and area limitations permitted under Section 406.5. The height and area of the portion of the building above the open parking garage shall not exceed the limitations in Section 503 for the upper occupancy. The height, in both feet and stories, of the portion of the building above the open parking garage shall be measured from grade plane and shall include both the open parking garage and the portion of the building above the parking garage.

- This section addresses a special mixed use condition, and is another circumstance wherein a building can be designated with two different types of construction for determining height and area. This provision is only to be applied when an open parking structure (Group S-2) is to be constructed below a Group A, I, B, M or R occupancy (see Figure 510.7). If an open parking structure is located below any other occupancy group, Section 508 must be applied, as for any other mixed use condition. In accordance with Section 510.1, this section is an alternative to the

---

For SI: 1 foot = 304.8 mm, 1 square foot = 0.0929 mm².

Figure 510.5
EXAMPLE TYPE IIIA, GROUP R-2 HEIGHT INCREASE
general mixed occupancy provisions in Section 508 that can be applied where advantageous to the design of buildings with open parking on the lower levels.

In the application of Section 510.7, there are two criteria that must be met for code compliance (see Figure 510.7):

1. The height and area of the open parking structure comprising a part of a mixed-use group building must not exceed the limitations for open parking structures permitted in Section 406.5.4 and Table 406.5.4.

2. The allowable height of the occupancy located above the open parking structure is to be determined in accordance with Section 503 and Table 503. The height is the vertical distance (measured in feet and stories) from the grade plane to the top of the average height of the highest roof surface, in accordance with the definition of "Building height" in Section 502.1. Allowable heights and areas may be modified in accordance with Section 504 and 506.

510.7.1 Fire separation. Fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711 between the parking occupancy and the upper occupancy shall correspond to the required fire-resistance rating prescribed in Table 508.4 for the uses involved. The type of construction shall apply to each occupancy individually, except that structural members, including main bracing within the open parking structure, which is necessary to support the upper occupancy, shall be protected with the more restrictive fire-resistance-rated assemblies of the groups involved as shown in Table 601. Means of egress for the upper occupancy shall conform to Chapter 10 and shall be separated from the parking occupancy by fire barriers having not less than a 2-hour fire-resistance rating as required by Section 706 with self-closing...
doors complying with Section 716 or horizontal assemblies having not less than a 2-hour fire-resistance rating as required by Section 711, with self-closing doors complying with Section 716. Means of egress from the open parking garage shall comply with Section 406.3.

- This section contains additional conditions for the use of Section 510.7 as an alternative to the general mixed use provisions in Section 508. It contains an additional five criteria:

1. The open parking structure and occupancy located above must be separated, both horizontally and vertically if necessary, by fire separation assemblies having a fire-resistance rating corresponding to that specified in Table 508.4.

   **Example:** An open parking structure, Group S-2, is located below an office (Group B); therefore, based on Table 508.4, all vertical and horizontal assemblies separating the two groups are required to have a minimum fire-resistance rating of 2 hours in a non-sprinklered building and 1 hour in a sprinklered building.

2. The upper and lower portions of the building may be constructed of a separate type of construction (except as discussed in Item 5 below). The minimum type of construction for an open parking structure is Type IIB or IV, depending on the thresholds established in Table 406.5.4.

   **Example:** The open parking structure may be of Type IIB construction and the offices located above the open parking structure may be of Type IB construction.

3. Regardless of the construction types being used, all structural members, including main bracing in the open parking structure for the stability of the upper occupancy, must be rated in accordance with the most restrictive fire-resistance-rating requirement in accordance with Table 601, which would be that for Type IB construction.

   **Example:** Consider a building where the upper occupancy is of Type IB protected construction, and the open parking structure is of Type IIB unprotected construction. In accordance with Table 601, all load-bearing walls and structural frames, including columns and girders necessary to support the upper occupancy, must have at least a 2-hour fire-resistance rating, in accordance with the requirements of Type IB construction. This typically applies to the columns and bracing in the entire structure, beams supporting the floor separating the upper occupancy from the open parking structure and any transfer beams located in the open parking structure. The story of the open parking structure and any members supporting these stories, however, are permitted to have a zero fire-resistance rating in accordance with the requirements for Type IIB construction.

4. Means of egress facilities within and from the upper occupancy are to conform to Chapter 10. In addition, the egress facilities from the upper occupancy must be separated from the parking area by fire-resistance-rated wall assemblies of
at least 2 hours, by fire barriers meeting the requirements of Section 707 or horizontal assemblies meeting Section 711. These egress facilities are required to maintain the 2-hour protection for their full height and must be continuous to the level of exit discharge. The fire-resistance rating reduction of interior exit stairways for structures less than four stories in height (see Section 1022.2) is not applicable to an exit passing through the open parking structure in accordance with this section. Door openings to the interior exit stairway must have self-closing doors that comply with Section 716, with a fire protection rating of 1 1/2 hours in accordance with Table 716.5.

5. Means of egress facilities within and from the open parking structure are to conform to Section 406.5.7, which also references Chapter 10.

510.8 Group B or M with Group S-2 open parking garage.
Group B or M occupancies located not higher than the first story above grade plane shall be considered as a separate and distinct building for the purpose of determining the type of construction where all of the following conditions are met:

1. The buildings are separated with a horizontal assembly having a fire-resistance rating of not less than 2 hours.
2. The occupancies in the building below the horizontal assembly are limited to Groups B and M.
3. The occupancy above the horizontal assembly is limited to a Group S-2 open parking garage.
4. The building below the horizontal assembly is of Type I or II construction but not less than the type of construction required for the Group S-2 open parking garage above.
5. The height and area of the building below the horizontal assembly does not exceed the limits set forth in Section 503.
6. The height and area of the Group S-2 open parking garage does not exceed the limits set forth in Section 405.7. The height, in both feet and stories, of the Group S-2 open parking garage shall be measured from grade plane and shall include the building below the horizontal assembly.
7. Exits serving the Group S-2 open parking garage discharge directly to a street or public way and are separated from the building below the horizontal assembly by 2-hour fire barriers constructed in accordance with Section 707 or 2-hour horizontal assemblies constructed in accordance with Section 711, or both.

This section addresses the inverse of the other circumsTances in Section 510: the parking, which must be an open parking garage, is located above the other groups, in this case, Group B or M. This is a common type of construction in metropolitan areas. The parking garage is an open parking structure, with developers using the street level part of the building as an opportunity to provide retail space or other

commercial space in a downtown application. The conditions under which this configuration of parking garage and Group B or M uses is similar to conditions for other circumstances is found in Section 510.

More specifically there are seven criteria that must be met.

1. Similar to Item 1 of Section 510.2, a horizontal separation is required to essentially divide the buildings into separate buildings. Again it is like having a horizontal fire wall. The separation is only required to be 2 hours, which is less than the 3 hours required by Item 1 of Section 510.2.
2. The occupancies below the separation are limited to Groups B and M, which relates to the likely application of such configurations.
3. The occupancy above the horizontal assembly is limited to a Group S-2 open parking garage.
4. The building below is required to be of Type I or II construction but must always be at least that of the Group S-2 above.
5. The height and area of the Group S-2 occupancy shall not exceed that of Section 406.5. In addition the overall height (measured in both the number of stories and building height in feet) is further restricted by the fact that the occupancies below the horizontal assembly must be addressed.
6. The height and area of the Group S-2 occupancy shall not exceed that of Section 406.5. In addition the overall height (measured in both the number of stories and building height in feet) is further restricted by the fact that the occupancies below the horizontal assembly must be addressed.
7. Lastly, similar to Section 510.7.1, the exits from the Group S-2 must be protected within 2-hour fire barriers or horizontal assemblies and extend directly to a street or public way.

See Figure 510.8 for an application of this section.

510.9 Multiple buildings above a horizontal assembly.
Where two or more buildings are provided above the horizontal assembly separating a Group S-2 parking garage or building below from the buildings above in accordance with the special provisions in Sections 510.2, 510.3 or 510.8, the buildings above the horizontal assembly shall be regarded as separate and distinct buildings from each other and shall comply with all other provisions of this code as applicable to each separate and distinct building.

A very common practice when applying the alternatives such as those found in Sections 510.2 and 510.3 is to have multiple buildings above the horizontal assemblies. Specifically, the concept in Section 510.2 is often called a "pedestal" building. In other words, the building below and including the horizontal assembly creates a "pedestal" on top of which many
buildings, which are considered separate from one another, can be located. This section is simply clarifying that the multiple buildings located on top of the pedestal are considered separate from one another. This can be realized by there being multiple and distinct structures separated by yards or courts between different structures, or can be the result of the use of fire walls dividing a single structure into multiple buildings.

Just as distinct buildings sitting on the ground, multiple buildings above the horizontal assemblies can be of different construction types from the pedestal building and of different construction types from each other (see Figure 510.9). This allowance is also applicable where Section 510.8 is utilized.

**Bibliography**

The following resource materials are referenced in this chapter or are relevant to the subject matter addressed in this chapter.

GENERAL BUILDING HEIGHTS AND AREAS

Chapter 6: Types of Construction

General Comments

Chapter 6 contains the requirements to classify buildings into one of five types of construction. Tables 601 and 602 provide the minimum hourly fire-resistance ratings for the structural elements based on the type of construction of the building and fire separation distance. Section 602 describes each construction type in detail. Section 603 describes the permitted use of combustible materials in buildings of noncombustible construction.

Correct classification of a building by its type of construction is essential. Many code requirements applicable to a building, such as allowable height and area (see Chapter 5), are dependent on its type of construction. If a building is placed in an incorrect construction classification (for example, one that is overly restrictive), its owner may be penalized by increased construction costs. On the other hand, when a building is incorrectly classified in an overly lenient type of construction, it will not be constructed in a manner that takes into account the relative risks associated with its size or function. The provisions of this chapter, coupled with Chapters 3 and 5 and Tables 601 and 602, establish the basis for the "equivalent risk theory" on which the entire code is based.

Purpose

The purpose of classifying buildings or structures by their type of construction is to account for the response or participation that a building's structure will have in a fire condition originating within the building as a result of its occupancy or fuel load.

The code requires every building to be classified as one of five possible types of construction: Type I, II, III, IV or V. Each type of construction denotes the kinds of materials that are permitted to be used [i.e., noncombustible steel, concrete, masonry, combustible (wood, plastic) or heavy timber (HT)], and the minimum fire-resistance ratings that are associated with the structural elements in a building having that classification, i.e., 0, 1, 1 1/2, 2 or 3 hours. Type I and II construction consists of building elements that are noncombustible. Buildings of Type III construction have noncombustible exterior walls and combustible or noncombustible interior elements. Type IV construction identifies those structures with noncombustible exterior walls and heavy-timber interior elements. Type V buildings are permitted to have building elements that are either combustible or noncombustible, or a combination of both. Types I, II, III and V construction are further subdivided into two categories (IA and IB, IIA and IIB, IIIA and IIIB, VA and VB) that identify differences in the degree of fire-resistance required.

SECTION 601
GENERAL

601.1 Scope. The provisions of this chapter shall control the classification of buildings as to type of construction.

This section requires that all buildings be assigned a type of construction classification as indicated in the "General Comments" above.

TABLE 601. See page 6-2.

Table 601 has three components: the top rows list the five general types of construction and their subclasses; the left column lists the various building elements that are regulated by the table; and each cell in the table contains the minimum required fire-resistance rating, in hours, for the various elements based on the required type of construction of the building. "Building element" is defined in Section 202 as a fundamental component of building construction which needs to be constructed of the materials and having the fire-resistance rating specified in this chapter in order for a building to be classified in a type of construction. Notes a through g apply as specifically referenced in the table.

Types I, II, III and V construction are further subdivided into two categories (A and B). Type A and B construction are not defined in the code. The designations simply refer to the hourly fire-resistance rating required for the structural elements. A Type A designation will have a higher fire-resistance rating for the structural element than a Type B designation. In other than Type I construction, Types A and B are often referred to as protected and unprotected construction, respectively. Please note this terminology does not refer to whether or not the building is protected by an installed automatic sprinkler system.

The following describes the items in the left column of the table, titled "Building Element."

Row 1: Primary structural frame. This category includes the structural (load-bearing) components of the building frame. Definitions of "Primary structural frame" and "Secondary members" are found in Section 202. Any structural item that provides
direct connections to columns and bracing members that are designed to carry a gravity load is considered part of the structural frame. To delay vertical (i.e., gravity) load-carrying collapse of a building due to fire exposure for a theoretical amount of time, the components that make up the primary structural frame are required to maintain a minimum degree of fire resistance. The components defined as part of the primary structural frame, with the exception of Type IV construction, must also comply with Section 704. Secondary members (e.g., floor or roof panels without a connection to the column) are not considered part of the structural frame (see Rows 5 and 6 of the table).

Row 2: Bearing walls—exterior and interior. Exterior bearing walls are the outermost walls that enclose the structure and support any structural load other than their own weight. Their required fire-resistance rating is established by the higher of two fire-resistance ratings. The first component of determining the fire-resistance rating is based on the type of construction of the building (Table 601). The second component of determining the fire-resistance rating is based on the exterior wall’s fire separation distance (Table 602). Whichever of the two tables requires the higher fire-resistance rating will dictate the minimum required fire-resistance rating of the exterior wall.

In addition to Tables 601 and 602, exterior walls must comply with Section 705 and Chapter 14. In addition, Section 706.5.1 has fire-resistance-rating requirements for exterior walls on each side of the intersection of fire wall.

There are also several requirements related to exterior walls mentioned in Chapter 10. Section 1007.7 has fire-resistance-rating requirements for exterior walls adjacent to exterior areas for assisted rescue. Section 1022.7 has specific fire-resistance-rating requirements for exterior walls adjacent to an interior exit stairway. Section 1026.6 has fire-resistance-rating requirements for exterior walls adjacent to exterior exit stairways. Section 1027.4.2 has fire-resistance-rating requirements for exterior walls adjacent to an egress court.

Additionally, this category includes the structural (load-bearing) interior walls of a building. To delay vertical load-carrying collapse of a building due to fire exposure for a predetermined amount of time, the structural partitions are required to maintain a minimum degree of fire resistance. Primary structural frame elements supporting such walls must comply with Table 601, as well as have at least the same degree of fire resistance as the supported wall. See the commentary to Section 602.1 regarding opening and penetration protection of bearing walls.

*For SI: 1 foot = 304.8 mm.*

a. Roof supports: Fire-resistance ratings of primary structural frame and bearing walls are permitted to be reduced by 1 hour where supporting a roof only.
b. Except in Group F-1, H, M and S-1 occupancies, fire protection of structural members shall not be required, including protection of roof framing and decking where every part of the roof construction is 20 feet or more above any floor immediately below. Fire-retardant-treated wood members shall be allowed to be used for such unprotected members.
c. In all occupancies, heavy timber shall be allowed where a 1-hour or less fire-resistance rating is required.
d. An approved automatic sprinkler system in accordance with Section 903.3.1.1 shall be allowed to be substituted for 1-hour fire-resistance-rated construction, provided such system is not otherwise required by other provisions of the code or used for an allowable area increase in accordance with Section 506.3 or an allowable height increase in accordance with Section 504.2. The 1-hour substitution for the fire resistance of exterior walls shall not be permitted.
e. Not less than the fire-resistance rating required by other sections of this code.
f. Not less than the fire-resistance rating based on fire separation distance (see Table 603).
g. Not less than the fire-resistance rating as referenced in Section 704.10
Row 3: Nonbearing walls and partitions—exterior. This category includes all exterior walls that only support their own weight. The minimum required fire-resistance rating, unlike for load-bearing walls, is based solely on the exterior wall’s fire separation distance (Table 602). Where nonbearing exterior walls occur in buildings of Type I or II construction, the walls can be constructed of fire-retardant-treated wood (FRTW) if no rating is required (see Section 603.1).

Row 4: Nonbearing walls and partitions—interior. This category includes all interior nonload-bearing walls and partitions (for example, the common wall separating two offices in the same suite). These walls need only comply with all of the material requirements associated with their type of construction classification and are not required to have a fire-resistance rating. Where they occur in buildings of Type I or II construction and are to be constructed of wood, the wood must be fire-retardant treated as indicated in Section 603.1. Nonload-bearing interior walls may be required to be fire-resistance rated when they also serve another purpose. Examples include interior walls also serving to separate mixed occupancies, dwelling units, sleeping units, and incidental uses, as well as corridor walls required to have a fire-resistance rating.

Row 5: Floor construction and associated secondary members. Floor construction provides a natural fire compartment in a building by means of a horizontal barrier that retards the vertical passage of fire from floor to floor. In order to accomplish this, floor assemblies, including the beams and secondary structural members supporting the floor, must comply with Table 601 and Section 711. Ceilings are included if they are part of the tested assembly. A definition of “Secondary member” is provided in Section 202. Secondary members are not considered part of the primary structural frame.

Row 6: Roof construction and associated secondary members. Proper roof construction is necessary to prevent collapse from fire as well as potential impingement on adjacent buildings. Roof construction must comply with Table 601 and Section 711 (see the definition of “Secondary member” in Section 202). Additionally, when a portion of the roof construction is less than 20 feet (6096 mm) above the floor immediately below, the entire structural member must be protected to meet the minimum fire-resistance-rating requirements. In Figure 601(2), the roof construction is assumed to be comprised of one structural member. While a majority of the roof construction is greater than 20 feet (6096 mm) above the floor below, a portion of the roof construction is only 15 feet (4572 mm) above the mezzanine. As such, the entire length of the structural member, or in this case, the entire roof, must be rated for 1 hour. The fire-resistance rating is not permitted to terminate at the portion where the roof is 20 feet (6096 mm) above the floor below unless the structural member ends at that point. The fire-resistance rating of a column must also be continuous for the full height of the column and not reduced or eliminated at a height of 20 feet (6096 mm) and above (see Note b). It should be noted that those members of the roof construction that are considered as primary structural frame members are not regulated by Row 5, but rather by Row 1.

Note a permits the fire-resistance ratings of primary structural frame and interior load-bearing walls in buildings of Type IA and IB construction to be reduced by 1 hour if the members are supporting only the roof.

Note b applies to the construction of the roof and related secondary members in all types of construction. It allows these elements to be of unprotected construction when all parts of the roof construction are more than 20 feet (6096 mm) above any floor below. This allowance only applies to the secondary members of the roof structure and not to primary structural frame located within the roof or at the roof level (see Figure 601(1)). This alternative is applicable for all occupancy classifications except Groups F-1, H, M, and S-1. Figure 601(2) shows an example where a mezzanine reduces the clearance to the roof to less than 20 feet (6096 mm) for a portion of the total roof. Designs similar to Figure 601(2) do not comply with note b, and elimination of fire resistance is not allowed for any of the roof.

In buildings of Type I and II construction, fire-retardant-treated wood (FRTW) may be utilized for unprotected roof members. Please note that FRTW is not required in the roof of buildings of Type IIIA or VA construction since combustible materials are already permitted by Sections 602.3 and 602.5, respectively.

Note c permits heavy timber (HT) construction to be utilized in the roof construction as an alternative to having a fire-resistance rating of 1 hour or less. Note that HT cannot be used in Type IA construction since the roof is required to have a rating greater than 1 hour (i.e., 1 1/2). The intent of the note is to allow the substitution of HT for 1-hour construction in roof construction; it is not intended to say that HT is 1-hour rated construction.

Note d permits buildings of Type II A, III A and VA construction to use an automatic sprinkler system in compliance with NFPA 13 as an alternative to 1-hour fire-resistance-rated construction. In order to utilize the substitution, the sprinkler system must not be required for any other reason, including for increases in allowable height and area or where it is required by Section 903 based on the occupancy of a building. The sprinkler system may not be used as an alternative to the fire-resistance rating for exterior walls. This means that this exception is applicable in very limited circumstances.
Note e is applicable only to interior nonload-bearing walls. While nonbearing interior walls are not required to have a rating in accordance with Table 601, other sections of the code may require a rating (e.g., corridor walls, dwelling unit separation, sleeping unit separation). If other sections of the code require a rating, this would override the requirements of Table 601 stating no rating is required. In addition, interior non-bearing walls in buildings of Type IV (Heavy Timber, HT) construction shall be of solid wood construction formed by not less than two layers of 1-inch (25 mm) matched boards or laminated construction 4 inches (102 mm) thick, or of 1-hour-rated construction (see Section 602.4.6).

Note f is a reminder that exterior load-bearing walls must also comply with the fire-resistance rating listed in Table 602 based on the fire separation distance. Exterior load-bearing walls must satisfy the higher of the two fire-resistance ratings required by these two tables.

Note g is a reminder of the provisions of Section 704.10 that load-bearing structural members located within the exterior walls or "outside" of the structure need to comply with the highest of three fire-resistance ratings: the requirement for the primary structural frame; the requirement for exterior bearing walls; and the requirement from Table 602 based on the fire separation distance of the exterior wall. In Type III
and IV construction, the rating for an exterior load-bearing wall is higher than that required for a primary structural frame alone.

**TABLE 602.** See below.

Table 602 establishes the minimum fire-resistance ratings for both load-bearing and nonload-bearing exterior walls based on fire separation distance as defined in Section 202. The required ratings are based on the fuel load, probable fire intensity of the various occupancy classifications and the physical separation between the exterior wall and the line used to determine fire separation distance as established in Section 202 [see Figure 602(1)]. In using the table, the occupancy classification of the building and the fire separation distance of the walls must be determined. Once determined, the required fire-resistance rating is obtained by referring to the appropriate row and column corresponding to these parameters.

Please note that where there is more than one building on a lot, an imaginary lot line must be assumed between the buildings in accordance with Section 705.3. Figure 602(1) shows an assumed line halfway between the two buildings. The imaginary lot line can be at any location between the structures. Wherever the line is established, fire separation distance for each wall must be measured from the line, and wall and opening protection based on the distance to the assumed location.

Note a indicates that the fire-resistance-rating requirements of Table 601, which are based on construction type, also apply. Exterior load-bearing walls must conform to the higher of the fire-resistance ratings specified in Tables 601 and 602. Exterior non-load-bearing walls need only comply with Table 602.

Note b refers to private garages and carpors that are no greater than 3,000 square feet (279 m²) in area. Where the fire separation distance is at least 5 feet (1524 mm), no fire-resistance rating would be required for the exterior walls. This footnote does not apply to those Group U occupancies not used for the storage of motor vehicles. Other Group U occupancies would have a minimum 1-hour fire-resistance rating for a fire separation distance of less than 10 feet (3048 mm).

Note c requires walls that are located on lot lines between adjacent buildings (i.e., zero fire separation distance) to be constructed as fire walls and be rated in accordance with Table 706.4.

Note d permits the exterior walls of an open parking garage to have no fire-resistance rating where the fire separation distance is at least 10 feet (3048 mm). Where the parking garage is adjacent to a covered mall building, the exception to Section 402.7.1 indicates that where the garage is more than 10 feet (3048 mm) from a covered mall building, Table 602 is to be used rather than the 2-hour fire-resistance rating. At a distance of 10 feet (3048 mm), the fire separation distance would be between 5 feet (1524 mm) and 10 feet (3048 mm). Table 705.8 allows the openings to be unlimited for open parking garages at 10 feet (3048 mm) of fire separation distance. If the amount of openings is no longer limited, then the entire wall could be removed.

Note e clarifies that the required minimum fire-resistance rating of each exterior wall in each story of a building must be determined separately. Should a multistory building be configured such that the fire separation distance of each story is different, the required fire-resistance ratings associated with each of the exterior walls in each of those stories is established separately [see Figure 602(2)].

Note f provides a reference for Group H occupancies to Section 415.3 where there are specific standards for fire separation distances and wall and opening protection which supersede those of Table 602.

Note g provides a reference to Section 412.4.1 reg-

For SI: 1 foot = 304.8 mm.

a. Load-bearing exterior walls shall also comply with the fire-resistance rating requirements of Table 601.

b. For special requirements for Group U occupancies, see Section 406.3.

c. See Section 706.1.1 for party walls.

d. Open parking garages complying with Section 406 shall not be required to have a fire-resistance rating.

e. The fire-resistance rating of an exterior wall is determined based upon the fire separation distance of the exterior wall and the story in which the wall is located.

f. For special requirements for Group H occupancies, see Section 415.5.

g. For special requirements for Group S aircraft hangars, see Section 412.4.1.

h. Where Table 705.8 permits non-bearing exterior walls with unlimited area of unprotected openings, the required fire-resistance rating for the exterior walls is 0 hours.

2012 INTERNATIONAL BUILDING CODE® COMMENTARY 6-5
ulating aircraft hangars where there are specific standards for fire separation distances which supersede Table 602.

Note h allows for an elimination of the required wall rating for those nonbearing exterior walls that are permitted to have unlimited unprotected openings by Table 705.8. If a nonbearing exterior wall is permitted to be entirely open, there is no validity in requiring those portions of the wall that are not openings to be fire-resistance rated. The note only affects the required rating of nonbearing exterior walls of sprinklered buildings of Type IIB and VB construction, and only where such walls have a fire separation distance of at least 20 feet (6096 mm) but less than 30 feet (9144 mm). It is also not applicable to Group H-1, H-2 and H-3 occupancies.

* FIRE SEPARATION DISTANCE

For SI: 1 foot = 304.8 mm.

Figure 602(1)
DETERMINING FIRE SEPARATION DISTANCE

Figure 602(2)
DETERMINING FIRE SEPARATION DISTANCE FOR MULTISTORY BUILDINGS
SECTION 602
CONSTRUCTION CLASSIFICATION

602.1 General. Buildings and structures erected or to be erected, altered or extended in height or area shall be classified in one of the five construction types defined in Sections 602.2 through 602.5. The building elements shall have a fire-resistance rating not less than that specified in Table 601 and exterior walls shall have a fire-resistance rating not less than that specified in Table 602. Where required to have a fire-resistance rating by Table 601, building elements shall comply with the applicable provisions of Section 703.2. The protection of openings, ducts and air transfer openings in building elements shall not be required unless required by other provisions of this code.

This section requires that each building or structure be put into one of five possible construction classifications: Type I, II, III, IV or V. All structural members are required to have a fire-resistance rating in accordance with Table 601. Additionally, the exterior walls of the structure must satisfy the requirements in Table 602, which bases the fire-resistance rating on the fire separation distance.

The use of multiple construction classifications in a single building is very limited and can only be done when specifically called out in the code. An example of combining types of construction is an office building of Type II A construction located above an open parking structure of Type IIB construction, as described in Sections 510.7 and 510.7.1. Several other special provisions found in Section 510 also permit a building of multiple construction classifications.

A more common example is where a single structure is divided into two compartments by using a fire wall, resulting in two separate buildings or structures—each of which may be of a different type of construction. While a structure may contain more than one building (for example, separation by a fire wall), each building is to be individually assigned a type of construction.

Also, a building may have elements that comply with the requirements of more than one type of construction, in which case the building as a whole must be assigned the less restrictive type of construction. The designer may have intended, however, to comply with a higher type of construction, in which case those elements not in compliance with the intended type of construction are to be brought into compliance. The selection of a construction type is the prerogative of the permit applicant. The applicant should have the designer indicate on the submitted construction documents which construction type has been selected. This will expedite the compliance review by the plans examiner.

Section 602.1 applies to both new construction and additions. The provisions in Chapter 34 on existing structures, Section 503 on general height and area limitations, Chapter 7 on fire and smoke protection features and construction, and other applicable portions of the code depend on the requirements of this section. Where Table 601 requires a building element to meet a fire-resistance rating, that rating is determined based on the criteria in Section 703. Building elements required to have a fire-resistance rating by Table 601 do not necessarily need opening protectives or dampers for penetrations through these elements. Opening protectives or dampers are only required for building elements listed in Table 601 that are also a specific type of wall or horizontal assembly that is required by other criteria in the code to have protected openings.

Where Table 601 requires a building element to meet a fire-resistance rating, that rating is determined based on the criteria in Section 703. Although a building element is required to have fire resistance by Table 601 this does not mean that the required openings in these building elements or duct penetrations through these elements have to be protected. However, a building element listed in Table 601 may also be a specific type of wall or horizontal assembly that is required by other criteria in the code to have protected openings. For example, an interior bearing wall inside a Type II A building is required to have a fire-resistance rating of not less than 1 hour. However, the openings in that wall need not be protected unless that bearing wall is also serving another purpose. This wall could also be part of the walls establishing a control area on the second story. In accordance with Section 414.2.2, such wall would also have to be a 1-hour-rated fire barrier, and in accordance with Table 716.5, openings in this 1-hour-rated fire barrier would need to have 45-minute-rated opening protection. It is essential to check the provisions of Chapter 7 to determine where building elements are required, or not required, to have protected openings, transfer openings, ducts, joints and other penetrations.

602.1.1 Minimum requirements. A building or portion thereof shall not be required to conform to the details of a type of construction higher than that type which meets the minimum requirements based on occupancy even though certain features of such a building actually conform to a higher type of construction.

These requirements permit design flexibility by allowing various building materials and components to be used. A building must, as a minimum, meet all of the requirements of a given type of construction to be classified as such, even though portions of that building meet the criteria of a higher construction type (i.e., greater fire-resistance ratings). This is consistent with the concept that the code is a minimum requirement. For example, a building classified as Type III construction is not prohibited from having construction that is superior, but it could not be reclassified into a higher type of construction unless it met all of the requirements for that construction type. In a normal situation, the design professional has identified the construction classification on the draw-
ings. When this assignment has not been made, the building official is placed in a position of verifying the designer's intent and selecting the least-restrictive type that will meet all of the code requirements.

602.2 Types I and II. Types I and II construction are those types of construction in which the building elements listed in Table 601 are of noncombustible materials, except as permitted in Section 603 and elsewhere in this code.

- Buildings of Type I and II construction are required to be constructed of noncombustible materials (see Section 703.5) and, therefore, are frequently referred to as "noncombustible construction." All Type I and II structural members have a fire-resistance rating as required by Table 601 and 602. A typical example of a building of Type IA, IB or IIA construction would be a high-rise structure or a very large low-rise structure. These buildings are permitted to be relatively large in height and area due to the fire resistance afforded the structure's components. The structural members of a building of Type IIB construction do not have the same fire resistance as structural members in a building of Type IA, IB or IIA construction. As such, the height and area requirements are not as large for Type IIB construction (see Figure 602.2 for an example of Type I or II construction).

