**712.1.8 Two-story openings.** In other than Groups I-2 and I-3, a floor opening that is not used as one of the applications listed in this section shall be permitted if it complies with all of the items below.

1. Does not connect more than two stories.
2. Does not contain a stairway or ramp required by Chapter 10.
3. Does not penetrate a horizontal assembly that separates fire areas or smoke barriers that separate smoke compartments.
4. Is not concealed within the construction of a wall or a floor/ceiling assembly.
5. Is not open to a corridor in Group I and R occupancies.
6. Is not open to a corridor on nonsprinklered floors.
7. Is separated from floor openings and air transfer openings serving other floors by construction conforming to required shaft enclosures.

A floor opening connecting two stories that is not covered by one of the other provisions for vertical openings in Section 712.2 may use this provision. This provision addresses the issue of floor openings that are not a part of the required means of egress, such as unenclosed openings providing the same purpose as an atrium between two stories. Unlike the atrium provisions in Section 404 which require sprinklers and smoke control, this section does not require sprinklers or smoke control. Such vertical openings cannot connect to exit access corridors in Group I or R because occupants can be sleeping and the integrity of the corridor system is especially important under such conditions. For a sprinklered Group B occupancy, Figure 712.1.8 illustrates the vertical opening connecting to an exit access corridor.

Under this provision such two-story vertical openings cannot be connected to any other floor opening that connects to an additional floor level. Such vertical openings must be separated from vertical openings serving other stories by construction that complies with this section for shaft enclosures. This requirement limits the use of this provision so that an opening between two stories does not openly communicate with another opening to an additional story and, therefore, interconnect three or more different levels.

A new section in the 2012 code allows unenclosed stairs for two stories (see Exception 1 of Section 1009.3). The new section permits an unenclosed exit access stair, even in a Group R occupancy with no regard to a vertical opening connecting to an exit access corridor.

**712.1.9 Parking garages.** Automobile ramps in open and enclosed parking garages shall be permitted where con-
constructed in accordance with Sections 406.5 and 406.6, respectively.

- Vertical openings between stories or tiers of parking in parking garages are permitted. It is impractical to consider not allowing those vertical openings created by the automobile ramps. While this section only applies to the vehicle ramps, Sections 712.1.15 and 712.1.16 apply to vertical openings for duct systems and elevator hoistways serving only the parking garage. Exit access stairways in enclosed parking garages may need enclosures if they do not meet one of the exceptions in Section 1009.3. The special code requirements in Sections 406.5 and 406.6 recognize the unique features of parking garages and adherence to those sections will mitigate the concerns about vertical openings.

712.1.10 Mezzanine. Vertical openings between a mezzanine complying with Section 505 and the floor below shall be permitted.

- Section 712.1.10 recognizes that vertical openings between a mezzanine and the floor below are actually an advantage. The limited-size mezzanine is considered a part of the story below in accordance with Section 505.1. The openness between the mezzanine level and the floor below allows smoke or other hazards to be readily observable to occupants of both levels.

712.1.11 Joints. Joints shall be permitted where complying with Section 715.

- A joint protected in accordance with Section 715 is considered a viable method of protection of vertical openings between floor levels. The purpose of the joint treatment is to restore or complete the assembly that has a gap provided for a structural purpose, such as expansion or seismic movement.

712.1.12 Unenclosed stairs and ramps. Vertical floor openings created by unenclosed stairs or ramps in accordance with Sections 1009.2 and 1009.3 shall be permitted.

- There are 10 separate conditions in Section 1009.3 that permit unenclosed exit access stairs or ramps. The vertical openings created by the unenclosed stairs that meet Section 1009.3 are allowed.

712.1.13 Floor fire doors. Vertical openings shall be permitted where protected by floor fire doors in accordance with Section 711.8.

- Vertical openings can be provided with fire doors in the plane of the floor. The door can be automatic closing. The floor fire door requirement is detailed in Section 711.8. These floor fire doors can be used to close a floor opening because they have a fire-resistance rating equal to that of the floor and, therefore, meet requirements that are similar to those of the floor itself. It should be noted that floor fire door assemblies must be installed in fire-resistance-rated floors and nonfire-resistance-rated floors.

712.1.14 Group I-3. In Group I-3 occupancies, vertical openings shall be permitted in accordance with Section 408.5.

- Vertical openings within a Group I-3 housing unit are allowed under the conditions of Section 408.5.1. This is to allow tiered cells with observation by supervisory personnel.

712.1.15 Elevators in parking garages. Vertical openings for elevator hoistways in open or enclosed parking garages that serve only the parking garage, and complying with Sections 406.5 and 406.6 respectively, shall be permitted.

- Vertical openings that contain elevator hoistways that only serve a parking garage (open or enclosed) need not be enclosed in fire-resistance-rated shaft construction. The tiered levels of parking are already

---

**Figure 712.1.8**

TWO-STORY SHAFT ENCLOSURE EXCEPTION
open; therefore, to provide fire-resistance-rated construction for the hoistway enclosures serves no useful purpose. Please note that if the elevator hoistway serves floors that are not part of the parking garage, then the fire-resistance-rated shafts would be required throughout the entire length of the elevator hoistway.

712.1.16 Duct systems in parking garages. Vertical openings for mechanical exhaust or supply duct systems in open or enclosed parking garages complying with Sections 406.5 and 406.6 respectively, shall be permitted to be unenclosed where such duct system is contained within and serves only the parking garage.

- This section is similar to Section 712.1.15. Fire-resistance-rated shafts are not required for vertical duct work that is contained within and serves only the parking structure.

712.1.17 Nonfire-resistance-rated joints. Joints in or between floors without a required fire-resistance rating shall be permitted in accordance with Section 711.4.1.

- While Section 712.1.11 covers joints in fire-resistance-rated floors, this section allows joints in non-fire-resistance-rated floors, provided the joints are protected in accordance with Section 711.4.1.

712.1.18 Openings otherwise permitted. Vertical openings shall be permitted where allowed by other sections of this code.

- With the 2012 code, an effort has been made to include or reference all the conditions that would allow vertical openings in one section. Previous editions did not try to include vertical openings in one section; therefore, any other requirement is covered with this reference.

SECTION 713
SHAFT ENCLOSURES

713.1 General. The provisions of this section shall apply to shafts required to protect openings and penetrations through floor/ceiling and roof/ceiling assemblies. Exit access stairways and exit access ramps shall be protected in accordance with the applicable provisions of Section 1009. Interior exit stairways and interior exit ramps shall be protected in accordance with the requirements of Section 1022.

- This section applies to vertical shafts enclosing vertical openings, such as vertical exhaust ducts; gas flues; metal chimneys; vertical supply ducts; return and outdoor air ducts; elevator hoistways, linen chutes and trash chutes. All openings or penetrations in floor/ceiling or roof/ceiling assemblies are required to be protected with a vertical shaft enclosure, except for the permitted uses in Section 712. Two types of shafts are not covered in this section: exit access stairways and ramps (Section 1009) and interior exit stairways and ramps (Section 1022).

The purpose of shafts is to confine a fire to the floor of origin and to prevent the fire or the products of the fire (smoke, heat and hot gases) from spreading to other levels.

713.2 Construction. Shaft enclosures shall be constructed as fire barriers in accordance with Section 707 or horizontal assemblies in accordance with Section 711, or both.

- Shafts are required to be enclosed in fire-resistance-rated fire barriers (Section 707) or a combination of fire barriers and horizontal assemblies (Section 712) where shafts are offset between stories.

713.3 Materials. The shaft enclosure shall be of materials permitted by the building type of construction.

- Material used for the construction of shaft walls must comply with the material requirements for partitions based on the building construction type in Section 602.

713.4 Fire-resistance rating. Shaft enclosures shall have a fire-resistance rating of not less than 2 hours where connecting four stories or more, and not less than 1 hour where connecting less than four stories. The number of stories connected by the shaft enclosure shall include any basements but not any mezzanines. Shaft enclosures shall have a fire-resistance rating not less than the floor assembly penetrated, but need not exceed 2 hours. Shaft enclosures shall meet the requirements of Section 703.2.1.

- The required fire-resistance rating for a shaft enclosure is related to the number of stories being connected. Please note that the shaft enclosure is required to be fire-resistance rated even though the floor may not be required to be fire-resistance rated, such as in a Type IIB, IIB or VB construction. The fire-resistance rating of shaft enclosures must be 2 hours in buildings four or more stories in height. The fire-resistance rating of shaft enclosures that connect less than four stories is required to be only 1 hour; however, in the case of a Type IA or IB, the shaft enclosure for a building height of three stories or less would have to be 2 hours. That is because the floors are 2-hour fire-resistance rated in those types of construction. The fire-resistance integrity of the floor construction must be maintained. The shaft wall construction shall never be allowed to be less than the fire-resistance rating of the floors being penetrated, but need not exceed 2 hours (see Figure 713.4). Another case where a two- or three-story building will require a 2-hour shaft enclosure is a mixed occupancy building using the separated option with a floor separating the occupancies rated for 2 hours.

There is one exception to the 2-hour fire-resistance rating for shaft enclosures in buildings meeting the high-rise provisions of Section 403. Section 403.2.1.2 allows a reduction to 1 hour in high-rise buildings less than 420 feet (128 m) in height for shaft enclosures other than exits and elevator hoistways where special sprinklers are installed in the shaft.

The reference to Section 703.2.1 is a 2009 revision to this section. The intent is that fire-resistance-rated shaft enclosure walls must be rated from fire expo-
sure from both sides. That is, they must be symmetrical assemblies or assume the rating of the least-rated side. Chase walls are not to be confused with shaft walls.

713.5 Continuity. Shaft enclosures shall be constructed as fire barriers in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both, and shall have continuity in accordance with Section 707.5 for fire barriers or Section 711.4 for horizontal assemblies as applicable.

- This section references the fire barrier and horizontal assembly provisions for details on the continuity requirements. For fire barriers, the continuity section is Section 707.5, which also contains the supporting structure provisions. For horizontal assemblies, Section 711.4 describes the continuity provisions. See the commentary for both of those sections. Nothing in this section prohibits offsets in shaft enclosures, provided that the enclosures are continuous to the roof.

713.6 Exterior walls. Where exterior walls serve as a part of a required shaft enclosure, such walls shall comply with the requirements of Section 705 for exterior walls and the fire-resistance-rated enclosure requirements shall not apply.

Exception: Exterior walls required to be fire-resistance rated in accordance with Section 1019.2 for exterior egress balconies, Section 1022.7 for interior exit stairways and ramps and Section 1026.6 for exterior exit stairways and ramps.

- If an exterior wall constitutes part of a shaft enclosure, the exterior wall is only required to comply with the fire-resistance-rating requirements in Section 705 for exterior walls. The intent of the fire barrier requirements is to subdivide or enclose areas to protect them from a fire within the building. The exterior wall need only have a fire-resistance rating if required for structural stability (see Table 601) or because of an exterior exposure potential based on FSD. The exception to Section 713.6 recognizes that an exterior wall of a shaft can also be an egress balcony wall or a wall separating an exterior exit stair. Exterior balcony, exit enclosure and ramp and stair requirements are referenced by the exception as areas required to be fire-resistance rated for reasons other than structural or FSD. Section 701.2, which is new to the 2012 code, also requires a wall serving multiple purposes to meet all the code requirements for each purpose.

713.7 Openings. Openings in a shaft enclosure shall be protected in accordance with Section 716 as required for fire barriers. Doors shall be self- or automatic-closing by smoke detection in accordance with Section 716.5.9.3.

- The integrity of the shaft enclosures must be maintained with approved opening protectives (see Section 716). An example of a protected opening is illustrated in Figure 713.7. Doors provided into shafts shall be self-closing or if automatic closing, must be smoke activated in accordance with Section 716.5.9.3. Table 716.5 provides the fire protection rating required. There is no requirement for the doors to meet the smoke and draft control assembly testing, unless the shaft door also serves as an opening into a corridor or through a smoke barrier.

Figure 713.4
VERTICAL SHAFTS—FIRE-RESISTANCE RATING
713.7.1 Prohibited openings. Openings other than those necessary for the purpose of the shaft shall not be permitted in shaft enclosures.

- In fire barrier walls forming shaft enclosures, openings are limited to only those necessary for the shaft to serve its intended purpose.

713.8 Penetrations. Penetrations in a shaft enclosure shall be protected in accordance with Section 714 as required for fire barriers. Structural elements, such as beams or joists, where protected in accordance with Section 714 shall be permitted to penetrate a shaft enclosure.

- Penetrations for items such as cables, cable trays, conduits, ducts and piping are required to be tested in accordance with ASTM E 814 or UL 1479 with some minor exceptions (see Section 714.3.1). The change in the 2012 code, permits structural members to penetrate shaft walls if the structural members have been tested in the assembly and meet ASTM E 814 and UL 1479. This change is only for shafts in Section 713 and does not address stair shafts in Sections 1009 and 1022. Neither does this change affect penetrations of fire barriers in general.

713.8.1 Prohibited penetrations. Penetrations other than those necessary for the purpose of the shaft shall not be permitted in shaft enclosures.

- The provisions of Section 713.8.1 mirror those of Section 713.7.1 for openings. Because a shaft provides a potential method for a fire or the products of combustion to spread throughout a building, especially when driven due to the stack effect, the code restricts penetrations so that the effectiveness of the shaft is maintained. For instance, horizontal plumbing piping cannot penetrate the walls of a shaft serving vertical air ducts.

713.9 Joints. Joints in a shaft enclosure shall comply with Section 715.

- See the commentary to Section 715.

713.10 Duct and air transfer openings. Penetrations of a shaft enclosure by ducts and air transfer openings shall comply with Section 717.

- These provisions reference the applicable protection features of Section 717 for duct openings. Since a duct is also a penetration, the limitations of Section 713.8.1 are applicable. For exit enclosures, it is important to note that duct openings are limited to those allowed in Section 1022.4. As stated in Section 717.1.1, if a duct is exempted from the need for a damper, the penetration of that duct through a fire-resistance-rated assembly must be protected as a through penetration in accordance with Section 714. Section 717.5.3 requires shaft enclosure penetrations by ducts and air transfer openings to be protected by both fire dampers and smoke dampers. For the exceptions, see the commentary to Section 717.5.3.

713.11 Enclosure at the bottom. Shafts that do not extend to the bottom of the building or structure shall comply with one of the following:

1. They shall be enclosed at the lowest level with construction of the same fire-resistance rating as the lowest floor through which the shaft passes, but not less than the rating required for the shaft enclosure.

2. They shall terminate in a room having a use related to the purpose of the shaft. The room shall be separated from the remainder of the building by fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both. The fire-resistance rating and opening protective shall be at least equal to the protection required for the shaft enclosure.

3. They shall be protected by approved fire dampers installed in accordance with their listing at the lowest floor level within the shaft enclosure.

Exceptions:

1. The fire-resistance-rated room separation is not required, provided there are no openings in or penetrations of the shaft enclosure to the interior of the building except at the bottom. The bottom of the shaft shall be closed off around the penetrating items with materials permitted by Section 718.3.1 for drafts stopping, or the room shall be provided with an approved automatic sprinkler system.

2. A shaft enclosure containing a refuse chute or laundry chute shall not be used for any other purpose and shall terminate in a room protected in accordance with Section 713.13.4.
3. The fire-resistance-rated room separation and the protection at the bottom of the shaft are not required provided there are no combustibles in the shaft and there are no openings or other penetrations through the shaft enclosure to the interior of the building.

In order to limit the spread of fire from story to story through vertical shafts, an enclosure is required throughout the length of the shaft, including the bottom, if the shaft does not extend to the bottom floor of the building. This section gives three separate methods of providing protection for the bottom of shafts that are not at the bottom of the building.

Method 1 is shown in Figure 713.11(1). Please note that the bottom of the shaft is supported by a horizontal assembly meeting Section 711. However, if the horizontal structural members are primary structural frames and not secondary structural members and the structural floor member supports shaft walls three stories or more in height, then individual encasement is required (see Section 704.3).

Method 2 is illustrated in Figure 713.11(2). Figure 713.11(2) shows a 1-hour fire-resistance-rated shaft, but this method is applicable to 2-hour fire-resis-
tance-rated shafts as well, although the room separation would be 2 hours. This method recognizes that the purpose of some shafts cannot be accomplished if the bottom must be enclosed as in Method 1; therefore, a room is permitted at the bottom of the shaft, but the function of the room must be related to the purpose of the shaft. Two common examples of this situation are either mechanical rooms that have vents from the room to the roof or refuse chutes that terminate at a room at the bottom for collection. Exceptions 1 and 2 to this section relate to this method.

Method 3 is similar to Method 1, but allows a fire damper to be provided at the bottom of the enclosure.

Please note that this method predates the requirement for both smoke and fire dampers in ducts penetrating shaft walls (Section 717.5.3). The code user must comply with both code sections; therefore, the code user must provide both fire and smoke dampers with this method unless the smoke damper is exempted by Section 717.5.3.

Exception 1 is illustrated by both Figures 713.11(3) and 713.11(4). This is an exception to Method 2 and eliminates the need for the room to be separated. With this exception there cannot be any openings or penetrations into the shaft enclosures anywhere except at the bottom and the top. A gas-fired appli-

Figure 713.11(3)
VERTICAL SHAFTS—BOTTOM ENCLOSURE ROOM METHOD 2—EXCEPTION 1

Figure 713.11(4)
VERTICAL SHAFTS—BOTTOM ENCLOSURE WITH SPRINKLERS—METHOD 2—EXCEPTION 1
FIRE AND SMOKE PROTECTION FEATURES

Flue or a commercial kitchen exhaust duct are good examples.

Exception 2 is specific to laundry and refuse chute termination rooms and requires compliance with Section 713.13.4.

Exception 3 is illustrated by Figure 713.11(5). This is an exception to the entire section and to all three methods. While the figure shows a very small light well shaft in a three-story building, this exception is not limited to three stories and the size of the shaft is not limited. The area and volume of the shaft can be considered as part of the story in which the bottom of the shaft terminates. The conditions of the exception are based on the fact that the shaft contents will not contribute to the fuel load and that the shaft serves and connects to only one story—the one in which it terminates. This is similar to an atrium with no openings except in the first story. Unlike an atrium, which is exempted from shaft enclosures, this actually is a shaft with shaft wall construction on all stories except the first.

713.12 Enclosure at top. A shaft enclosure that does not extend to the underside of the roof sheathing, deck or slab of the building shall be enclosed at the top with construction of the same fire-resistance rating as the topmost floor penetrated by the shaft, but not less than the fire-resistance rating required for the shaft enclosure.

Proper shaft enclosures must include all sides and the top unless the top of the shaft is also the roof of the building. Because the purpose of the shaft is to limit the spread of fire within the building, if the top of the shaft does not extend to or through the underside of the roof sheathing, deck or slab, then the code requires a fire-resistance-rated horizontal assembly at the top. The fire-resistance rating for the top of the shaft must not be less than the required fire resistance of the shaft enclosure or the fire-resistance rating of the highest floor penetrated (see Figure 713.12). The required rating for the top of the shaft that extends to the sheathing or roof deck must be consistent with the requirements of Table 601 and Section 711 for roof construction. The top of the shaft must be constructed using a horizontal assembly (see Section 711) with the proper fire-resistance rating. It is not permissible to simply take a fire barrier, such as the assembly used for the shaft wall, and turn it horizontally.

The code is silent on whether or not a fire damper is appropriate for use to enclose the top of a shaft. Fire dampers are expressly permitted to be used at the bottom of a fire-resistance-rated shaft in Section 713.11. The damper listing should be reviewed before any damper is installed at this location.

713.13 Refuse and laundry chutes. In other than Group I-2, refuse and laundry chutes, access and termination rooms and incinerator rooms shall meet the requirements of Sections 713.13.1 through 713.13.6.

Exceptions:

1. Chutes serving and contained within a single dwelling unit.
2. Refuse and laundry chutes in Group I-2 shall comply with the provisions of NFPA 82, Chapter 5.
3. Refuse- and laundry-handling systems represent a location that provides a rapid fire spread potential. The emphasis on the vertical chute systems in this

![Figure 713.11(5) VERTICAL SHAFTS—BOTTOM ENCLOSURE EXCEPTION 3](image-url)
section is because such systems interconnect multiple stories and can contain combustible material. Additionally, these systems all too often receive an ignition source, such as discarded chemicals and materials capable of producing spontaneous combustion, smoking materials that have not been extinguished and hot ashes, embers and charcoal. Such systems are also subject to acts of vandalism. The construction, fire suppression and termination requirements of refuse- and laundry-handling systems are interrelated in other code sections. Exception 1 recognizes the small size, limited use and occupant control of refuse and laundry chutes commonly installed within dwelling units. Exception 2 requires Group I-2 occupancies to meet NFPA 82 which has the same shaft enclosure requirements but also construction requirements for the chutes as well as the shafts and requires a vent through the roof.

713.13.1 Refuse, recycling and laundry chute enclosures. A shaft enclosure containing a refuse, recycling, or laundry chute shall not be used for any other purpose and shall be enclosed in accordance with Section 713.4. Openings into the shaft, including those from access rooms and termination rooms, shall be protected in accordance with this section and Section 716. Openings into chutes shall not be located in corridors. Doors shall be self- or automatic-closing upon the actuation of a smoke detector in accordance with Section 716.5.9.3, except that heat-activated closing devices shall be permitted between the shaft and the termination room.

This section requires that the vertical systems or chutes be enclosed in a fire-resistance-rated shaft in accordance with Section 713.4. As with all shafts, the fire-resistance integrity of the shaft must be protected at all penetrations of the shaft enclosure. All access openings and termination points must be treated as shaft enclosure penetrations requiring opening protective. Refuse and laundry access openings are prohibited from being located in corridors or exits.

While a corridor is a very convenient location for access to these chutes, in order to access the chute from a corridor, an intervening room (see Section 713.13.3) with an additional fire-rated opening protective provides redundancy that is justified by fire experience.

713.13.2 Materials. A shaft enclosure containing a refuse, recycling, or laundry chute shall be constructed of materials as permitted by the building type of construction.

The types of materials used in shaft enclosures are to be consistent with Sections 602 through 602.5 for the type of construction of the building. Fire barriers or horizontal assemblies that form shaft walls are permitted to be of combustible construction in Type III, IV and V construction and are required to be of noncombustible materials in Type I and II construction.

713.13.3 Refuse, recycling and laundry chute access rooms. Access openings for refuse, recycling and laundry chutes shall be located in rooms or compartments enclosed by not less than 1-hour fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both. Openings into the access rooms shall be protected by opening protective having a fire protection rating of not less than 3/4 hour. Doors shall be self- or automatic-closing upon the detection of smoke in accordance with Section 716.5.9.3.

The chutes themselves must have a rated fire door with closers in accordance with Section 713.13.1; therefore, the fire door in the shaft wall must be rated for 60 minutes or 90 minutes depending on the height of the shaft enclosure. In addition to this protection, such openings into the chute shaft must be located in a room or compartment. This room or compartment must be enclosed by fire barrier walls (Section 707) and horizontal assemblies (Section 711) with fire-resistance ratings of 1 hour. The door openings into the access room shall be fire-resistance rated for 45
minutes (see Figure 713.13.3). This requirement is necessary to provide an added measure of protection should the access door to the shaft fail to close due to refuse being stuck in the door and because these rooms are a catch-all for combustible material.

713.13.4 Termination room. Refuse, recycling, and laundry chutes shall discharge into an enclosed room separated from the remainder of the building by fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both. Openings into the termination room shall be protected by opening protective having a fire protection rating equal to the protection required for the shaft enclosure. Doors shall be self- or automatic-closing upon the detection of smoke in accordance with Section 716.5.9.3. Refuse chutes shall not terminate in an incinerator room. Refuse, recycling and laundry rooms that are not provided with chutes need only comply with Table 509.

- The chute termination rooms, like the access rooms, are a source of collection of combustible material, and thus must be separated from all other parts of the building by fire barriers (Section 707) and horizontal assemblies (Section 711). The fire-resistance ratings are the same as for access rooms. See also Exception 2 of Section 713.11, which allows the shaft to terminate into such a room. The incidental use separation requirements for waste and linen separation rooms in Table 509 are only applicable to collection rooms not connected to chutes. The termination room must never be connected to an incinerator room.

713.13.5 Incinerator room. Incinerator rooms shall comply with Table 509.

- This section refers to the incidental use separation table. Table 509 requires a 2-hour fire-resistance enclosure for such rooms and sprinkler protection.

713.13.6 Automatic sprinkler system. An approved automatic sprinkler system shall be installed in accordance with Section 903.2.11.2.

- In addition to meeting the requirements for shaft enclosures, laundry and refuse chutes must be provided with automatic sprinkler coverage. Most buildings with chutes will need to be fully sprinklered by other sections of the code. The chutes must have additional heads at the top and in the termination room and in the chute at every other floor level. The need for the sprinkler protection addresses the potential that a fire can occur in the chute or in the container below the chute.

713.14 Elevator, dumbwaiter and other hoistways. Elevator, dumbwaiter and other hoistway enclosures shall be constructed in accordance with Section 713 and Chapter 30.

- The hoistway enclosure is the fixed structure consisting of vertical walls or partitions that isolates the enclosure from all other building areas or from an adjacent enclosure in which the hoistway doors and door assemblies are installed. With the exception of observation elevators (usually in atriums), the hoistway is normally enclosed with fire barriers (see Section 707.3.1). Elevator hoistways in all parking structures that serve only the parking structure are exempt from enclosures by Section 712.1.15. In addition, shaft enclosures are not required for elevators located in an atrium since the hoistways are not concealed and there is no penetration of floor assemblies. Elevator hoistways are enclosed to ensure that flame, smoke and hot gases from a fire do not have an avenue of travel from one floor to another through a concealed space (see the discussion of stack effect in the commentary to Section 708.14.1). Enclosures are also provided to restrict contact with moving equipment and to prevent people from falling.

**Figure 713.13.3**

**REFUSE CHUTE (FIRE BARRIER OPTION)**

7-70

2012 INTERNATIONAL BUILDING CODE® COMMENTARY
713.14.1 Elevator lobby. An enclosed elevator lobby shall be provided at each floor where an elevator shaft enclosure connects more than three stories. The lobby enclosure shall separate the elevator shaft enclosure doors from each floor by fire partitions. In addition to the requirements in Section 708 for fire partitions, doors protecting openings in the elevator lobby enclosure walls shall also comply with Section 716.5.3 as required for corridor walls and penetrations of the elevator lobby enclosure by ducts and air transfer openings shall be protected as required for corridors in accordance with Section 717.5.4.1. Elevator lobbies shall have at least one means of egress complying with Chapter 10 and other provisions within this code.

Exceptions:

1. Enclosed elevator lobbies are not required at the level(s) of exit discharge, provided the level(s) of exit discharge is equipped with an automatic sprinkler system in accordance with Section 903.3.1.1.

2. Elevators not required to be located in a shaft in accordance with Section 712.1 are not required to have enclosed elevator lobbies.

3. Enclosed elevator lobbies are not required where additional doors are provided at the hoistway opening in accordance with Section 3002.6. Such doors shall comply with the smoke and draft control door assembly requirements in Section 716.5.3.1 when tested in accordance with UL 1784 without an artificial bottom seal.

4. Enclosed elevator lobbies are not required where the building is protected by an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2. This exception shall not apply to the following:
   4.1. Group I-2 occupancies;
   4.2. Group I-3 occupancies; and
   4.3. Elevators serving floor levels over 75 feet (22 860 mm) above the lowest level of fire department vehicle access in high-rise buildings.

5. Smoke partitions shall be permitted in lieu of fire partitions to separate the elevator lobby at each floor where the building is equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2. In addition to the requirements in Section 710 for smoke partitions, doors protecting openings in the smoke partitions shall also comply with Sections 710.5.2.2, 710.5.2.3, and 716.5.9 and duct penetrations of the smoke partitions shall be protected as required for corridors in accordance with Section 717.5.4.1.

6. Enclosed elevator lobbies are not required where the elevator hoistway is pressurized in accordance with Section 909.21.

7. Enclosed elevator lobbies are not required where the elevator serves only open parking garages in accordance with Section 408.5.

   An elevator lobby or one of its alternatives found in the exceptions to Section 713.14.1 is required whenever an elevator shaft connects more than three stories. Elevator shafts often constitute the largest vertical shaft in multistory buildings. Hoistways have the potential for accumulating and spreading hot smoke and gases from a fire to other stories in a building. The chimney or stack effect helps with the upward spread of the products of combustion. It is recognized that smoke is a major factor in fire deaths and smoke often migrates to areas remote from the source of the fire. Due to the typical operation and movement of the hoistway doors, they generally cannot provide the level of reduced air leakage that is required to reduce the spread of smoke.

In general, Chapter 7 provisions address the isolation or compartmentation of fire areas, rooms and stories, which prohibits the growth of fires. Analyses of fires in multistory buildings have documented the movement of smoke to upper levels. In the 1980 fire at the MGM Grand Hotel in Las Vegas, 70 of the 84 deaths occurred in the 14th to 24th floors, although the fire was on the first level. The Johnson City Retirement fire in 1989 also had a fire originating on the first level with all but two of the 16 fatalities occurring on the upper floors due to smoke movement via vertical shafts that included the elevator hoistway.

The elevator lobby requirement further isolates the fire-resistance-rated elevator shaft enclosures.