Types I and II construction are divided into four subclassifications: Types IA, IB, IIA and IIB. The only difference among the four subclassifications is the degree of fire-resistance rating required for similar elements and assemblies. For example, the required rating for structural frame members in Type IA construction is 3 hours, for Type IB it is 2 hours, for Type IIA it is 1 hour and for Type IIB it is 0 hours. Often, the fire-resistance ratings required by Tables 601 and 602 for structural elements are achieved by "fireproofing" structural members. Fireproofing is typically the process of creating a fire-resistance-rated assembly that incorporates the structural member by encapsulating it, either by boxing it in or by spraying on a coating to achieve the required fire-resistance rating. It should be noted that when a protective covering is used to provide the fire-resistance rating, it must be of noncombustible material, except as indicated in Section 603.1, Item 21.

Fire-retardant-treated wood (FRTW), although combustible, is permitted in limited uses in buildings of Type I and II construction (see Section 603 and Table 601, Note b). While FRTW is permitted in certain applications in buildings of Type I and II construction, it is not assumed to be fire-resistance rated, and generally does not afford any higher fire-resistance rating than untreated wood material. Other combustible items (as specified in Section 603.1) are also permitted in buildings of Type I or II construction.

602.3 Type III. Type III construction is that type of construction in which the exterior walls are of noncombustible materials and the interior building elements are of any material permitted by this code. Fire-retardant-treated wood framing complying with Section 2303.2 shall be permitted within exterior wall assemblies of a 2-hour rating or less.

- Buildings of Type III construction are typically constructed with both combustible and noncombustible materials. The exterior walls are required to be noncombustible with load-bearing exterior walls required to have a minimum 2-hour fire-resistance rating. Exterior nonloadbearing walls are not required by Table 601 to have a fire-resistance rating, but must comply with the provisions of Table 602. The ele-

![Figure 602.2](https://example.com/figure6022.png)

**Figure 602.2**

**EXAMPLES OF TYPE I AND II CONSTRUCTION**
ments within the perimeter established by the exterior walls (i.e., floors, roofs and walls) are permitted to be of combustible materials. An example of a typical building of Type III construction is a structure having its exterior walls constructed of concrete, masonry or other approved noncombustible materials, but with a wood frame floor, interior wall and roof construction. The structural members of a building of Type IIIIB construction are not required to have a fire-resistance rating with the exception of the exterior load-bearing walls.

Although fire-retardant-treated wood (FRTW) does not meet the specifications of the code as a noncombustible material, it is permitted as a substitute for noncombustible materials for framing within exterior wall assemblies of Type III construction. The exterior surfaces of the walls must be of noncombustible materials. While the exterior walls are permitted to be either nonload-bearing or load-bearing, to apply the allowance for FRTW the required fire-resistance rating of the exterior wall must be no greater than 2 hours. FRTW is required to comply with the provisions in Section 2303.2.

![Diagram of Type III Construction](image)

**Figure 602.3**

**EXAMPLE OF TYPE III CONSTRUCTION**

**602.4 Type IV.** Type IV construction (Heavy Timber, HT) is that type of construction in which the exterior walls are of noncombustible materials and the interior building elements are of solid or laminated wood without concealed spaces. The details of Type IV construction shall comply with the provisions of this section. Fire-retardant-treated wood framing complying with Section 2303.2 shall be permitted within exterior wall assemblies with a 2-hour rating or less. Minimum solid sawn nominal dimensions are required for structures built using Type IV construction (HT). For glued-laminated members the equivalent net finished width and depths corresponding to the minimum nominal width and depths of solid sawn lumber are required as specified in Table 602.4.

- This section provides the general regulations for Type IV (Heavy Timber, HT) construction. HT construction requires the exterior walls to be constructed of noncombustible materials. The interior elements are required to be constructed of solid or laminated wood without any concealed spaces. All of the combustible structural elements are permitted to be unprotected because of the massive element sizes and the requirement that there not be any concealed spaces, such as soffits, plenums or suspended ceilings. Sections 602.4.1 through 602.4.7 provide specific requirements for the connection of structural members and minimum dimensions. An examination of Table 603 indicates that the allowable height and area for Type IV construction is greater than that permitted for buildings of Type IIIB construction. This distinction is based on testing that demonstrated that HT structural members perform better structurally under fire conditions than comparable unprotected steel structural members because of charring, which insulates the wood mass.

As with Type III construction, fire-retardant-treated wood (FRTW) is permitted as a substitute for noncombustible materials within exterior wall assemblies of Type IV construction. Except as noted in Section 602.4.7, exterior structural members used externally must be noncombustible.

While the exterior walls are permitted to be either nonload-bearing or load-bearing, to apply the allowance for FRTW the required fire-resistance rating of the exterior wall must be no greater than 2 hours. FRTW is required to comply with the provisions of Section 2303.2.

For SI: 1 inch = 25.4 mm.

- Solid sawn wood members and glued-laminated timbers are manufactured using different methods and procedures and, therefore, do not have the same dimensions. However, they both have the same inherent fire-resistance capability. The dimensions noted in Sections 602.4.1 through 602.4.7 refer to the nominal dimensions of solid sawn lumber. These dimensions do not directly correlate to the actual dimensions of glued-laminated timbers. Table 602.4 provides a simple procedure to determine the dimen-
sions that are required for glued-laminated timbers when designing to meet the requirements of Type IV construction. The table provides minimum dimensions for glued-laminated wood members for each set of dimensions specified in the specific provisions of Section 602.4. The requirements for glued-laminated members were developed to recognize that the reduced width of glued-laminated members (compared to timbers with the same nominal dimension) shall be offset by increasing the depth to maintain similar cross-sectional areas. To use the table, compare the required minimum dimensions for sawn timber found in the two left-hand columns with the dimensions found in the two right-hand columns for glued-laminated wood members. For example, where the code requires a minimum sawn timber of 8 inches by 8 inches (203 mm by 203 mm), for a glued-laminated wood member to be used, it would need to be a minimum of 6 3/4 inches wide by 8 3/4 inches (171 mm by 210 mm) deep.

602.4.1 Columns. Wood columns shall be sawn or glued laminated and shall be not less than 8 inches (203 mm), nominal, in any dimension where supporting floor loads and not less than 6 inches (152 mm) nominal in width and not less than 8 inches (203 mm) nominal in depth where supporting roof and ceiling loads only. Columns shall be continuous or superimposed and connected in an approved manner.

- Minimum construction requirements and dimensions for timber columns are provided in this section. Columns are required to be a minimum of 8 inches (203 mm) nominal in any dimension if they support floor loads, or a minimum of 6 by 8 inches (152 by 203 mm) nominal if they support no more than a roof and ceiling. Timber columns are required to be continuous or superimposed, positioned on or over each other, through floors for the entire height of the building. The design engineer or architect must provide details of all column connections. As with all structural members, each column must also be adequately fastened to other structural members in order to withstand the loads that will be placed upon the column. Some typical examples include reinforced concrete or metal caps, steel or iron column caps and timber splice plates [see Figures 602.4.1(1) and 602.4.1(2)].

602.4.2 Floor framing. Wood beams and girders shall be of sawn or glued-laminated timber and shall be not less than 6 inches (152 mm) nominal in width and not less than 10 inches (254 mm) nominal in depth. Framed sawn or glued-laminated timber arches, which spring from the floor line and support floor loads, shall be not less than 8 inches (203 mm) nominal in any dimension. Framed timber trusses supporting floor loads shall have members of not less than 8 inches (203 mm) nominal in any dimension.

- Minimum construction requirements and dimensions for floor framing are provided in this section. Girders are the principal horizontal structural members that support columns or beams. Beams are the structural members that support a floor or roof. Both girders
and beams are required to be a minimum 6 inches (152 mm) wide and 10 inches (254 mm) deep. Both framed timber trusses supporting floor loads and framed sawn or glued-laminated timber arches that spring from the floor line and support floor loads are required to be at least 8 inches (203 mm) in any dimension.

602.4.3 Roof framing. Wood-frame or glued-laminated arches for roof construction, which spring from the floor line or from grade and do not support floor loads, shall have members not less than 6 inches (152 mm) nominal in width and have not less than 8 inches (203 mm) nominal in depth for the lower half of the height and not less than 6 inches (152 mm) nominal in depth for the upper half. Framed or glued-laminated arches for roof construction that spring from the top of walls or wall abutments, framed timber trusses and other roof framing, which do not support floor loads, shall have members not less than 4 inches (102 mm) nominal in width and not less than 6 inches (152 mm) nominal in depth. Spaced members shall be permitted to be composed of two or more pieces not less than 3 inches (76 mm) nominal in thickness where blocked solidly throughout their intervening spaces or where spaces are tightly closed by a continuous wood cover plate of not less than 2 inches (51 mm) nominal in thickness secured to the underside of the members. Splice plates shall be not less than 3 inches (76 mm) nominal in thickness.

Where protected by approved automatic sprinklers under the roof deck, framing members shall be not less than 3 inches (76 mm) nominal in width.

• Minimum construction requirements and dimensions for arches and other types of roof framing are provided in this section. Other types of roof framing included in this section are heavy timber trusses with spaced members. When the members of a heavy timber truss are split and placed on either side of a main member, such as a web connecting a chord, each component of the web must be 3 inches (76 mm) or more in nominal thickness. The space between the two web members must be protected with a 2-inch-thick (51 mm) cover plate [see Figure 602.4.3(1)], or solidly filled with blocking [see Figure 602.4.3(2)]. The size of the roof framing members is dependent on the configuration used and is regulated by this section.

If a building of Type IV construction is equipped with approved automatic sprinklers under the roof deck, the minimum required size of the roof framing members is reduced to 3 inches (76 mm). Roof framing members of a smaller size will have a lower resistance to fire than the 6-inch by 8-inch (152 mm by 203 mm) or 4-inch by 6-inch (102 mm by 152 mm) members required by this section where a sprinkler...
system is not present. However, the trade-off allowing smaller roof framing members when the building is equipped with an automatic sprinkler system is consistent with the concept of maintaining "equivalent risk" for the building.

602.4.4 Floors. Floors shall be without concealed spaces. Wood floors shall be of sawn or glued-laminated planks, splined or tongue-and-groove, of not less than 3 inches (76 mm) nominal in thickness covered with 1-inch (25 mm) nominal dimension tongue-and-groove flooring, laid crosswise or diagonally, or 0.5-inch (12.7 mm) particleboard or planks not less than 4 inches (102 mm) nominal in width set on edge close together and well spiked and covered with 1-inch (25 mm) nominal dimension flooring or 13/32-inch (12 mm) wood structural panel or 0.5-inch (12.7 mm) particleboard. The lumber shall be laid so that no continuous line of joints will occur except at points of support. Floors shall not extend closer than 0.5-inch (12.7 mm) to walls. Such 0.5-inch (12.7 mm) space shall be covered by a molding fastened to the wall and so arranged that it will not obstruct the swelling or shrinkage movements of the floor. Corbeling of masonry walls under the floor shall be permitted to be used in place of molding.

Heavy timber (HT) flooring is required to consist of minimum 3-inch-thick (76 mm) sawn or glued-laminated planks, splined floors or tongue-and-groove floors with an overlayment of 1-inch (25 mm) tongue-and-groove flooring, laid crosswise or diagonally. HT flooring may also consist of 1/2-inch (12.7 mm) particleboard or planks at least 4 inches (102 mm) in width set on edge and secured together, with an appropriate overlayment, such as 1-inch (25 mm) hardwood flooring or a 13/32-inch (12.7 mm) wood structural panel. Flooring in Type IV construction is

---

**Figure 602.4.3(1)**
SPACED MEMBERS WITH COVER PLATE

---

**Figure 602.4.3(2)**
SOLID BLOCKING OF SPACED MEMBERS
not permitted to have concealed spaces because an undetected fire can spread quickly in combustible concealed floor spaces [see Figure 602.4.4(1)]. Because of the support afforded by adjacent members, continuous joints must only occur over supports.

Wood flooring must be fastened to supports that are perpendicular to the planking. Fastening must not be made to beams or girders that are parallel to the planks [see Figure 602.4.4(2)]. This precaution is intended to prevent separation of the planks because of differential movement of the beam relative to the girders and possible expansion/contraction due to differing moisture or humidity levels. This section requires a minimum 1/4-inch (12.7 mm) clearance between the wood flooring and exterior walls. This will prevent damage to the walls if the flooring expands or moves due to factors such as use and natural forces. It should be emphasized that the integrity of the floor assembly must be maintained to provide the equivalent of a 1-hour fire-resistance rating. In addition, the 1/4-inch (12.7 mm) gap must be protected by a molding connected to the wall so that any possible contracting or expanding of the floor is not impeded. If masonry walls are utilized, corbeling of the masonry may be used as an alternate to the molding requirements.

For SI: 1 inch = 25.4 mm.

Figure 602.4.4(1)
CONCEALED SPACES
602.4.5 Roofs. Roofs shall be without concealed spaces and wood roof decks shall be sawn or glued laminated, splined or tongue-and-groove plank, not less than 2 inches (51 mm) nominal in thickness, $1\frac{1}{4}$-inch-thick (32 mm) wood structural panel (exterior glue), or of planks not less than 3 inches (76 mm) nominal in width, set on edge close together and laid as required for floors. Other types of decking shall be permitted to be used if providing equivalent fire resistance and structural properties.

- Minimum construction requirements and dimensions for roof decks are provided in this section. As required for floors, roofs are not permitted to have concealed spaces [see Figure 602.4.4(1)]. If the materials used in roof construction are different from those described in this section, the roof must have a minimum 1-hour fire-resistance rating and be of the same structural properties.

602.4.6 Partitions. Partitions shall be of solid wood construction formed by not less than two layers of 1-inch (25 mm) matched boards or laminated construction 4 inches (102 mm) thick, or of 1-hour fire-resistance-rated construction.

- Minimum construction requirements and dimensions for partitions in Type IV construction are provided in this section. Partitions must either be formed by not less than two layers of 1-inch (25 mm) matched boards or laminated construction 4 inches (102 mm) thick if the are constructed of solid wood. Partitions are permitted to be constructed of materials other than solid wood if they have at least a 1-hour fire-resistance rating. An example of the use of alternative materials is when a fire-resistance rating for a corridor wall is required. It is common practice to utilize a 1-hour fire-resistance-rated stud and gypsum wallboard assembly between the exposed columns to form the walls of the corridor.

602.4.7 Exterior structural members. Where a horizontal separation of 20 feet (6096 mm) or more is provided, wood columns and arches conforming to heavy timber sizes shall be permitted to be used externally.

- Heavy timber columns and arches that conform to minimum dimensional requirements may be used on the exterior if a fire separation distance of at least 20 feet (6096 mm) is maintained, although the exterior wall itself must be of noncombustible construction. If a fire separation distance of at least 20 feet (6096 mm) is maintained, the risk of exposure of the wood members to fire from an adjacent building is reduced, and the HT columns and arches are permitted to be exposed to the exterior.

If a building of Type IV construction has a fire separation distance of less than 20 feet (6096 mm), the wood columns and arches are to be located on the interior side of the exterior wall. The noncombustible construction of the exterior wall will provide some degree of protection to the interior timber members; therefore, placing the wood structural members inside an exterior wall is preferable to placing them within 20 feet (6096 mm) of a lot line or adjacent building with no exposure protection.

602.5 Type V. Type V construction is that type of construction in which the structural elements, exterior walls and interior walls are of any materials permitted by this code.

- Type V construction allows the use of all types of materials, both noncombustible and combustible, but Type V buildings are most commonly constructed of dimensional lumber (see Figure 602.5 for an example of Type V construction). It is divided into two sub classifications: Types VA and VB. An example of a typical building of Type VA construction is a wood frame building in which the interior and exterior load-bearing
walls, floors, roofs and all structural members are protected to provide a minimum 1-hour fire-resistance rating. Type V construction is required to comply with Table 601 and Chapter 23.

![Diagram of Type V Construction](Figure 602.5)

**EXAMPLE OF TYPE V CONSTRUCTION**

### SECTION 603

**CONSTRUCTIBLE MATERIAL IN TYPE I AND II CONSTRUCTION**

603.1 Allowable materials. Combustible materials shall be permitted in buildings of Type I or II construction in the following applications and in accordance with Sections 603.1.1 through 603.1.3:

1. *Fire-retardant-treated wood* shall be permitted in:
   1.1. Nonbearing partitions where the required fire-resistance rating is 2 hours or less.
   1.2. Nonbearing *exterior walls* where fire-resistance rated construction is not required.
   1.3. Roof construction, including girders, trusses, framing and decking.

   **Exception:** In buildings of Type 1A construction exceeding two stories above grade plane, *fire-retardant-treated wood* is not permitted in roof construction where the vertical distance from the upper floor to the roof is less than 20 feet (6096 mm).

2. Thermal and acoustical insulation, other than foam plastics, having a *flame spread index* of not more than 25.

   **Exceptions:**
   1. Insulation placed between two layers of non-combustible materials without an intervening airspace shall be allowed to have a *flame spread index* of not more than 100.

2. Insulation installed between a finished floor and solid decking without intervening airspace shall be allowed to have a *flame spread index* of not more than 200.

3. Foam plastics in accordance with Chapter 26.

4. Roof coverings that have an A, B or C classification.

5. *Interior floor finish* and floor covering materials installed in accordance with Section 804.

6. Millwork such as doors, door frames, window sashes and frames.

7. *Interior wall and ceiling finishes* installed in accordance with Sections 801 and 803.

8. *Trim* installed in accordance with Section 806.

9. Where not installed greater than 15 feet (4572 mm) above grade, show windows, nailing or furring strips and wooden bulkheads below show windows, including their frames, aprons and show cases.

10. Finish flooring installed in accordance with Section 805.

11. Partitions dividing portions of stores, offices or similar places occupied by one tenant only and that do not establish a corridor serving an occupant load of 30 or more shall be permitted to be constructed of *fire-retardant-treated wood*, 1-hour fire-resistance-rated construction or of wood panels or similar light construction up to 6 feet (1829 mm) in height.

12. Stages and platforms constructed in accordance with Sections 410.3 and 410.4, respectively.

13. Combustible *exterior wall coverings*, balconies and similar projections and bay or oriel windows in accordance with Chapter 14.

14. Blocking such as for handrails, millwork, cabinets and window and door frames.

16. Mastics and caulking materials applied to provide flexible seals between components of *exterior wall* construction.

17. Exterior plastic veneer installed in accordance with Section 2605.2.

18. Nailing or furring strips as permitted by Section 803.4.

19. Heavy timber as permitted by Note c to Table 601 and Sections 602.4.7 and 1406.3.

20. Aggregates, component materials and admixtures as permitted by Section 703.2.2.

21. Sprayed fire-resistant materials and intumescent and mastic fire-resistant coatings, determined
on the basis of fire-resistance tests in accordance with Section 703.2 and installed in accordance with Sections 1705.13 and 1705.14, respectively.

22. Materials used to protect penetrations in fire-resistance-rated assemblies in accordance with Section 714.

23. Materials used to protect joints in fire-resistance-rated assemblies in accordance with Section 715.

24. Materials allowed in the concealed spaces of buildings of Types I and II construction in accordance with Section 718.5.

25. Materials exposed within plenums complying with Section 602 of the International Mechanical Code.

Section 603.1 provides a listing of circumstances where combustible materials can be used in buildings of Type I and II construction, which are otherwise required to be constructed of noncombustible materials. The list of 25 items frequently references the code user to other sections of the code where specific allowances are found. Most of these listed items, while of combustible materials, are either of minor quantities in the overall building or are of materials with fire-resistive properties.

Treated wood: Fire-retardant-treated wood (FRTW) does not meet the criteria in the code for a noncombustible material. It is, however, permitted as an alternative to noncombustible materials in specific locations in Type I and II construction (see Items 1, 11, and 13). For example, the use of FRTW in walls of Type I and II construction has been limited to non-load-bearing partitions with a fire-resistance rating of no greater than 2 hours and non-load-bearing exterior walls without a fire-resistance rating. Additionally, roofs in buildings of Type I and II construction are permitted to be constructed of FRTW. The exception to Item 1.3 does not permit FRTW in the roofs of buildings of Type IA construction over two stories in height if the distance from the uppermost floor to the roof is less than 20 feet (6096 mm). If the distance is 20 feet (6096 mm) or greater, then FRTW is acceptable in the roof. FRTW is permitted in the roof of any Type IA building two stories or less in height regardless of the distance from the floor to the roof. Similarly, FRTW is permitted in the roof of any Type IB or Type II building (no height restrictions) regardless of the distance from the floor to the roof.

Untreated wood: Numerous items in the list of Section 603.1 permit the use of untreated wood in Type I and II construction. Blocking or nailers used to support fixtures, railings, cabinets or interior and exterior finishes are permitted within walls and partitions required to be of noncombustible construction in accordance with Item 14. Item 18 permits combustible nailers and blocking as stipulated in accordance with Section 803.11. Section 803.11.1 indicates that "furring strips not exceeding 1.75 inches (44 mm)" are permitted to be used in concrete or masonry construction for securing trim and finishes. Although locating these combustible elements within noncombustible frame partitions is not specifically identified in this section, the presence of combustible nailers within noncombustible construction types, other than concrete and masonry, represents an equivalent circumstance. Therefore, it is the intent of the code to permit the use of combustible nailers and blocking within Type I and II construction.

According to Item 11, partitions within a small store or office can include untreated wood in their construction (or FRTW), provided the partitions do not exceed 6 feet (1829 mm) in height. The limitations to 30 occupants and to not forming a corridor restrict this exception from introducing extensive amounts of combustible materials. Item 9 permits the use of untreated wood for show windows and related construction up to a height 15 feet (4572 mm) above grade. This permits a broader range of materials for storefronts without jeopardizing the overall integrity of these buildings.

Item 19 references three different code sections where heavy timber construction can occur within and on the outside of noncombustible buildings.

Plastics: Items 2, 3, 15 and 17 specifically address allowed plastics within or on the surfaces of Type I and II buildings. These items include allowances for thermal and acoustical insulation having a flame spread index of no greater than 25 when tested in accordance with ASTM E 84 or UL 723; foam and light-transmitting plastics complying with Chapter 26; and exterior plastic veneers complying with Section 2605.2. Plastic materials are often included in installations allowed for interior finishes and within the construction of the building, in accordance with Item 7.

Roof construction and roof coverings: While combustible roofs must be of FRTW if used in a Type I or II building, roof coverings, blocking, nailers and furring strips are also permitted to be combustible without the use of FRTW (see Items 4, 14 and 18).

"Roof covering" is defined as the membrane covering the roof that provides weather resistance, fire resistance and appearance. As long as a noncombustible roof deck (or FRTW) is provided as the structural element, foam plastic insulation, wood structural panels, nailing/furring strips and roof coverings may be applied.

Exterior wall coverings and projections: Item 13 provides a reference to Chapter 14 where provisions address combustible wall coverings and use of combustible materials in projections such as balconies and eaves. Combustible wall coverings need to be applied on top of a noncombustible wall meeting the required rating of Table 601. The coverings cannot be a substitute for the exterior face of a tested assembly. Plastic veneers (Item 17) are allowed in accordance with Section 2605.2.
Concealed spaces and construction: Many combustible materials are used, and allowed to be used within the elements of a building. Often these are used to help protect a fire-resistance-rated assembly where it is penetrated by pipes, ducts or conduit. Many of these materials are tested for the specific purposes and installations such as protection of joints or are used to actually resist, or react to, fire (see Items 16, 20, 21, 22, 23, 24 and 25).

Finish and interior materials: Finish materials for floors, walls and ceilings need to comply with various provisions of Chapter 8. Allowed materials do include combustible materials, but typically they are limited in flame spread index and smoke generation. Items 5, 7 and 8 address interior finishes. Stages and platforms can be combustible when in compliance with Section 410 (see Item 12). And, finally, doors and windows are not among the elements required to be noncombustible in accordance with Item 6.

603.1.1 Ducts. The use of nonmetallic ducts shall be permitted where installed in accordance with the limitations of the International Mechanical Code.

- Ducts are not addressed by construction-type requirements and their use is not controlled by construction-type provisions. The International Mechanical Code® (IMC®) provides requirements for nonmetallic ducts and addresses issues including flammability and flame spread. This section clarifies that this chapter is not intended to override those requirements.

603.1.2 Piping. The use of combustible piping materials shall be permitted where installed in accordance with the limitations of the International Mechanical Code and the International Plumbing Code.

- Piping is not addressed by construction-type requirements and the use of piping is not controlled by construction-type provisions. The International Plumbing Code® (IPC®) provides requirements for combustible piping materials, such as plastic, that address the issues of flammability and flame spread. This section clarifies that this chapter is not intended to override those requirements.

603.1.3 Electrical. The use of electrical wiring methods with combustible insulation, tubing, raceways and related components shall be permitted where installed in accordance with the limitations of this code.

- Electrical wiring and equipment are not addressed by construction-type requirements and their use is not controlled by construction-type provisions. NFPA 70, National Electrical Code, provides requirements for combustible wiring materials that address the issue of flammability and flame spread. This section clarifies that this chapter is not intended to override those requirements.

Bibliography

The following resource materials are referenced in this chapter or are relevant to the subject matter addressed in this chapter:

Chapter 7: Fire and Smoke Protection Features

General Comments

Chapter 7 provides detailed requirements for fire-resistance-rated construction, including structural members, walls, partitions and horizontal assemblies. Other portions of the code tell us when certain fire-resistance-rated elements are required. This chapter specifies how these elements are constructed, how openings in walls and partitions are protected, and how penetrations of such elements are protected.

Fire-resistance-rated construction is one form of fire protection in building design. It is often referred to as "passive protection." Fire-resistance-rated building elements provide resistance to the advance of fire, as opposed to active fire protection systems, such as automatic sprinkler systems, which actively attempt to suppress a fire.

At the core of fire-resistance-rated construction is test standard ASTM E 119. This test standard specifies how to test different building elements for fire resistance, and defines what the level of fire-resistance performance is, based upon this test.

Restriction of fire growth, or passive protection, has been a key part of building codes since their inception.

Other sections of the code require elements to have a fire-resistance rating or a degree of resistance to flame spread because of the relative hazard associated with the type of construction, the occupancy of the building, or the function of the element.

The construction features that are dealt with in this chapter that are required to have some degree of fire resistance include structural members (see Section 704), exterior walls (see Section 705), fire walls (see Section 706), fire barriers (see Section 707), shaft enclosures (see Section 708), fire partitions (see Section 709), smoke barriers (see Section 710), smoke partitions (see Section 711), and horizontal assemblies (see Section 712). Additionally, the method of protecting penetrations, joints, doors, windows, ducts, and air transfer openings in the fire-resistant elements is covered in Sections 713, 714, 715 and 716. This chapter also covers draftstopping and fireblocking of concealed spaces in Section 717. The flame spread and smoke development of insulation are regulated by Section 719. As an alternative to tested assemblies, some prescriptive and calculated methods of determining fire-resistant assemblies are given in Sections 720 and 721.

SECTION 701 GENERAL

Chapter 7 provides detailed requirements for fire-resistance-rated construction, including structural members, walls, partitions and horizontal assemblies. Other portions of the code tell us when certain fire-resistance-rated elements are required. This chapter specifies how these elements are constructed, how openings in walls and partitions are protected, and how penetrations of such elements are protected.

Fire-resistance-rated construction is one form of fire protection in building design. It is often referred to as "passive protection." Fire-resistance-rated building elements provide resistance to the advance of fire, as opposed to active fire protection systems, such as automatic sprinkler systems, which actively attempt to suppress a fire.

At the core of fire-resistance-rated construction is test standard ASTM E 119. This test standard specifies how to test different building elements for fire resistance, and defines what the level of fire-resistance performance is, based upon this test.

Restriction of fire growth, or passive protection, has been a key part of building codes since their incep-
FIRE AND SMOKE PROTECTION FEATURES

701.1 Scope. The provisions of this chapter shall govern the materials, systems and assemblies used for structural fire resistance and fire-resistance-rated construction separation of adjacent spaces to safeguard against the spread of fire and smoke within a building and the spread of fire to or from buildings.

- The provisions of Chapter 7 apply to the materials, assemblies and systems used to protect against the passage of fire and smoke. Each of the walls and partitions outlined herein provides various degrees of protection. The required fire-resistant rating varies with the potential fire hazard associated with type of construction, occupancy, height and area of the building and degree of protection for different elements of the means of egress. The potential fire hazard associated with various occupancies is reflected in Tables 508.4, 509, 704.4 703.3.10 and 1018.1. Chapter 7 provides the details and the extent of the protection (horizontal and vertical continuity); however, the actual fire-resistance-rated construction is mandated by provisions in Chapters 4, 5, 6, 7 and 10.

- Whenever the code mandates the use of materials or assemblies required to be noncombustible or have a degree of fire or smoke resistance, the performance of the material or assembly is required to be evaluated in accordance with the provisions of this chapter and the referenced standards.

- The important criteria for the terms “combustible” and “noncombustible” used in this chapter and elsewhere throughout the code are contained in Section 703.5.

701.2 Multiple use fire assemblies. Fire assemblies that serve multiple purposes in a building shall comply with all of the requirements that are applicable for each of the individual fire assemblies.

- Some building elements are required by two or more different code provisions to be fire-resistance rated. The same wall can serve as a load-bearing wall in Type IIA construction, an incidental use separation wall and a corridor wall. The structural load-bearing wall must meet Section 704.1, the incidental use separation wall is a fire barrier and must meet Section 707, while the corridor wall is a fire partition and must meet Section 708.

SECTION 702
DEFINITIONS

702.1 Definitions. The following terms are defined in Chapter 2:

SECTION 703
FIRE-RESISTANCE RATINGS AND FIRE TESTS

703.1 Scope. Materials prescribed herein for fire resistance shall conform to the requirements of this chapter.

- Standard fire test methods for determining fire-resistance ratings and combustibility of materials are covered in this section. Section 703.2 addresses the
acceptable testing method to be used in determining the fire-resistance ratings of building assemblies and structural elements, while Section 703.3 provides alternative methods. Section 703.4 clarifies that sprinklers cannot be utilized when testing passive fire-resistance ratings. Section 703.5 defines methods to determine if a material is combustible or non-combustible. Section 703.6 references the testing and labeling requirements for fire-resistance-rated glazing. The signage requirements for various fire-resistance-rated walls and partitions are in Section 703.7.

Fire-resistance ratings of structural members are one of the factors taken into consideration when determining the allowable height and area of buildings. By using materials and construction methods that result in the required fire-resistance ratings (see commentary, Table 503), the inherent fire hazards associated with different uses are, in part, addressed. Other sections of the code also contain provisions for required fire-resistance ratings in specific applications based on the need to separate uses, processes, fire areas or building areas.

**703.2 Fire-resistance ratings.** The fire-resistance rating of building elements, components or assemblies shall be determined in accordance with the test procedures set forth in ASTM E 119 or UL 263 or in accordance with Section 703.3. Where materials, systems or devices that have not been tested as part of a fire-resistance-rated assembly are incorporated into the building element, component or assembly, sufficient data shall be made available to the building official to show that the required fire-resistance rating is not reduced. Materials and methods of construction used to protect joints and penetrations in fire-resistance-rated building elements, components or assemblies shall not reduce the required fire-resistance rating.

**Exception:** In determining the fire-resistance rating of exterior bearing walls, compliance with the ASTM E 119 or UL 263 criteria for unposed surface temperature rise and ignition of cotton waste due to passage of flame or gases is required only for a period of time corresponding to the required fire-resistance rating of an exterior non-bearing wall with the same fire separation distance, and in a building of the same group. When the fire-resistance rating determined in accordance with this exception exceeds the fire-resistance rating determined in accordance with ASTM E 119 or UL 263, the fire exposure time period, water pressure and application duration criteria for the hose stream test of ASTM E 119 or UL 263 shall be based upon the fire-resistance rating determined in accordance with this exception.

The fire-resistance properties of materials and assemblies must be measured and specified in accordance with a common test standard. For this reason, the fire-resistance ratings of building assemblies and structural elements are required to be determined in accordance with ASTM E 119 or UL 263. The ASTM E 119 and UL 263 test methods evaluate the ability of an assembly to contain a fire, to retain its structural integrity or both in terms of endurance time during the test conditions. The test standard also contains conditions for measuring heat transfer through membrane elements protecting framing or surfaces. The fire exposure is based on the standardized time-temperature curve (see Figure 703.2).

The extent to which the test specimen is representative of in-place conditions is determined by the test standard and what is actually tested. For example, the test standard does not provide for the effect on fire endurance of conventional openings in the assembly, such as electrical outlets, plumbing pipes, etc., unless specifically included in the construction assembly tested. The test reports will, however, typically indicate an allowance for openings for steel electrical outlet boxes that do not exceed 16 square inches (0.0103 m²) in area, provided that the area of such openings does not exceed 100 square inches (0.645 m²) for any 100 square feet (9.3 m²) of wall area. Since, in actuality, assemblies are often penetrated by cables, conduits, ducts, pipes, vents and similar materials, such penetrations that are not part of the tested assembly must be adequately protected and sealed for the assembly to perform as required in resisting the spread of fire. This section, therefore, also mandates that adequate documentation be submitted in order for the building official to verify that the fire-resistance rating of the assembly is not compromised by the penetration. In addition, the materials and methods used to protect joints in or between fire-resistance-rated assemblies must be submitted to
determine that the required fire-resistance ratings are maintained. The documentation submitted as evidence that the required fire-resistance ratings are not reduced can be in the form of specific product, assembly or system listings (see the definition of "Listed" in Section 202), engineering judgments provided by accredited testing laboratories, product manufacturers that are based on similar tested conditions or, less frequently, data reports for specific fire tests conducted to evaluate a specific penetration method. However, care must be taken to determine that the materials and methods of the proposed penetration or joint protection correspond to the details of the actual penetration or joint protection assembly that was tested. In the case of engineering judgments submitted for through-penetration firestops or fire-resistive joint systems, the publication Recommended IFC Guidelines for Evaluating Firestop Engineering Judgments (EJ's) can be used as a tool in evaluating the submitted documentation. It is available as a free download from the International Firestop Council (www.firestop.org).

ASTM E 119 or UL 263 states that it is not intended to determine the following:

- Contribution of the tested assembly to the fire hazard;
- Measurement of the degree of control or limitation of the passage of smoke or products of combustion;
- Simulation of the fire behavior at joints between building elements, such as floor-to-wall or wall-to-wall connections; or
- Measurement of the flame spread over the surface of the tested element.

Documentation that a component or assembly has been tested to ASTM E 119 or UL 263 is typically in the form of a test report issued by an approved, qualified testing agency. The test report contains certain information, including the time periods of fire resistance (e.g., 1 hour, 11/2 hours, 2 hours, etc.) and other significant details of the material or assembly. In lieu of an actual copy of a test report, the building official may accept the use of a design number found in a compendium of ASTM E 119 or UL 263 test reports such as, but not limited to, the Fire Resistance Design Manual published by the Gypsum Association, the Fire Resistance Directory published by Underwriters Laboratories Inc. or Certification Listings published by Warnock Hersey. Each publication includes a detailed description of the assembly, its hourly fire-resistance rating and other pertinent details, such as specifications of materials and alternative assembly details.

These publications detail the design of columns, beams, walls, partitions and floor/ceiling and roof/ceiling assemblies that have been tested or analyzed in accordance with ASTM E 119 or UL 263. The designs are classified in accordance with their use and fire-resistance rating. Often, wall, partition and floor/ceiling assemblies are further classified with sound transmission class (STC) ratings. Many floor/ceiling assemblies also include impact insulation class (IIC) ratings. The designs indicate whether an assembly was tested under load-bearing or non-load-bearing conditions, and what structural height limitations there are for non-load-bearing assemblies. Many of the publications have introductory material that provides details on the uses and limitations of the tested assemblies, such as the amount of penetrations permitted in an assembly for electrical outlet boxes.

The exception to the section applies to exterior load-bearing walls that are required to have a fire-resistance rating for structural integrity and not as a fire barrier (e.g., due to fire separation distance in accordance with Table 705.8). The exception is necessary because ASTM E 119 or UL 263 does not distinguish between structural and fire-containment features of a wall. For example, assume that a concrete double-tee wall assembly was tested in accordance with ASTM E 119 or UL 263. The flanges of the double-tees were 1 1/2 inches thick (38 mm) and the load applied to the wall was 9,600 pounds per linear foot (14 150 kg/m). Because the temperature of the unexposed surface rose an average of 250°F (121°C) in 21 minutes, the fire-resistance rating assigned to the assembly was 21 minutes. The fire exposure was continued after the unexposed surface temperature criterion was exceeded and the wall assembly continued to support the applied load for 2 hours, at which time the test was terminated. Thus, the wall should be acceptable where structural performance for 2 hours is required and prevention of fire spread from building to building is not under consideration because of the fire separation distance. The exception, therefore, allows exterior load-bearing walls to be tested after the first failure criterion of ASTM E 119 or UL 263 is reached, if the failure is other than a failure to sustain the applied load, and allows a structural fire-resistance rating to be determined. It should be noted that the hose stream test procedure is to be based on the fire exposure time period related to the structural fire-resistance rating.

703.2.1 Nonsymmetrical wall construction. Interior walls and partitions of nonsymmetrical construction shall be tested with both faces exposed to the furnace, and the assigned fire-resistance rating shall be the shortest duration obtained from the two tests conducted in compliance with ASTM E 119 or UL 263. When evidence is furnished to show that the wall was tested with the least fire-resistant side exposed to the furnace, subject to acceptance of the building official, the wall need not be subjected to tests from the opposite side (see Section 705.5 for exterior walls).

- In applying Sections 703.2 and 703.2.1, it is the intent of the code that the required fire-resistance rating of interior walls be based on a fire exposure from either side. For example, it is appropriate to expect the required fire performance of an exit access corridor wall from the corridor side, as well as from the room.
FIRE AND SMOKE PROTECTION FEATURES

side. If the corridor becomes involved in a fire, the corridor wall must restrict the spread of fire into adjacent spaces; however, Section 704.5 does allow exterior walls with a fire separation distance of more than 5 feet (1524 mm) to be fire-resistance rated from the interior only.

Section 703.2.1 permits testing from only one side of nonsymmetrical assemblies, provided it can be demonstrated that the tested side results in the lower value (i.e., the nontested side, if tested, would result in a higher value). For example, a 2-inch by 4-inch (51 mm by 102 mm) wood stud wall with two layers of 1/4-inch (15.9 mm) Type X gypsum board on one side and only one layer on the opposite side is an illustration of a "nonsymmetrical" assembly. This assembly would be permitted to be tested only from the side with the single layer of gypsum board. This is because testing from the side with the two layers would result in a higher rating.

703.2.2 Combustible components. Combustible aggregates are permitted in gypsum and Portland cement concrete mixtures for fire-resistance-rated construction. Any component material or admixture is permitted in assemblies if the resulting tested assembly meets the fire-resistance test requirements of this code.

- The combustibility of materials is regulated by the code when it has been determined that the material or assembly could significantly contribute to a fire hazard; however, the limited use of combustible materials, such as combustible aggregates, is permitted as long as the desired fire-resistance rating can still be obtained. The use of a combustible aggregate in the material or assembly will not significantly contribute to fire growth or severity.

703.2.3 Restrained classification. Fire-resistance-rated assemblies tested under ASTM E 119 or UL 263 shall not be considered to be restrained unless evidence satisfactory to the building official is furnished by the registered design professional showing that the construction qualifies for a restrained classification in accordance with ASTM E 119 or UL 263. Restrained construction shall be identified on the plans.

- The effect on the fire-resistance rating of a structural element that is part of an assembly is addressed, to an extent, through the distinction in ASTM E 119 or UL 263 between "restrained" and "unrestrained" conditions. The standard defines this distinction as follows: "A restrained condition in fire tests, as used in this test method, is one in which expansion of the supports of a load-carrying element resulting from the effects of the fire is resisted by forces external to the element. An unrestrained condition is one in which the load-carrying element is free to expand and rotate at its supports." In evaluating fire-resistance ratings of structural elements, the conditions of support must be consistent with the tested condition as described in the test report.

A restrained classification yields higher fire-resistance ratings than unrestrained; therefore, the code takes the conservative approach, and thus the lesser rating by assuming the in-place conditions to be unrestrained unless structural documentation is provided that supports a restrained condition.

703.3 Alternative methods for determining fire resistance. The application of any of the alternative methods listed in this section shall be based on the fire exposure and acceptance criteria specified in ASTM E 119 or UL 263. The required fire resistance of a building element, component or assembly shall be permitted to be established by any of the following methods or procedures:

1. Fire-resistance designs documented in sources.
2. Prescriptive designs of fire-resistance-rated building elements, components or assemblies as prescribed in Section 721.
3. Calculations in accordance with Section 722.
4. Engineering analysis based on a comparison of building element, component or assemblies designs having fire-resistance ratings as determined by the test procedures set forth in ASTM E 119 or UL 263.
5. Alternative protection methods as allowed by Section 104.11.

- When based on the fire exposure and acceptance criteria of ASTM E 119 or UL 263, an analytical method can be used in lieu of an actual ASTM E 119 or UL 263 fire test to establish the fire-resistance rating of a single component or assembly.

   1. The commentary to Section 703.2.2 also identifies additional resource materials relative to test reports.
   2. Sections 721 and 722 provide further methods of determining fire-resistance ratings (see the commentary to these sections).

For example, methods for determining fire-resistance ratings of concrete or masonry assemblies have been standardized in ACI 216.1/TMS 0216.1 (see commentary, Section 722.1), as well as in the following:

- PCI MNL 124, Precast/Prestressed Concrete Institute.
- Reinforced Concrete Fire Resistance, Concrete Reinforcing Steel Institute.
- CMIFC SR267.01B, Concrete and Masonry Industry Fire Safety Committee.
- A Compilation of Fire Tests on Concrete Masonry Assemblies, National Concrete Masonry Association.
- NCMA TEK 6A, National Concrete Masonry Association.
- NCMA 35D, National Concrete Masonry Association.

4. An approved engineering analysis allows the fire protection properties of a component or assembly to be determined using information generated from previous fire tests through
empirical calculations. There are several analytical methods available to designers for many types of construction materials. An engineering analysis is available for calculating fire-resistance ratings of heavy timber construction. This analysis uses an empirical mathematical method that generates a design for the minimum dimensions of a wood beam or column. These dimensions account for the changes that occur in the member due to charring of the wood after any given period of fire exposure. American Iron and Steel Institute (AISI) Designing Fire Protection for Steel Columns presents the factors that influence the fire-resistance ratings of steel columns in frequently used sizes and shapes. The publication also contains a discussion of the fire protection materials most often used with steel columns and provides accepted methods for calculating the fire-resistance rating of steel columns predicated on the ASTM E 119 or UL 263 fire exposure standard. Similarly, AISI's Designing Fire Protection for Steel Beams presents the factors that influence the fire-resistance ratings of steel beams in frequently used sizes. As typical test reports specify minimum beam sizes only, three different ways of evaluating beam substitutions are provided. Since the ASTM E 119 or UL 263 test furnace is incapable of testing assemblies that incorporate large structural members, AISI's Designing Fire Protection for Steel Trusses proposes concepts for determining fire protection designs by applying existing test data. The application of these methods, as well as information on the fire resistance of archaic construction, is summarized in the International Code Council's (ICC®) publication, 2001 Guidelines for Determining Fire Resistance of Building Elements. It is important to emphasize that all analytical methods of calculating fire-resistance ratings must be substantiated as being based on the fire exposure and acceptance criteria of ASTM E 119 or UL 263. Upon submission of such documentation to the building official, the analytical methods mentioned herein, or any other such analytical methods, can be approved as the basis for showing compliance with the fire-resistance ratings required by the code.

5. As indicated in Section 104.11, alternative protection may be provided if approved by the building official. An example of an alternative protection method is the water-filled steel column system. The system consists of hollow, liquid-filled columns that are interconnected with pipe loops to allow the water to circulate freely. Engineering studies confirmed by tests have shown that critical temperatures are not reached in the steel columns as long as they remain filled with liquid.

703.4 Automatic sprinklers. Under the prescriptive fire-resistance requirements of the International Building Code, the fire-resistance rating of a building element, component or assembly shall be established without the use of automatic sprinklers or any other fire suppression system being incorporated as part of the assembly tested in accordance with the fire exposure, procedures, and acceptance criteria specified in ASTM E 119 or UL 263. However, this section shall not prohibit or limit the duties and powers of the building official allowed by Sections 104.10 and 104.11.

- The fire-resistive requirements for structural members and walls and partitions separating areas in a building are passive fire-resistive measures and, when required, are required in addition to any other sprinkler requirements in the code. Required fire-resistance ratings must be established by tests not utilizing sprinklers. This section does not prohibit the building official from accepted alternatives in accordance with Sections 104.10 and 104.11.

703.5 Noncombustibility tests. The tests indicated in Sections 703.5.1 and 703.5.2 shall serve as criteria for acceptance of building materials as set forth in Sections 602.2, 602.3 and 602.4 in Type I, II, III and IV construction. The term "noncombustible" does not apply to the flame spread characteristics of interior finish or trim materials. A material shall not be classified as a noncombustible building construction material if it is subject to an increase in combustibility or flame spread beyond the limitations herein established through the effects of age, moisture or other atmospheric conditions.

- The restrictions on the use of combustible materials are primarily found in Chapter 6; however, certain sections of Chapter 7 (such as use of combustibles in Section 703.2.2 and fire walls in Section 706.3) contain restrictions on the use of combustible materials or separate provisions, depending on whether the material is combustible or noncombustible. Sections 703.5.1 and 703.5.2 contain the appropriate test criteria by which a material is to be evaluated to ascertain whether it is combustible or noncombustible.

Materials that are considered noncombustible must be capable of maintaining the required performance characteristics (noncombustibility and flame spread ratings) regardless of age, moisture or other atmospheric conditions. If exposure to atmospheric conditions results in an increase in combustibility or flame spread rating beyond the limitations specified, the material is considered combustible.

The criteria established by this section are primarily based on the National Board of Fire Underwriters' (NBFU) National Building Code, 1955 edition, which permitted a noncombustible material to contain a limited amount of combustible material, provided that it did not contribute to fire propagation. The requirement for noncombustibility is considered to apply to certain materials used for walls, roofs and other structural elements, but not to surface finish materials. The determination of whether a material is noncombustible from the standpoint of minimum required clear-
ances to heating appliances, flues or other sources of high temperature is based on the ASTM E 136 definition of "Noncombustibility," not the prescriptive definition in Section 703.5.2. Note that the International Mechanical Code® (IMC®) contains a definition of "Noncombustible materials," which does not contain provisions for the use of composite materials (defined in Section 703.5.2) as acceptable noncombustible materials.

**703.5.1 Elementary materials.** Materials required to be noncombustible shall be tested in accordance with ASTM E 136.

- Materials intended to be classified as noncombustible are to be tested in accordance with ASTM E 136. In accordance with Section 8 of ASTM E 136, such materials are acceptable as noncombustible when at least three of four specimens tested conform to all of the following criteria:
  1. The recorded temperature of the surface and interior thermocouples shall not at any time during the test rise more than 54°F (30°C) above the furnace temperature at the beginning of the test.
  2. There shall not be flaming from the specimen after the first 30 seconds.
  3. If the weight loss of the specimen during testing exceeds 50 percent, the recorded temperature of the surface and interior thermocouples shall not at any time during the test rise above the furnace air temperature at the beginning of the test, and there shall not be flaming of the specimen.

The use of the test standard is limited to elementary materials and excludes laminated and coated materials because of the uncertainties associated with more complex materials and with products that cannot be tested in a realistic configuration. The test standard is also limited to solid materials and does not measure the self-heating tendencies of large masses of materials, such as resin-impregnated mineral fiber insulation.

The defined furnace temperature in the standard, 1,382°F (750°C), is representative of temperatures that are known to exist during building fires, although temperatures between 1,800°F (982°C) and 2,200°F (1,204°C) are frequently achieved during intense fires. For most building materials, however, complete burning of the combustible fraction will occur as readily at 1,382°F (750°C) as compared to higher temperatures. The criterion for requiring four specimens to be tested recognizes the variable nature of the measurements and the fact that there are difficulties in observing the presence and duration of flaming.

The need to measure and limit the duration of flaming and the rise in temperature recognizes that a brief period of flaming and a small amount of heating are not considered serious limitations on the use of building materials. Test results have shown that such criteria limit the combustible portion of noncombustible materials to a maximum of 3 percent. The 50-percent weight-loss limitation precludes the possibility that combustion of low-density materials will occur so rapidly that the recorded temperature rise and the measured flaming duration will be less than the prescribed limitations. The 50-percent limitation is considered appropriate for materials that contain appreciable quantities of combined water or gaseous components.

**703.5.2 Composite materials.** Materials having a structural base of noncombustible material as determined in accordance with Section 703.5.1 with a surfacing not more than 0.125 inch (3.18 mm) thick that has a flame spread index not greater than 50 when tested in accordance with ASTM E 84 or UL 723 shall be acceptable as noncombustible materials.

- In recognition that an essentially noncombustible material with a thin combustible coating will not contribute appreciably to an ambient fire, this section provides criteria by which a composite material may be determined acceptable as a noncombustible material. The structural base of the composite material must meet the criteria for elementary materials (see Section 703.5.1). The material may have a surfacing not more than 1/32 inch (3.2 mm) thick applied to the noncombustible base. This surfacing is required to have a flame spread rating no greater than 50 when tested in accordance with ASTM E 84 or UL 723. For a discussion of both the ASTM E 84 and UL 723 test methods, refer to the commentary to Section 803.1.

In accordance with this section, material such as gypsum board—which consists of a noncombustible base and a combustible (paper) surface—is considered to be a composite material. As noted in the commentary to Section 703.5, a composite material is considered a noncombustible material in the context of the code. The IMC, however, intentionally includes only limited applications of the criteria of this section in the definition of a noncombustible material; therefore, composite materials are not considered acceptable noncombustible materials from the standpoint of clearances to heating appliances, flues or other sources of high temperature because of their potentially poor response to radiant heat exposure.

**703.6 Fire-resistance-rated glazing.** Fire-resistance-rated glazing, when tested in accordance with ASTM E 119 or UL 263 and complying with the requirements of Section 707, shall be permitted. Fire-resistance-rated glazing shall bear a label marked in accordance with Table 716.3 issued by an agency and shall be permanently identified on the glazing.

- Fire-resistance rated glazing is one of two designated types of fire-rated glazing—fire-protection rated glazing being the other. Fire-rated glazing is allowed in three separate locations depending on which tests the glazing has passed. The label is required to provide the location and the fire-resistance rating in minutes. There are door labels, window labels and wall labels. Section 703.6 concerns only the fire-resistance-rated glazing. Table 716.3 indicates that glazing meeting ASTM E 119 or UL 263 shall bear a "W"
FIRE AND SMOKE PROTECTION FEATURES

label and is considered a wall; therefore, it is not subject to the limitations on doors and windows. This section indicates that fire-resistance-rated glazing with the "W" designation on the label is good for fire walls and fire barriers. It follows that it would be good for shaft walls and stair enclosures as well. It could also be used as a fire partition, smoke partition or smoke barrier.

Fire-resistance-rated glazing is also mentioned in Table 716.5 for doors and windows.

703.7 Marking and identification. Fire walls, fire barriers, fire partitions, smoke barriers and smoke partitions or any other wall required to have protected openings or penetrations shall be effectively and permanently identified with signs or stenciling. Such identification shall:

1. Be located in accessible concealed floor, floor-ceiling or attic spaces;
2. Be located within 15 feet (4572 mm) of the end of each wall and at intervals not exceeding 30 feet (9144 mm) measured horizontally along the wall or partition; and
3. Include lettering not less than 3 inches (76 mm) in height with a minimum $\frac{3}{8}$ inch (9.5 mm) stroke in a contrasting color incorporating the suggested wording, "FIRE AND/OR SMOKE BARRIER—PROTECT ALL OPENINGS" or other wording.

Exception: Walls in Group R-2 occupancies that do not have a removable decorative ceiling allowing access to the concealed space.

The concern addressed by this code requirement is the need for installed fire-resistance-rated assemblies to maintain their fire resistance over the life of the building. This identification will allow tradespeople, craftsmen, installers, maintenance workers or inspectors to know that the wall is a fire-resistance-rated wall and openings or penetrations of it must be protected.

SECTION 704
FIRE-RESISTANCE RATING OF STRUCTURAL MEMBERS

704.1 Requirements. The fire-resistance ratings of structural members and assemblies shall comply with this section and the requirements for the type of construction as specified in Table 601. The fire-resistance ratings shall not be less than the ratings required for the fire-resistance-rated assemblies supported by the structural members.

Exception: Fire barriers, fire partitions, smoke barriers and horizontal assemblies as provided in Sections 707.5, 708.4, 709.4 and 711.4, respectively.

This section contains provisions that apply to structural members that are required to have a fire-resistance rating. The required rating of structural members is usually based on the type of construction and Table 601. Other sections of the code, such as the continuity provisions of Sections 707.5, 709.4, 710.4 and 711.4, may require structural members to have a fire-resistance rating because they support fire-resistance-rated construction. The minimum required fire-resistance rating for the structural member is, therefore, the more restrictive of the above two criteria.

There are instances in which the code does not require the supporting structural members to have a fire-resistance rating. An example includes the supporting construction for tenant and sleeping unit separations, exit access corridors and smoke partitions in Type IIB, IIIB, and VB construction (see Sections 708.4 and 709.4).

Protection of structural members differs for various members. Required column fire-resistance protection must be afforded in accordance with Section 704.2. Certain primary structural frames (see definition in Section 202) must be protected by individual encasement in accordance with Section 704.3. Secondary structural members (see definition in Section 202) may be protected by membrane protection in accordance with Section 704.4. Special requirements apply to fire-resistance protection of trusses (see Section 704.5).

Section 704 addresses issues such as protection of attachments to structural members (see Section 704.6), embedment of service facilities (see Section 704.8), impact protection (see Section 704.9), exterior structural members (see Section 704.10), bottom flange protection (see Section 704.11), seismic isolation systems (see Section 704.12) and sprayed fire-resistant materials (SFRM) (see Section 704.13).

704.2 Column protection. Where columns are required to have protection to be fire-resistance rated, the entire column shall be provided individual encasement protection by protecting it on all sides for the full column length, including connections to other structural members, with materials having the required fire-resistance rating. Where the column extends through a ceiling, the encasement protection shall be continuous from the top of the foundation or floor/ceiling assembly below through the ceiling space to the top of the column.

Columns required to be fire-resistance rated must be encased on all four sides. This is true even if the column is located on the exterior of the structure. The ceiling membrane or ceiling protection of a floor/ceiling or roof/ceiling fire-resistance-rated assembly is prohibited from being considered as the protection for columns required to have a fire-resistance rating; therefore, the materials that encase or provide individual protection must continue through the concealed space above a ceiling, even if the ceiling membrane is part of a fire-resistance-rated assembly (see Figure 704.2). Connections of structural members to columns must also be individually protected (see Section 704.6). Columns that provide inherent fire resistance, such as heavy timber, are considered as not requiring protection and do not need to comply with this section.
704.3 Protection of the primary structural frame other than columns. Members of the primary structural frame other than columns that are required to have protection to achieve a fire-resistance rating and support more than two floors or one floor and roof, or support a load-bearing wall or a nonload-bearing wall more than two stories high, shall be provided individual encasement protection by protecting them on all sides for the full length, including connections to other structural members, with materials having the required fire-resistance rating.

**Exception:** Individual encasement protection on all sides shall be permitted on all exposed sides provided the extent of protection is in accordance with the required fire-resistance rating, as determined in Section 703.

All primary structural frames do not need to comply with this section. Only those primary structural frame members that are required to have a fire-resistance rating and support more than two floors, more than one floor and a roof, a bearing wall of any height or a nonload-bearing wall more than two stories high, are required to be protected by individual encasement. Individual encasement, though not defined, is attained by using tested design assemblies that provide gypsum board applied directly to the member or to studs that are directly attached to all sides of the member, mastic and intumescent coatings, and sprayed fire-resistant materials.

Individual encasement is required for the primary structural frame members receiving tributary loads from multiple levels in order to reduce the risk associated with catastrophic failure. The risk represented by structural collapse during a fire is significantly increased in multistory buildings, since the occupants require additional time of egress and a single structural element that supports multiple elements requires more conservative protection methods.

Though the text states that the encasement must be on all four sides of the structural member, the exception will allow tested assemblies that have the encasement on only the exposed sides of a member. Figure 704.3 is an example of individual encasement protection.

Note that some structural members such as heavy wood beams may not require any protection (encasement or membrane) to attain a fire rating (see calculated fire resistance, Section 722.1).

704.4 Protection of secondary members. Secondary members that are required to have a fire-resistance rating shall be protected by individual encasement protection, by the membrane or ceiling of a horizontal assembly in accordance with Section 711, or by a combination of both.

Where fire-resistance-rated structural members are required, membrane or ceiling fire-resistance protection is only permitted for structural members (primary...
or secondary) that support two floors or less, only one floor and a roof, or a nonload-bearing wall two stories or less in height. Please note that ceiling membrane protection is never allowed for column protection (see Section 704.2). Figure 704.4 is an example of membrane protection.

Remember that the fire-resistance requirements are established based upon a fire test in accordance with ASTM E 119 or UL 263. Although the fire temperature in the furnace is the same, the test protocols in both standards have different temperature rise limits for the elements and different temperature couple locations between a structural member test and a wall or horizontal assembly test. Therefore, although a wall may obtain a 1-hour fire-resistance rating, it does not mean that a column placed within that wall would also obtain a 1-hour fire-resistance rating. Also, a floor/ceiling assembly rated for 2 hours cannot be assumed to protect a beam that was not in the tested assembly. If the beam was in the tested assembly, the fire-resistance rating of the floor/ceiling may be different than the beam. It is important that the structural members located within the assemblies were also in the tested floor/ceiling and roof/ceiling assemblies.

![Figure 704.4](image)

**Figure 704.4** MEMBRANE FIRE PROTECTION METHOD

704.4.1 Light-frame construction. King studs and boundary elements that are integral elements in load-bearing walls of light-frame construction shall be permitted to have required fire-resistance ratings provided by the membrane protection provided for the load-bearing wall.

Historically, codes have considered king and jack studs in light-frame construction as standard parts of the wall assembly. King studs have essentially the same function, load ratio and thermal properties as the other studs in the load-bearing wall and there is no need for them to be considered as separate distinct column elements. In seismic design, boundary elements for light-frame steel construction are required to be designed for amplified seismic forces. Rather than placing multiple studs, designers frequently specify larger members which still serve the function of studs. These boundary elements are not always at openings.

704.5 Truss protection. The required thickness and construction of fire-resistance-rated assemblies enclosing trusses shall be based on the results of full-scale tests or combinations of tests on truss components or on approved calculations based on such tests that satisfactorily demonstrate that the assembly has the required fire resistance.

- Trusses can be of an almost infinite number of configurations and sizes. By nature, they are typically designed and constructed of different structural components. This leads to the impracticality of such trusses being tested. The code acknowledges this by allowing full-scale tests, tests on the individual components or some form of calculations that demonstrate that the structural elements that form the truss are provided with the requisite protection to attain the fire-resistance rating.

704.6 Attachments to structural members. The edges of lugs, brackets, rivets and bolt heads attached to structural members shall be permitted to extend to within 1 inch (25 mm) of the surface of the fire protection.

- This section is intended to limit the transfer of heat to the structural element from the connection elements by requiring the connection element to be protected with at least 1 inch (25 mm) of some form of fire-resistance protection. No attaching elements are allowed to the structural element that would allow heat to transfer through the protection and to the structural element. At least 1 inch (25 mm) of cover is required on all the attaching elements.