The lobby enclosure walls shall separate the elevator hoistway doors from the rest of the building by 1-hour fire-resistance-rated partitions constructed as fire partitions. As a point of difference, the chute access rooms require fire barrier construction whereas the elevator lobby requirements are for fire partition construction. The elevator lobby separation does not require a horizontal assembly for the floor/ceiling assembly either, as does a chute access room. But on a positive note, this section references Sections 716.5.3 and 717.5.4.1 for door openings and duct openings; therefore, the elevator lobby separation requires the 20-minute doors to be smoke and draft control doors (Section 716.5.3) and also requires duct penetrations to have smoke and fire dampers (Section 717.5.4.1) unless exempted by those sections. The purpose of the special opening protectives in the elevator lobby enclosures is to delay or prevent the vertical spread of smoke to other floors through the hoistway doors and the shaft.

This section also requires at least one means of egress from the elevator lobby enclosure. Multistory buildings have increasing security concerns that have often resulted in controlled access from elevator lob-
bies to the remainder of the floor. Section 713.14.1 clearly establishes that every elevator lobby shall have at least one means of egress, ensuring that no occupant in a lobby is left isolated from escape. Although elevators are not considered required exits, they will not be available in a fire situation anyway since they are recalled during Phase I elevator recall as required by Chapter 30. ASME A17.1, Safety Code for Elevators and Escalators, details the recall requirements, which are adopted by reference in Chapter 30. While this section requires one door from the elevator lobby, every room or space on the floor, including the lobby, must have access to the required number of exits (usually two) on that story without traveling through tenant spaces. In other words, once an occupant leaves the elevator lobby, he or she must have access to two exits. Egress through elevator lobbies from corridors on both sides is also allowed.

Two questions often arise. First, can a space have its only exit access path through an elevator lobby? The answer is yes, if it meets all the other egress requirements. Second, can an exit enclosure open into an elevator lobby? Yes, an elevator lobby is a normally occupied space in the same manner that a corridor is a normally occupied space. Of course, the elevator hoistway doors can never open into an exit enclosure.

There are seven exceptions that eliminate the requirement for enclosed elevator lobbies or modify the enclosure.

Exception 1 removes the requirement for an enclosed elevator lobby on the level(s) of exit discharge of a building when the entire level(s) of exit discharge is provided with automatic sprinkler protection. The exception is notable in that it is not conditioned upon the entire building being sprinklered, but just the first floor. All fully sprinklered buildings would be relieved of the elevator lobby requirements on the floor exit discharge.

Exception 2 eliminates the requirement for enclosed elevator lobbies if the elevator is not required to be enclosed in a fire-resistance-rated shaft. Section 712.1.15 exempts elevator hoistways in buildings exclusively used for parking. Although Section 712.1.6 is for floor openings in an atrium, it is often considered to allow elevator hoistways located entirely within the atrium to be unenclosed. If an elevator is not required to have a fire-resistance-rated enclosure, it serves no purpose to require a fire-resistance-rated elevator lobby enclosure.

Exception 3 eliminates the need for a lobby area, but still requires the additional layer of fire resistance and smoke control. Doors in addition to the normal hoistway door are provided in front of the hoistway opening. These doors or door must meet two requirements. First, they must be easily opened in accordance with Section 3002.6. This ensures that if the door or doors do close, they can be opened by someone who arrives at that level on the elevator, such as fire department personnel. This is very important if the doors are horizontal power-operated doors, such as those in Section 1008.1.4.3 of the code. Section 3002.6 states that the doors shall be readily openable from the car side without a key, tool, special knowledge or effort. The second requirement is the testing of the additional door or doors. They must be tested in accordance with UL 1784. This test is titled “Air Leakage Tests of Door Assemblies.” This test does not provide a fire-resistance rating for the door. It also has no failure criteria as it only measures the leakage rate. The leakage rate for smoke and draft control doors in Section 716.5.3.1 is a maximum of 3.0 cubic feet per minute per square foot of door opening at 0.10 inch of water column pressure. It is assumed that they must meet the leakage rate requirements in Section 716.5.3.1 and they must be identified as smoke and draft control doors in accordance with Section 716.5.7.3.

Exception 4 does not require an elevator lobby in other than Group I-2, Group I-3 and elevators serving the floors 75 feet (22 860 mm) above the lowest level of fire department vehicle access in high-rise buildings if the building is protected by an NFPA 13 or 13R sprinkler system. This recognizes the importance of sprinkler systems in controlling the spread of smoke. This exception does not apply to elevators serving floor levels over 75 feet (22 860 mm) above the lowest level of fire department vehicle access in high-rise buildings or to Groups I-2 and I-3, regardless of height. Elevators not serving the upper floors of a high rise are exempted under this exception.

Exception 5 still requires an elevator lobby. This exception requires either an NFPA 13 or 13R sprinkler system. It also allows nonfire-resistance-rated smoke partitions to enclose the lobby in lieu of the normal 1-hour fire-resistance-rated fire partitions. Door openings in the lobby enclosure must still meet the air leakage rate in Section 716.5.3.1 and must be self- or automatic closing (Section 716.5.9). Duct penetrations through the smoke partitions must also be provided with smoke dampers in accordance with Section 717.5.4.1. Use Exception 5 for Group I-2, Group I-3 and high-rise buildings; otherwise, use Exception 4.

Exception 6 allows elevator hoistway pressurization to be used in lieu of elevator lobbies in all buildings, regardless of height. This is similar to pressurization of stair enclosures, which is used in lieu of smokeproof enclosures for stairs in Section 909.20.5. The hoistway pressurization requirements are in Section 909.21.

Exception 7 is similar to vertical openings permitted in Section 712.1.15. Tiers of parking levels are already open between levels by necessity; therefore, elevators used exclusively to serve only parking levels do not need enclosures or lobby separation.
713.14.1.1 Areas of refuge. Areas of refuge shall be provided as required in Section 1007.

- This is a good cross reference to the accessible egress requirements. Where a required accessible floor is four or more stories above the level of exit discharge, at least one elevator must comply with Section 1007.4. Section 1007.4 requires the elevator used as an accessible means of egress to be accessed from an area of refuge or a horizontal exit. Of course, elevators in fully sprinklered buildings are exempt from the area-of-refuge requirement.

SECTION 714 PENETRATIONS

714.1 Scope. The provisions of this section shall govern the materials and methods of construction used to protect through penetrations and membrane penetrations of horizontal assemblies and fire-resistance-rated wall assemblies.

- This section addresses the specific requirements for maintaining the integrity of fire-resistance-rated assemblies at penetrations. The provisions of this section apply to penetrations of fire-resistance-rated walls (see Section 714.3), fire-resistance-rated horizontal assemblies (see Section 714.4.1) and nonfire-resistance-rated assemblies (see Section 714.4.2). Penetrations of fire-resistance-rated assemblies range from combustible pipe and tubing to noncombustible wiring with combustible covering to noncombustible items such as pipe, tube, conduit and ductwork.

Each type of penetration requires a specific method of protection, which is based on the type of fire-resistance-rated assembly that is penetrated and the type of penetrating item. To determine the type of penetration protection required, the first step is to identify whether the penetrated assembly is a fire-resistance-rated wall; a fire-resistance-rated horizontal assembly or a nonfire-resistance-rated horizontal assembly. Next, identify the type of penetrating item in the applicable section and determine the applicable method of penetration protection necessary.

714.1.1 Ducts and air transfer openings. Penetrations of fire-resistance-rated walls by ducts that are not protected with dampers shall comply with Sections 714.2 through 714.3.3. Penetrations of horizontal assemblies not protected with a shaft as permitted by Section 717.6, and not required to be protected with fire dampers by other sections of this code, shall comply with Sections 714.4 through 714.4.2.2. Ducts and air transfer openings that are protected with dampers shall comply with Section 717.

- Duct penetrations are typically protected with fire and smoke dampers in accordance with Section 717.5; however, if the code does not require them and the designer does not provide such dampers, as it may interfere with the system design, Section 714.1.1 allows for such removal, provided the penetration is protected as part of a tested assembly (see Section 714.3.1.1) or is protected with some type of through-penetration firestop system (see Section 714.3.1.2).

This section coordinates with Section 717.1.1, which states the appropriate section to go to in order to determine the proper protection for ducts when they penetrate a fire-resistance-rated wall assembly. Where ducts or air transfer openings penetrate a fire-resistance-rated wall assembly, fire dampers can be installed to maintain the rating of the assembly as required by Section 717. However, in addition to maintaining the fire-resistant integrity of the floor, wall or roof/ceiling assembly, the damper also serves an additional function as an active component of the fire management design. Unlike through-penetration firestop systems, fire dampers can restrict the spread of fire through the air duct system within a building to areas remote from the fire or into a building from the outside. In addition, the air duct system can be used for the purpose of emergency smoke control, either manually or automatically. Although fire dampers and through-penetration firestop systems both are intended to maintain the rating of the assembly at the point where an opening occurs for the ventilation system, they are not optional or equivalent alternatives for one another.

The placement (or the elimination) of fire dampers within the ventilation system is based on additional factors other than the point at which the duct penetrates a fire-resistance-rated assembly.

Other sections of the code may permit fire dampers to be eliminated due to the installation of an automatic sprinkler system or the design may not include a fire damper to interface with the ventilation system and fire management design at specific locations. This section addresses the protection of the fire rating of the assembly when such conditions occur and provides that the duct penetration is protected as part of a tested assembly (see Section 714.3.1.1) or is protected with some type of through-penetration firestop system (see Section 714.3.1.1), tested and listed for use on ducts without fire dampers.

714.2 Installation details. Where sleeves are used, they shall be securely fastened to the assembly penetrated. The space between the item contained in the sleeve and the sleeve itself and any space between the sleeve and the assembly penetrated shall be protected in accordance with this section. Insulation and coverings on or in the penetrating item shall not penetrate the assembly unless the specific material used has been tested as part of the assembly in accordance with this section.

- Sleeves are typically installed when the opening penetrates an assembly with interior voids, such as a steel stud-framed wall. The sleeve must be securely fastened to the penetrated assembly to prevent the sleeve from becoming dislodged and adversely affecting the performance of the annular space protection. The space between the sleeve and the penetrating item, as well as between the sleeve and the rated assembly, must be protected in accordance
FIRE AND SMOKE PROTECTION FEATURES

with Section 714.3.1. Without attention to these conditions, a sleeved penetration may not perform as required by the code. A sleeve may also exist when a segment of plastic or metal pipe or tube is cast into a concrete floor, thus creating the needed opening for an anticipated penetration. In this case, the need for secure fastening to the underlying assembly is essentially guaranteed, and there would be no space needing to be sealed between the sleeve and the assembly being penetrated.

Section 714.3.1 requires that combustible penetrations be protected with assemblies that have been tested in accordance with ASTM E 119 or UL 263 (see Section 714.3.1.1) or ASTM E 814 or UL 1479 (see Section 714.3.1.2). If a sleeve is used in conjunction with the penetrating items, then the annular space within and around the sleeve must also be protected with materials that meet the conditions of the test standards. The purpose of this section is to provide the building official with the necessary text to enforce the conditions of the penetration protection standards.

If combustible insulation material or coverings on the penetrating item could provide a path for the line of fire to travel through the assembly, the method of protection must have also been fire tested using that specific type and thickness of insulation. This section clarifies that either the insulation or covering must be part of the tested assembly, whether the assembly was tested under ASTM E 119 or UL 263 or is a through-penetration firestop system tested in accordance with ASTM E 814 or UL 1479, or else the insulation or covering is not allowed to pass through the penetration. In the latter case, the insulation or covering should be removed from the penetrated item at the point of penetration through the fire-resistance-rated assembly, assuming that the removal would not cause other problems and that the removal would be compliant with other applicable codes [e.g., International Plumbing Code® (IPC®), IMC].

714.3 Fire-resistance-rated walls. Penetrations into or through fire walls, fire barriers, smoke barrier walls and fire partitions shall comply with Sections 714.3.1 through 714.3.3. Penetrations in smoke barrier walls shall also comply with Section 714.5.

In order to maintain the integrity of the fire-resistance-rated wall assembly (fire walls, fire barriers, smoke barriers and fire partitions), penetrations into and through the rated assembly must be properly protected. Acceptable protection methods for various penetrations of wall assemblies are identified in Sections 714.3.1 through 714.3.4. Additionally, penetrations of smoke barriers are required to meet the test requirements for air leakage given in Section 714.5.

714.3.1 Through penetrations. Through penetrations of fire-resistance-rated walls shall comply with Section 714.3.1.1 or 714.3.1.2.

Exception: Where the penetrating items are steel, ferrous or copper pipes, tubes or conduits, the annular space between the penetrating item and the fire-resistance-rated wall is permitted to be protected as follows:

1. In concrete or masonry walls where the penetrating item is a maximum 6-inch (152 mm) nominal diameter and the area of the opening through the wall does not exceed 144 square inches (0.0929 m²), concrete, grout or mortar is permitted where it is installed the full thickness of the wall or the thickness required to maintain the fire-resistance rating;

2. The material used to fill the annular space shall prevent the passage of flame and hot gases sufficient to ignite cotton waste when subjected to ASTM E 119 or UL 263 time-temperature fire conditions under a minimum positive pressure differential of 0.01 inch (2.49 Pa) of water at the location of the penetration for the time period equivalent to the fire-resistance rating of the construction penetrated.

Combustible cables, wires, pipes, tubes and conduits that penetrate fire-resistance-rated walls are required to be properly protected (see Figures 714.3.1(1) and 714.3.1(2). These penetrations are required to be tested in accordance with ASTM E 119 or UL 263 (see Section 714.3.1.1) or ASTM E 814 or UL 1479 (see Section 714.3.1.2). Because combustible materials have a greater propensity to spread fire through a penetration, the requirements for combustible penetrating items are considerably more restrictive than for noncombustible penetrating items, to which the exception can apply. Penetration of fire-resistance-rated walls by cables, wires, pipes, tubes, conduits and vents represents a weak link in the continuity of the required fire-resistance rating. These penetrations are to be protected with materials that will maintain the integrity of the wall for the duration of the required fire-resistance rating. In lieu of a system tested in accordance with ASTM E 119 or UL 263 (see Section 714.3.1.1) or ASTM E 814 or UL 1479 (see Section 714.3.1.2), penetrations with steel, ferrous or copper pipes, tubes or conduits may be protected by filling the annular space. Annular space protection is permitted for the protection of penetrations of wall assemblies by only the mentioned noncombustible items. “Annular space” is defined in Section 202 as the perimeter space between the penetrating item and the rated assembly. If sleeves are used, the annular space includes the space between the penetrating item and the sleeve, as well as the space between the sleeve and the rated assembly [see Figure 714.3.1(3)]. Item 1 of the exception permits the use of concrete, grout or mortar to provide annular space protection for certain penetrations of concrete and masonry wall assemblies. The concrete, grout or mortar must be provided for the full thickness of the wall, unless evidence can be provided that demonstrates that the required fire-resistance rating can be achieved with a lesser depth.