704.7 Reinforcing. Thickness of protection for concrete or masonry reinforcement shall be measured to the outside of the reinforcement except that stirrups and spiral reinforcement ties are permitted to project not more than 0.5-inch (12.7 mm) into the protection.

- Since load-bearing assemblies must sustain the superimposed load while being subjected to standard time-temperature fire conditions, concrete, masonry and reinforcing steel must be able to provide the required strength at elevated temperatures. This involves providing adequate cover over the steel reinforcement so that the stress induced in the reinforcement is less than its yield stress, which is commonly referred to as "yield strength." Tests of steel reinforcing bars show that at a temperature of approximately 1,100°F (593°C), the yield strength of steel is reduced to approximately 50 percent of that at ambient temperature conditions. Similar tests of prestressing tendons show that at approximately 800°F (427°C) the tensile strength is approximately 50 percent of that at ambient conditions. Cover requirements, therefore, are typically based on limiting the reinforcing and prestressing steel temperatures to 1,100 and 800°F (593 and 427°C), respectively. This section allows for stirrups and spiral column ties to project into the required cover by a minimal distance, acknowledging the prac-
ticality of construction tolerances while providing ade-
quate cover to the main reinforcing steel, which is
located inside of the stirrups and ties. This also
acknowledges that the stirrups are not continuous for
the length of the member and are spaced at intermit-
tent intervals. Therefore, they only reduce the actual
cover to the main reinforcing steel at a percentage of
its length. The 1/2-inch (12.7 mm) dimension reflects a
No. 4 reinforcing bar.

704.8 Embedments and enclosures. Pipes, wires, conduits,
ducts or other service facilities shall not be embedded in the
required fire protective covering of a structural member that
is required to be individually encased.

- Piping, wires, conduits, ducts and other service facili-
ties are not to be embedded in the fire protective cov-
ering of a structural member that is required to be
individually encased in accordance with Section
704.3. The fire protection performance of encase-
ment materials is critical to achieve the required fire-
resistance rating, and would be impaired if the con-
nectivity of the encasement is interrupted. This does not,
however, prevent the installation if these items are
installed in hollow spaces that may be created by the
encasement method. When items are installed in
such hollow spaces, penetrations of the protective
assembly must be properly protected so that the fire-
resistance rating is maintained.

704.9 Impact protection. Where the fire protective cov-
ering of a structural member is subject to impact damage from
moving vehicles, the handling of merchandise or other activ-
ity, the fire protective covering shall be protected by corner
guards or by a substantial jacket of metal or other noncom-
bustible material to a height adequate to provide full protec-
tion, but not less than 5 feet (1524 mm) from the finished
floor.

- Exception: Corner protection is not required on concrete
columns in open or enclosed parking garages.

To aid in the reliability of the fire protective covering,
impact protection must be provided if the covering is
subject to impact from moving vehicles, handling of
merchandise or other activities. The impact protection
is to be provided to at least 5 feet (1524 mm) above
the finished floor or as needed to prevent impact
damage.

The type of protection required is not specified
within the code, but it should be determined based on
the type of fire protection used and also the expected
impact that the protection may be expected to
encounter. For example, if the fire-resistance protec-
tion of a column is provided by either spray-on fire-
proofing or gypsum board, that would be more likely
to be damaged than a concrete-encased column.
Additionally, if the column was in a grocery store and
the only expected item to impact the column was a
shopping cart, then it may be determined acceptable
to simply cover the gypsum board with a piece of thin
sheet metal. On the other hand, if the column is
located in a warehouse or parking garage where a

vehicle such as a forklift or automobile could strike it,
then the protection may require the installation of
steel plates or bollards.

704.10 Exterior structural members. Load-bearing struc-
tural members located within the exterior walls or on the out-
side of a building or structure shall be provided with the
highest fire-resistance rating as determined in accordance
with the following:

1. As required by Table 601 for the type of building ele-
ment based on the type of construction of the building;

2. As required by Table 601 for exterior bearing walls
based on the type of construction; and

3. As required by Table 602 for exterior walls based on
the fire separation distance.

- Exterior load-bearing structural members, such as
columns or girders, must have the same fire-resis-
tance rating as is required for exterior load-bearing
walls. As such, the required fire-resistance rating is
the higher rating of that found in Table 601 for type of
construction for structural elements or bearing walls
or as required in Table 602 based on the fire separa-
tion distance.

704.11 Bottom flange protection. Fire protection is not
required at the bottom flange of lintels, shelf angles and
plates, spanning not more than 6 feet 4 inches (1931 mm)
whether part of the primary structural frame or not, and from
the bottom flange of lintels, shelf angles and plates not part of
the structural frame, regardless of span.

- Structural frame elements located over an opening in
a wall required to be fire-resistance rated, particularly
a masonry wall with an exposed steel lintel or angle
over the wall opening, are covered by this section.
The bottom flanges of such lintels or angles if less
than 6 feet 4 inches (1930 mm) in length are not
required to be protected even if part of the primary
structural frame. Regardless of the span, the bottom
flange of such lintels or angles is not required to be
protected if the member is not part of the primary
structural frame.

704.12 Seismic isolation systems. Fire-resistance ratings for
the isolation system shall meet the fire-resistance rating
required for the columns, walls or other structural elements
in which the isolation system is installed in accordance with
Table 601. Isolation systems required to have a fire-resis-
tance rating shall be protected with approved materials or
construction assemblies designed to provide the same degree
of fire resistance as the structural element in which it is
installed when tested in accordance with ASTM E 119 or UL
263 (see Section 703.2).

Such isolation system protection applied to isolator units
shall be capable of retarding the transfer of heat to the isolator
unit in such a manner that the required gravity load-carrying
capacity of the isolator unit will not be impaired after expo-
sure to the standard time-temperature curve fire test pre-
scribed in ASTM E 119 or UL 263 for a duration not less than
that required for the fire-resistance rating of the structure ele-
ment in which it is installed.
FIRE AND SMOKE PROTECTION FEATURES

Such isolation system protection applied to isolator units shall be suitably designed and securely installed so as not to dislodge, loosen, sustain damage or otherwise impair its ability to accommodate the seismic movements for which the isolator unit is designed and to maintain its integrity for the purpose of providing the required fire-resistance protection.

- This section states that the fire-resistance requirements for seismic isolation systems are the same as those for other structural elements, as required in Table 601. Additionally, the fire-resistance method used must be able to withstand the anticipated movement of the system without the fire-resistance application methods and systems affecting its functionality during a seismic event. Elements of the system can either be individually protected or contained within a tested assembly. Another key element of this section is that, when tested under exposure to the standard time-temperature curve test, the structural elements are still able to carry the gravity load as designed.

704.13 Sprayed fire-resistant materials (SFRM). Sprayed fire-resistant materials (SFRM) shall comply with Sections 704.13.1 through 704.13.5.

- The intent of this code section is to increase the in-place durability of spray-applied fire-resistant materials (SFRM). The National Institute of Standards and Technology's (NIST) investigation on the World Trade Center tragedy documented that the proximate cause of the actual collapse was the action of a building contents fire on light steel members in the absence of spray-applied fire-resistive material, which had been dislodged. Events far less dramatic than an airplane attack have been known to dislodge SFRM. Events as simple as an elevator movement, building sway or maintenance activities can dislodge SFRM if it is not adhered properly. These code requirements as well as the special testing requirements in Section 1705.13 are necessary to increase the in-place capability of SFRM assemblies. Section 403.2.4 in the high-rise buildings section gives the bond strength requirements for SFRM.

704.13.1 Fire-resistance rating. The application of SFRM shall be consistent with the fire-resistance rating and the listing, including, but not limited to, minimum thickness and dry density of the applied SFRM, method of application, substrate surface conditions and the use of bonding adhesives, sealants, reinforcing or other materials.

- In order for the fire-resistance rating that is actually realized by sprayed fire-resistant materials to equal or exceed the required fire-resistance rating, it is necessary to install the materials in accordance with their listing. In this section, minimum thicknesses, proper conditions of the substrate, method of application, and correct bonding materials are all items that are necessary to ensure the proper performance of these materials.

704.13.2 Manufacturer's installation instructions. The application of SFRM shall be in accordance with the manufacturer's installation instructions. The instructions shall include, but are not limited to, substrate temperatures and surface conditions and SFRM handling, storage, mixing, conveyance, method of application, curing and ventilation.

- Sections 704.13.1 and 704.13.2 require that the application of SFRM be in accordance with all terms and conditions of the listing and the manufacturer's instruction.

704.13.3 Substrate condition. The SFRM shall be applied to a substrate in compliance with Sections 704.13.3.1 through 704.13.3.2.

- The in-place adhesion of SFRM can be reduced by a factor of 10 when applied over certain primers when compared to the adhesion obtained by the rated material applied on bare clean steel. This section gives the requirements for the surface condition of the substrate receiving the SFRM.

704.13.3.1 Surface conditions. Substrates to receive SFRM shall be free of dirt, oil, grease, release agents, loose scale and any other condition that prevents adhesion. The substrates shall also be free of primers, paints and encapsulants other than those fire tested and listed by a nationally recognized testing agency. Primed, painted or encapsulated steel shall be allowed, provided that testing has demonstrated that required adhesion is maintained.

- This section gives the minimum temperature for the air and the material itself, which must be maintained during application and for 24 hours after, unless the manufacturer's instructions allow otherwise.

704.13.3.2 Primers, paints and encapsulants. Where the SFRM is to be applied over primers, paints or encapsulants other than those specified in the listing, the material shall be field tested in accordance with ASTM E 736. Where testing of the SFRM with primers, paints or encapsulants demonstrates that required adhesion is maintained, SFRM shall be permitted to be applied to primed, painted or encapsulated wide flange steel shapes in accordance with the following conditions:

1. The beam flange width does not exceed 12 inches (305 mm); or
2. The column flange width does not exceed 16 inches (400 mm); or
3. The beam or column web depth does not exceed 16 inches (400 mm).
4. The average and minimum bond strength values shall be determined based on a minimum of five bond tests conducted in accordance with ASTM E 736. Bond tests conducted in accordance with ASTM E 736 shall indicate a minimum average bond strength of 80 percent and a minimum individual bond strength of 50 percent, when compared to the bond strength of the SFRM as applied to clean uncoated 1/8-inch thick (3 mm) steel plate.

- When there is some sort of material, such as paint or primer, on the steel structural members where it is desired to install SFRM, it is still possible to apply the SFRM to the steel without removing the material. However, this section specifies that a field test in
accordance with ASTM E 736 be done on the SFRM so applied. This ensures that a bond strength is achieved and that the material will remain in place. Note that there are limitations on the sizes of structural members that can utilize this field test (Conditions 1-3).

**704.13.4 Temperature.** A minimum ambient and substrate temperature of 40°F (4.4°C) shall be maintained during and for a minimum of 24 hours after the application of the SFRM, unless the manufacturer’s installation instructions allow otherwise.

- This section gives the minimum temperature for the air and the material itself, which must be maintained during application and for 24 hours after, unless the manufacturer’s instructions allow otherwise.

**704.13.5 Finished condition.** The finished condition of SFRM applied to structural members or assemblies shall not, upon complete drying or curing, exhibit cracks, voids, spalls, delamination or any exposure of the substrate. Surface irregularities of SFRM shall be deemed acceptable.

- This section and the special inspections required by Section 1704.12 establish the acceptance criteria for the finished condition of the SFRM.

**SECTION 705 EXTERIOR WALLS**

**705.1 General.** Exterior walls shall comply with this section.

- In order to accomplish these functions, this section regulates the fire protection capability of the exterior wall, including limitations on openings in the walls. The requirements contained herein and in Table 602 are based on the fire separation distance, the occupancy that represents a relative fuel loading and the percentage of openings in the wall. Section 705.8.5 also regulates the location of openings in order to prevent ignition of materials in adjacent stories. All other applicable provisions of the code concerning exterior walls still apply. The provisions of this section refer to the fire-resistance requirements contained in Tables 601 and 602 (see Section 705.5). Table 601 establishes minimum fire-resistance ratings for load-bearing exterior walls based on the type of construction that addresses the structural integrity of the building under fire conditions. Table 602 establishes ratings based on fire separation distance in an effort to address conflagration concerns.

**705.2 Projections.** Cornices, eave overhangs, exterior balconies and similar projections extending beyond the exterior wall shall conform to the requirements of this section and Section 1406. Exterior egress balconies and exterior exit stairways and ramps shall also comply with Sections 1019 and 1026, respectively. Projections shall not extend any closer to the line used to determine the fire separation distance than shown in Table 705.2.

**Exception:** Buildings on the same lot and considered as portions of one building in accordance with Section 705.3 are not required to comply with this section.

- Horizontal projections, similar to walls and openings, are a potential source of the spread of fire from building to building. Some projections from the building exterior wall may even shelter combustible materials; as such, limits on the allowable projections are necessary. Examples of horizontal projections are roof overhangs, exterior balconies, canopies and covered porches. Balcony projections must also meet the requirements of Section 1406, while exterior egress balconies must meet Section 1019.

The first column in Table 705.2 is Fire Separation Distance (FSD) and is measured from the lot line or assumed lot line to the exterior wall—not to the edge of the overhang. The second column is distance from the line used to determine the FSD to the vertical edge of the overhang. For examples of the application of Table 705.2, see Figure 705.2.

The exception addresses buildings on the same lot that together qualify as one aggregate building under the limitations of Chapter 5. Projections on the exterior walls of these buildings that face each other are not limited in length.

**TABLE 705.2 MINIMUM DISTANCE OF PROJECTION**

<table>
<thead>
<tr>
<th>FIRE SEPARATION DISTANCE (FSD)</th>
<th>MINIMUM DISTANCE FROM LINE USED TO DETERMINE FSD</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 feet to less than 2 feet</td>
<td>Projections not permitted</td>
</tr>
<tr>
<td>2 feet to less than 5 feet</td>
<td>24 inches</td>
</tr>
<tr>
<td>5 feet or greater</td>
<td>40 inches</td>
</tr>
</tbody>
</table>

For SI: 1 foot = 304.8 mm; 1 inch = 25.4 mm.

**705.2.1 Type I and II construction.** Projections from walls of Type I or II construction shall be of noncombustible materials or combustible materials as allowed by Sections 1406.3 and 1406.4.

- The code requires projections from walls of Type I and II materials to be noncombustible. An exception for combustible materials is for balconies (Section 1406.3) and bay windows (Section 1406.4). Buildings of Type I through IV construction require the exterior walls to be noncombustible; however, the code places a higher restriction on projections on the two highest types of construction, while Section 705.2.2 allows combustible projections on buildings of Type III and IV construction. This approach mirrors the general requirements that all elements of Type I and II buildings be noncombustible, while those of Type III and IV are permitted to be constructed of combustible interior materials.
705.2.2 Type III, IV or V construction. Projections from walls of Type III, IV or V construction shall be of any approved material.

- See also Section 1406. When combustible materials are used, the provisions of Section 705.2.3 must be followed.

705.2.3 Combustible projections. Combustible projections extending to within 5 feet (1524 mm) of the line used to determine the fire separation distance, or located where openings are not permitted, or where protection of some openings is required shall be of at least 1-hour fire-resistance-rated construction. Type IV construction, fire-retardant-treated wood or as required by Section 1406.3.

Exception: Type VB construction shall be allowed for combustible projections in Group R-3 and U occupancies with a fire separation distance greater than or equal to 5 feet (1524 mm).

- This section states the requirements for protecting combustible projections and does not state when combustible projections are allowed. That is covered in Sections 705.2.1, 705.2.2 and 1406.3. There are three locations where protection is required for combustible projections:

  • The first possible location where protection is required is simply where the combustible projection extends to within 5 feet (1524 mm) of the line (either the property line or the assumed line) used to determine the fire separation distance (FSD) (see Section 202). Every projection, if allowed by Section 705.2.2 or 1406.3 to be of combustible construction, will have to be protected according to this section if the projection is within 5 feet (1524 mm) of the line used to determine the FSD.

  • The second location is a combustible projection that extends closer than 3 feet (914 mm) from the line used to determine the FSD. That is the point at which Table 705.8 prohibits openings. Of course it is obvious that a projection that is within 3 feet is already within 5 feet.

  • The third location is a combustible projection that extends closer to the lot line than the plane at which protected openings are required. According to Table 705.8, that plane is 3 feet (914 mm) from the line used to determine the FSD for sprinklered buildings and is at 5 feet (1524 mm) for nonsprinklered buildings. Again the projection within 3 feet (914 mm) is already within 5 feet (1524 mm) and by the first condition is already required to be protected according to this section.

A frequently asked question is: Should the entire projection be protected or just the portion of the projection within the 5 feet (1524 mm)? From a practical standpoint the entire projection must be protected.

The four types of protection for the combustible projections enumerated in this section are:

- The projection must be 1-hour fire-resistance-rated construction;
- The projection must be of heavy timber size combustible members;
- The projection must be constructed of fire-retardant-treated wood; or
- The projection must be as required by Section 1406.3.

The first three are self-explanatory. Section 1406.3 has construction requirements for balconies and similar projections regardless of their location on the property. The only other protection method mentioned in Section 1406.3 is sprinklers. Balconies and similar projections in Type III, IV and V construction may be combustible if sprinklers are extended into the balcony area.

There is an exception to combustible projection protection for Type VB construction in Group R-3 and Group U occupancies with a FSD equal or greater than 5 feet (1524 mm).

705.3 Buildings on the same lot. For the purposes of determining the required wall and opening protection, projections and roof-covering requirements, buildings on the same lot shall be assumed to have an imaginary line between them.

Where a new building is to be erected on the same lot as an existing building, the location of the assumed imaginary line with relation to the existing building shall be such that the exterior wall and opening protection of the existing building meet the criteria as set forth in Sections 705.5 and 705.8.

Exception: Two or more buildings on the same lot shall either be regulated as separate buildings or shall be considered as portions of one building if the aggregate area of such buildings is within the limits specified in Chapter 5 for a single building. Where the buildings contain different occupancy groups or are of different types of construction, the area shall be that allowed for the most restrictive occupancy or construction.

This section addresses buildings on the same lot and requires that an imaginary lot line be established between buildings in order to determine exterior wall fire ratings and opening protective (see the definition of “Fire separation distance”). This section takes the approach of limiting the conflagration hazard between buildings on the same property.

The exception permits two buildings on the same lot to be exempt from Sections 705.5 and 705.8 when considered as one building in accordance with Section 503.1.2. The provisions of Sections 705.8.5 and 705.8.6 would still apply, since a need exists to restrict fire spread between stories within a building. Although not specifically identified in the exception, Section 705.11 would not apply, since it is dependent on the exterior wall being required to have a fire-
resistance rating in accordance with Section 705.5, which relates to measurement of FSD. The last sentence of the exception reminds the user that the normal code requirements would still be applicable once the two buildings are considered as one. Therefore, if two types of construction are involved, then the lowest type of construction would be assumed for the entire building because there is no fire wall between them. In applying this last sentence it is probably easiest to determine what the requirement is if the user imagines what the code requirement would be if the buildings were pushed together. In such a case, it would be easier to see that a fire wall would be needed between portions of a building that are of two different construction types or the entire building would have to be viewed as the lowest possible type of construction. Regarding occupancies and associated allowable areas, they would be separated per Section 508.4 or considered as nonseparated occupancies per Section 508.3 and, therefore, use the most restrictive allowable area.

In order to help make sense of the last sentence of the exception, the idea of imagining the two buildings being pushed together, as mentioned above, is helpful. Then realize that simply pulling the building apart should not increase or lessen the code requirements for that "single" building.

### 705.4 Materials

**Exterior walls** shall be of materials permitted by the building type of construction.

- The material (combustible or noncombustible) requirements for exterior walls are found in Sections 602.1 through 602.5. Only Type V construction allows exterior walls to be combustible construction. Other types of construction require exterior walls, or at least the framing members, to be noncombustible. Type I and II construction allows limited use of fire retardant wood for exterior nonload-bearing walls. All types of construction allow insulation, exterior wall coverings and interior finish to be combustible within limits. See Sections 603, 720 and 1405.5 for materials allowed within and on framed exterior walls.

### 705.5 Fire-resistance ratings

**Exterior walls** shall be fire-resistance rated in accordance with Tables 601 and 602 and this section. The required fire-resistance rating of exterior walls with a fire separation distance of greater than 10 feet...
FIRE AND SMOKE PROTECTION FEATURES

(3048 mm) shall be rated for exposure to fire from the inside. The required fire-resistance rating of exterior walls with a fire separation distance of less than or equal to 10 feet (3048 mm) shall be rated for exposure to fire from both sides.

Table 601 states the requirements for the fire-resistance ratings for load-bearing exterior walls. All load-bearing exterior walls except those in Type IIB and VB construction require some degree of fire-resistance rating. Table 602 states the requirements for the fire-resistance ratings for both load-bearing and non-load-bearing exterior walls. Whereas Table 602 is based on the fire separation distance, the type of construction and the occupancy group, Table 601 requirements are only a function of the type of construction. Whichever one of the two tables results in the highest fire-resistance rating shall be used.

Fire exposure from the outside of the building is thought to be from other buildings either on the same property or another property. Therefore, with increased FSD, the spread of fire from building to building is lessened. For years the code required the fire-resistance rating to be from both sides of the exterior wall when the FSD was 5 feet (1524 mm) or less. During the development of the IBC, it was decided that exterior walls that had no required fire-resistance rating according to Tables 601 and 602 could have unlimited unprotected openings (see Section 705.8.1, Exception 2). This would allow an exterior wall in a Type IIB or VB building of nearly any occupancy group to have unlimited openings and a nonfire-resistant-rated wall at an FSD of 10 feet (3048 mm). You could have another building 15-plus feet (4572 mm) from the first building with an exterior wall without fire-resistance rating from the exterior exposure because that building would have an FSD of 5 feet (1524 mm). The consensus now is that an FSD of 10 feet (3048 mm) is more practical for allowing the fire-resistance ratings of the exterior wall to be based on interior surface-exposure only. Now the fire-resistance rating of the exterior wall is from both sides when the FSD is 10 feet (3048 mm) or less.

705.6 Structural stability. The wall shall extend to the height required by Section 705.11 and shall have sufficient structural stability such that it will remain in place for the duration of time indicated by the required fire-resistance rating. Where exterior walls have a minimum fire separation distance of not less than 30 feet (9144 mm), interior structural elements which brace the exterior wall but which are not located within the plane of the exterior wall shall have the minimum fire-resistance rating required in Table 601 for that structural element. Structural elements which brace the exterior wall but are located outside of the exterior wall or within the plane of the exterior wall shall have the minimum fire-resistance rating required in Tables 601 and 602 for the exterior wall.

Structural stability of fire-resistant-rated construction is an important concern. Section 705.6 requires that the fire-resistant-rated exterior wall must be constructed to remain in place for the required duration of time equal to the required fire-resistance-rated construction. Similar sections describe stability, support and continuity for fire walls (Section 706.2), fire barriers (Section 707.5.1), fire partitions (Section 708.4), smoke barriers (Section 709.4) and horizontal assemblies (Section 711.4). This section on structural integrity for exterior walls does not require that the wall remains in place when the structure collapses. That language is only used for fire wall structural integrity.

The ability of the exterior wall to remain in place for the required duration of time will require that the supporting elements also be fire-resistance rated for the same duration of time as the wall. In light-frame platform construction this will require that the band joist or beam supporting the floor and the wall above must also be of fire-resistant construction. Although the floor construction itself may not be required to be of fire-resistance-rated construction in Type IIB and VB construction, some effort must be made to ensure that the floor joists at least at the exterior wall are of fire-resistant-rated construction. Although the floor framing acts as a lateral support for the exterior wall, this section does not require that the entire floor system be of fire-resistance-rated construction. To state otherwise would prohibit Type IIB and VB buildings with an FSD of less than 10 feet (3048 mm). Only the structural element within the floor system that supports the vertical load of the wall must be of fire-resistance-rated construction.

For exterior walls, this section requires the required fire-resistance-rated construction to extend to the roof construction or to the top of the parapet if a parapet is required (see Section 705.11). This begs the question—in conventional light-frame platform construction, is the floor system supported by the lower exterior wall and supporting the exterior wall above part of the exterior wall? And, if so, how and to what limits do you go to provide a fire-resistance rating? This is a valid concern in Type IIB and VB construction with an FSD of less than 10 feet (3048 mm) because the floor system is not required to be fire-resistant rated but the exterior wall is required to have a fire-resistance rating. Both the continuity and the structural integrity issue are illustrated in Figure 705.6.

When parapet walls are not required, the exterior wall for fire-resistant rating purposes stops at the roof/ceiling construction.

A new sentence in the 2012 code exempts interior structural elements which brace an exterior wall with a 30-foot (9144 mm) FSD from having a fire-resistance rating equal to the wall it braces. However, the structural element must have a fire-resistance rating as required by Table 601 for that structural element.
705.7 Unexposed surface temperature. Where protected openings are not limited by Section 705.8, the limitation on the rise of temperature on the unexposed surface of exterior walls as required by ASTM E 119 or UL 263 shall not apply. Where protected openings are limited by Section 705.8, the limitation on the rise of temperature on the unexposed surface of exterior walls as required by ASTM E 119 or UL 263 shall not apply provided that a correction is made for radiation from the unexposed exterior wall surface in accordance with the following formula:

\[ A_e = A + (A_r \times F_{eo}) \]  

(Equation 7-1)

where:

- \( A_e \) = Equivalent area of protected openings.
- \( A \) = Actual area of protected openings.
- \( A_r \) = Area of exterior wall surface in the story under consideration exclusive of openings, on which the temperature limitations of ASTM E 119 or UL 263 for walls are exceeded.
- \( F_{eo} \) = An "equivalent opening factor" derived from Figure 705.7 based on the average temperature of the unexposed wall surface and the fire-resistance rating of the wall.

The purpose of this provision is to allow the use of an exterior fire-resistance-rated wall assembly that does not meet all of the conditions of acceptance of ASTM E 119 or UL 263. The only condition that may not apply is the limitation on the rise of temperature on the unexposed surface of the wall. To pass the standard the rise of temperature cannot exceed 250°F (121°C) above the initial temperature. All listed fire-resistance-rated exterior walls and partitions meet all of the conditions of acceptance. If a particular required fire-resistance-rated exterior wall was not listed by an approved testing agency for the required duration of time, then this section could be applicable.

For exterior walls with FSDs of 20 feet (6096 mm) or greater, the limitation on the rise of temperature on the unexposed surface of the exterior wall does not apply. This is practical because at 20 feet (6096 mm) an unlimited area of protected openings can be installed; protected openings are treated as windows or doors and the standard fire test for windows and doors does not have a limit on the temperature rise. To accept a nonlisted exterior wall assembly, the failed test data would have to be provided showing that the assembly did indeed pass all of the conditions of acceptance except rise of temperature on the unexposed surface.

For required exterior walls with FSDs of less than 20 feet (6096 mm), the limitation on the rise of temperature on the unexposed surface of the exterior wall may not apply. To accept a nonlisted exterior wall assembly, the failed test data would have to be provided showing that the assembly did indeed pass all of the conditions of acceptance except rise of temperature on the unexposed surface. The test data must also state the average temperature of the unexposed surface at the time duration for which the exterior wall is required to be rated. We must make a correction for the radiation from the unexposed exterior wall surface. We convert the wall surface which has too much temperature rise to an equivalent amount of protected openings. Then we check for compliance with the opening provisions of Section 705.8.1 as always. See Example 705.7:

Example 705.7:

The exterior bearing wall of a Type VA nonsprinklered building with a Group B occupancy is 16 feet (4877 mm) from an interior lot line. The designer chose to use an exterior wall assembly which failed the ASTM E 119 fire test because of the rise of temperature of the unexposed surface. The designer supplies the failed test data which clearly shows that the wall met all conditions of acceptance for a 1-hour fire-resistance rating except the rise of temperature on the unexposed side which was an average of 1200°F (649°C) at 1-hour fire duration. Since the temperature rise exceeds the allowed, we must treat the wall surface as though it had an equivalent area of protected openings.

Solution:

- From Table 602: the exterior wall must be fire-resistant rated for 1 hour.
- From Table 705.8: the wall may have 75-percent protected wall openings or 25-percent
FIRE AND SMOKE PROTECTION FEATURES

unprotected wall openings or a combination of the two in accordance with Section 705.8.4.

- From drawing of exterior wall elevation: total area of wall = 700 sq. ft. (65 m²).
  total area of protected openings = 0
  total area of unprotected openings = 120 sq. ft. (11 m²).
  total area of exterior wall surface minus the openings = 580 sq. ft. (54 m²).

- First we compute the equivalent area of protected openings using Equation 7-1:
- We can calculate from the drawings the actual area of protected openings which is \( A_p \), \( A = 0 \)
- We can calculate \( A_e \) from the drawings. It is the total area of the wall surface minus the openings. 700-120 = 540 sq. ft.
- We can obtain \( F_{eo} \) from Figure 705.7. Using the given average temperature rise on the unex-

For SI: \( ^{\circ}C = \left( ^{\circ}F - 32 \right) / 1.8 \).

**FIGURE 705.7**
EQUIVALENT OPENING FACTOR

**Example 705.7**
ELEVATION OF EXTERIOR WALL

For SI: 1 foot = 304.8 mm.
posed side which was 1200°F and the curve on the figure for 1 hour and reading to the left legend we find that \( F_{eo} \) for this assembly is 0.34.

- Equation 7-1 yields: \( A_e = 0 + (540 \times 0.34) \) or \( A_e = 197 \) sq. ft.

Having solved for the equivalent area of protected openings we can now proceed as normal by checking compliance with Section 705.8.4 since we have a mix of protected and unprotected openings in the fire-resistance-rated exterior wall.

- From Table 705.8: Seventy-five percent of the total wall area may be protected openings or \( 0.75 \times 700 = 525 \) sq. ft.
- From Table 705.8: Twenty-five percent of the total wall area may be unprotected openings or \( 0.25 \times 700 = 175 \) sq. ft.
- From Equation 7-2: \( (A_e / A_o) + (A_u / A_o) \leq 1 \) or we have too many openings in the wall.
- From Equation 7-2 and using \( A_e \) computed above for \( A_e \), we have \((197/525) + (120/175) \leq 1\) or \(0.375 + 0.685 = 1.06\) which is not less than or equal to 1. The wall does not meet the code. Too many openings.

**705.8 Openings.** Openings in exterior walls shall comply with Sections 705.8.1 through 705.8.6.

- The requirements of this section limit the allowable area of openings in exterior walls and are applicable to buildings with or without walls with FSDs less than 30 feet (9144 mm). The limitations on openings in exterior walls is a function of FSD (see definition this chapter), and the degree of protection provided for the opening. The degree of protection of the openings is either unprotected in a nonsprinklered building (UP, NS), unprotected in a sprinklered building (UP, S) or protected openings (P). Protected openings are openings with fire doors, fire shutters or fire window assemblies which comply with Sections 716.5 and 716.6. Sprinklered buildings are buildings with an NFPA 13 sprinkler system. Buildings with only an NFPA 13 R system shall be considered nonsprinklered for the purpose of opening limitations in exterior walls. The percentage of openings allowed is in Table 705.8, subject to the exceptions in Section 705.8.1.

**TABLE 705.8.** See page 7-20.

- Table 705.8, on page 7-20, provides allowable areas for exterior wall openings for structures based on the FSD of the exterior wall and the degree of protection afforded to the opening, such as fire shutters and automatic sprinkler systems. The more protection provided, the larger the area of openings can get.

**705.8.1 Allowable area of openings.** The maximum area of unprotected and protected openings permitted in an exterior wall in any story of a building shall not exceed the percentages specified in Table 705.8.

**Exceptions:**

1. In other than Group H occupancies, unlimited unprotected openings are permitted in the first story above grade plane either:

   1.1. Where the wall faces a street and has a fire separation distance of more than 15 feet (4572 mm); or

   1.2. Where the wall faces an unoccupied space. The unoccupied space shall be on the same lot or dedicated for public use, shall not be less than 30 feet (9144 mm) in width and shall have access from a street by a posted fire lane in accordance with the *International Fire Code.*

2. Buildings whose exterior bearing walls, exterior non-bearing walls and exterior primary structural frame are not required to be fire-resistance rated shall be permitted to have unlimited unprotected openings.

- The allowable area is given as a percentage of the total wall area at any story. Each story must comply independently.

   - Exception 1.1 only applies to the exterior walls on the first story above grade. For all occupancies except Group H, the first-story exterior wall which faces a street and which is at least 15 feet (4572 mm) from the wall to the centerline of the street shall be allowed unlimited unprotected openings.

   - Exception 1.2 also applies to the exterior walls on only the first story above grade. For all occupancies except Group H, the first-story exterior wall which faces a minimum 30-foot-wide (9144 mm) unoccupied space on the same lot or dedicated for public use, at least 30 feet (9144 mm) wide with access from a street by a fire lane, shall be allowed unlimited unprotected openings.

Since the first story above grade is generally readily available for fire department access, unprotected openings are not limited in the above exception. See Figure 705.8.1 for examples of first-story openings.

- Exception 2 is for openings in all exterior walls in all stories where Tables 601 and 602 do not require any exterior wall (bearing or nonbearing) or primary structural member to be fire-resistance rated. Therefore, this exception is only applicable to Type II B and VB construction with an FSD of 10 feet (3048 mm) or greater. This allows unlimited unprotected openings in Type II B and VB construction for all exterior walls facing an FSD of 10 feet (3048 mm) or more.

</tbody>
</table>

For SI: 1 foot = 304.8 mm.

UP, NS = Unprotected openings in buildings not equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1.

UP, S = Unprotected openings in buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1.

P = Openings protected with an opening protective assembly in accordance with Section 705.8.2.

a. Values indicated are the percentage of the area of the exterior wall, per story.

b. For openings in a fire wall for buildings on the same lot, see Section 706.8.

c. For the requirements for fire walls of buildings with differing heights, see Section 706.6.1.

d. The maximum percentage of unprotected and protected openings shall be 25 percent for Group R-3 occupancies.

e. Unprotected openings shall not be permitted for openings with a fire separation distance of less than 15 feet for Group H-2 and H-3 occupancies.
f. The area of unprotected and protected openings shall not be limited for Group R-3 occupancies, with a fire separation distance of 5 feet or greater.
g. The area of openings in an open parking structure with a fire separation distance of 10 feet or greater shall not be limited.
h. Includes buildings accessory to Group R-3.
i. Not applicable to Group H-1, H-2 and H-3 occupancies.
j. For special requirements for Group U occupancies, see Section 406.3.2.
the exterior openings are protected by a water curtain using automatic sprinklers approved for that use.

- To be considered protected, the opening must have a listed and labeled fire door, fire shutter or fire window meeting the requirements of Sections 716.5 and 716.6. The required fire protection rating of doors in protected openings of exterior walls shall be in accordance with Table 716.5. Protected window assemblies shall have the fire protection rating as indicated in Table 716.6.

The exception to Section 705.8.2 is irrelevant for most occupancies. Table 705.8 allows the same percentage of opening area for protected openings and unprotected openings in sprinklered buildings and Table 705.8 does not have the water curtain requirement as the exception does. In a building sprinklered throughout with a full NFPA 13 system, the same percentage of openings is allowed, whether they are protected or unprotected.

The exception to Section 705.8.2 would be relevant for Group H occupancies since Note 1 to Table 705.8 makes the unprotected sprinklered category not applicable to Group H-1, H-2, and H-3 occupancies.

705.8.3 Unprotected openings. Where unprotected openings are permitted, windows and doors shall be constructed of any approved materials. Glazing shall conform to the requirements of Chapters 24 and 26.

- Unprotected openings can be windows and doors of any approved material. Glazing must meet the structural requirements and the safety requirements as applicable in Chapters 24 and 26. All openings in wind-borne debris regions must be protected by impact-resistant material in accordance with Section 1609.1.2. For purposes of exterior wall fire-resistance requirements and opening limitations, an unprotected opening can have nothing at all in it as a partial enclosed building. Sheds without exterior walls must also meet Section 705.8 and Table 705.8.

705.8.4 Mixed openings. Where both unprotected and protected openings are located in the exterior wall in any story of a building, the total area of openings shall be determined in accordance with the following:

\[
(A_p/a_p) + (A_u/a_u) \leq 1
\]  
(Equation 7-2)

where:

- \(A_p\) = Actual area of protected openings, or the equivalent area of protected openings, \(A_e\) (see Section 705.7).
- \(a_p\) = Allowable area of protected openings.
- \(A_u\) = Actual area of unprotected openings.
- \(a_u\) = Allowable area of unprotected openings.

- The opening limitations in Table 705.8 vary according to the degrees of opening protection. The table establishes the acceptable percentage for openings if all openings were of one degree of protection. For instance, at 12 feet (3658 mm) if all openings are unprotected in a nonsprinklered building you can have only 15 percent of the wall area in unprotected...
openings. In that same exterior wall if all openings were protected, you could have 45 percent of the wall area in protected openings. If any exterior wall area in any story has both protected and unprotected openings, then the actual areas of both types of openings must meet Equation 7-2.

Example 705.8.4:
In a Type IIA building, the exterior wall is required to be of 1-hour fire-resistance-rated construction by Table 602. The wall has an FSD of 12 feet (3658 mm). The building is nonsprinklered. The wall in the first story has a total area of 1000 sq. ft. (93 m²). The designer has 150 sq. ft. (14 m²) of protected openings in the wall and 100 sq. ft. (9.3 m²) of unprotected openings. Does this comply with the code, particularly Section 705.8.4?

Solution:
• Use Equation 7-2
• From the example in the protected openings are 150 sq. ft. (14 m²). This value is $A_p$.
• From Table 705.8 the allowable area (if only protected openings are used) is 45 percent. Forty-five percent of 1000 sq. ft. (93 m²) is 450 sq. ft. (42 m²) (1000 x 0.45 = 450). This value is $a_p$ in the equation.
• From the building in the example the unprotected openings are 100 sq. ft. (9.3 m²) This value is $A_u$ in the equation.
• From Table 705.8 the allowable area (if only unprotected openings are used) is 15 percent. Fifteen percent of 1000 sq. ft. (93 m²) is 150 sq. ft. (14 m²) (1000 x 0.15 = 150). This value is $a_u$ in the equation.
• Equation 7-2 ($A_p/a_p$) + ($A_u/a_u$) ≤ 1 or ($150/450$) + ($100/150$) ≤ 1 or 0.333 + 0.666 = 1
• $A_p/A_u$ This amount of openings exactly complies with the code. Had the sum of the ratios exceeded 1 the opening mixture would not be allowed.

705.8.5 Vertical separation of openings. Openings in exterior walls in adjacent stories shall be separated vertically to protect against fire spread on the exterior of the buildings where the openings are within 5 feet (1524 mm) of each other horizontally and the opening in the lower story is not a protected opening with a fire protection rating of not less than 1/2 hour. Such openings shall be separated vertically at least 3 feet (914 mm) by spandrel girders, exterior walls or other similar assemblies that have a fire-resistance rating of at least 1 hour and by flame barriers that extend horizontally at least 30 inches (762 mm) beyond the exterior wall. Flame barriers shall also have a fire-resistance rating of at least 1 hour. The unexposed surface temperature limitations specified in ASTM E 119 or UL 263 shall not apply to the flame barriers or vertical separation unless otherwise required by the provisions of this code.

Exceptions:
1. This section shall not apply to buildings that are more than three stories or less above grade plane.
2. This section shall not apply to buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2.
3. Open parking garages.

Where unprotected openings occur in adjacent stories, a fire that breaks out of an opening in a lower story can spread vertically to upper stories of the building. A fire at the Hilton Hotel in Las Vegas provides a good illustration of this problem. In that incident a fire broke out in an elevator lobby at a lower level and then quickly spread upwards to a number of other stories simply due to the flame plume from the lower level impinging on the windows above and causing the combustible materials in those upper levels to ignite. A vertical panel or horizontal flame barrier is necessary to minimize the possibility of vertical flame spread. The vertical panel is to be at least 3 feet (914 mm) in height and have a fire-resistance rating of at least 1 hour [see Figure 705.8.5(1)]. Full-scale fire tests have shown that the vertical panel...
should extend at least 30 inches (762 mm) above the finished floor level. This is to prevent the transfer of radiant heat to furnishings and other combustibles located in the lower portion of the room in the story above the assumed fire exposure. Horizontal flame barriers are required to extend at least 30 inches (762 mm) beyond the face of the exterior wall and have a fire-resistance rating of at least 1 hour [see Figure 705.8.5(2)].

This section requires such protection when the opening on the lower level is not fire-protection rated for \( \frac{3}{4} \) hour or more. The use of glazing is one example of why this section is so specific. Wired glass, for example, has been shown to retain its integrity with limited fire exposure when exposed to a fire condition for a certain period of time. For this reason, wired glass has historically been recognized as a suitable exterior opening protective within size and mounting methods defined by its listing.

Wired glass permits a significant percentage, typically recognized as high as 50 percent, of radiant heat energy to pass through. Since the initial concern is heat radiated from the flame plume, wired glass does little to prevent ignition of combustibles in the room on the upper floor. This section permits the elimination of the unexposed surface temperature limitations prescribed by ASTM E 119 for flame barriers and vertical shields. Fire spread between floors is primarily the result of radiant heat, not conductive heat transfer. Full-scale tests have shown that only a small degree of fire resistance is required for adequate protection since radiant energy is the primary concern and glazing in the unprotected openings above the story of fire origin may break within 1 minute.

Protection is not required for buildings three stories or less in height. This exception is consistent with Table 503, which permits buildings of three stories in height to be of Type IIB, IIC and VB construction when these buildings do not require a fire-resistance rating for the floor construction.

The exception for buildings protected with an automatic sprinkler system is consistent with the code’s approach to limiting fire size and, thus limiting spread of fire beyond the area or room of origin. The exception is based on the effectiveness and reliability of automatic sprinkler systems in decreasing fire size. The reference to Section 903.3.1.1 or 903.3.1.2 reinforces that the system must be a code-compliant automatic sprinkler system per NFPA 13 as modified by Section 903.3.1.1 or in accordance with NFPA 13R as modified by Section 903.3.1.2. Exception 3 acknowledges the practicality of constructing open parking structures and the need to have a significant amount of openings for natural ventilation.

705.8.6 Vertical exposure. For buildings on the same lot, opening protectives having a fire protection rating of not less than \( \frac{3}{4} \) hour shall be provided in every opening that is less than 15 feet (4572 mm) vertically above the roof of an adjacent building or structure based on assuming an imaginary line between them. The opening protectives are required where the fire separation distance between the imaginary line and the adjacent building or structure is less than 15 feet (4572 mm).

Exceptions:

1. Opening protectives are not required where the roof assembly of the adjacent building or structure has a fire-resistance rating of not less than 1 hour for a minimum distance of 10 feet (3048 mm) from the exterior wall facing the imaginary line and the entire length and span of the supporting elements for the fire-resistance-rated roof assembly has a fire-resistance rating of not less than 1 hour.

2. Buildings on the same lot and considered as portions of one building in accordance with Section 705.3 are not required to comply with Section 705.8.6.

A fire in a building that is adjacent to a taller building can be the source of fire exposure to openings in the taller building. Although the height of a fire plume is dependent on several factors, this section requires \( \frac{3}{4} \) hour or greater opening protectives in the wall where the openings are within 15 feet (4572 mm) above the roof of a building that is within a horizontal FSD of 15 feet (4572 mm) (see Figure 705.8.6). Full-scale tests have indicated that exterior flame plumes may extend higher than 16 feet (4877 mm) above a window using a fuel load of 8 pounds per square foot (psf) (39 kg/m²). Since this provision is based on a fire exposure from the roof of the lower building, it does not apply where the roof construction is 1-hour fire-resistance rated, which reduces the potential for fire exposure.

For SI: 1 inch = 25.4 mm.

Figure 705.8.5(2)
EXTERIOR WALL HORIZONTAL FLAME BARRIER
705.9 Joints. Joints made in or between exterior walls required by this section to have a fire-resistance rating shall comply with Section 715.

**Exception:** Joints in exterior walls that are permitted to have unprotected openings.

- Joints, such as expansion or seismic, are another form of openings in exterior walls, and therefore, must be considered with regard to maintaining the fire-resistance ratings of the exterior walls. This section requires that all joints located in exterior walls required to be fire-resistance rated are to be protected by a joint system that has a fire-resistance rating and complies with the requirements of Section 715 (see commentary for Section 715). The exception to joint protection here and in Section 715 is for exterior walls which are permitted by Table 705.8 to have unprotected openings. Therefore, this section requires fire-resistant joint systems to protect joints in exterior walls of nonsprinklered buildings with an FSD of 5 feet (1524 mm) or less; in sprinklered buildings with an FSD of 3 feet (914 mm) or less; and in Group H-2 or H-3 buildings with an FSD of 15 feet (4572 mm) or less (see note e to Table 705.8). This implies that the building may have joints in fire-resistance-rated walls with an FSD of less than 3 feet (914 mm). In this context, joints are not treated like openings which are not permitted in walls with an FSD of less than 3 feet (914 mm).

705.9.1 Voids. The void created at the intersection of a floor/ceiling assembly and an exterior curtain wall assembly shall be protected in accordance with Section 715.4.

- See the commentary to Section 715.4.

705.10 Ducts and air transfer openings. Penetrations by air ducts and air transfer openings in fire-resistance-rated exterior walls required to have protected openings shall comply with Section 717.

**Exception:** Foundation vents installed in accordance with this code are permitted.

- This section requires air outlets in exterior walls, including air intake and air exhaust outlets, to be protected by fire dampers where Table 705.8 requires protected openings. That is a wall with an FSD from 3 feet to 5 feet (914 mm to 1524 mm) for nonsprinklered buildings. For sprinklered buildings protected openings are never required, so air outlets can be located in an exterior wall with an FSD of 3 feet (914 mm) or more. There can be no openings in a wall with

---

**Figure 705.8.6**

**Vertical Fire Exposure of Adjacent Building**

For SI: 1 foot = 304.8 mm.
an FSD of less than 3 feet (914 mm). Fire damper assembly standards are in accordance with Section 717. Exhaust outlets that cannot have fire dampers (such as commercial kitchen hood exhausts) cannot be located in exterior walls in locations where openings are required to be protected in accordance with Table 705.8. This is also stated in Section 508.3.12.2 of the IMC.

705.11 Parapets. Parapets shall be provided on exterior walls of buildings.

Exceptions: A parapet need not be provided on an exterior wall where any of the following conditions exist:

1. The wall is not required to be fire-resistance rated in accordance with Table 602 because of fire separation distance.
2. The building has an area of not more than 1,000 square feet (93 m²) on any floor.
3. Walls that terminate at roofs of not less than 2-hour fire-resistance-rated construction or where the roof, including the deck or slab and supporting construction, is constructed entirely of noncombustible materials.
4. One-hour fire-resistance-rated exterior walls that terminate at the underside of the roof sheathing, deck or slab, provided:

   4.1. Where the roof/ceiling framing elements are parallel to the walls, such framing and elements supporting such framing shall not be of less than 1-hour fire-resistance-rated construction for a width of 4 feet (1220 mm) for Groups R and U and 10 feet (3048 mm) for other occupancies, measured from the interior side of the wall.

   4.2. Where roof/ceiling framing elements are not parallel to the wall, the entire span of such framing and elements supporting such framing shall not be of less than 1-hour fire-resistance-rated construction.

   4.3. Openings in the roof shall not be located within 5 feet (1524 mm) of the 1-hour fire-resistance-rated exterior wall for Groups R and U and 10 feet (3048 mm) for other occupancies, measured from the interior side of the wall.

   4.4. The entire building shall be provided with not less than a Class B roof covering.

5. In Groups R-2 and R-3 where the entire building is provided with a Class C roof covering, the exterior wall shall be permitted to terminate at the underside of the roof sheathing or deck in Type III, IV and V construction, provided:

   5.1. The roof sheathing or deck is constructed of approved noncombustible materials or of fire-retardant-treated wood for a distance of 4 feet (1220 mm); or

   5.2. The roof is protected with 0.625-inch (16 mm) Type X gypsum board directly beneath the underside of the roof sheathing or deck, supported by a minimum of nominal 2-inch (51 mm) ledgers attached to the sides of the roof framing members for a minimum distance of 4 feet (1220 mm).

6. Where the wall is permitted to have at least 25 percent of the exterior wall areas containing unprotected openings based on fire separation distance as determined in accordance with Section 705.8.

Parapets are required to restrict spread of fire from building to building and are therefore a function of the FSD. Parapets are not required to extend above the roofs on all buildings. There are six exceptions. Exceptions 1 and 6 apply to all buildings.

   • Exception 1 exempts exterior walls with a 30-foot (9144 mm) or greater FSD for all types of construction except Types IIB and VB. Exterior walls of Types IIB and VB (except for H occupancy) with greater than 10 feet (3048 mm) of FSD are exempt from parapets.

   • Exception 6 exempts all sprinklered buildings from parapet walls when the exterior walls have an FSD of 5 feet (1524 mm) or greater. Exception 6 exempts all nonsprinklered buildings from parapets with an FSD of 15 feet (4572 mm) or greater. Exception 6 is the greater exemption for all but Type IIB and VB nonsprinklered buildings, when Exception 1 is better. These two exceptions yield the following:

     • Parapet walls are not required on sprinklered buildings with an FSD of 5 feet (1524 mm) or greater.

     • Parapet walls are not required for nonsprinklered Type IIB and VB construction with an FSD of 10 feet (3048 mm) or more.

     • Parapet walls are not required for nonsprinklered buildings of all types of construction other than Types IIB and VB with an FSD of 15 feet (4572 mm) or more.

   • Exception 2 exempts buildings with 1000 sq. ft. (93 m²) or less on any floor.

   • Exceptions 3, 4 and 5. While Exceptions 1, 2 and 6 completely exempt the exterior walls from parapets, Exceptions 3, 4 and 5 deal with special credit for the roof construction.

Exception 3, 4 and 5 require the exterior walls to extend to the roof deck or underside of roof sheathing and require special attention to the roof construction to eliminate the need for the parapet extension, thus they are not subject to any FSD requirements and
can have an FSD of zero. Exceptions 1, 2 and 6 simply exempt the walls from extending above the roof without any special roof construction and do not require that the walls must extend to the roof deck.

Exception 1 applies to bearing and nonload-bearing walls and would also exempt bearing walls from parapets if the bearing wall was not required to have a fire-resistance rating by Table 602, even if said bearing wall was required to have a fire-resistance rating by Table 601.

705.11 Parapet construction. Parapets shall have the same fire-resistance rating as that required for the supporting wall, and on any side adjacent to a roof surface, shall have noncombustible faces for the uppermost 18 inches (457 mm), including counterflashing and coping materials. The height of the parapet shall not be less than 30 inches (762 mm) above the point where the roof surface and the wall intersect. Where the roof slopes toward a parapet at a slope greater than two units vertical in 12 units horizontal (16.7-percent slope), the parapet shall extend to the same height as any portion of the roof within a fire separation distance where protection of wall openings is required, but in no case shall the height be less than 30 inches (762 mm).

- Parapet wall construction shall be of combustible or noncombustible material depending on the exterior wall requirements of the type of construction and shall be of fire-resistance-rated construction as required for the exterior wall. The interior wall covering facing the roof, including the flashing, shall be noncombustible to a height of 18 inches (457 mm) above the roof. The required height of the parapet shall be 30 inches (762 mm) above the roof surface unless the roof slopes upward away from the wall on a pitch of 2 in 12 or greater. In some cases, the last part of this section requires a higher parapet, depending on the FSD. When the slope of the roof is over 2 in 12, the parapet shall extend to a height equal to the height of the roof at the point determined as follows:
  - In a nonsprinklered building, Table 705.8 requires protected openings for any FSD between 3 and 5 feet (914 mm and 1524 mm); therefore, the height of the roof at 5 feet (1524 mm) is the height to which the parapet wall extension must extend, but must always extend at least 30 inches (762 mm) above the roof at the exterior wall. For a nonsprinklered building, the height of the roof at the plane where protected openings are required according to Table 705.8 is the height at 5 feet (1524 mm) from the common lot line or assumed property line. See Figure 705.11.1(1).
  - For a sprinklered building, Table 705.8 never requires protected openings. Therefore, for a sprinklered building the parapet need only extend 30 inches (762 mm) above the roof, regardless of the slope of the roof or the FSD. See Figure 705.11.1(2).

SECTION 706
FIRE WALLS

706.1 General. Each portion of a building separated by one or more fire walls that comply with the provisions of this section shall be considered a separate building. The extent and location of such fire walls shall provide a complete separation. Where a fire wall also separates occupancies that are required to be separated by a fire barrier wall, the most restrictive requirements of each separation shall apply.

- Fire walls serve to create separate buildings for purposes of allowable area and type of construction requirements (see the definition of "Area, building" in Section 202). All code provisions that apply to buildings would be applied individually to the "building" on each side of the fire wall. Because of the special allowances for allowable areas, a fire wall must provide a higher level of fire safety, continuity and structural integrity than other types of fire-resistance-rated walls. When the designer utilizes a fire wall he or she must design the fire wall to meet this section.

It is not intended that fire walls can be provided in the horizontal plane to create separate buildings. Fire walls cannot be utilized to increase the allowable building height. However, offsetting two vertical sections of fire walls is permissible as long as the required fire-resistance rating and structural stability are maintained.

706.1.1 Party walls. Any wall located on a lot line between adjacent buildings, which is used or adapted for joint service between the two buildings, shall be constructed as a fire wall in accordance with Section 706. Party walls shall be constructed without openings and shall create separate buildings.

Exception: Openings in a party wall separating an anchor building and a mall shall be in accordance with Section 402.7.3.1.

- A party wall is a fire wall on an interior lot line, adapted for joint use by both buildings. It is distinguished from other fire walls in that it is on the property line and serves to separate buildings usually owned by two separate parties. When two separate structures are built up to the property line, the designer has the option of using two separate exterior walls with zero FSD or a party wall. Since there is a real property line involved, the prohibition for openings between the two buildings is important and even utilities cannot penetrate the party wall. Unlike fire walls in other buildings, which can have openings in them, party walls cannot have any openings in them (see Section 706.8 for opening limits on other fire walls).

The exception to allow openings is important since many anchor stores are actually owned by the major department store while the mall is owned by a separate entity. The fact that there is a real property line at the separation walls between an anchor and a mall means that technically there is a party wall, but openings are normally present and a necessary function of the mall and anchor.
For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

Figure 705.11.1(1)
PARAPET WALL EXTENSION WITH SLOPING 100% NONSPRINKLERED BUILDING

For SI: 1 inch = 25.4 mm.

Figure 705.11.1(2)
PARAPET WALL EXTENSION WITH SLOPING ROOF SPRINKLERED BUILDING
706.2 Structural stability. Fire walls shall have sufficient structural stability under fire conditions to allow collapse of construction on either side without collapse of the wall for the duration of time indicated by the required fire-resistance rating or shall be constructed as double fire walls in accordance with NFPA 221.

- Since the collapse of one building from fire conditions should not cause the collapse of an adjacent building, a fire wall is required to be capable of withstanding the collapse of the construction on either side of the wall. An exception to the provision is found in Exception 5 to Section 706.6. In this situation, the issue of structural stability would still apply if the fire was in the buildings located above the horizontal separation required in Section 509.2, Item 1. However, it would clearly be impossible for the buildings above the separation or for that matter the fire wall to be able to withstand the collapse of the building beneath it. Since the building below is of Type IA construction and the separation has a 3-hour fire-resistance rating, this should not be a problem. See 706.6, Exception 5, regarding fire walls in this situation.

There are various methods of designing and constructing fire walls for structural stability during a fire. Among the systems used are cantilevered or freestanding walls, laterally supported and tied walls, and double wall construction. For masonry walls, the NCMA TEK Bulletin 5-8B contains helpful information. For an example with a masonry fire wall, see Figure 706.2(1). The Gypsum Association’s Fire Resistance Design Manual contains construction details for area separation walls (party wall/fire walls) which have been accepted as fire walls. For an example of a gypsum board fire wall, see Figure 706.2(2).

The collapse of structural members at some distance from the wall can generally be ignored, but the structural members that are supported by the wall or that are attached directly to the wall for lateral support do require special attention.

Double fire walls shall be assumed to have the required structural stability if they are constructed in accordance with NFPA 221. NFPA 221 covers more than double fire walls, but the IBC only references it for double fire walls.

706.3 Materials. Fire walls shall be of any approved noncombustible materials.

Exception: Buildings of Type V construction.

- This section requires that fire walls be constructed of noncombustible materials unless both buildings are of Type V (combustible) construction. This is consistent with the provisions of Section 602, which require exterior walls of buildings of Type I, II, III and IV to be built of noncombustible construction, while buildings of Type V construction are permitted to be built of combustible exterior walls.

706.4 Fire-resistance rating. Fire walls shall have a fire-resistance rating of not less than that required by Table 706.4.

- The required fire-resistance rating must comply with the more restrictive occupancy of Table 706.4. For example, if two buildings of Type II construction with occupancies in Groups S-1 and B are built of any construction type and separated by a fire wall, the fire wall is required to have a fire-resistance rating of 3 hours (in accordance with Table 706.4 based on Group S-1). The provisions of Section 706.1 should also be reviewed when determining the required fire-resistance rating. If the occupancies involved require a separation, or are not permitted in a mixed occupancy building, then the most restrictive requirement between that and the fire wall provisions will apply.

- In Type II or V construction, walls shall be permitted to have a 2-hour fire-resistance rating.
- For Group H-1, H-2 or H-3 buildings, also see Sections 415.6 and 415.7.

The fire-resistance ratings represent a relationship between the fuel load and an exposure to fire severity that is equivalent to the standard time-temperature curve. The relationship is based on a number of full-scale fire tests by the U.S. Department of Commerce’s National Bureau of Standards (NBS) conducted in the 1920s to determine how actual building fires compared with the temperatures represented by the standard time-temperature curve (see commentary, Section 703.2).

An analysis of tests documented by S.H. Ingber indicates that the weight per square foot (psf) of ordinary combustibles, such as wood and paper, with a heat of combustion of 7,000 to 8,000 British thermal units (Btu) per pound (16 282 to 18 608 kJ/kg), is related to hourly fire severity as described in Figure 706.4(1). By comparing Table 706.4 to Figure 706.4(2), it shows that the table is not based solely on the average fuel load of the occupancy. Not only are other factors, such as occupant density and evacuation capability, incorporate into the required fire-resistance rating, but it must also be recognized that fuel loads in a building are not evenly distributed. For example, the average fuel load for an occupancy in Group B may be 5 to 10 psf (24 to 49 kg/m²). The fuel load in file and storage rooms, however, may be 10 to 20 psf (49 to 98 kg/m²). While other sections of the code may address these areas by mandating an automatic fire suppression system with a partition capable of resisting the passage of smoke or a fire-resistance-rated enclosure of the incidental use area,

FIRE AND SMOKE PROTECTION FEATURES

the potential for higher fuel loads is also factored into determining the required fire-resistance rating.

The minimum fire-resistance ratings required in Table 706.4 generally correlate with the fire-resistance ratings required by Table 508.3.3; however, Table 706.4 contains provisions that acknowledge the need for more conservative ratings for fire walls due to their unique role in creating separate buildings.

Note a allows a reduction in the fire-resistance rating of the fire walls in buildings of Type II or V construction. For instance, the fire-resistance rating of a fire wall separating a Type II building from a Type V building can be only 2 hours. If the buildings on both sides of the fire wall are Type II construction, the same reduction is allowed. If the buildings on both sides of the fire wall are Type V construction then the same reduction is allowed. If the building on either side of the fire wall is of another type of construction than Type II or V, then the greater fire-resistance rating is required.

Due to the unique nature of the hazards presented by occupancies of Groups H-1, H-2 and H-3, Table 706.4 includes Note b, which references Sections 415.4 and 415.5 for specific requirements relative to the construction of such buildings (see commentary, Sections 415.4 and 415.5).