Concrete, grout and mortar have traditionally been
used as protection for the annular space in penetrations of concrete and masonry walls. The presumption has been that experience has shown this form of protection to be viable.

Under Item 2 of the exception, because the penetrating items are limited and the annular space protection is not based on specific performance testing of each penetration arrangement and detail, the performance of the protection is dependent on the annular space protection material alone. As such, for walls other than concrete or masonry, Item 2 requires that the material be prequalified as to its ability to prevent the passage of flame and hot gases sufficient to ignite cotton waste and when subjected to the time-temperature criteria of ASTM E 119 or UL 263. This is consistent with the criteria required for through-penetration protection systems (ASTM E 814 or UL 1479) in which the T rating is not required. Since it is very likely that the penetration in an actual fire will be exposed to a positive pressure, this section specifies that the test fire exposure include a positive pressure of 0.01 inch (0.25 mm) of water column as a further means to verify the performance of this protection method as required by the code.

714.3.1 Fire-resistance-rated assemblies. Penetrations shall be installed as tested in an approved fire-resistance-rated assembly.

- This section requires, as an option, that the tested assembly in accordance with ASTM E 119 or UL 263 include the penetrations along with the proposed type of protection. In other words, the entire assembly is

COMBUSTIBLE PIPE PENETRATION OF FIRE-RESISTANCE-RATED WALL

---

2012 INTERNATIONAL BUILDING CODE® COMMENTARY 7-75
tested. As an option, this section is not used frequently due to the limitations placed on the tested assembly relative to its application. Penetration protection is most often provided in accordance with the exception to Section 714.3.1 and the provisions of Section 714.3.1.2.

714.3.1.2 Through-penetration firestop system. Through penetrations shall be protected by an approved penetration firestop system installed as tested in accordance with ASTM E 814 or UL 1479, with a minimum positive pressure differential of 0.01 inch (2.49 Pa) of water and shall have an F rating of not less than the required fire-resistance rating of the wall penetrated.

In order to maintain effective compartmentation of a building to restrict the spread of fire, all penetrations through fire-resistance-rated assemblies must be protected. In recent history, there have been several examples of buildings where extensive fire damage and loss of life was attributed, at least in part, to lack of or improper installation of penetration protection. In the absence of a through-penetration firestop system to protect penetrations of fire-resistance-rated assemblies, the potential exists for fire to spread beyond the initial area of fire origin. One report on the source of origin of fires in buildings indicated that 23 percent of all building fires originate from electrical systems. This fact, coupled with the number of penetrations through walls and floors created by electrical distribution piping, helps to underscore the necessity for the protection of all penetrations through rated assemblies. It must be noted that penetrations are not limited to electrical systems only, but that openings to accommodate plumbing and mechanical systems also contribute to the number of penetrations through any given assembly.

A through-penetration firestop system consists of specific materials or an assembly of materials that are designed to restrict the passage of fire and hot gases for a prescribed period of time through openings made in fire-resistance-rated walls or horizontal assemblies. In certain instances, the through-penetration firestop system is also required to limit the transfer of heat from the fire side to the unexposed side. In order to determine the effectiveness of a through-penetration firestop system in restricting the

![Diagram of through-penetration firestop system]

Figure 714.3.1(3) EXAMPLES OF ANNULAR SPACE PROTECTION

7-76

2012 INTERNATIONAL BUILDING CODE® COMMENTARY
passage of fire and the transfer of heat, firestop systems are required to be subjected to fire testing. ASME E 814 and UL 1479 are the test methods developed specifically for the evaluation of a firestop system's ability to resist the passage of flame and hot gases, withstand thermal stresses and restrict transfer of heat through the penetrations in an assembly.

The basic provisions of ASME E 814 and UL 1479 require that a test assembly consisting of a specific wall or floor construction, containing through penetrations of various types and sizes, be constructed. The through-penetration firestop system to be tested is installed in accordance with the manufacturer's instructions around the penetrations. The test assembly is then exposed to a test fire that corresponds to the time-temperature curve established by ASME E 119 or UL 263 (see the commentary to Section 703.2 for more discussion on ASME E 119 or UL 263). After the fire test exposure, the through-penetration firestop system is subjected to a hose stream, which evaluates the ability of the through-penetration firestop system to resist the effects of erosion and thermal shock. After completion of the ASME E 814 or UL 1479 procedure, two ratings for the test subject are established, which indicate how the test specimen withstands exposure to the test fire for a specified period of time.

Ratings for the through-penetration firestop system are generated based on the results of the testing, and are reported as an F (flame) rating and a T (temperature) rating. The F rating indicates the period of time, in hours, the tested through-penetration firestop system remained in place without allowing the passage of fire during exposure or water during the hose stream. The T rating indicates the time, in hours, it took for the temperature, as recorded by thermocouples placed at specified locations on the unexposed side of the test assembly, to reach 325°F (162°C) above ambient. It must be noted that in order to obtain a T rating, the system must first obtain an F rating. F ratings are required for all through-penetration firestop systems and must be equal to the fire-resistance rating of the assembly penetrated. A T rating is not required for wall penetrations, but a minimum of 1 hour is required where the through-penetration firestop system is installed in a floor assembly where the penetrating item is a pipe, tube or conduit that is in direct contact with a combustible material. This requirement is intended to minimize the potential for ignition of the combustible material on the unexposed side of the assembly due to elevated temperatures transmitted via the pipe, tube or conduit.

An ASME International (ASME) standard practice is available that can be used in cases where a standardized methodology is desired for the inspection of installed through-penetration firestop systems. Such a standardized procedure can be particularly useful in cases where a third-party inspection firm is used. ASME E 2174, Standard Practice for On-site Inspection of Installed Firestops, includes items such as pre-construction meetings to review submittals, details, variances, building mock-ups for destructive testing and scheduling witnessed inspection of a specified percentage of installations or conducting destructive testing on a specified percentage of installations. This standard practice also identifies what actions should be taken based on the percentage of noncompliant installations identified, as well as providing a standardized reporting form.

Two of the most common types of materials used in through-penetration firestop systems are intumescent and endothermic materials. Intumescent materials expand to approximately eight to 10 times their original volume when exposed to temperatures exceeding 250°F (121°C). The expansion of the material fills the voids or openings within the penetration to resist the passage of flame, while the outer layer of the expanded intumescent material forms an insulating charred layer that assists in limiting the transfer of heat. The expansion properties of intumescent materials allow them to seal openings left by combustible penetrating items that burn away during a fire, but do not retard heat as well as endothermic materials. Intumescent materials are typically used with combustible penetrating items or where a higher T rating is not required.

Endothermic materials provide protection through chemically bound water released in the form of steam when exposed to temperatures exceeding 600°F (316°C). This released water provides a cooling of the penetration and retards heat transfer through the penetration. Endothermic materials tend to be superlatively resistant to heat transfer and have higher T ratings, but do not expand to fill voids left by combustible penetrating items that burn away during a fire. Endothermic materials are, therefore, typically used with noncombustible penetrating items and where a higher T rating is required.

**714.3.2 Membrane penetrations.** Membrane penetrations shall comply with Section 714.3.1. Where walls or partitions are required to have a fire-resistance rating, recessed fixtures shall be installed such that the required fire-resistance rating will not be reduced.

**Exceptions:**

1. Membrane penetrations of maximum 2-hour fire-resistance-rated walls and partitions by steel electrical boxes that do not exceed 16 square inches (0.0103 m²) in area, provided the aggregate area of the openings through the membrane does not exceed 100 square inches (0.0645 m²) in any 100 square feet (9.29 m²) of wall area. The annular space between the wall membrane and the box shall not exceed 3/8 inch (3.1 mm). Such boxes on opposite sides of the wall or partition shall be separated by one of the following:

   1.1. By a horizontal distance of not less than 24 inches (610 mm) where the wall or partition
FIRE AND SMOKE PROTECTION FEATURES

is constructed with individual noncommunicating stud cavities;

1.2. By a horizontal distance of not less than the depth of the wall cavity where the wall cavity is filled with cellulose loose-fill, rock-wool or slag mineral wool insulation;

1.3. By solid fireblocking in accordance with Section 718.2.1;

1.4. By protecting both outlet boxes with listed putty pads; or

1.5. By other listed materials and methods.

2. Membrane penetrations by listed electrical boxes of any material, provided such boxes have been tested for use in fire-resistance-rated assemblies and are installed in accordance with the instructions included in the listing. The annular space between the wall membrane and the box shall not exceed $\frac{1}{8}$ inch (3.1 mm) unless listed otherwise. Such boxes on opposite sides of the wall or partition shall be separated by one of the following:

2.1. By the horizontal distance specified in the listing of the electrical boxes;

2.2. By solid fireblocking in accordance with Section 718.2.1;

2.3. By protecting both boxes with listed putty pads; or

2.4. By other listed materials and methods.

3. Membrane penetrations by electrical boxes of any size or type, which have been listed as part of a wall opening protective material system for use in fire-resistance-rated assemblies and are installed in accordance with the instructions included in the listing.

4. Membrane penetrations by boxes other than electrical boxes, provided such penetrating items and the annular space between the wall membrane and the box, are protected by an approved membrane penetration firestop system installed as tested in accordance with ASTM E 814 or UL 1479, with a minimum positive pressure differential of 0.01 inch (2.49 Pa) of water, and shall have an F and T rating of not less than the required fire-resistance rating of the wall penetrated and be installed in accordance with their listing.

5. The annular space created by the penetration of an automatic sprinkler, provided it is covered by a metal escutcheon plate.

"Membrane penetrations" are defined in Section 202 as "a breach in one side of a floor/ceiling, roof/ceiling or wall assembly to accommodate an item installed into or passing through the breach." Therefore they are different from a through penetration in that they do not pass through the entire assembly. Membrane penetrations are treated similarly to through penetrations; namely, noncombustible conduits, pipes and tubes that penetrate only one membrane of a fire-resistance-rated wall assembly are required to have the annular space protected in accordance with Section 714.3.1 or comply with the exception of that section. Combustible penetrations through only one membrane of a wall assembly would require either a tested assembly (see Section 714.3.1.1) or a through-penetration firestop system that complies with Section 714.3.1.2 for the penetrated membrane.

Penetrations, such as electrical outlet boxes, can affect the fire-resistance rating of an assembly. The criteria in Exception 1 [see Figure 714.3.2(1)] limits the size of steel electrical outlet boxes [16 square inches (.0103 m²) and the amount allowed in a 100-square-foot (9.3 m²) area. Although not directly stated in the code, based on the supporting text in one of the legacy codes, when membrane penetrations of electrical outlet boxes were first regulated in 1979, it would appear that the original intent was to permit 100 square inches (0.0645 m²) of openings on each side of a floor/ceiling (9.3 m²) wall section. These criteria are consistent with the criteria determined from fire tests that have generally shown that, within these limitations, these penetrations will not adversely affect the fire-resistance rating of the wall. The design information section of the Ul. Fire Resistance Directory states that the opening in a wallboard facing is to be cut such that the clearance between the box and the wallboard does not exceed $\frac{1}{8}$ inch (3.2 mm).

Electrical outlet boxes of steel or materials other than steel (see Exception 2) can be utilized in the fire-resistance-rated wall if they have been specifically tested as part of a fire-resistance-rated assembly. Steel outlet boxes that exceed the size limitations of Exception 1 would also require the same prequalification by testing. Exceptions 1 and 2 allow electrical boxes on opposite sides of the wall if they meet one of several criteria, such as separation by a horizontal distance of 24 inches (610 mm).

Exception 3 relates to electrical boxes listed as part of an assembly by a testing agency. Certification and listing agencies have published listings covering proprietary compositions that are used to maintain the hourly ratings of fire-resistance walls and partitions incorporating flush-mounted devices, such as outlet boxes, electrical cabinets and mechanical cabinets penetrating membranes of fire-resistance-rated assemblies. The individual systems indicate the specific applications and the method of installation for which the materials have been evaluated. The basic standards used to investigate these products are UL 263 and ASTM E 119. For example, UL classifies these materials and systems as "wall opening protective materials." This category includes classifications for both generic steel electrical boxes as well as specific types and models of outlet and switch boxes composed of other materials, all listed for specific usage in fire-resistance-rated wall assemblies. The UL listings for wall opening protective materials indicate that, depending upon the testing conducted for
the individual listing, their use can allow for any combination of: (1) reducing the spacing between boxes contained on opposite sides of the wall; (2) increasing the size of the boxes; (3) increasing the density of the boxes and (4) allowing the use of boxes on each side of staggered stud walls. Because these systems are tested for the specific end-use applications, the individual and aggregate restrictions on maximum sizes and quantities (i.e., 16 square inches (10 322 mm²) for an individual box, and the aggregate maximum of 100 square inches (64 516 mm²) per 100 square feet (9.3 m²)) are not required for these systems to maintain the fire-resistance ratings of the assemblies penetrated.

Exception 4 creates a direct parallel between the requirements for electrical outlet boxes and other membrane penetration boxes, such as dryer exhaust boxes, washing machine hose connection boxes, fire or police alarm boxes, manual fire alarm boxes, switch boxes, valve boxes, special purpose boxes, electrical panels and hose cabinets. The protection systems are to be tested for use in fire-resistance-rated assemblies and installed in accordance with the instructions included in the listings. Because these utility boxes can exceed 100 square inches (64 516 mm²) aggregate area, however, both an F and T rating are required in order to be directly equivalent to the fire-resistance rating of the assemblies penetrated. Given that these are membrane penetrations, there is a greater likelihood that someone could unknowingly place or store combustible materials, potentially even furniture and bedding, directly in contact with the unpenetrated membrane on the opposite side of the wall. This could significantly increase threat of a fire spread. The information provided for each classification would include the model numbers for the products, a description of the rated assemblies, the spacing limitations for the boxes and the installation details.

Exception 5 provides an alternative to the annular space protection provisions of Section 714.3.1 for fire sprinklers that penetrate a single membrane, provided that the annular space around the fire sprinkler head or fitting is completely covered by an escutcheon plate of noncombustible material [see Figure 714.3.2(2)]. The nature of the hazard posed by single membrane penetrations of sprinkler piping is limited due to the size of the opening, the potential amount of openings and the presence of a sprinkler system. The installation of a noncombustible escutcheon provides protection against free passage of fire through the annular space as well as allowing for the movement of sprinkler piping without breaking during a seismic event. These provisions correlate with the requirements of the National Earthquake Hazard Reduction Program (NEHRP) provisions recommended by the Building Seismic Safety Council (BSSC) for installation of sprinkler systems to resist seismic forces. Wall-mounted sprinkler heads installed back to back in fire-resistance-rated walls would be treated as through penetrations and not membrane penetrations.