706.5 Horizontal continuity. Fire walls shall be continuous from exterior wall to exterior wall and shall extend at least 18 inches (457 mm) beyond the exterior surface of exterior walls.

Exceptions:

1. Fire walls shall be permitted to terminate at the interior surface of combustible exterior sheathing or siding provided the exterior wall has a fire-resistance rating of at least 1 hour for a horizontal distance of at least 4 feet (1220 mm) on both sides of the fire wall. Openings within such exterior walls shall be protected by opening protectives having a fire protection rating of not less than \( \frac{1}{2} \) hour.

2. Fire walls shall be permitted to terminate at the interior surface of noncombustible exterior sheathing, exterior siding or other noncombustible exterior finishes provided the sheathing, siding, or other exterior noncombustible finish extends a horizontal distance of at least 4 feet (1220 mm) on both sides of the fire wall.

3. Fire walls shall be permitted to terminate at the interior surface of noncombustible exterior sheathing where the building on each side of the fire wall is protected by an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2.

Historically, the codes have addressed the hazards of fire exposure at the fire wall from only a vertical perspective; namely, at the roof (see Section 706.6). Section 706.5 addresses a similar fire hazard concern from the horizontal perspective; namely, at the intersection of the fire wall and the exterior wall.

The 18-inch (457 mm) extension is intended to abate the potential for fire to travel from one building to the other around the fire wall. The 18-inch (457 mm) extension is required to extend the full height of the fire wall. The three exceptions acknowledge the effect certain types of construction will have on fire breaching the exterior wall and exposing the adjacent building; namely, fire-resistance-rated construction (see Exception 1), noncombustible finish materials (see Exception 2) and noncombustible sheathing materials coupled with sprinkler protection (see Exception 3) provide the necessary barrier to limit fire spread across the exterior surface. The difference between Exceptions 2 and 3 is that Exception 2

**Figure 706.4(2)**

OCCUPANCIES—FUEL LOAD—FIRE SEVERITY
would not permit a combustible exterior finish to be placed over the noncombustible exterior wall construction, while Exception 3 would allow a combustible exterior finish, provided the building is sprinklered with either an NFPA 13 or 13R system.

706.5.1 Exterior walls. Where the fire wall intersects exterior walls, the fire-resistance rating and opening protection of the exterior walls shall comply with one of the following:

1. The exterior walls on both sides of the fire wall shall have a 1-hour fire-resistance rating with 3/4-hour protection where opening protection is required by Section 705.8. The fire-resistance rating of the exterior wall shall extend a minimum of 4 feet (1220 mm) on each side of the intersection of the fire wall to exterior wall. Exterior wall intersections at fire walls that form an angle equal to or greater than 180 degrees (3.14 rad) do not need exterior wall protection.

2. Buildings or spaces on both sides of the intersecting fire wall shall assume to have an imaginary lot line at the fire wall and extending beyond the exterior of the fire wall. The location of the assumed line in relation to the exterior walls and the fire wall shall be such that the exterior wall and opening protection meet the requirements set forth in Sections 705.5 and 705.8. Such protection is not required for exterior walls terminating at fire walls that form an angle equal to or greater than 180 degrees (3.14 rad).

This section deals only with fire walls that terminate at an exterior wall that does not continue in the same horizontal plane but the exterior walls on each side of the fire wall form an angle of less than 180 degrees (3.14 rad). For example, the required fire wall may end at an inside corner of an L-shaped building. Should this occur, not only does Section 705.5 apply but this section has extra requirements to mitigate the exterior wall fire exposure from one building to another. This section states two methods of complying. See Figures 706.5.1(1), 706.5.1(2) and 706.5.1(3).

706.5.2 Horizontal projecting elements. Fire walls shall extend to the outer edge of horizontal projecting elements such as balconies, roof overhangs, canopies, marquees and similar projections that are within 4 feet (1220 mm) of the fire wall.

Exceptions:

1. Horizontal projecting elements without concealed spaces, provided the exterior wall behind and below the projecting element has not less than 1-hour fire-resistance-rated construction for a distance not less than the depth of the projecting element on both sides of the fire wall. Openings within such exterior walls shall be protected by opening protectives having a fire protection rating of not less than 3/4 hour.

2. Noncombustible horizontal projecting elements with concealed spaces, provided a minimum 1-hour fire-

Fire walls are typically used to reduce the building area for the purpose of code compliance; however, many structures divided by fire walls are still detailed as a contiguous structure with projecting elements located on the exterior wall that extend across the fire wall. These projecting elements represent a potential conduit for fire to be transferred from one side of the building to the other side of the building. Even if the projecting elements are terminated at a distance in close proximity to the fire wall, the potential for fire spread to the adjacent projecting element still exists. In this section, 4 feet (1219 mm) (measured from the fire wall) is considered the appropriate threshold.

This section requires the fire wall to extend to the outer edge of the projecting element when such an element is located within 4 feet (1219 mm) of the fire wall. For example, in a contiguous residential structure with interior lot lines and fire walls or party walls between each dwelling unit, and where balconies are located within 4 feet (1219 mm) of the party or fire wall, then the fire/party wall must be extended to the outer edge of the balcony or to a point in line with the outer edge of the balcony.

Exception 1 acknowledges the reduction in hazard due to the lack of a concealed space crossing the fire wall; however, since the projecting element provides a connection between the buildings, there is still a potential for fire to transfer across the wall, thus the need for a rated exterior wall separation between the inside of the building and the projection. Exceptions 2 and 3 address projecting elements with concealed spaces of noncombustible and combustible construction, respectively.
706.6 Vertical continuity. *Fire walls* shall extend from the foundation to a termination point at least 30 inches (762 mm) above both adjacent roofs.

**Exceptions:**

1. Stepped buildings in accordance with Section 706.6.1.

2. Two-hour fire-resistance-rated walls shall be permitted to terminate at the underside of the roof sheathing, deck or slab, provided:

   2.1. The lower roof assembly within 4 feet (1220 mm) of the wall has not less than a 1-hour fire-resistance rating and the entire length and span of supporting elements for the rated roof assembly has a fire-resistance rating of not less than 1 hour.

2.2. Openings in the roof shall not be located within 4 feet (1220 mm) of the fire wall.

2.3. Each building shall be provided with not less than a Class B roof covering.

3. Walls shall be permitted to terminate at the underside of noncombustible roof sheathing, deck or slabs where both buildings are provided with not less than a Class B roof covering. Openings in the roof shall not be located within 4 feet (1220 mm) of the fire wall.

4. In buildings of Type III, IV and V construction, walls shall be permitted to terminate at the underside of combustible roof sheathing or decks, provided:

   4.1. There are no openings in the roof within 4 feet (1220 mm) of the fire wall.
4.2. The roof is covered with a minimum Class B roof covering, and

4.3. The roof sheathing or deck is constructed of fire-retardant-treated wood for a distance of 4 feet (1220 mm) on both sides of the wall or the roof is protected with \( \frac{5}{8}\)-inch (15.9 mm) Type X gypsum board directly beneath the underside of the roof sheathing or deck, supported by a minimum of 2-inch (51 mm) nominal ledgers attached to the sides of the roof framing members for a minimum distance of 4 feet (1220 mm) on both sides of the fire wall.

5. In buildings designed in accordance with Section 510.2, fire walls located above the 3-hour horizontal assembly required by Section 510.2, Item 1 shall be permitted to extend from the top of this horizontal assembly.

6. Buildings with sloped roofs in accordance with Section 706.6.2.

* One of the primary purposes of a fire wall is to provide protection from an exposure fire. A fire wall must be continuous from the foundation to or through the roof. The fire wall is required to extend to 30 inches (762 mm) above the roof surface (see Figure 706.6 for a diagram of a typical fire wall). Where other provisions are met that will restrict the spread of fire, this

---

A - NO OPENINGS

B - 15% UNPROTECTED

C - 25% UNPROTECTED

---

2012 INTERNATIONAL BUILDING CODE® COMMENTARY
30-inch (762 mm) extension is not required (see Exceptions 1 through 5). Exception 1 stipulates that fire walls separating two buildings that have different roof levels must comply with the provisions of Section 706.6.1.

Exception 2 to this section's requirement for a parapet applies to buildings where: (a) the maximum required fire-resistance rating of the fire wall is 2 hours; (b) the roof assembly located within 4 feet (1219 mm) of the fire wall has a minimum fire-resistance rating of 1 hour (including all supporting elements and structural members); (c) no roof openings are located within 4 feet (1219 mm) of the fire wall and (d) the buildings on either side of the fire wall have a minimum Class B roof covering. The provisions of Exception 2 are not applicable to buildings with combustible roof construction where a fire wall is required to have a fire-resistance rating of 3 hours or greater. Buildings where the fire wall is required to have a 3-hour or greater fire-resistance rating must comply with the general provisions of Section 706.6, or with Exceptions 3 or 4 in order to qualify for the parapet extension exception.

Exception 3 states that, since the intent of the parapet is to prevent fire spread over the roof, it is not required if the entire roof is of noncombustible con-
FIRE AND SMOKE PROTECTION FEATURES

struction; the fire wall is continuous to the underside of the roof deck, roof slab or roof sheathing; the roof-covering material has a minimum Class B classification in accordance with the provisions of Section 1505.3 (see commentary, Section 1505.3) and there are no roof openings located within 4 feet (1219 mm) on either side of the fire wall.

The intent of the requirement for a Class B roof covering is due to the fact that roof coverings are not considered part of the roof, and therefore, are not subject to the noncombustibility requirements of this section. This section requires that the roof covering be effective against moderate fire test exposure to reduce the potential for fire spread across the roof. The restriction on the location of roof openings is intended to minimize the potential of the spread of fire from one building to an adjacent building via roof openings, such as skylights, penetrations or roof windows. This fire spread could occur from something such as a fan that breaches the roof opening in the involved building and exposes roof openings in the adjacent building to direct fire or to burning brands, which could land on the roof, burn through the roof opening and ignite combustibles in the interior of the adjacent building. The 4-foot (1219 mm) threshold provides a reasonable approximation of a fire plume, beyond which the exposure to fire of the adjacent building is reduced. Exception 4 to the requirement in Section 706.6 for a parapet is the condition in buildings of Type III, IV and V construction where the sheathing or deck is constructed of noncombustible materials or approved fire-retardant-treated wood for a distance of 4 feet (1219 mm) on both sides of the wall (see the commentary to Section 2303.2 for additional information on fire-retardant-treated wood) or where the prescribed application of 3/8-inch (15.9 mm) Type X gypsum board is applied to the underside of the deck for a distance of 4 feet (1219 mm) on both sides of the wall. The roof coverings on both buildings must have a minimum Class B rating and no roof openings are to be located within 4 feet (1219 mm) of the fire wall (see commentary, Section 508.2). The intent is the same: to resist the passage of flame beyond the fire wall.

706.6.1 Stepped buildings. Where a fire wall serves as an exterior wall for a building and separates buildings having different roof levels, such wall shall terminate at a point not less than 30 inches (762 mm) above the lower roof level, provided the exterior wall for a height of 15 feet (4572 mm) above the lower roof is not less than 1-hour fire-resistance-rated construction from both sides with openings protected by fire assemblies having a fire protection rating of not less than 1/2 hour.

Exception: Where the fire wall terminates at the underside of the roof sheathing, deck or slab of the lower roof, provided:

1. The lower roof assembly within 10 feet (3048 mm) of the wall has not less than a 1-hour fire-resistance rating and the entire length and span of supporting

![Figure 706.6](Source: National Gypsum Company)
elements for the rated roof assembly has a fire-resistance rating of not less than 1 hour.

2. Openings in the lower roof shall not be located within 10 feet (3048 mm) of the fire wall.

- The basic provisions of Section 706.6 require that a parapet extend a minimum of 30 inches (762 mm) above the roof surfaces on both sides of the fire wall, which would then require fire walls separating buildings with different roof heights to extend 30 inches (762 mm) above the highest roof surface. The provisions of Section 706.6.1 address situations where a fire wall separates adjacent buildings with a difference in roof height. These provisions acknowledge that fire exposure to the exterior wall of an adjacent building from the roof of a lower building represents, to a certain extent, a reduced hazard.

This section retains the fire wall extension above the lower roof surface and places a 15-foot (4572 mm) limit on rated wall construction and opening protective, while the exception allows the fire wall extension to be eliminated as long as a fire barrier, in the form of 1-hour-rated roof construction, is provided that extends a minimum of 10 feet (3048 mm) from the fire wall. The option provided by this section permits openings in an exterior wall that extend above the fire wall, where the fire wall extends 30 inches (762 mm) above the lower roof surface and the exterior wall extending above the fire wall is constructed as a 1-hour fire-resistance-rated wall, rated for exposure from both sides, for a distance of 15 feet (4572 mm) above the lower roof surface. Where the fire wall and exterior wall comply with these requirements, openings are permitted in the exterior wall extension, provided that all openings located within 15 feet (4572 mm) of the lower roof surface are protected with 1/2-hour-rated opening protective. Openings located more than 15 feet (4572 mm) above the lower roof surface are not required to have opening protective [see Figure 706.6.1(1)]. The provisions of this section are similar to those contained in Section 704.10 for vertical exposure of exterior openings. They require that when the difference in height between the roof surfaces of the adjacent buildings is less than 15 feet (4572 mm), the exterior wall extension is required to extend to the underside of the upper roof deck [see Figure 706.6.1(2)]. The exception permits openings in the roof that extend above the fire wall, where: (a) the fire wall terminates at the bottom of the roof deck of the lower roof; (b) the lower roof assembly has a minimum 1-hour fire-resistance rating for a minimum distance of 10 feet (3048 mm) from the fire wall and (c) there are no openings located in the lower roof within 10 feet (3048 mm) of the fire wall. Openings located in the exterior wall above the lower roof surface are not required to have opening protective [see Figure 706.6.1(3)]. It must be noted that all structural elements, including beams, columns and bearing walls that provide support for the fire-resistance-rated roof assembly, must also have a 1-hour fire-resistance rating for their entire length or span in order to maintain the effectiveness of the rated roof assembly. The provisions of this section are similar to those contained in Section 1022.7 for the protection of the exterior walls of exit stairways. The provisions for stepped buildings only apply where a fire wall is required in between the buildings and do not apply to party walls on real property lines.

---

**Figure 706.6.1(1)**
FIRE WALLS—STEPPED BUILDINGS

For St: 1 inch = 25.4 mm, 1 foot = 304.8 mm.
706.6.2 Buildings with sloped roofs. Where a fire wall serves as an interior wall for a building, and the roof on one side or both sides of the fire wall slopes toward the fire wall at a slope greater than two units vertical in 12 units horizontal (2:12), the fire wall shall extend to a height equal to the height of the roof located 4 feet (1219 mm) from the fire wall plus 30 inches (762 mm). In no case shall the extension of the fire wall be less than 30 inches (762 mm).

- This requirement is similar to that of stepped buildings. This section only applies if the roof slopes upward away from the fire wall at a slope greater than two units vertical in 12 units horizontal (2:12). The sloping roof presents a greater hazard to the building from fire exposure on either side than a roof at the same elevation on each side. The hazard would increase as the slope of the roof increases. Figure 706.6.2 illustrates this requirement. This section requires the extension above the roof regardless of the material of the roof construction on either side. For roofs sloping two units vertical in 12 units hori-
706.7 Combustible framing in fire walls. Adjacent combustible members entering into a concrete or masonry fire wall from opposite sides shall not have less than a 4-inch (102 mm) distance between embedded ends. Where combustible members frame into hollow walls or walls of hollow units, hollow spaces shall be solidly filled for the full thickness of the wall and for a distance not less than 4 inches (102 mm) above, below and between the structural members, with noncombustible materials approved for fireblocking.

In order to retain the fire-resistance capability of the wall where combustible members will frame into it, hollow walls or walls of hollow units must be solidly filled for the thickness of the wall and for a distance of not less than 4 inches (102 mm) above, below and between the structural members. Consistent with the construction of the walls, the fireblocking materials are to be noncombustible and approved for fireblocking in accordance with Section 717.2. If combustible members enter both sides of a fire wall, there must be at least 4 inches (102 mm) of masonry between the embedded ends.

In order to maintain structural integrity where wood beams or joist are supported in and on masonry fire walls, the joist and beams should be shaped so that they can rotate out of the pocket without exerting undue force on the wall.

706.8 Openings. Each opening through a fire wall shall be protected in accordance with Section 716.5 and shall not exceed 156 square feet (15 m²). The aggregate width of openings at any floor level shall not exceed 25 percent of the length of the wall.

Exceptions:
1. Openings are not permitted in party walls constructed in accordance with Section 706.1.1.
2. Openings shall not be limited to 156 square feet (15 m²) where both buildings are equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1.

In order to maintain the integrity of the fire wall, the maximum area and percent of openings in the wall are restricted. When provided, the openings must be properly protected so that the fire-resistance rating of the wall is maintained. This section prescribes the maximum area and the percent of openings that may be permitted in a fire wall at any one floor level. The provisions must be used in concert with Section 706.1.1, which limits openings for party walls.

Fire wall openings have restrictive limitations in their size and total area because of the critical function that a fire wall serves. To maintain the required fire performance of the fire wall, each opening through a fire wall is restricted in area to 156 square feet (11 m²) and the aggregate width of all openings at any one floor level may not constitute more than 25 percent of the length of the wall. The 156-square-foot (11 m²) limitation provides a reasonable size through which industrial machinery may pass and corresponds with the maximum area limitations of many tested fire doors.

Recognizing the effectiveness of automatic sprinklers, the 156-square-foot (11 m²) opening limitation does not apply where the buildings on both sides of the fire wall are fully sprinklered (see Exception 2); however, the aggregate width of all openings in a fire wall at any one floor level is still limited to 25 percent of the length of the wall.

706.9 Penetrations. Penetrations of fire walls shall comply with Section 714.

In order to maintain the integrity of the required fire-resistance rating, penetrations through the fire wall must be properly protected. Acceptable protection methods for various penetrations of fire walls are identified in Sections 714.2 and 714.3.

706.10 Joints. Joints made in or between fire walls shall comply with Section 715.

Joints, such as expansion or seismic, are another form of openings in fire walls and, therefore, must be considered with regard to maintaining the fire-resistance ratings of fire walls. This section requires all joints that are located in fire walls to be protected by a joint system with a fire-resistance rating and to comply with the requirements of Section 715.
FIRE AND SMOKE PROTECTION FEATURES

706.11 Ducts and air transfer openings. Ducts and air transfer openings shall not penetrate fire walls.

Exception: Penetrations by ducts and air transfer openings of fire walls that are not on a lot line shall be allowed provided the penetrations comply with Section 717. The size and aggregate width of all openings shall not exceed the limitations of Section 706.8.

The general provisions of this section mirror those of Section 706.1.1 for party walls. The exception permits duct and transfer openings for fire walls not located on a lot line, provided the maximum aggregate area provisions of Section 706.8 are met and that the openings are protected in accordance with Section 717.

SECTION 707
FIRE BARRIERS

707.1 General. Fire barriers installed as required elsewhere in this code or the International Fire Code shall comply with this section.

The provisions of this section apply to assemblies that are required to have a fire-resistance rating and are required to be constructed as "fire barriers." As addressed in Section 707.3, fire barriers are used for separating exits, incidental use areas, shafts, hazardous materials control areas and fire areas. Fire barriers provide a higher degree of protection than fire partitions (see Section 708), but lack the inherent structural integrity of fire walls. Fire barriers limit the number of openings. Fire barrier wall assemblies must be continuous from the top of a fire-resistance-rated floor/ceiling assembly to the bottom of the floor or roof slab/deck above. Unlike fire partitions, addressed in Section 708, there are no circumstances under which a fire barrier wall is permitted to terminate at a ceiling.

Fire barriers are used for a variety of purposes, such as mixed occupancies, shafts, exit access stairways and exit and floor opening enclosures. Fire barriers also include interior walls that serve to subdivide a space by separating one fire area from an adjacent fire area and for separating incidental use areas (see Section 509.4.1). Fire-resistance-rated assemblies used to separate exit access corridors in many applications as well as tenant, dwelling unit and guestroom separations are fire partitions (see Section 708). This section provides minimum requirements for the fire-resistance rating, continuity, combustibility and protection of openings and penetrations in order to help maintain the reliability of the fire separation assembly. As with any fire-resistance-rated assembly, consideration must be given to the openings and penetrations that are provided within the assembly. The intent is to maintain the fire-resistance rating of the assembly. These sections recognize that fire spread beyond a fire-resistance-rated compartment is often attributed to the protection given to any opening or penetration in the fire barrier, or the lack thereof.

Since the fire barrier is intended to provide a reliable subdivision of areas, the construction that structurally supports the assembly is required to provide at least the same hourly fire-resistance rating as the fire barrier. This is applicable regardless of the type of construction of the building. Structural stability is regulated by Section 707.5.

707.2 Materials. Fire barriers shall be of materials permitted by the building type of construction.

The types of materials used in fire barriers are to be consistent with Sections 602 through 602.5 for the type of construction classification of the building. The fire-resistance ratings of fire barriers used to separate mixed occupancies are determined in accordance with Section 508.4 (see commentary, Section 508.4). Fire barriers are permitted to be of combustible materials in Type III, IV and V construction and are required to be of noncombustible materials in Type I and II construction.

707.3 Fire-resistance rating. The fire-resistance rating of fire barriers shall comply with this section.

The elements that are identified in this section must be constructed as required for fire barriers and must be fire-resistance rated as required by the code sections referenced in this section.

707.3.1 Shaft enclosures. The fire-resistance rating of the fire barrier separating building areas from a shaft shall comply with Section 713.4.

See Section 713.4 for the fire-resistance rating for shaft enclosures.

707.3.2 Interior exit stairway and ramp construction. The fire-resistance rating of the fire barrier separating building areas from an interior exit stairway or ramp shall comply with Section 1022.1.

See Section 1022.2 for the fire-resistance rating of the fire barrier separating building areas from interior exit stairways and ramps (vertical exit enclosures).

707.3.3 Enclosures for exit access stairways. The fire-resistance rating of the fire barrier separating building areas from an exit access stairway or ramp shall comply with Section 1009.3.1.2.

See Sections 1009.2.2 and 1022.2 for the enclosure requirements for exit access stairways and ramps. Unlike exit stairway enclosures, there are numerous exceptions to the enclosure requirements in Section 1009.2.2.
707.3.4 Exit passageway. The fire-resistance rating of the fire barrier separating building areas from an exit passageway shall comply with Section 1023.3.

- See Section 1023.3 for the fire-resistance rating for fire barriers forming exit passageways. Exit passageway enclosures may be fire barriers complying with this section or horizontal assemblies complying with Section 711.

707.3.5 Horizontal exit. The fire-resistance rating of the separation between building areas connected by a horizontal exit shall comply with Section 1025.1.

- See Section 1025.1 for the fire-resistance rating of the fire barriers forming horizontal exits. Horizontal exits may be formed by fire walls meeting Section 706, fire barriers complying with this section or horizontal assemblies complying with Sections 1025.2 and 711.

707.3.6 Atriums. The fire-resistance rating of the fire barrier separating atriums shall comply with Section 404.6.

- See Section 404.6 for the fire-resistance rating of the fire barrier walls separating the atrium area from other building use areas. Horizontal assemblies meeting Section 711 can also separate the atrium area.

707.3.7 Incidental uses. The fire barrier separating incidental uses from other spaces in the building shall have a fire-resistance rating of not less than that indicated in Table 509.

- Table 509 states the fire-resistance requirements for fire barrier walls separating incidental use areas. For some incidental uses there is a sprinkler option in lieu of the fire-resistance-rated fire barrier wall. With the sprinkler option, the wall is not required to be fire-resistance rated but must be capable of resisting the passage of smoke. Those nonrated wall assemblies are not required to be constructed as fire barriers.

707.3.8 Control areas. Fire barriers separating control areas shall have a fire-resistance rating of not less than that required in Section 414.2.4.

- Control areas refer to areas within a building where limited quantities of hazardous materials are stored or used. Section 414.2.4 references Table 414.2.4 for the design and number of control areas. The required fire-resistance rating for the fire barriers separating the control areas from the rest of the area is also found within the table.

707.3.9 Separated occupancies. Where the provisions of Section 508.4 are applicable, the fire barrier separating mixed occupancies shall have a fire-resistance rating of not less than that indicated in Table 508.4 based on the occupancies being separated.

- Where separation of mixed occupancies is the chosen option for mixed uses in a building, the required fire separation is either a fire barrier meeting the requirements of this section or a horizontal fire separation assembly meeting the requirements of Section 711 (see Section 508.4). The required fire-resistance rating for the fire barrier or horizontal assembly is found in Table 508.4, but in no case shall the fire-resistance rating be less than the highest value in Table 707.3.10 for the occupancies being separated.

707.3.10 Fire areas. The fire barriers or horizontal assemblies, or both, separating a single occupancy into different fire areas shall have a fire-resistance rating of not less than that indicated in Table 707.3.10. The fire barriers or horizontal assemblies, or both, separating fire areas of mixed occupancies shall have a fire-resistance rating of not less than the highest value indicated in Table 707.3.10 for the occupancies under consideration.

- One of the alternatives available in addressing fire protection systems in many buildings is to divide the building into separate fire areas (see the definition of "Fire areas" in Chapter 2). Since many of the fire suppression system thresholds (see Section 903.2) are based upon the fire area, separation of a single occupancy into small fire areas can be an acceptable method for avoiding the use of sprinklers. This is a classic type of design decision: sprinklers versus compartmentation. If the separation is provided in accordance with Table 707.3.10, each fire area may be evaluated separately for purposes of determining the applicable provisions of the code.

Areas separated with fire barriers are not considered separate buildings; they are considered separate fire areas. Two areas must be separated by a fire wall or exterior walls to be considered separate buildings. Two areas separated with fire barriers are still considered as part of a single building. This distinction is critical in determining compliance with allowable height and area and other code provisions.

Table 707.3.10 provides the minimum required fire-resistance ratings of the fire barrier wall or horizontal assembly separating two fire areas of the same occupancy group.

707.4 Exterior walls. Where exterior walls serve as a part of a required fire-resistance-rated shaft or stairway or ramp enclosure, or separation, such walls shall comply with the requirements of Section 705 for exterior walls and the fire-resistance-rated enclosure or separation requirements shall not apply.

**Exception:** Exterior walls required to be fire-resistance rated in accordance with Section 1019 for exterior egress.
balconies, Section 1022.7 for interior exit stairways and ramps and Section 1028.6 for exterior exit stairways and ramp.

- If an area is required to be enclosed by fire barriers and an exterior wall constitutes part of the enclosure, the exterior wall is only required to comply with the fire-resistance-rating requirements in Section 705, unless the exterior wall is protecting part of an exterior egress balcony, an exit enclosure or an exterior stairway or ramp (see commentary, Sections 1019, 1022.7 and 1026.6). The intent of the fire barrier requirements is to subdivide or enclose areas to protect them from a fire in the building. In general, the exterior wall need only have a fire-resistance rating if required for structural stability (see Table 601) or because of exterior exposure potential (see Table 601 and Section 705.5). The exception, however, points to three sections of the code where the exterior wall must be rated for reasons other than the FSD.

**707.5 Continuity.** *Fire barriers shall extend from the top of the foundation or floor/ceiling assembly below to the underside of the floor or roof sheathing, slab or deck above and shall be securely attached thereto. Such fire barriers shall be continuous through concealed space, such as the space above a suspended ceiling. Joints and voids at intersections shall comply with Sections 707.8 and 707.9.*

- To minimize the potential for fire spread from one area to another over a fire barrier wall, such fire barrier assemblies must be continuous from the fire-resistance-rated floor/ceiling assembly below to the underside of the floor slab or roof deck above (see Figure 707.5). To maintain the efficiency of the fire barrier, it must be continuous through all concealed spaces (such as a space above a suspended ceiling), be constructed tight and securely attached to the underside of the floor slab or roof deck. The joint at the intersection of fire barrier walls and other fire barriers; the underside of fire-resistance-rated floors or roof decks; slabs; decks and exterior walls must be an approved fire-resistance joint system meeting ASTM E 119 or UL 263.

**707.5.1 Supporting construction.** The supporting construction for a fire barrier shall be protected to afford the required fire-resistance rating of the fire barrier supported. Hollow vertical spaces within a fire barrier shall be fireblocked in accordance with Section 718.2 at every floor level.

**Exceptions:**

1. The maximum required fire-resistance rating for assemblies supporting fire barriers separating tank storage as provided for in Section 415.8.2.1 shall be 2 hours, but not less than required by Table 601 for the building construction type.

2. Shaft enclosures shall be permitted to terminate at a top enclosure complying with Section 713.12.

3. Supporting construction for 1-hour fire barriers required by Table 509 in buildings of Type IIb, IIIb and VB construction is not required to be fire-resistance rated unless required by other sections of this code.

4. Interior exit stairway and ramp enclosures required by Section 1022.2 and exit access stairway and ramp enclosures required by Section 1009.3 shall be permitted to terminate at a top enclosure complying with Section 713.12.

- In general, fire barriers must be supported by construction having an equivalent fire-resistance rating. If the supporting structure is a primary structural frame (see the definition in Chapter 2) and supports a fire barrier wall more than two stories in height, the fire-resistance rating for the supporting structure must be protected by the individual encasement method in Section 704.3. If the supporting members are a secondary structural member, then the supporting structure can be protected by a membrane as in Section 711 for horizontal assemblies. The intent of this requirement is to prevent the effectiveness of the
assembly from being circumvented by a fire that threatens the supporting elements. The requirement for the supporting construction to be fire-resistance rated applies to buildings of all types of construction, even to buildings of Type II B, II B and VB construction for all fire barrier walls except those separating incidental use areas.

Exception 1 is not an exception at all but a requirement that supporting structures for fire barriers separating flammable or combustible tank storage be 2-hour fire-resistance rated.

Exception 2 is an exception to the continuity requirement for shaft enclosure walls.

Exception 3 allows only incidental use area separation walls in Type II B, II B and VB construction to be supported on nonfire-resistance-rated construction if no other code section requires the supporting elements to be fire-resistance rated.

Exception 4 allows exit stair enclosures and exit access stairway enclosures to terminate at a top enclosure complying with Section 713.12.

Fire barrier walls will usually be built on top of a floor and will terminate at the floor above. Should a fire barrier wall, as in the case of some shaft walls, be constructed through a floor, any hollow space within that wall could provide a passage for fire or smoke and, therefore, must be fireblocked as specified in the last sentence of Section 707.5.1. Any hollow vertical spaces within fire barrier walls must be fireblocked in accordance with Section 718.2.

707.6 Openings. Openings in a fire barrier shall be protected in accordance with Section 716. Openings shall be limited to a maximum aggregate width of 25 percent of the length of the wall, and the maximum area of any single opening shall not exceed 156 square feet (15 m²). Openings in enclosures for exit access stairways and ramps, interior exit stairways and ramps and exit passageways shall also comply with Sections 1022.3 and 1023.5, respectively.

Exceptions:

1. Openings shall not be limited to 156 square feet (15 m²) where adjoining floor areas are equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1.

2. Openings shall not be limited to 156 square feet (15 m²) or an aggregate width of 25 percent of the length of the wall where the opening protective is a fire door serving enclosures for exit access stairways, exit access ramps, interior exit stairways and interior exit ramps.

3. Openings shall not be limited to 156 square feet (15 m²) or an aggregate width of 25 percent of the length of the wall where the opening protective has been tested in accordance with ASTM E 119 or UL 263 and has a minimum fire-resistance rating not less than the fire-resistance rating of the wall.

4. Fire window assemblies permitted in atrium separation walls shall not be limited to a maximum aggregate width of 25 percent of the length of the wall.

5. Openings shall not be limited to 156 square feet (15 m²) or an aggregate width of 25 percent of the length of the wall where the opening protective is a fire door assembly in a fire barrier separating an enclosure for exit access stairways, exit access ramps, interior exit stairways and interior exit ramps from an exit passageway in accordance with Section 1022.2.1.

To function as intended, buildings must provide access into different building areas. This access requires openings within fire barriers. Section 707.6 defines what openings are permitted and how they have to be protected to maintain the integrity of the fire barrier. To maintain the viability of the fire barrier, the aggregate width of openings is restricted to a maximum of 25 percent of the length of the wall. This limitation is based on the fact that the criteria for opening protective do not include limitations on unexposed surface temperature or radiant heat transfer. Consistent with typical listing limitations, a single opening protective is limited to a maximum of 156 square feet (15 m²). It should be noted, however, that certain opening protective, such as fire windows, are often limited to much smaller areas per opening.

Traditionally, the limiting size on openings in fire resistance-rated walls has been based on the maximum sizes identified in the fire door listings. The previous size limitation was 120 square feet (11 m²) due to the limitations of such listings. In 2006, the code increased the maximum permitted size of an opening protective to 156 square feet (15 m²) in a fire barrier, based upon the current listing limitations of steel fire doors. The maximum length of any single opening is limited to 13 feet, 6 inches (4114 mm) for the same reason when used during the testing process.

The reference to Sections 1022.4 and 1023.5 specifies that in exit enclosures and exit passageways, only openings for the purpose of exiting from normally occupied spaces are permitted. Spaces that are not normally occupied, such as janitor closets or mechanical and electrical rooms, are not permitted to open directly into those protected exit systems since fire in those areas may produce large volumes of heat and smoke that could readily enter the exit enclosure and delay or prevent egress. In order to maintain the required fire-resistance rating of the assembly, opening protective must have a fire protection rating in accordance with Section 716. The reference to Section 716 is intended to identify the required fire protection rating for the opening protective, as indicated in Table 716.5, installation requirements and the applicable test standards.

Openings in fire barriers are not limited to 156 square feet (15 m²) when all fire areas separated by
the assembly are equipped throughout with automatic sprinkler protection (see Exception 1). This exception is similar to the one made for fire walls (see Section 706.8), based on the historical fire record of automatic sprinkler systems. Although the openings in the fire barrier are not limited in size under this exception, they are still required to be protected by opening protective systems that meet the requirements of Section 716.

Exception 2 acknowledges the practicality of the 25-percent limitation for walls enclosing interior exit stairways and exit access stairways. Most exit enclosures are of such limited size that the placement of the fire door in the wall of the enclosure often exceeds 25 percent of the wall.

Exception 3 addresses new openings for protective products that have been tested to the more rigorous provisions of ASTM E 119 or UL 263 rather than, or in addition to, the opening protective standard NFPA 252 or UL 10C. Since the opening protective system has been tested to the same standard as the wall itself, it is then logical to allow such an opening protective system without restrictions (see commentary, Section 703.6).

Exception 4 acknowledges the inclusive requirements for openings into atriums addressed in Section 404 that include glazing material allowances not found elsewhere in Chapter 7.

Exception 5 is similar to Exception 2 in that the wall area between the exit enclosure and the exit passageway is usually so very small that the door opening will nearly always exceed the 25-percent limitation.

707.7 Penetrations. Penetrations of fire barriers shall comply with Section 714.

- In order to maintain the integrity of the fire barrier, penetrations into and through the fire-resistance-rated wall must be properly protected. Acceptable methods for various penetrations of fire barriers are identified in Section 714.3. The provisions of Section 707.7.1 must be used when the penetration is into an exit enclosure or exit passageway.

707.7.1 Prohibited penetrations. Penetrations into enclosures for exit access stairways, exit access ramps, interior exit stairways, interior exit ramps or an exit passageway shall be allowed only when permitted by Section 1009.3.1.5, 1022.5 or 1023.6, respectively.

- This section reminds the code user that although the penetration firestop systems do provide protection for the penetration, the code prohibits most penetrations through exit enclosures. Only penetrations of items such as sprinkler piping, necessary ductwork for stair pressurization, and electrical conduit that serve the exit enclosure are allowed. There can never be a penetration through a fire barrier that separates an adjacent exit enclosure.

707.8 Joints. Joints made in or between fire barriers, and joints made at the intersection of fire barriers with underside of a fire-resistance rated floor or roof sheathing, slab, or deck above, and the exterior vertical wall intersection shall comply with Section 715.

- This section contains requirements for joints or linear openings created between building assemblies, which are sometimes referred to as construction, expansion or seismic joints. These joints are most often created where the structural design of a building necessitates a separation between building components in order to accommodate anticipated structural displacements caused by thermal expansion and contraction, seismic activity, wind or other loads. Figure 715.1 illustrates some of the most common locations of these joints.

These linear openings create a "weak link" in fire-resistance rated assemblies, which can compromise the integrity of the tested assembly. By allowing an opening for the passage of fire and the products of combustion through the assembly, in order to maintain the efficacy of the fire-resistance rated assembly, these openings must be protected by a joint system with a fire-resistance rating equal to the adjacent assembly. It is not the intent of this section to regulate joints installed in assemblies that are provided to control shrinkage cracking, such as a saw-cut control joint in concrete (see Section 715).

707.9 Voids at intersections. The voids created at the intersection of a fire barrier and a non-fire resistance-rated roof assembly shall be filled. An approved material or system shall be used to fill the void, which shall be securely installed in or on the intersection for its entire length so as not to dislodge, loosen or otherwise impair its ability to accommodate later expected building movements and to retard the passage of fire and hot gases.

- This new section is meant to give some prescriptive requirements for the joint formed by the intersection of a fire barrier wall and a non-fire resistance-rated roof. Since fire barrier walls must extend to the roof deck, the method of sealing the resulting joint is prescribed here. Unlike a joint formed by a fire barrier wall and a fire-resistance rated roof, which requires a joint meeting the test criteria of ASTM E 1986 or UL 2079, this joint or void must only be filled with a material approved by the building official. It is not the intent of this section to require any performance-based tested assembly.

707.10 Ducts and air transfer openings. Penetrations in a fire barrier by ducts and air transfer openings shall comply with Section 717.

- Section 717 details the protection of ducts and air transfer openings at the point where they penetrate a fire-resistance-rated assembly. Section 717.5 indicates which situations will require the installation of a damper. As stated in Section 717.1.1, if a duct does not require a damper, the penetration of that duct through a fire-resistance-rated assembly must be protected as a through penetration in accordance with Section 714.
SECTION 708
FIRE PARTITIONS

708.1 General. The following wall assemblies shall comply with this section.

1. Walls separating dwelling units in the same building as required by Section 420.2.

2. Walls separating sleeping units in the same building as required by Section 420.2.

3. Walls separating tenant spaces in covered and open mall buildings as required by Section 402.4.2.1.

4. Corridor walls as required by Section 1018.1.

5. Elevator lobby separation as required by Section 713.14.1.

"Fire partitions," as defined in Section 202, are wall assemblies that enclose an exit access corridor, separate dwelling units, separate sleeping units and separate tenants in covered and open mall buildings and separate elevator lobbies. There are some exceptions to the requirement that corridor walls and elevator lobby walls be fire partitions. Those exceptions are found in Sections 713.14.1 and 1018.1.

Corridor walls not required to be fire-resistance rated by Table 1018.1 are not required to meet this section. Elevator lobby walls not required to be fire-resistance rated by the exceptions to Section 713.14.1 are not required to meet this section.

This section contains fire-resistance rating requirements, continuity requirements, opening requirements, penetration requirements, joint requirements and duct and air transfer opening requirements for fire partitions.

For horizontal assemblies separating dwelling and sleeping units, see Section 711.

708.2 Materials. The walls shall be of materials permitted by the building type of construction.

The types of materials used in fire partitions are to be consistent with Sections 602.2 through 602.5 for the type of construction classification of the building. Fire partitions are permitted to be of combustible construction in Type III, IV and V construction and are required to be of noncombustible materials in Type I and II construction, except as allowed by Exception 1 to Section 603.1.

708.3 Fire-resistance rating. Fire partitions shall have a fire-resistance rating of not less than 1 hour.

Exceptions:

1. Corridor walls permitted to have a 1/2 hour fire-resistance rating by Table 1018.1.

2. Dwelling unit and sleeping unit separations in buildings of Type IIB, IIIB and VB construction shall have fire-resistance ratings of not less than 1/2 hour in buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1.

This requirement is for fire partitions to be 1-hour fire-resistance rated. There are two exceptions.

Exception 1 states that corridor walls not required by Table 1018.1 to be fire-resistance rated need not comply with this section at all, since according to Section 1018.1 they are not fire partitions. Table 1018.1 also contains a reduction of the 1-hour fire-resistance rating down to 30 minutes for sprinklered Group R occupancies.

A reduction in the fire-resistance rating for dwelling and sleeping unit separation is allowed for Type IIB, IIIB and VB construction which is sprinklered with an NFPA 13 sprinkler system. This is not allowed with an NFPA 13R system according to Exception 2, which reduces the rating from 1 hour to only 30 minutes. There is a similar reduction for the horizontal assemblies separating dwelling and sleeping units in Section 711.3.

708.4 Continuity. Fire partitions shall extend from the top of the foundation or floor/ceiling assembly below to the underside of the floor or roof sheathing, slab or deck above or to the fire-resistance-rated floor/ceiling or roof/ceiling assembly above, and shall be securely attached thereto. In combustible construction where the fire partitions are not required to be continuous to the sheathing, deck or slab, the space between the ceiling and the sheathing, deck or slab above shall be fire-blocked or draftstopping in accordance with Sections 718.2 and 718.3 at the partition line. The supporting construction shall be protected to afford the required fire-resistance rating of the wall supported, except for walls separating tenant spaces in covered and open mall buildings, walls separating dwelling units, walls separating sleeping units and corridor walls, in buildings of Type IIB, IIIB and VB construction.

Exceptions:

1. The wall need not be extended into the crawl space below where the floor above the crawl space has a minimum 1-hour fire-resistance rating.

2. Where the room-side fire-resistance-rated membrane of the corridor is carried through to the underside of the floor or roof sheathing, deck or slab of a fire-resistance-rated floor or roof above, the ceiling of the corridor shall be permitted to be protected by the use of ceiling materials as required for a 1-hour fire-resistance-rated floor or roof system.

3. Where the corridor ceiling is constructed as required for the corridor walls, the walls shall be permitted to terminate at the upper membrane of such ceiling assembly.

4. The fire partitions separating tenant spaces in a covered or open mall building, complying with Section 402.7.2, are not required to extend beyond the underside of a ceiling that is not part of a fire-resis-
FIRE AND SMOKE PROTECTION FEATURES

tance-rated assembly. A wall is not required in attic or ceiling spaces above tenant separation walls.

5. Attic fireblocking or draftstopping is not required at the partition line in Group R-2 buildings that do not exceed four stories above grade plane, provided the attic space is subdivided by draftstopping into areas not exceeding 3,000 square feet (279 m²) or above every two dwelling units, whichever is smaller.

6. Fireblocking or draftstopping is not required at the partition line in buildings equipped with an automatic sprinkler system installed throughout in accordance with Section 903.3.1.1 or 903.3.1.2, provided that automatic sprinklers are installed in combustible floor/ceiling and roof/ceiling spaces.

To minimize the potential for fire spread from the exposed side of the fire partition to the unexposed side, such partitions must be continuous from the floor assembly to the underside of a fire-resistance-rated floor/ceiling or roof/ceiling assembly. In the absence of a rated floor/ceiling or roof/ceiling assembly, the fire partition is to be continuous to the floor slab or roof deck above [see Figures 708.4(1) and 708.4(2)(A)]. All hollow vertical spaces in a combustible fire partition must be fireblocked at the ceiling and floor or roof levels in accordance with Section 718.2. If the fire-resistance-rated floor/ceiling or roof/ceiling assembly are of combustible construction, then draftstopping is required in the space above and in line with the partition. The draftstopping must meet Section 718.3. Fire partitions are not always required to be continuous through concealed spaces, whereas fire barriers are to be continuous (see Section 707.5). This is the primary difference between fire barriers and fire partitions.

Fire partitions serving as exit access corridor walls and tenant and guestroom separation walls in buildings of Type IIIB, IIB and VB construction are not required to be supported by structural elements having the same fire-resistance rating. The primary purpose of rated corridor walls is to prevent fire or smoke spread from a room to the corridor in order to maintain the protection of the means of egress. Secondly, the rated corridor wall also prevents fire or smoke spread from a corridor to adjacent rooms should the fire involve the corridor; therefore, the fire-resistance rating of the floor construction supporting the wall is not critical to the performance of the corridor wall.

The construction supporting tenants and guestroom separation walls is exempted from the requirements for a fire-resistance rating since the compartmentalization provided by these walls is similar to that provided by corridor walls. Additionally, if the supporting construction were required to be fire-resistant rated, this section would effectively result in all buildings containing guestrooms (occupancies in Groups R-1, R-2 and I-I) being built of protected construction only. The remaining construction types are not included, since the supporting structural elements (floors and columns) are required to have at least a 1-hour rating (per Table 601), which is the maximum fire-resistance rating required for corridor walls. Similarly, tenant separations in covered mall buildings of Type IIB construction are not required to be supported by construction having an equivalent fire-resistance rating.

While supporting members in Types IIB, IIB and VB are not required to be protected by the same fire resistance as the separation walls between a dwelling and sleeping unit, the horizontal floor assembly between dwelling and sleeping units is required to be fire-resistance-rated construction by Section 711.3.

Exception 1 modifies the continuity requirement for the various tenant, dwelling unit or sleeping unit separations where a crawl space is found below. As discussed above, because corridors and elevator lobby

---

Figure 708.4(1)
CONTINUITY OF FIRE PARTITIONS
separations are intended for protection from hazards on that floor level, they would not require a fire partition within the crawl space.

Although this exception provides a blanket exclusion for extending the partition into the crawl space, it may be prudent to consider each building on an individual basis. If the crawl space is arranged or provided so that each dwelling unit has access to it or it may be intended for storage or equipment, then it may be wise to consider the crawl space as a part of the dwelling unit; therefore, it may be reasonable to apply the exception to circumstances where the crawl space is not considered to be a part of the dwelling unit.

Although the exception requires that the floor above the crawl space have a 1-hour fire-resistance rating, it would still be permissible to use the provisions of Section 711.3.3 and eliminate the ceiling membrane if the crawl space is considered an unusable space.

Exception 2 allows for only one side (the room side) of a fire-resistance-rated wall assembly to be continuous to the rated assembly above. The membrane on the corridor side of the wall is carried up to the underside of the corridor ceilings, provided the corridor ceiling is constructed of materials that have been tested as part of a 1-hour assembly [see Figure 708.4(2)(B)].

Exception 3 allows for a corridor to be constructed in a "tunnel" fashion—with rated walls and a rated top. In these cases, the walls are not required to extend to the underside of a rated assembly. This is a unique provision in the code and the fact that it permits a wall assembly to be turned into a horizontal position should not be applied to other sections of the code or other rated assemblies. In this one situation, the code will permit an assembly that has been tested as a wall to be turned and used horizontally. Because of the differences in the fire test and the fact that a horizontal test is generally a more severe condition, most assemblies will not obtain the same fire-resistance rating when installed in a horizontal position. In this case, because one of the primary purposes of a corridor is to stop the spread of smoke versus necessarily stopping a fire, this level of protection and construction has been accepted [see Figure 708.4(2)(C)].

In order to limit the spread of smoke, tenant separation walls in a mall are required to be fire partitions (see Sections 702.4.2.1 and 708.1) having a fire-resistance rating of a least 1 hour and extending from the floor to the underside of the ceiling. Exception 4 acknowledges that extending tenant separations to the floor slab or roof deck above is not always practical or possible because of operation of the heating, ventilating and air-conditioning (HVAC) system and, in some cases, to particularly tall story heights. The effectiveness of the automatic sprinkler system as well as the location of the fuel loading is also a reason for not requiring tenant separations to extend above the ceiling, including attic spaces.
FIRE AND SMOKE PROTECTION FEATURES

Within combustible construction in the situations where the fire partition is stopped at the ceiling line instead of being continuous up to the roof deck, Exception 5 permits draftstopping or fireblocking above every other dwelling unit or at a maximum spacing of 3,000 square feet (279 m²). This design requirement allows for proper ventilation of the attic space above dwelling units. In typical multiple-family construction, with dwelling units along the front and back of the building, trusses run front to rear with soffit vents at each end. If draftstopping or fireblocking were required at each dwelling unit, it would block cross ventilation, eliminating the use of ridge vents. Soffit and ridge venting allows natural air circulation that, in turn, lowers the roof sheathing temperature in the winter, relieving many of the problems associated with ice dams. This exception is the same as permitted for draftstopping in Section 718.4.2, Exception 3.

Exception 6 recognizes the added protection afforded a building that is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2 and NFPA 13 and 13R, respectively, and permits those fire partitions used for dwelling unit and guestroom separations to terminate at the underside of the ceiling membrane without the need for fireblocking or draftstopping above the partition. For buildings equipped with a sprinkler system that conforms to the NFPA 13 standard, the attic and other concealed areas are required to be sprinklered, thus providing protection that offsets the fact that the dwelling unit separations, fireblocking or draftstopping do not extend to the deck above. In buildings equipped throughout with an NFPA 13R system, the attic and other concealed areas may not be sprinklered. NFPA 13R allows the omission of sprinkler protection in combustible attics and concealed spaces, provided the space is not used for living purposes or storage. When using this exception, sprinkler protection, however, is necessary and required since the protection is considered available to control fires in the incipient stage and keep unoccupied concealed spaces and attic areas from becoming involved. For these buildings, the exception requires sprinkler protection and the fire partitions do not need to extend to the deck above.

Although Exception 6 provides a blanket exclusion for fireblocking or draftstopping within floor/ceiling and roof/ceiling spaces, this may need to be reviewed on a case-by-case basis. The intent of this section is to address concealed spaces that are not used for any purpose. When an attic space is provided, it would be necessary to decide if the attic is simply a concealed space or if it is an occupied portion of the dwelling unit. For example, if each dwelling unit had access to the attic above its unit by means of a pull-down ladder and an area of the attic was provided with flooring so that storage could be placed there, it would be prudent to consider that attic as being a part of the dwelling unit and, therefore, requiring a fire partition, instead of draftstopping, to be provided between the adjacent attics.

FIRE PARTITION CONTINUITY

7-48

2012 INTERNATIONAL BUILDING CODE® COMMENTARY
708.5 Exterior walls. Where exterior walls serve as a part of a required fire-resistance-rated separation, such walls shall comply with the requirements of Section 705 for exterior walls, and the fire-resistance-rated separation requirements shall not apply.

Exception: Exterior walls required to be fire-resistance rated in accordance with Section 1019.2 for exterior egress balconies, Section 1022.7 for interior exit stairways and ramps and Section 102.6.6 for interior exit stairways and ramps.

This section pertains to exterior walls that are a part of an enclosure, such as corridors on the exterior face of a building or elevator lobbies that have exterior walls. Such exterior walls do not need to be fire-resistance-rated construction unless required by Table 601 or 602. The exception noted in this section is identical to the exceptions for Sections 707.4 and 713.6 for fire barriers and shaft enclosures. See the commentary for both of those sections.

708.6 Openings. Openings in a fire partition shall be protected in accordance with Section 716.

Section 716.4 includes the requirements for fire doors in fire partitions. Generally, 1/2-hour doors are required for corridors and 1/2-hour doors for tenant dwelling and sleeping unit separations in accordance with Table 716.4. Where 1/2-hour fire-resistance-rated assemblies are permitted for partitions, the doors are required to be 1/2-hour doors. It is important to note that Section 716.4.3 requires smoke and draft control doors for corridors. Section 716.5 includes the requirements for windows located in a corridor.

708.7 Penetrations. Penetrations of fire partitions shall comply with Section 714.

This section simply states that penetrations through fire partitions must conform to the requirements of Sections 714.2 and 714.3. This is the same as the penetration requirements for fire barriers.

708.8 Joints. Joints made in or between fire partitions shall comply with Section 715.

Joints, such as expansion or seismic, are another form of openings in fire partitions and, therefore, must be considered with regard to maintaining the fire-resistance ratings of these walls. This section requires all joints that are located in fire partitions to be protected by a joint system that has a fire-resistance rating and complies with the requirements of Section 715 (see commentary, Section 715).

708.9 Ducts and air transfer openings. Penetrations in a fire partition by ducts and air transfer openings shall comply with Section 717.

Section 717 details the protection of ducts and air transfer openings at the point where they penetrate a fire-resistance-rated assembly. Sections 717.5 and 717.5.4 indicate which situations will require the installation of a damper. As stated in Section 717.1.1,
if a duct does not require a damper, the penetration of that duct through a fire-resistance-rated assembly must be protected as a through penetration in accordance with Section 714.

SECTION 709
SMOKE BARRIERS

709.1 General. Smoke barriers shall comply with this section.

- Smoke barriers divide areas of a building into separate smoke compartments. A smoke barrier is designed to resist fire and smoke spread so that occupants can be evacuated or relocated to adjacent smoke compartments. This concept has proven effective in Group I-2 and I-3 occupancies. Sections 407.4 and 408.6 identify where smoke barriers are required. Also, while not cross referenced in this section, smoke barriers may be utilized in other applications, such as part of a smoke control system (see Section 909.5) and accessible means of egress (see Section 1007.6.2), accessible areas of refuge (see Section 1007.6), compartmentation of underground buildings (see Section 405.4.2) and elevator lobbies in underground buildings (see Section 405.4.3).

Other than the wall itself, all of the elements in the smoke barrier that can potentially allow smoke travel through the smoke barrier are required to have a quantified resistance to leakage. This includes doors, joints, through penetrations and dampers. The maximum leakage limits are as established in the individual code sections referenced for each element.

709.2 Materials. Smoke barriers shall be of materials permitted by the building type of construction.

- The types of materials used in smoke barriers are to be consistent with Sections 602.2 through 602.5 for the type of construction classification of the building. Smoke barriers are permitted to be of combustible construction in Type III, IV and V construction and are required to be of noncombustible materials in Type I and II construction, except as permitted in the exceptions to Section 603.1.

Exception: Smoke barriers constructed of minimum 0.10-inch-thick (2.5 mm) steel in Group I-3 buildings.

- Smoke barriers are intended to create an area of refuge; therefore, they are to be capable of resisting the passage of smoke (see Section 709.4). Smoke barriers are also required to have a fire-resistance rating of at least 1 hour. The smoke barrier is not intended or expected to be exposed to fire for extended periods and is, therefore, not required to have a fire-resistance rating exceeding 1 hour. The occupancies in which smoke barriers are required are generally required to be sprinklered (see Section 903.2). The exception of this section allows smoke barriers in occupancies in Group I-3 to be constructed of nominal 0.10-inch (2.5 mm) steel plate. This exception to the 1-hour fire-resistance-rated assembly recognizes the security needs of such facilities and at the same time provides the requisite smoke barrier performance.

709.4 Continuity. Smoke barriers shall form an effective membrane continuous from outside wall to outside wall and from the top of the foundation or floor/ceiling assembly below to the underside of the floor or roof sheathing, deck or slab above, including continuity through concealed spaces, such as those found above suspended ceilings, and interstitial structural and mechanical spaces. The supporting construction shall be protected to afford the required fire-resistance rating of the wall or floor supported in buildings of other than Type IIIB, IIIB or VB construction.

Exceptions:

1. Smoke-barrier walls are not required in interstitial spaces where such spaces are designed and constructed with ceilings that provide resistance to the passage of fire and smoke equivalent to that provided by the smoke-barrier walls.

2. Smoke barriers used for elevator lobbies in accordance with Section 405.4.3, 3007.4.2 or 3008.11.2 are not required to extend from outside wall to outside wall.

3. Smoke barriers used for areas of refuge in accordance with Section 1007.6.2 are not required to extend from outside wall to outside wall.

- Smoke barriers are to be continuous from outside wall to outside wall and from the top of the foundation or floor/ceiling assembly below to the underside of the floor or roof sheathing, deck or slab. The provisions require the barrier to be continuous through all concealed and interstitial spaces, including suspended ceilings and the space between the ceiling and the floor or roof sheathing, deck or slab above. Smoke barriers are not required to extend through interstitial spaces if the space is designed and constructed such that fire and smoke will not spread from one smoke compartment to another; therefore, the construction assembly forming the bottom of the interstitial space must provide the required fire-resistance rating and be capable of resisting the passage of smoke from the spaces below.

As mentioned in the commentary for the general provisions of Section 709.1, the air leakage performance of the smoke barrier itself is not typically regulated. This is because of the general assumption that a barrier which provides a fire-resistance rating will be capable of limiting the spread of smoke through it. When a smoke barrier is being used with a smoke control system the barrier does have limitations on the air leakage (see Section 909.5). Therefore, under those circumstances and when using Exception 1 in Section 709.4, it may be necessary to provide a "hard ceiling" instead of a lay-in suspended ceiling in order

7-50

2012 INTERNATIONAL BUILDING CODE® COMMENTARY
to prevent the spread of smoke.

Since the primary performance of smoke barriers is to achieve protection on the fire floor, the supporting construction is not required to provide the same degree of fire resistance for buildings of Type IIIB, IIIB and VB construction.

As with fire partitions serving as exit access corridor walls (see Section 709.4), these three construction types are identified because the floor construction is not otherwise required to have a fire-resistance rating, and it is not considered essential to only require fire-resistance-rated floor construction because the floor is supporting a smoke barrier.

When designing for occupancies in Groups I-2 and I-3, it is often desirable to incorporate a horizontal exit and a smoke barrier. The code does not prevent such a combination, but in such cases, the wall construction must meet the provisions of this section as well as Section 707 for fire barrier assemblies and Section 1025 for horizontal exits. The most restrictive provisions of each section would apply. For example, the building would be required to have a fire barrier with a fire-resistance rating of at least 2 hours (see Section 1025.2) and duct penetrations would need to be protected with a combination fire and smoke damper (see Sections 717.5.2 and 717.5.2.1) or with separate fire and smoke dampers.

Furthermore, the supporting construction would then be required to provide at least the same fire-resistance rating as the wall in all types of construction (see Section 707.5.1).

Exception 1 states that smoke barrier walls may not need to be continuous through interstitial spaces, provided that the wall terminates at the ceiling of a fire-resistance-rated ceiling/floor assembly, and the ceiling is resistant to the passage of smoke.

Exceptions 2 and 3 do not require that the smoke barrier partitions enclosing elevator lobbies and areas of refuge continue to the exterior walls.

### 709.5 Openings

Openings in a smoke barrier shall be protected in accordance with Section 716.

#### Exceptions:

1. In Group I-2 and ambulatory care facilities, where doors are installed across corridors, a pair of opposite-swinging doors without a center mullion shall be installed having vision panels with fire-protection-rated glazing materials in fire-protection-rated frames, the area of which shall not exceed that tested. The doors shall be close fitting within operational tolerances, and shall not have undercuts in excess of 1/4 inch, louvers or grilles. The doors shall have head and jamb stops, astragals or rabbits at meeting edges and shall be automatic-closing by smoke detection in accordance with Section 716.5.9.3. Where permitted by the door manufacturer's listing, positive-latching devices are not required.

2. In Group I-2 and ambulatory care facilities, horizontal sliding doors installed in accordance with Section 1008.1.4.3 and protected in accordance with Section 716.

- In order to maintain the integrity of the smoke barrier, door assemblies and double means of egress corridor doors are required to have a fire protection rating of at least 20 minutes when tested in accordance with Section 716. In occupancies in Group I-2 and ambulatory care facilities, however, double means of egress cross-corridor doors are not required to have positive latching hardware, since center mullions are prohibited, as they could serve as a possible obstruction in moving beds through the door opening. Without a center mullion, the latching hardware would utilize the floor below and the door frame above for latching purposes. The required stops and door-closing devices will assist in keeping the doors closed. Doors, other than cross-corridor doors, are required to be provided with positive latches as required for the fire protection rating of the door.