AGGREGATE AREA OF OUTLET BOXES MUST NOT EXCEED 100 SQ IN PER 100 SQ FT OF WALL AREA OR SHAFT ENCLOSURE WALL AREA.

For SI: 1 inch = 25.4 mm, 1 square inch = 645 mm².

Figure 714.3.2(1)
OUTLET BOXES IN RATED ASSEMBLIES
714.3 Dissimilar materials. Noncombustible penetrating items shall not connect to combustible items beyond the point of firestopping unless it can be demonstrated that the fire-resistance integrity of the wall is maintained.

This section limits the common practice of using a short metal nipple to penetrate a rated assembly, fire-stopping for the metal penetration (which is substantially less expensive than firestopping for plastic) and then connecting to plastic pipe or conduit on the room side of the wall. Arguably, there is a distance at which such connection is safe; however, this distance is variable and cannot be specified in the body of the code, hence the requirement for demonstration of fire-resistance integrity. An identical provision is found in Section 714.4.1.3 regarding penetrations of horizontal assemblies.

714.4 Horizontal assemblies. Penetrations of a floor, floor/ceiling assembly or the ceiling membrane of a roof/ceiling assembly not required to be enclosed in a shaft by Section 712.1 shall be protected in accordance with Sections 714.4.1 through 714.4.2.2.

Penetrations of horizontal assemblies are required to be protected by a shaft enclosure unless otherwise exempted by Section 712.1. The acceptable methods by which a floor or roof assembly can be interrupted by a penetration are identified in Sections 714.4.1 through 714.4.2.

As noted in the commentary to Section 711, roof construction that is required to have a fire-resistance rating is intended to minimize the threat of premature structural failure of the roof construction under fire conditions and not to create a barrier to contain fire within the building. Section 711.4 permits unprotected penetrations in fire-resistance-rated roof assemblies, provided that the structural integrity of the roof assembly is not reduced.

714.4.1 Fire-resistance-rated assemblies. Penetrations of the fire-resistance-rated floor, floor/ceiling assembly or the ceiling membrane of a roof/ceiling assembly shall comply with Sections 714.4.1.1 through 714.4.1.4. Penetrations in horizontal smoke barriers shall also comply with 714.5.

This section is similar to the requirement found in Section 714.3 but it applies to horizontal assemblies. The application of this section is limited to floors, floor/ceiling assemblies or the ceiling membrane of a roof/ceiling assembly. This section, therefore, does not apply to the roof of a roof/ceiling assembly or a roof, which by itself, provides the required rating.

714.4.1.1 Through penetrations. Through penetrations of fire-resistance-rated horizontal assemblies shall comply with Section 714.4.1.1.1 or 714.4.1.1.2.

Exceptions:

1. Penetrations by steel, ferrous or copper conduits, pipes, tubes or vents or concrete or masonry items through a single fire-resistance-rated floor assembly where the annular space is protected with materials that prevent the passage of flame and hot gases sufficient to ignite cotton waste when subjected to ASTM E 119 or UL 263 time-temperature fire conditions under a minimum positive pressure differential of 0.01 inch (0.29 Pa) of water at the location of the penetration for the time period equivalent to the fire-resistance rating of the construction penetrated. Penetrating items with a maximum 6-inch (152 mm) nominal diameter shall not be limited to the penetration of a single fire-resistance-rated floor assembly, provided the aggregate area of the openings through the assembly does not exceed 144 square inches (92900 mm²) in any 100 square feet (9.3 m²) of floor area.

2. Penetrations in a single concrete floor by steel, ferrous or copper conduits, pipes, tubes or vents with a maximum 6-inch (152 mm) nominal diameter, provided the concrete, grout or mortar is installed the full thickness of the floor or the thickness required to maintain the fire-resistance rating. The penetrating items shall not be limited to the penetration of a single concrete floor, provided the area of the opening through each floor does not exceed 144 square inches (92900 mm²).

3. Penetrations by listed electrical boxes of any material, provided such boxes have been tested for use in fire-resistance-rated assemblies and installed in accordance with the instructions included in the listing.

The code addresses the penetration of fire-resistance-rated horizontal separations in much the same way as penetrations through vertical assemblies;
namely, by requiring the penetrations to either be part of a total assembly or be protected with a through-penetration firestop system (see commentary, Section 714.3.1).

Exception 1 is similar to Exception 2 of Section 714.3.1. This exception allows the noncombustible penetrating item to connect two stories (penetrate one floor), regardless of the size of the penetrating item [see Figure 714.4.1(1)]. Where the size of the individual penetration [6-inch diameter (152 mm)] and the aggregate area [144 square inches (0.095 m²)] is limited in any 100 square feet (9.3 m²), the code allows such penetrations of noncombustible construction to be through an unlimited number of floors.

Exception 2 allows a 6-inch-diameter (152 mm) penetration through a concrete floor similar to Exception 1 of Section 714.3.1. Where the area of the penetration is limited to 144 square inches (0.095 m²), such a penetration is permitted to be through an unlimited number of floors [see Figure 714.4.1(2) for methods of annular space protection for Exceptions 1 and 2].

Exception 3 mirrors Exception 2 to Section 714.3.2 for membrane penetrations, but is applicable to through penetrations of a horizontal assembly, provided the outlet box has been tested.

714.4.1.1.1 Installation. Through penetrations shall be installed as tested in the approved fire-resistance-rated assembly.

This section addresses membrane penetrations that were tested as a part of the normal fire test of the assembly (see commentary, Section 714.3.1.1).

714.4.1.1.2 Through-penetration firestop system. Through penetrations shall be protected by an approved through-penetration firestop system installed and tested in accordance with ASTM E 814 or UL 1479, with a minimum positive pressure differential of 0.01 inch of water (2.49 Pa). The system shall have an F rating/T rating of not less than 1 hour but not less than the required rating of the floor penetrated.

Exceptions:

1. Floor penetrations contained and located within the cavity of a wall above the floor or below the floor do not require a T rating.

2. Floor penetrations by floor drains, tub drains or shower drains contained and located within the concealed space of a horizontal assembly do not require a T rating.

This section differs slightly from Section 714.3.1.2 for wall penetrations in that a T rating is required for penetrations of horizontal assemblies, but is not required for penetrations of wall assemblies (see commentary, Section 714.3.1.2).

When permitted as an alternative to a shaft enclosure, cables, cable trays, conduits, tubes and pipes may penetrate a floor assembly when an approved through-penetration firestop system is used. An approved through-penetration firestop system is one that has been tested in accordance with ASTM E 814 or UL 1479. The test method determines the performance of the protection system with respect to exposure to a standard time-temperature fire and hose stream test. The performance of the protection system is dependent on the specific assembly of materials tested, including the number, type and size of penetrations and the types of floors or walls in which it is installed. It should also be noted that tests have been conducted at various pressure differentials; however, the current criterion used is 0.01 inch (2.49 Pa) of water gauge, and only tests with such minimum pressure throughout the test period are to be accepted. In evaluating test reports, the building official must determine that the tested assembly is truly representative of the manner in which the system is
to be installed. It should be noted that the ASTM E 814 and UL 1479 test establishes two ratings: the F rating, which identifies the ability of the material to resist the passage of flame, and the T rating, which identifies the thermal transmission characteristics of the material or assembly. Exception 1 is intended to set aside the T rating requirement where the penetrating item is located in a cavity of a wall and is separated from contact with adjacent materials in the occupiable floor area. Exception 2 allows floor penetrations for plumbing drains located within a concealed horizontal assembly without a T rating.

Meeting the T-rating requirement can be very challenging for penetrants that are metallic and therefore conduct heat. A through-penetration firestop system for such penetrants would not typically meet the T-rating requirement simply by sealing the penetrant within the floor. Additional insulation or covering of the through penetrant is typically required above and below the floor to prevent heat transmission via the penetrant. Listings for through-penetration firestop systems will indicate the T rating obtained for any specific system. Figure 714.4.1.1.2 shows an example of typical firestop details that would be needed for a cable bundle to meet the T rating requirement of Section 714.4.1.1.2. For other types of metallic penetrants, listed systems with suitable T ratings would typically have insulation wrapped around the penetrant for some distance above the floor and below the floor.

714.4.1.2 Membrane penetrations. Penetrations of membranes that are part of a horizontal assembly shall comply with Section 714.4.1.1.1 or 714.4.1.1.2. Where floor/ceiling assemblies are required to have a fire-resistance rating, recessed fixtures shall be installed such that the required fire resistance will not be reduced.

Exceptions:

1. Membrane penetrations by steel, ferrous or copper conduits, pipes, tubes or vents, or concrete or masonry items where the annular space is protected either in accordance with Section 714.4.1.1 or to prevent the free passage of flame and the products of combustion. The aggregate area of the openings through the membrane shall not exceed 100 square inches (64 500 mm²) in any 100 square feet (9.3 m²) of ceiling area in assemblies tested without penetrations.

![Diagram of firestop systems](image)

**Figure 714.4.1(2)**

**EXAMPLES OF ANNULAR SPACE PROTECTION WITH SLEEVES**
2. Ceiling membrane penetrations of maximum 2-hour horizontal assemblies by steel electrical boxes that do not exceed 16 square inches (10323 mm²) in area, provided the aggregate area of such penetrations does not exceed 100 square inches (44 500 mm²) in any 100 square feet (9.29 m²) of ceiling area, and the annular space between the ceiling membrane and the box does not exceed 1/8 inch (3.2 mm).

3. Membrane penetrations by electrical boxes of any size or type, which have been listed as part of an opening protective material system for use in horizontal assemblies and are installed in accordance with the instructions included in the listing.

4. Membrane penetrations by listed electrical boxes of any material, provided such boxes have been tested for use in fire-resistance-rated assemblies and are installed in accordance with the instructions included in the listing. The annular space between the ceiling membrane and the box shall not exceed 1/8 inch (3.2 mm) unless listed otherwise.

5. The annular space created by the penetration of a fire sprinkler, provided it is covered by a metal escutcheon plate.

6. Noncombustible items that are cast into concrete building elements and that do not penetrate both top and bottom surfaces of the element.

7. The ceiling membrane of 1- and 2-hour fire-resistance-rated horizontal assemblies is permitted to be interrupted with the double wood top plate of a fire-resistance-rated wall assembly, provided that all penetrating items through the double top plates are protected in accordance with Section 714.4.1.1.1 or 714.4.1.1.2. The fire-resistance rating of the wall
shall not be less than the rating of the horizontal assembly.

- Penetrations of fire-resistance-rated floor/ceiling and roof/ceiling assemblies that have a ceiling membrane as a component of the tested assembly, such as steel or wood joist assemblies using acoustical tiles or gypsum wallboard, are limited to those penetrations that are listed in the tested assembly (see Section 714.4.1.1.1) or those protected in accordance with ASTM E 814 or UL 1479 [see Section 714.4.1.1.2 and Figure 714.4.1.2(1)]. Penetrations of a ceiling membrane by items that are not part of a tested assembly create a point for possible fire penetration into the space above the ceiling membrane, which in turn could jeopardize the fire-resistance rating of the assembly. The exceptions contain protection requirements for specific types of penetrations that are not required to be part of the tested assembly.

Exception 1 allows for a maximum aggregate amount of noncombustible pipe, tube, vents and conduit penetrations of a floor or a ceiling that is part of a fire-resistance-rated assembly to be 100 square inches (0.0645 m²) per 100 square feet (9.3 m²) of ceiling area. The annular space of the penetration can be protected by either annular space protection (see Exception 1 of Section 714.4.1.1) or a through-penetration firestop system tested to ASTM E 814 or UL 1479 [see Section 714.4.1.1.2 and Figure 714.4.1.2(2)].

Annular space protection is not an option for combustible items because it does not have the ability to protect the resulting void created when the combustible penetrating item burns away.

![Diagram of Fire and Smoke Protection Features](image)

**Figure 714.4.1.2(1)**
PROTECTION OF PENETRATIONS THROUGH CEILING MEMBRANE OF FIRE-RESISTANCE-RATED ASSEMBLY

![Diagram of Noncombustible Pipe Penetrations](image)

**Figure 714.4.1.2(2)**
NONCOMBUSTIBLE PIPE PENETRATIONS OF CEILING MEMBRANE OF A FIRE-RESISTANCE-RATED FLOOR/CEILING ASSEMBLY

---

For SI: 1 square inch = 645 mm², 1 square foot = 0.0929 m².
Exception 2 allows penetrations of electrical outlet boxes that can affect the fire-resistance rating of an assembly. The criteria of this section limit the size of noncombustible electrical outlet boxes that penetrate a ceiling membrane to 16 square inches and an aggregate area that shall not exceed 100 square inches (0.0645 m²) in 100 square feet (9.3 m²) of ceiling area. All of the openings at the penetrations of the outlets are required to be protected as mentioned above. The area limitations are consistent with the criteria determined from fire tests, which have shown that within these limitations, these penetrations will not adversely affect the fire-resistance rating of the floor/ceiling assembly.

The exception permits electrical outlet boxes and fittings, which have been evaluated and found suitable for this purpose, to be located in the floor or ceiling of the fire-resistance-rated assembly. Reference sources for fire-resistance-rated assemblies, such as the UL Fire Resistance Directory, state that certain tested floor assemblies will permit the installation of electrical and communication connection inserts that appear in the UL listing category "Outlet Boxes and Fittings Classified for Fire Resistance" without reducing the fire-resistance rating of the assembly. However, classified outlet boxes and fittings installed in floor/ceiling assemblies that do not specify their use will jeopardize the rating unless compensating protection is provided.

Exception 3 is related to membrane penetrations of fire-resistance-rated assemblies by electrical boxes of any size or type that have been listed for their particular use in a horizontal assembly.

Certification and listing agencies have published listings covering proprietary compositions that are used to maintain the hourly ratings of fire-resistant walls and partitions incorporating flush-mounted devices, such as outlet boxes, electrical cabinets and mechanical cabinets penetrating membranes of fire-resistance-rated assemblies. The individual systems indicate the specific applications and the method of installation for which the materials have been evaluated. The basic standards used to investigate these products are ANSI/UL 263 and ASTM E 119.

For example, UL classifies nonmetallic outlet boxes for installation in floors, walls and partitions and ceilings in accordance with the provisions of NFPA 70, National Electrical Code® (NEC®). These systems are required to provide a degree of fire resistance when installed in the particular floors, walls and ceiling assemblies. The systems listed for this application include nonmetallic outlet and switch boxes for use in fire-resistance-rated wall assemblies. Listing information includes the model numbers for the products, a description of the rated assemblies in which they can be used, the spacing limitations for the boxes and the installation details.

Product listings specify the conditions under which listed metallic outlet and switch boxes may be installed within fire-resistance-rated wall assemblies constructed with bearing and nonbearing wood or steel studs and gypsum board facings. Listings also exist for nonmetallic outlet boxes along with the conditions under which such outlet and switch boxes may be installed within fire-resistant wall assemblies. With either type of outlet or switch box, it may be possible to install the boxes under less-stringent conditions when such boxes are used in conjunction with wall opening protective materials. Use of wall opening protective materials may allow for any combination of: (1) reducing the spacing between boxes contained on opposite sides of the wall; (2) increasing the size of the boxes; (3) increasing the density of the boxes installed and (4) allowing the use of boxes on each side of staggered stud walls. The individual systems tested for compliance in these categories indicate the specific applications and the method of installation for which the materials have been evaluated.

Exception 4 is similar to Exception 3 and probably could be combined. This exception addresses the annular space between the box and the ceiling membrane and limits it to \( \frac{3}{4} \) inch (3.2 mm) unless listed otherwise.

Exception 5 covers fire sprinkler heads in fire-resistant ceiling membranes and allows them without any testing, when they are installed with metal escutcheon plates. This is identical to the membrane wall penetration for sprinkler heads in Exception 3 to Section 714.3.2 [see Figure 714.3.2(2)].

Exception 6 allows any noncombustible penetration that is cast into a concrete floor slab, provided that it does not penetrate but one surface. It may penetrate the top surface or the bottom surface but not both.

Exception 7 is a very important addition to the code, because it allows a common construction practice. For instance, a 1- or 2-hour fire-resistance-rated floor/ceiling or roof/ceiling assembly is tested and rated with a continuous \( \frac{3}{4} \)-inch (15.8 mm) gypsum wallboard ceiling. In conventional light platform framing, the bearing walls and nonbearing walls are framed with the floor joists typically resting directly on the studs. The ceiling membrane is then attached, which creates a membrane penetration where the top wall plates intersect the floor joists. This was previously a matter not provided for in the codes requiring special analysis to be submitted to the building official for specific approval. This new exception allows this, but gives special requirements. The wall must have double top plates (two-2X5s), the wall must also be rated the same as the floor or roof assembly and all pipes and wires penetrating the wall top plate must be protected with through-penetration firestops or one of the exceptions in Section 714.4.1.1.1 or 714.4.1.1.2. Invariably the question arises, "why can't a Type VB, Group R-2 occupancy be built since Table 503 states it can be done?" It can, but the ceiling membrane will need to be continuous across the
walls. UL Fire Resistance Directory, UL 263 Article III, Section 19, states: "When a nonfire-rated wood stud wall assembly abuts the bottom of a wood joist floor-ceiling assembly employing a membrane ceiling, the membrane shall be continuous above the top plate of the wall assembly."

714.4.1.3 Dissimilar materials. Noncombustible penetrating items shall not connect to combustible materials beyond the point of firestopping unless it can be demonstrated that the fire-resistance integrity of the horizontal assembly is maintained.

- This section mirrors that of Section 714.3.3 for direct penetrations through walls (see commentary, Section 714.3.3).

714.4.2 Nonfire-resistance-rated assemblies. Penetrations of nonfire-resistance-rated floor or floor/ceiling assemblies or the ceiling membrane of a nonfire-resistance-rated roof/ceiling assembly shall meet the requirements of Section 713 or shall comply with Section 714.4.2.1 or 714.4.2.2.

- This section limits the penetrations of nonfire-resistance-rated floor assemblies to prevent the migration of smoke through a building, despite being of an unprotected type of construction. Penetrating items such as pipes are required to be in shafts or one of the permitted protection methods outlined in Sections 714.4.2.1 and 714.4.2.

Where penetrations of the ceiling membrane of a nonfire-resistance-rated roof/ceiling assembly occur, the penetrations are required to be protected by fire-blocking in accordance with the requirements of Section 718.2.5 to restrict the spread of fire through the concealed roof space above the ceiling membrane (see commentary, Section 718.2.5).

714.4.2.1 Noncombustible penetrating items. Noncombustible penetrating items that connect not more than five stories are permitted, provided that the annular space is filled to resist the free passage of flame and the products of combustion with an approved noncombustible material or with a fill, void or cavity material that is tested and classified for use in through-penetration firestop systems.

- Noncombustible penetrations connecting five stories or less (penetrating four floors or less) are permitted when the annular space of the penetrating item is filled with an approved noncombustible material. As required in Section 718.2.5, this material shall be tested in the form and manner intended for use to demonstrate that it will stay in place and resist the passage of flame and products of combustion. It can also be filled with a material that is tested as a through-penetration firestop system (see Figure 714.4.2.1).

714.4.2.2 Penetrating items. Penetrating items that connect not more than two stories are permitted, provided that the annular space is filled with an approved material to resist the free passage of flame and the products of combustion.

- This section is not limited as to the combustibility of the penetrating item. This section allows both combustible and noncombustible penetrations of a single nonfire-resistance-rated floor (thus connecting two stories), provided the annular space is fireblocked in accordance with Section 718.2.5. This section does not require a noncombustible firestop to protect the annular space, while Section 714.4.2.1 does require a noncombustible firestop material.

714.5 Penetrations in smoke barriers. Penetrations in smoke barriers shall be protected by an approved through-penetration firestop system installed and tested in accordance with the requirements of UL 1479 for air leakage. The L rating of the system measured at 0.30 inch (7.47 Pa) of water in both the ambient temperature and elevated temperature tests, shall not exceed:

1. 5.0 cfm per square foot (0.025m²/s/m²) of penetration opening for each through-penetration firestop system, or

2. A total cumulative leakage of 50 cfm (0.24m³/s) for any 100 square feet (9.3 m²) of wall area, or floor area.

- Smoke barriers are utilized to create compartments within a building where, under fire conditions, they are intended to provide protection from both fire and smoke. As such compartments are critical in providing the necessary level of fire and smoke protection, enforceable language is deemed necessary to help ensure that the intention of the code is met. Previous language in the code included terms such as "limit," "restrict" and "resist" to indicate the degree of smoke protection required, creating inconsistent application of the provisions.

The L rating provides a quantitative indication of the through-penetration system's ability to resist the passage of smoke. Although the test is performed using air, the flow properties of air and of smoke are sufficiently close for engineering purposes as to provide a reasonable quantification of smoke leakage. The L rating test is an optional test within the UL 1479 test standard; therefore, not all through-penetration firestop systems that are tested and listed will have this information. In the 2005 UL Fire Resistance Directory (Vol. 2), there are approximately 550 through-penetration firestop systems that are listed that also have an L rating of 5 or less. This should provide a sufficient selection to allow for code compliance in all situations.

Smoke barriers, in general, have limited areas where smoke will leak through, such as at doors, dampers, penetrations and joints. Fire door assemblies and smoke dampers have previously had allowable leakage rates established by the code and referenced standards. When the 2006 edition of the
SECTION 715
FIRE-RESISTANT JOINT SYSTEMS

715.1 General. Joints installed in or between fire-resistance-rated walls, floor or floor/ceiling assemblies and roofs or roof/ceiling assemblies shall be protected by an approved fire-resistant joint system designed to resist the passage of fire for a time period not less than the required fire-resistance rating of the wall, floor or roof in or between which it is installed. Fire-resistant joint systems shall be tested in accordance with Section 715.3.

Exception: Fire-resistant joint systems shall not be required for joints in all of the following locations:

1. Floors within a single dwelling unit.
2. Floors where the joint is protected by a shaft enclosure in accordance with Section 713.
3. Floors within atriums where the space adjacent to the atrium is included in the volume of the atrium for smoke control purposes.
4. Floors within malls.
5. Floors and ramps within open and enclosed parking garages or structures constructed in accordance with Sections 406.5 and 406.6, respectively.
7. Walls that are permitted to have unprotected openings.
8. Roofs where openings are permitted.
9. Control joints not exceeding a maximum width of 0.625 inch (15.9 mm) and tested in accordance with ASTM E 119 or UL 263.

This section regulates joints or linear openings created between building assemblies, which are sometimes referred to as head-of-wall, expansion or seismic joints. These joints are most often created where the structural design of a building necessitates...
a separation between building components in order to accommodate anticipated structural displacements caused by thermal expansion and contraction, seismic activity, wind or other loads. Figure 715.1 illustrates some of the most common locations of these joints.

Seismic joints in multistory buildings are intended to allow differential lateral displacement of separate portions of a building during a seismic event. Expansion joints permit separate portions of the structural frame to contract and expand due to temperature change or wind sway without adversely affecting the building functions or structural integrity.

Joints can also occur in fire barriers at the intersection of the top of a wall and the underside of the floor or roof above (head of wall); within a wall or floor at any specific point to accommodate the structural design or at the edge of the floor at the intersection of the floor and exterior wall. All of these linear openings create a "weak link" in fire-resistance-rated assemblies that can compromise the integrity of the tested assembly by allowing an avenue for the passage of fire and the products of combustion through the assembly. In order to maintain the efficacy of the fire-resistance-rated assembly, these openings must be protected by a fire-resistance-rated joint system with a rating equal to the assembly in the same plane. Where two assemblies intersect, the fire rating of the joint must be the same as the fire rating of the assembly (or assemblies) of the same plane as the assembly where the joint occurs. It is not the intent of this section to regulate joints installed in assemblies that are provided to control shrinkage cracking, such as a saw-cut control joint in concrete. This section contains nine locations where a fire-resistant joint system is not required to be installed to protect the joint. These generally are locations where a separation or protected openings are not required or where the joint occurs within an area that is bounded by other means of protection.

Exception 1 states that a fire-resistant joint is not required for joints contained within a single dwelling unit. This exception is similar to Section 712.1.2. Unlike Section 712.1.2, the joints can be in concealed spaces.

Exception 2 exempts fire-resistant joints completely enclosed in a shaft that complies with Section 713.

Exception 3 exempts the requirement for fire-resistant joints that are located in floors in an atrium that complies with Section 404. This exception is similar to Section 712.1.6. Exception 4 exempts joints located in malls that comply with Section 402. Although this appears to be a general exception that would affect all floors within a covered or open mall building, it only applies to the mall. The mall is the common pedestrian area.

Exception 5 exempts joints located in open parking structures that comply with Section 406.5 and is similar to Section 712.1.9.

Exception 6 exempts joints in mezzanines that comply with Section 505 and is similar to Section 712.1.10. As a type of opening/penetration, a joint represents a similar hazard to exterior wall fire exposures as other openings.

Exception 7 acknowledges that if an exterior wall is
permitted to have unprotected openings (see Table 705.8), then the joint does not require protection as well. A joint is a much smaller opening than an unprotected opening.

Exception 8 exempts joints located in roof decks that are not required to have protected openings and is similar to that contained in Section 711.4, which allows skylights and other penetrations in rated roof decks, provided the structural integrity is not affected.

Exception 9 exempts control joints that have been tested as part of the overall assembly in accordance with ASTM E 119 and UL 263. This allowance is in recognition of fire test data that has existed since the 1960s regarding control joints and perimeter relief joints in fire-rated systems, the performance of these devices and systems in the field and a rational approach regarding minor movement (defined here as a maximum of ½ inch (15.9 mm)) where no appreciable damage or fatigue is incurred by the joint system that would have a profound impact on the joint’s fire performance. Since all buildings move slightly, it is not prudent to have to cycle and test joint systems that only move a few millimeters. Although their movement is limited, control joint systems must still pass the rigors of ASTM E 119 or UL 263 in accordance with this exception.

715.1.1 Curtain wall assembly. The void created at the intersection of a floor/ceiling assembly and an exterior curtain wall assembly shall be protected in accordance with Section 715.4.

- The void at the intersection of floor/ceiling assemblies and exterior curtain walls is a joint. To provide continuity for the horizontal assembly and block the vertical opening, fire-resistance joint material is required. This section references Section 715.4 for the performance standard that must be met.

715.2 Installation. A fire-resistant joint system shall be securely installed in accordance with the listing criteria in or on the joint for its entire length so as not to dislodge, loosen or otherwise impair its ability to accommodate expected building movements and to resist the passage of fire and hot gases.

- This section requires that joint systems be installed for their full length or height, due to the fact that the openings to be protected by these types of joints are most often continuous. The required listing will have installation criteria.

715.3 Fire test criteria. Fire-resistant joint systems shall be tested in accordance with the requirements of either ASTM E 1966 or UL 2079. Nonsymmetrical wall joint systems shall be tested with both faces exposed to the furnace, and the assigned fire-resistance rating shall be the shortest duration obtained from the two tests. When evidence is furnished to show that the wall was tested with the least fire-resistant side exposed to the furnace, subject to acceptance of the building official, the wall need not be subjected to tests from the opposite side.

Exception: For exterior walls with a horizontal fire separation distance greater than 5 feet (1524 mm), the joint system shall be required to be tested for interior fire exposure only.

- In order to determine the anticipated protection provided by a given assembly, the hourly fire-resistance rating must be determined by testing the joint system in accordance with UL 2079 or ASTM E 1966. This standard includes specific criteria for test specimen preparation, placement, configuration, size and testing conditions of joint systems. Also included in the test protocol is the minimum positive pressure differential to be used for the test, which is intended to assist in evaluating whether or not the joint will remain in place during a fire condition. A joint splice must be tested, since the presence and orientation of a splice in a joint system can affect the fire performance of the joint. These splices may occur where the length of the joint to be protected exceeds the length of a prefabricated joint or where a cold joint occurs in a field-installed system. The maximum joint width must be tested when in a fully expanded or extended condition in order to evaluate the fire-resistance rating. Joints that are designed to transfer structural building loads are required to have a superimposed load during the test, which is consistent with the requirements for the testing of load-bearing fire-resistance-rated assemblies. Finally, the test addresses requirements for joints that are intended to accommodate building movement, such as expansion, seismic and wind sway joints, including pre conditioning cycling, which is intended to allow for evaluation of the joint’s ability to withstand cyclical movement over its anticipated life.

Test data has indicated that the orientation of nonsymmetrical joints can have an effect on the performance of the joint. As a result, in accordance with this section, all joint systems must be tested for fire exposure from both sides so that the required protection will be provided regardless of which side of the joint is exposed to fire. The exception for joints in exterior walls correlates with Section 705.5 for the fire exposure rating of exterior walls.

Though not required by the code, an ASTM standard practice is available that can be used in cases where a standardized methodology is desired for the inspection of installed fire-resistant joint systems and perimeter fire barrier systems. Such a standardized procedure can be particularly useful in cases where a third-party inspection firm is used. ASTM E 2393, Standard Practice for On-Site Inspection of Installed Fire Resistive Joint Systems and Perimeter Fire Barriers, includes items such as preconstruction meetings to review submittals, details, variances, building.
mock-ups for destructive testing and scheduling a witnessed inspection of a specified percentage of installations or conducting destructive testing on some types of installed joint systems. This standard practice also identifies what actions should be taken based on the percentage of noncompliant installations identified, as well as providing a standardized reporting form.