When double egress corridor doors are provided, they are required to have a vision panel consisting of protection-rated glazing, in accordance with Section 716.5.3.2. Vision panels are required to reduce the likelihood of an injury caused by opening the door into a person standing at or approaching the door from the opposite side. Vision panels enable an individual to be alerted to a fire or smoke condition on the other side before opening the door. Since the primary purpose of a smoke barrier is to resist smoke spread, the doors are not to have undercuts, louvers or grilles. The only openings permitted in the door assembly are those clearances that are necessary for the proper operation of the door. The opening that occurs at the meeting edges of the door is to be protected with rabbits or astragals (see Figure 709.5). In this manner, the doors will close completely, thus preventing the spread of smoke. Stops are to be provided on the head and jambs of all doors in smoke barriers. Such doors must also comply with UL 1784 in accordance with Section 716.5.3.1, which requires these doors to have a leakage rating of 3 cfm per square foot [0.02 m³/(s • m²)] or less as tested at a pressure of 0.10 inch of water (0.02 kPa).

### 709.6 Penetrations

Penetrations of smoke barriers shall comply with Section 714.

- The provisions for penetrations of smoke barriers are found in Sections 713.2, 713.3 and 713.5. To prevent through penetrations from becoming a source of significant smoke spread across the smoke barrier, the firestop system provided for each through penetration must have not only the appropriate F rating, but must also have a leakage rating (L rating) of 5 cfm per square foot [2.78 m³/(s • m²)] or less as tested at a pressure of 0.30 inch of water (0.07 kPa) (see commentary, Section 713.5).
709.7 Joints. Joints made in or between smoke barriers shall comply with Section 715.

- Joints, such as expansion or seismic, are another form of openings in smoke barriers and, therefore, must be considered with regard to maintaining the fire-resistance ratings of these walls. This section requires all joints that are located in smoke barriers to be protected by a joint system that has a fire-resistance rating and complies with the requirements of Section 715 (see commentary, Section 715.1). To prevent joints from becoming a source of significant smoke spread across the smoke barrier, fire-resistant joint systems used in a smoke barrier must have a leakage rating (L rating) of 5 cfm per linear foot or less (see commentary, Section 715.6).

709.8 Ducts and air transfer openings. Penetrations in a smoke barrier by ducts and air transfer openings shall comply with Section 717.

- To prevent ducts and air transfer openings from becoming a source of significant smoke spread across the smoke barrier, a listed smoke damper must be provided for duct or air transfer openings penetrating the smoke barrier (see Section 717.5.5). The smoke damper leakage rating, as tested per UL 555S; shall not be less than Class II (see Section 717.3.2.1).

Section 717.5.5 indicates which situations will require the installation of a damper. For smoke barriers, there is one exception to that requirement. If all the duct outlets are limited to one of the smoke compartments and the ducts are constructed of steel, then no smoke damper is required. As stated in Section 717.1.1, if a duct does not require a damper, the penetration of that duct through a fire-resistance-rated assembly must be protected as a through penetration in accordance with Section 714.

SECTION 710
SMOKE PARTITIONS

710.1 General. Smoke partitions installed as required elsewhere in the code shall comply with this section.

- Unlike a 1-hour fire-resistance-rated smoke barrier, smoke partitions are nonrated walls that serve to resist the spread of fire and the unmitigated movement of smoke for an unspecified period of time. A smoke partition is intended to provide less protection than a smoke barrier and is not required to be continuous through the concealed spaces and through the ceiling. The construction of a smoke partition is described in this section; however, the level of performance or a method of testing them is not provided. Some elements of this section (see Sections 710.5 and 710.8) will provide a performance level and test method to verify the protection provided by doors or dampers. In addition, some specific features of a smoke partition may be triggered by other sections of the code.

At this point, the application of smoke partitions is still fairly limited. The smoke partition requirements apply to Section 407.3, which permits corridor walls in Group I-2 to have no fire-resistance rating, but it does require that they be constructed as smoke partitions. A smoke partition can also be used under the provisions of Section 713.14.1, Exception 5, to form the elevator lobby in a sprinklered building.

It is important to realize that like all other elements found in Chapter 7, a smoke partition is not required unless the specific text of the code states that it is required. For example, the two sections listed in the previous paragraph do require the use of a smoke partition. On the other hand, Section 509.4.2, when dealing with incidental uses, will permit the elimination of a fire barrier and only require the wall constructed around the incidental use area to be
"capable of resisting the passage of smoke." In this circumstance, the wall is not required to comply with the smoke partition requirements of Section 710 and is only required to comply with the details listed in Section 509.4.2.

710.2 Materials. The walls shall be of materials permitted by the building type of construction.

- As with most wall or partition assemblies, except for fire walls, there are no additional requirements or restrictions on the materials used, except that they meet the requirements for the type of construction.

710.3 Fire-resistance rating. Unless required elsewhere in the code, smoke partitions are not required to have a fire-resistance rating.

- The primary purpose of smoke partitions is to prevent the ready and quick passage of smoke into corridors in Group I-2 or for elevator lobby protection in a sprinklered building. The automatic sprinkler system installed in those instances eliminates the need for a fire-resistance-rated assembly; however, the issue of smoke propagation must be addressed with the use of a smoke partition. Because a performance level or a method of testing the partition is not established, any rated or nonrated assembly would be permitted, provided it is approved by the building official.

710.4 Continuity. Smoke partitions shall extend from the top of the foundation or floor below to the underside of the floor or roof sheathing, deck or slab above or to the underside of the ceiling above where the ceiling membrane is constructed to limit the transfer of smoke.

- The continuity provisions for smoke partitions are similar to those for fire partitions (see Section 708.4), except that the issue is smoke spread, not fire. Therefore, the allowance for termination at the underside of the ceiling membrane (as opposed to the underside of the floor or roof deck above) relates to the ability of the ceiling membrane to limit the spread of smoke. Typical "lay in" ceiling tiles, for instance, would probably not serve this function; however, a drywall ceiling that is taped and finished would be an example of construction that could resist the passage of smoke.

710.5 Openings. Openings in smoke partitions shall comply with Sections 710.5.1 and 710.5.2.

- Limiting smoke movement in buildings with smoke partitions includes opening protective that resist the passage of smoke.

710.5.1 Windows. Windows in smoke partitions shall be sealed to resist the free passage of smoke or be automatically closing upon detection of smoke.

- Windows in smoke partitions do not require a fire-resistance rating. There are no limits on the amount of glazing. They must be fixed glazing or automatic closing upon the activation of smoke detectors.

710.5.2 Doors. Doors in smoke partitions shall comply with Sections 710.5.2.1 through 710.5.2.3.

- Doors in smoke partitions do not require a fire-resistance rating and may not need self-closing devices. For instance, doors in hospital corridors do not require closer; however, they must be smoke and draft control doors.

710.5.2.1 Louvers. Doors in smoke partitions shall not include louvers.

- Louvers in doors allow smoke to move from one area to the remainder of the building. This would defeat the sole purpose of a smoke partition.

710.5.2.2 Smoke and draft control doors. Where required elsewhere in the code, doors in smoke partitions shall meet the requirements for a smoke and draft control door assembly tested in accordance with UL 1784. The air leakage rate of the door assembly shall not exceed 3.0 cubic feet per minute per square foot (0.015424 m³/(s • m²)) of door opening at 0.10 inch (24.9 Pa) of water for both the ambient temperature test and the elevated temperature exposure test. Installation of smoke doors shall be in accordance with NFPA 105.

- Only doors in smoke partitions that are required elsewhere in the code to be smoke and draft control doors must meet this section. Section 407.3.1 requires corridor doors in Group I-2 to "limit the transfer of smoke," therefore, those doors must meet this section. Exception 5 of Section 713.14.1 requires smoke and draft control doors for the smoke partition exception to elevator lobby enclosures (see commentary, Section 716.5.3.1).

710.5.2.3 Self- or automatic-closing doors. Where required elsewhere in the code, doors in smoke partitions shall be self- or automatic-closing by smoke detection in accordance with Section 716.5.9.3.

- The requirement for doors to be self-closing or automatic closing does not automatically apply to all walls that must be built as smoke partitions. That requirement must be mandated elsewhere in the code for this provision to apply. In the case of corridor walls for Group I-2 occupancies, there is no requirement for self-closing or automatic-closing doors so as to accommodate the normal operational requirements of that occupancy. In that situation, it is anticipated that doors would be manually closed by personnel in the event of a fire emergency based upon a defend-in-place strategy. Having doors arranged for automatic closing or self-closing, however, is not prohibited as it would potentially increase the reliability of smoke partitions. Exception 5 to Section 713.14.1 that allows elevator lobby smoke partition enclosures in lieu of fire partitions does require closers on the doors to the lobby as a part of the conditions for the exception.
710.6 Penetrations. The space around penetrating items shall be filled with an approved material to limit the free passage of smoke.

- There is no prescriptive requirement for a material used to seal penetrations in smoke partitions. The intent is to limit the transfer of smoke through the partition. See the commentary to Section 710.7 for more information.

710.7 Joints. Joints shall be filled with an approved material to limit the free passage of smoke.

- There is no requirement for a material used to seal penetrations or joints to be applied to both sides of the wall, as would usually be the case when the penetrations and joints are in a fire-resistance-rated wall. The intent of this section will have been met as long as the space around penetrating items and in joints is filled in a way that would prevent a continuous channel from one side of the wall to the other. In selecting a material to seal these gaps, consideration should be given to the fact that smoke may have a temperature that is above the normal ambient temperature. The code does not mandate any specific temperature resistance; however, as one possible reference point, Underwriters Laboratories uses a gas temperature of 325°F (180°C) above ambient to represent "warm smoke." With a common ambient temperature of 75°F (24°C), the "warm smoke" temperature would therefore be 400°F (204°C). Sealing materials that would not maintain their integrity to at least this temperature would be inferior choices for the purpose of limiting the free passage of smoke. Porous materials (e.g., fibrous insulation) that would not provide any significant resistance to the passage of smoke through them would also be inferior choices for sealing of joints and through penetrations for this purpose. Again, because the level of performance is not clearly established, the word "approved" and the building official's decision will determine what materials are required or accepted.

710.8 Ducts and air transfer openings. The space around a duct penetrating a smoke partition shall be filled with an approved material to limit the free passage of smoke. Air transfer openings in smoke partitions shall be provided with a smoke damper complying with Section 717.3.2.2.

**Exception:** Where the installation of a smoke damper will interfere with the operation of a required smoke control system in accordance with Section 909, approved alternative protection shall be utilized.

- Smoke dampers are required to be provided to maintain the integrity of the smoke partition as a means to prevent the spread of smoke when an "air transfer opening" exists. If a ducted system is used, then the code specifies that the annular space around the duct must be protected. Because the code does not define what an "air transfer opening" is, the provision may not be consistently enforced. The general intent is that a ducted system does not require a damper, but an opening such as an air transfer grille or louvered opening would be dampered. A ducted system must be protected in accordance with Section 710.6. The exception relating to the required operation of a smoke control system is consistent with the exceptions given elsewhere regarding air transfer openings and ducts with fire dampers or smoke dampers (see Section 717). An effective smoke control system will protect the building against the spread of smoke and it is important to ensure such installation of a smoke damper will not lessen the effectiveness of a smoke control system.

SECTION 711
HORIZONTAL ASSEMBLIES

711.1 General. Floor and roof assemblies required to have a fire-resistance rating shall comply with this section. Nonfire-resistance-rated floor and roof assemblies shall comply with Section 714.4.2.

- Horizontal assemblies may be either a floor or roof assembly and may rely on the ceiling as a part of a floor/ceiling or roof/ceiling assembly. The ceiling assembly is often an integral part of a fire-resistance-rated floor/ceiling or roof/ceiling assembly; therefore, the integrity of the ceiling assembly must be maintained in order to reduce the potential for premature failure of the floor or roof of a building. Much of the information contained in the section is obtained from and based on conditions of testing various assemblies. One focus of the section is on maintaining the integrity of ceiling membranes, which are an integral component of the fire-resistance rating of floor/ceiling and roof/ceiling assemblies.

711.2 Materials. The floor and roof assemblies shall be of materials permitted by the building type of construction.

- The types of materials used in floor and roof assemblies are to be consistent with Sections 602.2 through 602.5 for the type of construction classification of the building. Floors and roofs are permitted to be of combustible construction in Type III, IV and V construction and are required to be of noncombustible materials in Type I and II construction, except as permitted in the exceptions to Section 603.1 or in Notes c and d from Table 601.

711.3 Fire-resistance rating. The fire-resistance rating of floor and roof assemblies shall not be less than that required by the building type of construction. Where the floor assembly separates mixed occupancies, the assembly shall have a fire-resistance rating of not less than that required by Section 508.4 based on the occupancies being separated. Where the floor assembly separates a single occupancy into different fire areas, the assembly shall have a fire-resistance rating of not less than that required by Section 707.3.10. Horizontal assemblies separating dwelling units in the same building and horizontal assemblies separating sleeping units in the same
building shall be a minimum of 1-hour fire-resistance-rated construction.

**Exception:** Dwelling unit and sleeping unit separations in buildings of Type IIB, IIB, and VB construction shall have fire-resistance ratings of not less than 1/2 hour in buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1.

- Floor and roof assemblies could have a fire-resistance rating for several reasons:
  - Required for the type of construction in Table 601.
  - Required for separation of mixed uses in Section 508.4.
  - Separate fire areas of like or different occupancies in order to reduce the size of fire areas to below threshold values for sprinkler requirements in Section 903.
  - Separation of dwelling units in the same building.
  - Separation of sleeping units in Group R-1 hotels, R-2 and I-1.

As an example, consider a nonsprinklered two-story building of Type IIA construction and a Group B occupancy, with the basement having a storage occupancy in Group S-2. Assume the designer has chosen Section 508.4 for separated occupancies as the option for compliance with the mixed occupancy condition. In this case, even though Table 601 requires a 1-hour fire-resistance-rated floor throughout the building, the assembly separating the basement from the first floor of the building is also regulated by Section 508.4 for mixed occupancies. Ultimately, Section 508.4.4 references Table 508.4, which requires that floor/ceiling construction separating Group S-2 from Group B provides a 2-hour fire-resistance-rated separation.

Chapter 6 also contains provisions governing materials that may be used in the construction of such assemblies based on the type of construction of the building and whether combustible or noncombustible materials are used.

The requirement for 1-hour floor assemblies separating dwelling and sleeping units mirrors that found in Section 708 for fire partitions. There are other sections of the code that require a fire-resistance rating for the floor or roof assembly or where other provisions are dependent on the fire-resistance rating or construction of the assembly (examples of such sections include Sections 704.1, 705.6, 707.5.1, 708.4 and 709.4).

The exception for dwelling and sleeping unit separations in unprotected types of construction is based on the protection provided by a sprinkler system installed in accordance with Section 903.3.1.1 (NFPA 13). This presumably will reduce the potential fire exposure of the unit separation to that which makes a minimum 1/2-hour fire-resistance rating adequate. The reason that only unprotected types of construction are permitted to take advantage of this trade-off is because Table 601 would not otherwise require the floor construction of such structures to be fire-resistance rated, whereas all other types of construction require the floor construction to provide at least a 1-hour fire-resistance rating.

**711.3.1 Ceiling panels.** Where the weight of lay-in ceiling panels, used as part of fire-resistance-rated floor/ceiling or roof/ceiling assemblies, is not adequate to resist an upward force of 1 pound per square foot (48 Pa), wire or other approved devices shall be installed above the panels to prevent vertical displacement under such upward force.

- Where a ceiling membrane constitutes part of a fire-resistance-rated floor/ceiling or roof/ceiling assembly, the ability of the ceiling membrane to remain in place and not be displaced by the upward pressure of a fire condition is necessary to maintain the viability of the fire-resistance rating. Figure 711.3.1 shows a floor/
ceiling assembly that uses hold-down clips to keep the ceiling panels in place. When the weight of the ceiling panel is less than 1 pound per square foot (psf) (48 Pa), wire or other approved means must be provided to prevent uplift of the ceiling panels. Manufacturers' literature can be used to determine the weight of the panel.

711.3.2 Access doors. Access doors shall be permitted in ceilings of fire-resistance-rated floor/ceiling and roof/ceiling assemblies provided such doors are tested in accordance with ASTM E 119 or UL 263 as horizontal assemblies and labeled by an approved agency for such purpose.

- Access doors are often necessary in order to service mechanical and plumbing systems above the ceiling. This section states that if such doors are used where the ceiling provides part of the protection, they must be tested in accordance with ASTM E 119 or UL 263 as a horizontal assembly. This makes it clear that the standard fire test for doors (NFPA 80 or 257) is not acceptable. This ensures that the thermal transmission through the access door and its effect on the assembly is considered. The provisions of this section are not applicable if the ceiling membrane does not provide any portion of the fire-resistant protection. Therefore, in a nonrated ceiling, this access door requirement would not apply.

711.3.3 Unusable space. In 1-hour fire-resistance-rated floor assemblies, the ceiling membrane is not required to be installed over unusable crawl spaces. In 1-hour fire-resistance-rated roof assemblies, the floor membrane is not required to be installed where unusable attic space occurs above.

- The section is a special exception for specific assemblies to allow the deletion of floor or roof decking or the ceiling membrane from a required fire-resistance-rated floor/ceiling or roof/ceiling assembly used in certain applications. In an attic application, the floor sheathing may be deleted from a fire-resistance-rated assembly as long as the joist and ceiling remain identical to the tested assembly and the attic space is not usable space where potential combustible materials or ignition sources may be located [see Figure 711.3.3(1)]. Over a crawl space, the ceiling membrane may be deleted subject to the same conditions [see Figure 711.3.3(2)]. In determining whether a space is "unusable," the building official must verify that combustible materials other than construction elements will not be located therein and ignition sources will be minimal. As such, pipes, conduit and ducts may be permitted in an unusable space.

711.3.4 Continuity. Assemblies shall be continuous without openings, penetrations or joints except as permitted by this section and Sections 712.1, 714.4, 715, 1009.3 and 1022.1. Skylights and other penetrations through a fire-resistance-rated roof deck or slab are permitted to be unprotected, provided that the structural integrity of the fire-resistance-rated roof assembly is maintained. Unprotected skylights shall not be permitted in roof assemblies required to be fire-resistance rated in accordance with Section 705.8.6. The supporting construction shall be protected to afford the required fire-resistance rating of the horizontal assembly supported.

Exception: In buildings of Type III, IIIB or VB construction, the construction supporting the horizontal assembly is not required to be fire-resistance-rated at the following:

1. Horizontal assemblies at the separations of incidental use as specified by Table 509, provided the required fire-resistance rating does not exceed 1 hour.

2. Horizontal assemblies at the separations of dwelling units and sleeping units as required by Section 420.3.

3. Horizontal assemblies at smoke barriers constructed in accordance with Section 709.

- All floors, roofs and ceilings of horizontal assemblies are to be continuous without openings or penetrations, except as permitted by this section. The continuity of the assembly is critical to its ability to limit fire.
and smoke spread. The continuity provision applies regardless of whether a fire-resistance rating is required, since floor/ceiling assemblies are also intended to restrict vertical smoke movement [see Figure 711.4(1)]. Penetrations or openings of the assembly are permitted in accordance with Sections 712.1, 714.4, 715, 1009.3 and 1022.1, provided that the fire-resistance rating, if required, is maintained [see Figure 711.4(2)]. The fire-resistance rating required by Table 601 for roof construction is intended to minimize the threat of premature structural failure of the roof construction under fire conditions. The provisions for rated roof construction in Table 601 do not apply to openings in the roof. Fire-resistance-rated roof construction is not intended to create a barrier in order to contain the fire within the building, except for Exception 1 of Section 705.8.6 and the exception to Section 706.6.1. Nonfire-resistance-rated penetrations and skylight and roof window assemblies are, therefore, permitted to be installed in fire-resistance-rated roof assemblies, provided that the structural integrity of the roof assembly is not reduced and the provisions of Section 705.8.6 for protection of vertical exposure do not apply (see commentary, Section 705.8.6). The issue of structural integrity refers to the effect the collapse of a skylight assembly, under fire conditions, would have on the roof structure. Section 713.12, regarding the extension of a shaft to the roof level, would also permit the same unprotected openings to the exterior. Code users should also review the fireblocking and draftstopping requirements that are found in Section 718. Fireblocking and draftstopping requirements apply to combustible concealed locations and it is a separate issue from fire-resistance ratings and may impose additional requirements for the assembly.

The exception deals with three specific applications of horizontal assemblies where it is unnecessary to provide a fire-resistance rating of the supporting construction of horizontal assemblies in buildings of Type
FIRE AND SMOKE PROTECTION FEATURES

IIB, IIIIB or VB construction since Table 601 would never require the horizontal assembly or the supporting structural members to have a fire-resistance rating in these types of construction. This exception exempts the supporting construction of horizontal assemblages in the same manner as the code currently exempts the supporting construction of fire barriers, fire partitions and smoke barriers, but only in those circumstances where the horizontal assembly is a component of the same fire containment assembly as the fire barrier, fire partition or smoke barrier.

711.4.1 Nonfire-resistance-rated assemblies. Joints in or between floor assemblies without a required fire-resistance rating shall comply with one of the following:

1. The joint shall be concealed within the cavity of a wall.
2. The joint shall be located above a ceiling.
3. The joint shall be sealed, treated or covered with an approved material or system to resist the free passage of flame and the products of combustion.

Exception: Joints meeting one of the joint exceptions listed in Section 715.1.

The spread of fire from story to story is a concern for all buildings whether or not the floors are required to be fire-resistance rated or not. This is why shaft enclosures are required for buildings even with no requirement for fire-resistance-rated floors. This section addresses joints in nonrated floor assemblies. Requirements for penetrations of nonrated floor assemblies are found in Section 714.4.2.

711.5 Penetrations. Penetrations of horizontal assemblies, whether concealed or unconcealed, shall comply with Section 714.

Penetration protection for horizontal assemblies is found in Section 714.4. It should be remembered that, as mentioned in the commentary for Section 714.4, the horizontal assembly requirements also apply to nonrated assemblies. The penetration of nonfire-resistance-rated assemblies is regulated in Section 714.4.2, unless dealt with in accordance with shafts in Section 713.

711.6 Joints. Joints made in or between horizontal assemblies shall comply with Section 715. The void created at the intersection of a floor/ceiling assembly and an exterior curtain wall assembly shall be protected in accordance with Section 715.4.

Joints, such as expansion or seismic, are another form of openings in horizontal assemblies and, therefore, must be considered with regard to maintaining the fire-resistance ratings of these floors or roofs. This section requires all joints that are located in rated horizontal assemblies to be protected by a joint system that has a fire-resistance rating and complies with the requirements of Section 715 (see commentary, Section 715). The provisions of this section also include the protection of joints/voids that may occur at the intersection of the horizontal assembly and an exterior wall.

711.7 Ducts and air transfer openings. Penetrations in horizontal assemblies by ducts and air transfer openings shall comply with Section 717.

See the commentary to Section 717.

711.8 Floor fire door assemblies. Floor fire door assemblies used to protect openings in fire-resistance-rated floors shall be tested in accordance with NFPA 288, and shall achieve a fire-resistance rating not less than the assembly being penetrated. Floor fire door assemblies shall be labeled by an approved agency. The label shall be permanently affixed and shall specify the manufacturer, the test standard and the fire-resistance rating.

Floor fire doors are specifically addressed as an opening protective in horizontal floor assemblies. The code requires that these doors have a fire-resistance rating instead of just a fire protection rating. By requiring a fire-resistance rating, it will restore the opening in the horizontal assembly to the same level of protection that was originally established during the fire test by limiting the temperature transmission to the unexposed side of the assembly.

711.9 Smoke barrier. Where horizontal assemblies are required to resist the movement of smoke by other sections of
this code in accordance with the definition of smoke barrier, penetrations and joins in such horizontal assemblies shall be protected as required for smoke barriers in accordance with Sections 714.5 and 715.6. Regardless of the number of stories connected by elevator shaft enclosures, doors located in elevator shaft enclosures that penetrate the horizontal assembly shall be protected by enclosed elevator lobbies complying with Section 713.14.1. Openings through horizontal assemblies shall be protected by shaft enclosures complying with Section 713. Horizontal assemblies shall not be allowed to have unprotected vertical openings.

- This section is intended to clarify the requirements for horizontal assemblies that are used to support smoke barrier walls, such as in Group I-2 occupancies where smoke barriers are required to subdivide floors by Section 407.5. It is clear from the definition for "Smoke barrier" that a smoke barrier can be a horizontal assembly (see Section 202). Furthermore, to the continue the smoke protection for smoke compartments created by vertical smoke barriers in order to provide for relative safe areas for horizontal movement of patients in a fire emergency, it follows that the floors supporting those smoke barrier walls should also be able to resist the passage or movement of smoke through the assembly to maintain the appropriate level of protection for the occupants (see Section 407.5.3). Generally, occupants of Group I-2 occupancies are moved into a smoke barrier that is away from the area where the fire occurred so that they can remain there until they need to move as necessary or until the fire has been extinguished by the responding fire department; therefore, the integrity of these horizontal assemblies is essential for the protection of the occupants of the building. This section requires elevator lobbies meeting Section 713.14.1 where smoke compartments are required (Group I-2) regardless of the height of the building.

SECTION 712

VERTICAL OPENINGS

712.1 General. The provisions of this section shall apply to the vertical opening applications listed in Sections 712.1.1 through 712.1.18.

- Section 712 lists the applications when the code allows vertical openings between stories or levels within a building. The conditions that are necessary to allow the vertical openings are enumerated in this section or the appropriate sections are referenced.

712.1.1 Shaft enclosures. Vertical openings contained entirely within a shaft enclosure complying with Section 713 shall be permitted.

- The first condition through which vertical openings between stories is allowed is fully enclosing the opening in shaft wall construction complying with Section 713. These types of openings contain ducts, vents, piping, chutes or elevator hoistways. Stairways are also vertical openings between floors and Section 713 references Sections 1009 and 1022 for stairway enclosures and the exceptions to their enclosures.

712.1.2 Individual dwelling unit. Unconcealed vertical openings totally within an individual residential dwelling unit and connecting four stories or less shall be permitted.

- The keyword in this section is "unconcealed." Vertical openings in view of the occupants, such as open exit access stairs, are allowed. The unconcealed floor opening connecting no more than four stories within a dwelling unit is permitted without a shaft enclosure. This is generally consistent with the permitted omission of stairway enclosures in such uses in accordance with Exception 2 to Section 1009.3.

712.1.3 Escalator openings. Where a building is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1, an escalator opening shall be protected according to Section 712.1.3.1 or 712.1.3.2.

- Vertical openings containing escalators in buildings that are fully sprinklered in accordance with NFPA 13 are allowed under either of the two protection methods stated in Sections 712.1.3.1 and 712.1.3.2.

712.1.3.1 Opening size. Protection by a draft curtain and closely spaced sprinklers in accordance with NFPA 13 shall be permitted where the area of the vertical opening between stories does not exceed twice the horizontal projected area of the escalator. In other than Groups B and M, this application is limited to openings that do not connect more than four stories.

- Under this method a draft curtain is required to protect the vertical opening. The details of the draft curtain and sprinkler spacing are in NFPA 13. The size of the vertical opening cannot exceed twice the horizontal projection of the escalator [see Figure 712.1.3.1]. This method allows such floor openings to occur for the full height of the building, regardless of the number of stories for Groups B and M. For all other occupancies, there is a four-story limitation (three floors permitted to contain openings). This is similar to the Exceptions 3 and 4 for exit access stairways in Section 1009.3.

712.1.3.2 Automatic shutters. Protection of the opening by approved shutters at every penetrated floor shall be permitted in accordance with this section. The shutters shall be of noncombustible construction and have a fire-resistance rating of not less than 1.5 hours. The shutter shall be so constructed as to close immediately upon the actuation of a smoke detector installed in accordance with Section 907.3.1 and shall completely shut off the well opening. Escalators shall cease operation when the shutter begins to close. The shutter shall operate at a speed of not more than 30 feet per minute (152.4 mm/s) and shall be equipped with a sensitive leading edge to arrest its progress when in contact with any obstacle, and to continue its progress on release there from.

- This method of protecting vertical openings containing escalators requires automatic shutters at each floor opening and is not limited as to height or occupancy [see Figure 712.1.3.2].
712.1.4 Penetrations. Penetrations shall be protected in accordance with Section 714.

- Vertical openings are formed at the penetrations of horizontal assemblies by pipe, tube, conduit, wire, cable and other utilities. The annular spaces around the penetrating item must be protected in accordance with Section 714.4 or the penetrating items must be in shafts meeting Section 712.1.1.

712.1.5 Ducts. Penetrations by ducts shall be protected in accordance with Section 717.6. Grease ducts shall be protected in accordance with the *International Mechanical Code*.

- Ducts for HVAC supply, return and exhaust through horizontal assemblies can be a source for the spread of smoke and fire from story to story. This section references Section 717.6, which states that the first option is to enclose the vertical ducts in shaft walls, but gives several other options as well (see commentary, Section 717.6).

712.1.6 Atriums. In other than Group H occupancies, atriums complying with Section 404 shall be permitted.

- "Atriums" are defined as an opening connecting two or more stories. Vertical openings connecting two or more stories may be allowed under the provisions and conditions in Section 404. All vertical openings connecting two or more stories are not required to meet Section 404. For openings connecting only two stories, the provisions of Section 712.1.8 may also be used to allow vertical openings. Vertical openings consisting of unenclosed exit access stairs may also be allowed when meeting Exceptions 3 and 4 of Section 1009.3.

712.1.7 Masonry chimney. Approved masonry chimneys shall be permitted where the annular space is fireblocked at each floor level in accordance with Section 718.2.5.

- A masonry chimney must meet Section 2113 in order to be approved. According to Section 718.2.5, the

---

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

Figure 712.1.3.1
SHAFT ENCLOSURE—DRAFT CURTAIN EXCEPTION
annular space surrounding the masonry chimney must be fireblocked with a material specifically tested in the form and manner intended for use to demonstrate its ability to remain in place and resist the free passage of flame and the products of combustion. Furthermore, Section 2113.20 requires the annular space to be fireblocked with a noncombustible material at the ceiling and floor. This section does not apply to factory-built fireplaces and chimneys. Factory-built chimneys require shaft enclosures when penetrating floors.