**715.4 Exterior curtain wall/floor intersection.** Where fire resistance-rated floor or floor/ceiling assemblies are required, voids created at the intersection of the exterior curtain wall assemblies and such floor assemblies shall be sealed with an approved system to prevent the interior spread of fire. Such systems shall be securely installed and tested in accordance with ASTM E 2307 to provide an F rating for a time period at least equal to the fire-resistance rating of the floor assembly. Height and fire-resistance requirements for curtain wall spandrels shall comply with Section 705.8.5.

**Exception:** Voids created at the intersection of the exterior curtain wall assemblies and such floor assemblies where the vision glass extends to the finished floor level shall be permitted to be sealed with an approved material to prevent the interior spread of fire. Such material shall be securely installed and capable of preventing the passage of flame and hot gases sufficient to ignite cotton waste where subjected to ASTM E 119 time-temperature fire conditions under a minimum positive pressure differential of 0.01 inch (0.254 mm) of water column (2.5 Pa) for the time period at least equal to the fire-resistance rating of the floor assembly.

- The void created between a floor and a curtain wall requires sealing to prevent the spread of flames and products of combustion between adjacent stories. Most fire-rated horizontal assemblies are required to extend from outside wall to outside wall, that is from the inside faces of the exterior walls. The void in question is the one between the intersection of the edge of the fire-resistance-rated horizontal assembly and the interior face of the exterior wall or curtain wall. The void does not include the exterior wall cavity.

A fire test standard was specifically developed to evaluate the interface between a fire-resistance-rated horizontal assembly and an exterior curtain wall. This particular standard is ASTM E 2307, *Standard Test Method for Determining Fire Resistance of Perimeter Fire Barrier Systems Using Intermediate-Scale, Multistory Test Apparatus.* The “perimeter fire barrier system” is the assembly of materials that prevents the passage of flame and hot gases at the void space between the interior surface of the wall assembly and the adjacent edge of the floor. For the purposes of the ASTM E 2307 test standard, the interior face is at the interior surface of the wall’s framework. The width of the joint, which has maximum allowable dimensions specified in the perimeter fire barrier system listings, is therefore the distance between the edge of the framing nearest the floor and the adjacent floor edge.

The void space or cavity between framing members is not considered joint space. Figure 715.4 shows the typical components that are specified in listings of tested perimeter fire barrier systems.

Tested and listed perimeter fire barrier systems do not include the interior finished wall (e.g., “knee wall”) details. This makes the systems applicable to any and all finished wall configurations. The existence of the interior wall surface, even if made of fire-resistant materials, such as fire-resistance-rated gypsum board, does not eliminate the need to have an appropriately tested material or system to protect the curtain wall from interior fire spread at the perimeter gap, unless that interior wall detail has been specifically tested and shown to meet the requirements of this section of the code.

Although not required by the code, an ASTM standard practice is available that can be used in cases where a standardized methodology is desired for the inspection of installed perimeter fire barrier systems. Such a standardized procedure can be particularly useful in cases where a third-party inspection firm is used. ASTM E 2393, *Standard Practice for On-Site Inspection of Installed Fire Resistive Joint Systems and Perimeter Fire Barriers,* includes items such as preconstruction meetings to review submittals, details, variances, building mock-ups for destructive testing and scheduling a witnessed inspection of a specified percentage of installations or conducting destructive testing on a specified percentage of installations. This standard practice also identifies what actions should be taken based on the percentage of noncompliant installations identified, as well as providing a standardized reporting form.

The exception, which allows the option of using materials or systems that have been tested by subjecting them to an ASTM E 119 or UL 263 time-temperature fire exposure under positive pressure, is the protection of the perimeter gap that existed in previous editions of the code before the 2009 edition. These systems and materials tested in the years before the formal issuance of ASTM E 2307 can continue to be used to comply with Section 715.4. Those assemblies that were tested using the ASTM E 119 or UL 263 time-temperature fire exposure in a multi-story apparatus would be expected to be in substantial compliance with ASTM E 2307 and are expected to provide an equivalent level of protection.

The option of using materials or systems that have been tested by subjecting them to an ASTM E 119 or UL 263 time-temperature fire exposure under positive pressure is the requirement for protection of the perimeter gap that existed in previous editions of the code. These systems and materials tested in the years before the formal issuance of ASTM E 2307 can continue to be used to comply with Section 714.4. Those assemblies that were tested using the ASTM E 119 or UL 263 time-temperature fire exposure in a multi-story apparatus would be expected to be in substantial compliance with ASTM E 2307, and
FIRE AND SMOKE PROTECTION FEATURES

are expected to provide an equivalent level of protection.

The exterior wall construction must comply with Section 705.8.5. Section 705.8.5 requires a 3-foot-high (914 mm) 1-hour fire-resistance-rated spandrel wall in unsprinklered buildings four stories or greater in height.

715.4.1 Exterior curtain wall/nonfire-resistance-rated floor assembly intersections. Voids created at the intersection of exterior curtain wall assemblies and nonfire-resistance-rated floor or floor/ceiling assemblies shall be sealed with an approved material or system to retard the interior spread of fire and hot gases between stories.

- Where the joint between walls involves a nonfire-resistance-rated floor and an exterior curtain wall, there is no reason to try to maintain a fire-resistance rating with a rated joint system. However, spread of smoke is a concern and, therefore, the code calls for a tight joint to protect rapid spread of smoke from a floor of fire origin to other floors of the building. The exterior wall construction must also comply with Section 705.8.5 even though the floors are not fire-resistance rated.

715.5 Spandrel wall. Height and fire-resistance requirements for curtain wall spandrels shall comply with Section 705.8.5. Where Section 705.8.5 does not require a fire-resistance-rated spandrel wall, the requirements of Section 715.4 shall still apply to the intersection between the spandrel wall and the floor.

- This provision serves as a cross reference to the vertical separation of openings in exterior wall requirements found in Section 705.8.5. This section still requires that where a floor intersects with a nonrated spandrel wall, the void space must be protected by an approved joint system.

715.6 Fire-resistant joint systems in smoke barriers. Fire-resistant joint systems in smoke barriers, and joints at the intersection of a horizontal smoke barrier and an exterior curtainwall, shall be tested in accordance with the requirements of UL 2079 for air leakage. The L rating of the joint system shall not exceed 5 cfm per linear foot (0.00775 m³/s m) of joint at 0.30 inch (7.47 Pa) of water for both the ambient temperature and elevated temperature tests.

- The leakage, or L rating, provides a quantitative indication of a fire-resistant joint system’s ability to resist the passage of smoke. Although the test is performed using air, the flow properties of air and of smoke are sufficiently close for engineering purposes as to provide a reasonable quantification of smoke leakage. The L-rating test is an optional test within the UL

![Figure 715.4: Exterior Curtain Wall/Floor Intersection](image-url)
2079 test standard; therefore, not all fire-resistant joint systems that are tested and listed will have this information. In the 2005 UL Fire Resistance Directory (Vol. 2), there are 335 fire-resistant joint systems that are listed that also have an L rating of 5 or less. This should provide a sufficient selection to allow for code compliance in all situations.

SECTION 716
OPENING PROTECTIVES

716.1 General. Opening protective required by other sections of this code shall comply with the provisions of this section.

- This section regulates two types of opening protective: fire doors (Section 716.5) and fire protection-rated glazing (Section 716.6). As covered in Section 716.2, fire-resistance-rated glazing is not addressed by the balance of the requirements in Section 716. Fire doors are a type of opening protective and are installed in openings in fire-resistance-rated assemblies, including fire walls, fire barriers, fire partitions and exterior walls where the openings are required to be protected. Where a load-bearing exterior wall requires a fire-resistance rating in accordance with Table 601, it is for structural integrity purposes. The openings are not required to be protected unless an opening protective is provided by another section of the code, including Section 705.8.

In addition to fire doors, another form of an opening protective is fire protection-rated glazing (commonly referred to as "fire windows"). Fire windows refer to the entire assembly, which may consist of a frame and the glazing material and mounting components. A glass-block assembly is also considered a window assembly.

The fire protection ratings in this section are based on the acceptance criteria of NFPA 252, 257 and UL 10A, 14B or 14C. The fire protection rating acceptance criteria are not the same as those required for a fire-resistance rating for building structural elements. Fire-resistance ratings of building construction are determined by ASTM E 119 or UL 263. The fire protection rating required for an opening protective is generally less than the required fire resistance of the wall (see Tables 716.5 and 716.6). This is based upon the ability of a wall to have material or a fuel package directly against the assembly while fire doors and windows are assumed to have the fuel package remote from the surface of the assembly. Sections 716.5 and 716.6 (and subsections) reference the appropriate test standards and require that all opening protective be labeled (see Section 716.5.7.1 for doors, Section 716.5.8.3 for glazing in doors and Section 716.6.8 for glazing in windows), with the exception being oversized doors that require a certificate of inspection by an approved agency (see Section 716.5.7.2).

716.2 Fire-resistance-rated glazing. Fire-resistance-rated glazing tested as part of a fire-resistance-rated wall assembly in accordance with ASTM E 119 or UL 263 and labeled in accordance with Section 703.5 shall be permitted in fire doors and fire window assemblies where tested and installed in accordance with their listings and shall not otherwise be required to comply with this section.

- There are glazing materials used as and tested as a wall assembly under ASTM E 119 or UL 263 that are not covered by Section 716. Because these materials can meet the same fire-resistance requirements of the wall, they are not required to be regulated as an opening that would require the lower level of protection that fire protection-rated glazing provides (see commentary, Section 703.6).

716.3 Marking fire-rated glazing assemblies. Fire-rated glazing assemblies shall be marked in accordance with Tables 716.3, 716.5, and 716.6.

- With two types of fire-rated glazing, it is very important to understand the labeling system and the meaning of each mark. The type of wall, the type of opening and the size of the opening determine the minimum required type of fire-rated glazing. Table 716.3 defines the markings, while Tables 716.5 and 716.6 give the requirements for fire-rated glazing by type of wall and location in the wall. There are three different requirements depending on whether the glass is in a door, in a sidelite or transom door frame or in a fire window. Figure 716.3(1) and Table 716.3(1) show the required fire-rated glazing markings by type of wall and location.

</tbody>
</table>

1. Markings in brackets [ ] are fire protection-rated glazing. Fire protection-rated glazing in doors, sidelights and transoms meets NFPA 252. Fire protection-rated glazing in windows meets NFPA 257 or UL 9.
2. Fire-resistance-rated glazing meeting ASTM E 119 or UL 263.
3. Glazing meeting both the standard for fire protection-rated glazing in fire doors (NFPA 252) and the standard fire-resistance-rated glazing (ASTM E 119 or UL 263).
4. Glazing requirements where protected openings are required by Table 705.8.
5. Only openings necessary for egress are allowed in exit access stairways and interior exit stairs.
716.3.1 Fire-rated glazing that exceeds the code requirements. Fire-rated glazing assemblies marked as complying with hose stream requirements (H) shall be permitted in applications that do not require compliance with hose stream requirements. Fire-rated glazing assemblies marked as complying with temperature rise requirements (T) shall be permitted in applications that do not require compliance with temperature rise requirements. Fire-rated glazing assemblies marked with ratings (XXX) that exceed the ratings required by this code shall be permitted.

- Fire-protection-rated glazing with an "H" marking has been tested and has passed the hose stream requirements of NFPA 252. Fire protection-rated glazing with a "T" marking has been tested and has passed the hose stream requirements of NFPA 252. For example, a door view panel less than 100 square inches (64516 mm²) in area in a 2-hour exit enclosure requires only a glazing mark of [D-H-90], but a glazing panel marked with [D-H-T-90] could also be used since it exceeds the requirements for the particular location. If Table 716.5 requires glazing with a marking [D-H-T-60], then a panel with a marking of [D-H-T-90] could be used.

716.4 Alternative methods for determining fire protection ratings. The application of any of the alternative methods listed in this section shall be based on the fire exposure and acceptance criteria specified in NFPA 252, NFPA 257 or UL 9. The required fire resistance of an opening protective shall be permitted to be established by any of the following methods or procedures:

1. Designs documented in approved sources.
2. Calculations performed in an approved manner.
3. Engineering analysis based on a comparison of opening protective designs having fire protection ratings as determined by the test procedures set forth in NFPA 252, NFPA 257 or UL 9.
4. Alternative protection methods as allowed by Section 104.11.

Section 716.4 contains language similar to Section 703.3 regarding fire-resistance ratings. The intent of this section is to recognize approved calculations, an engineering analysis or alternative protection methods as permitted in Section 104.11 as an acceptable alternative means to determine a fire protection rating.

716.5 Fire door and shutter assemblies. Approved fire door and fire shutter assemblies shall be constructed of any material or assembly of component materials that conforms to the test requirements of Section 716.5.1, 716.5.2 or 716.5.3 and the fire protection rating indicated in Table 716.5. Fire door frames with transom lights, sidelights or both shall be permitted in accordance with Section 716.5.6. Fire door assemblies and shutters shall be installed in accordance with the provisions of this section and NFPA 80.

Exceptions:

1. Labeled protective assemblies that conform to the requirements of this section or UL 10A, UL 14B and UL 14C for tin-clad fire door assemblies.
2. Floor fire door assemblies in accordance with Section 711.8.

When the code refers to a fire door assembly, the intent is that the term "fire door" (see the definition in Section 202) applies to the door itself, while the term "fire door assembly" includes the fire door, the frame, related hardware and accessories, unless otherwise noted (see the definition of "Fire door assembly" in Section 202). Therefore, it is important to realize that a fire door by itself is not generally accepted. An assembly that includes the door is needed. A door by itself cannot provide the protection; it needs to be supported by the hinges, held into a specific frame and generally have latching and closing hardware. By requiring an assembly tested to the specified standards, all of the components needed for protection will be provided. For example, although there is not a direct mention in the section relative to mandating latching hardware, the referenced installation standard, NFPA 80, addresses the requirements relative to positive latch devices.

Note that reference to Section 716.5.6 is made for fire door assemblies that include transoms and a sidelite. Fire door assemblies with sidelites or transoms must be fire protection-rated glazing if the opening protective is 1/2 hour or less and fire-resistive rated if the open protective is 1 hour or more.

Labels that indicate compliance with UL 10A, 14B or 14C are acceptable (see Exception 1). Exception 2 exempts floor fire door assemblies from the requirements of this section, since Section 711.8 requires floor fire doors to comply with a different test standard (NFPA 288) and their rating must not be less than the rating of the horizontal assembly being penetrated (see the commentary to Section 711.8 for a discussion of floor fire doors).

TABLE 716.5. See page 7-96

This table lists the minimum fire protection ratings for fire doors relative to the nature and fire-resistance rating of the wall. Once the purpose and fire-resistance rating of the wall are identified, the minimum required fire protection rating of the door can be determined using the table. Typically, the minimum permitted fire door fire protection rating is less than the required fire-resistance rating of the wall.

The allowable size and required marking of glazed door vision panels are shown in the fourth and fifth
columns. The last column indicates the minimum glazing marking for the sidewall and transom. The glazing markings are explained in Section 716.5.8.3.1 and Table 716.3.

In addition to the fire protection ratings in Table 716.5, other sections of the code prescribe additional performance criteria for fire door assemblies. For example, Section 716.5.5 requires doors in exit enclosures to have a maximum temperature increase on the unexposed surface of 450°F (232°C) after 30 minutes. Although temperature rise is not a condition of acceptance, test standards require that unexposed surface temperatures be measured and documented in the test report. Another requirement not in the table is related to corridor doors. Required fire-rated corridor doors must also meet the requirements for smoke and draft control in Section 716.5.3.1.

The exterior wall opening protective in Table 716.5 are not required where Section 705.8 does not require protected openings.

716.5.1 Side-hinged or pivoted swinging doors. Fire door assemblies with side-hinged and pivoted swinging doors shall be tested in accordance with NFPA 252 or UL 10C. After 5 minutes into the NFPA 252 test, the neutral pressure level in the furnace shall be established at 40 inches (1016 mm) or less above the sill.

- Fire door assemblies that contain side-hinged or pivoted swinging doors are to be tested in accordance with the referenced test standards.

When first introduced in one of the early editions of the code, the requirement for the door to be tested with a pressure differential (positive pressure at the top and a negative pressure at the bottom) and a specific neutral pressure point was a major revision in the way that doors were tested. The intent of this provision is to better approximate the conditions found in an actual building fire where smoke, heat and hot gasses rise to the top of the room and increase the pressure in the upper portion of the room. Test method UL 10C contains the requirements for positive pressure testing.

716.5.2 Other types of assemblies. Fire door assemblies with other types of doors, including swinging elevator doors and fire shutter assemblies, bottom and side-hinged chute intake doors, and top-hinged chute discharge doors, shall be tested in accordance with NFPA 252 or UL 10B. The pressure in the furnace shall be maintained as nearly equal to the atmospheric pressure as possible. Once established, the pressure shall be maintained during the entire test period.

- This section also references NFPA 252 for fire door assemblies containing other than the typical side-hinged-type doors. NFPA 252 is a general test standard that is not specific to any type of door. UL 10B was developed for negative pressure testing of fire door and fire shutter assemblies and is viewed as a viable test method, provided that the pressure is maintained at or nearby at atmospheric pressure. It is important to distinguish that the pressure testing that is required for side-hinged or pivoted swinging doors by Section 716.5.1 is not applicable to this section and other door types.

716.5.3 Door assemblies in corridors and smoke barriers. Fire door assemblies required to have a minimum fire protection rating of 20 minutes where located in corridor walls or smoke barrier walls having a fire-resistance rating in accordance with Table 716.5 shall be tested in accordance with NFPA 252 or UL 10C without the hose stream test.

Exceptions:

1. Viewports that require a hole not larger than 1 inch (25 mm) in diameter through the door, have at least a 0.25-inch-thick (6.4 mm) glass disc and the holder is of metal that will not melt out where subject to temperatures of 1,700°F (927°C).

2. Corridor door assemblies in occupancies of Group I-2 shall be in accordance with Section 407.3.1.

3. Unprotected openings shall be permitted for corridors in multitheater complexes where each motion picture auditorium has at least one-half of its required exit or exit access doorways opening directly to the exterior or into an exit passageway.

4. Horizontal sliding doors in smoke barriers that comply with Sections 408.3 and 408.8.4 in occupancies in Group I-3.

- This section covers doors in fire partitions specifically for corridors and doors in smoke barriers. NFPA 252 and UL 10C standards require a hose stream test on all fire door assemblies. The hose stream test is intended to provide a measurement of structural integrity by evaluating the ability of the assembly to withstand impact. It has come to be accepted that a hose stream is not justified for 20-minute doors.

Exception 1 accepts certain viewports that are not required to be tested as a part of a door assembly. The use of viewports is fairly common in corridors of a Group R-1 occupancy or other similar locations. Because of the limited size and materials, the overall performance of the door will not be greatly affected by including the viewport.

Exception 2 serves as a cross reference to the requirements for a Group I-2 occupancy, which does not require the door to have a fire protection rating.

Exception 3 has little application now due to the requirements of Sections 1018.1 and 903.2.1.1, Item 4. This exception was originally intended to allow the removal of latching hardware on the corridor door and, therefore, reduce the level of noise that was made when it was opened during a movie. Since the code now requires all multitheater complexes to be sprinklered and corridors in sprinklered Group A occupancies do not require a fire-resistive rating, the other provisions of the code would eliminate the need for the door to have a fire-protection rating and the latch that was considered as the problem is then generally not required.

Exception 4 serves as a cross reference to Section 408 for Group I-3 occupancies that contain require-
FIRE AND SMOKE PROTECTION FEATURES

ments specific to smoke-tight door assemblies for specific locations within resident housing areas.

716.5.3.1 Smoke and draft control. Fire door assemblies shall also meet the requirements for a smoke and draft control door assembly tested in accordance with UL 1784. The air leakage rate of the door assembly shall not exceed 3.0 cubic feet per minute per square foot (0.01524 m³/s • m²) of door opening at 0.10 inch (24.9 Pa) of water for both the ambient temperature and elevated temperature tests. Louvers shall be prohibited. Installation of smoke doors shall be in accordance with NFPA 105.

This section is only applicable to fire doors in corridors or smoke barrier walls. When a corridor wall is required to be fire protection rated, a degree of smoke control is needed to provide a tenable space for egress. Fire doors in corridors and smoke barriers are also required to meet the criteria of UL 1784. This standard measures the movement of smoke through a door assembly. The installation of the doors is to be done according to NFPA 105 requirements. This standard, entitled Standard for the Installation of Smoke Door Assemblies, is a companion to the previously referenced NFPA 80. The criteria for air leakage are also provided in this section.

716.5.3.2 Glazing in door assemblies. In a 20-minute fire door assembly, the glazing material in the door itself shall

For SI: 1 square inch = 645.2 mm.

- a. Two doors, each with a fire protection rating of 1½ hours, installed on opposite sides of the same opening in a fire wall, shall be deemed equivalent in fire protection rating to one 3-hour fire door.
- b. For testing requirements, see Section 716.6.3.
- c. Fire-resistance-rated glazing tested to ASTM E 119 in accordance with Section 716.2 shall be permitted, in the maximum size tested.
- d. Except where the building is equipped throughout with an automatic sprinkler and the fire-rated glazing meets the criteria established in Section 716.5.5.
- e. Under the column heading “Fire-rated glazing marking door vision panel,” W refers to the fire-resistance rating of the glazing, not the frame.

- Glazing in 20-minute-rated doors must also have a 20-minute fire protection rating and is not required to pass the hose stream test. Sidelites and transoms, which are not part of the fire door but instead are part of the fire-door assembly (see definitions in Section 202) are required to pass the hose stream test as detailed in NFPA 257 or UL 9.

### 716.5.4 Door assemblies in other fire partitions

Fire door assemblies required to have a minimum fire protection rating of 20 minutes where located in other fire partitions having a fire-resistance rating of 0.5 hour in accordance with Table 716.5 shall be tested in accordance with NFPA 252, UL 10B or UL 10C with the hose stream test.

- Section 708.1 lists the locations requiring fire partitions. Fire partitions, other than corridor walls, would be dwelling unit separation walls, sleeping unit separation walls, tenant space walls in malls and elevator lobby separation walls. Unlike the corridor doors in Section 716.5.3, these doors must be tested with the hose stream.

### 716.5.5 Doors in interior exit stairwells and ramps and exit passageways

Fire door assemblies in interior exit stairways and ramps and exit passageways shall have a maximum transmitted temperature rise of not more than 450°F (250°C) above ambient at the end of 30 minutes of standard fire test exposure.

**Exception:** The maximum transmitted temperature rise is not required in buildings equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2.

- This section requires that door assemblies utilized in interior exit stairways, ramp enclosures and exit passageways comply with the requirements of Section 715 and be tested in accordance with either NFPA 252 or UL 10C. This section adds a requirement that door construction is limited to a temperature rise of 450°F (250°C) on the unexposed side during the first 30 minutes of the standard fire test (NFPA 252). The labels for these doors are required to indicate that the temperature on the unexposed side is 450°F (250°C) or less above ambient temperature. The temperature rise rating is not required on doors in sprinklered buildings.

It should be noted that the temperature rise criterion is not otherwise a limitation with respect to a door receiving a fire protection rating. Therefore, simply specifying a 1½-hour fire protection rating on the door does not ensure the additional requirements of Section 715.4.4 are met. The basis for limiting the temperature rise of the unexposed surface of exit doors to 450°F (250°C) is that a higher allowable temperature would provide enough radiant heat to discourage or even prevent building occupants from closely approaching or passing by the door assembly.
during a fire emergency. The intent is to protect the occupants in the vertical exit enclosure and exit passageway from excessive radiant heat. The exception provides relief from providing doors meeting temperature rise ratings when buildings are equipped throughout with either an NFPA 13 or 13R automatic sprinkler system.

716.5.5.1 Glazing in doors. Fire-protection-rated glazing in excess of 100 square inches (0.065 m²) is not permitted. Fire-resistance-rated glazing in excess of 100 square inches (0.065 m²) shall be permitted in fire door assemblies when tested as components of the door assemblies, and not as glass lights, and shall have a maximum transmitted temperature rise of 450°F (250°C) in accordance with Section 716.5.5.

This section only addresses glazing in doors in stairway enclosures and exit passage enclosures. Glazing 100 square inches (0.065 m²) or less may be fire-protection-rated glazing. Glazing over 100 square inches (0.065 m²) must be fire-resistance-rated glazing. The larger glazing panels in fire doors shall have a temperature rise rating of 450°F (250°C). This increased glazing is to be tested as a component of the door. The test methods to be utilized are listed in Section 716.5 and include NFPA 252, UL 10B and UL10C. The 100-square-inch (0.065 m²) threshold is consistent with the glazing size limitations contained in Section 716.5.8.1.2.1. Glazing over 100 square inches (0.065 m²) (in doors shall have the temperature rise rating in a sprinklered building, even though the door itself does not need the temperature rise rating.

716.5.6 Fire door frames with transom lights and sidelights. Fire doors with transom lights, sidelite, or both, shall be permitted where a 3/4-hour fire protection rating or less is required in accordance with Table 716.5. Fire door frames with transom lights, sidelite, or both, installed with fire-resistance-rated glazing tested as an assembly in accordance with ASTM E 119 or UL 263 shall be permitted where a fire protection rating exceeding 3/4 hour is required in accordance with Table 716.5.

The purpose of this section is to address the use of fire-resistance-rated glazing in fire doors frames with transoms or sidelite, where the fire protection rating exceeds 3/4 hour. For instances where the required rating is 3/4 hour or less, fire protection-rated glazing meeting the test requirements of NFPA 252 shall apply. Fire-resistance-rated glazing is required where the required rating exceeds 3/4 hour and the assembly must be tested in accordance with ASTM E 119 or UL 263. Testing the assemblies to these criteria exposes the glazing to the appropriate temperature rise to substantiate the higher fire protection rating.

716.5.7 Labeled protective assemblies. Fire door assemblies shall be labeled by an approved agency. The labels shall comply with NFPA 80, and shall be permanently affixed to the door or frame.

The requirement that fire doors be labeled leads to the provisions of Section 1703.5 being applied. A label indicates that the door assembly has not only passed the required fire test but that a follow-up inspection was also performed during production (see Section 1703.5.2). The building official should, therefore, verify that fire door assemblies are properly labeled, and not rely solely on a test report. To provide specific guidance, compliance with NFPA 80 is required.

716.5.7.1 Fire door labeling requirements. Fire doors shall be labeled showing the name of the manufacturer or other identification readily traceable back to the manufacturer, the name or trademark of the third-party inspection agency, the fire protection rating and, where required for fire doors in interior exit stairways and ramps and exit passageways by Section 716.5.5, the maximum transmitted temperature end point. Smoke and draft control doors complying with UL 1784 shall be labeled as such and shall also comply with Section 716.5.7.3. Labels shall be approved and permanently affixed. The label shall be applied at the factory or location where fabrication and assembly are performed.

Labels on fire doors apply to the door only. The building official should verify that the remaining portions of the assembly (door frame, hardware and accessories) are also labeled for use with a labeled fire door. In addition to the appropriate fire protection rating, the label for interior exit stairways and ramps and exit passageways doors is required to indicate the temperature rise on the unexposed surface after 30 minutes (see commentary, Section 716.5.5). A label is also to serve as evidence of both a required fire protection rating and third-party inspection—not solely as a manufacturer's identification (see commentary, Section 1703.5). To ensure appropriate labeling, it is required to occur at the actual location where fabrication and assembly occur.

716.5.7.1.1 Light kits, louvers and components. Listed light kits and louvers and their required preparations shall be considered as part of the labeled door where such installations are done under the listing program of the third-party agency. Where tested for such use, fire doors and door assemblies shall be permitted to consist of components, including glazing, vision light kits and hardware that are labeled, listed or classified by different third-party agencies.

The code allows the use of listed light kits and listed louvers and their required preparation material to be considered as part of a labeled door where such light kits and louvers are installed under the conditions of their listing. Where such components are listed for use in such doors, they may be listed, labeled or classified by different third-party agencies. Louvers would be required to be listed with shutters and could not be used where prohibited elsewhere in the code.

716.5.7.2 Oversized doors. Oversized fire doors shall bear an oversized fire door label by an approved agency or shall be provided with a certificate of inspection furnished by an approved testing agency. When a certificate of inspection is furnished by an approved testing agency, the certificate shall state that the door conforms to the requirements of design,
FIRE AND SMOKE PROTECTION FEATURES

materials and construction, but has not been subjected to the fire test.

- Recognizing that doors may exceed the required tested size, the code indicates that oversized doors that have a certificate of inspection from an approved testing agency are acceptable. For example, rolling steel-type fire doors are normally listed for 120 square feet (11 m²) with no dimension in excess of 12 feet (3658 mm). Rolling steel-type doors that exceed these dimensions are permitted as long as they have certification indicating that they are constructed of materials of the same grade, thickness, shape, etc., as labeled doors. This is normally indicated with a certificate that reads “Oversized Fire Door Certificate.” The code does not specify what is considered as an “oversized door.” This information would be dependent on the test standard and the dimensions listed within it. Note that the provisions of Sections 706.8 and 707.6 allow openings up to 156 square feet (14 m²) in area.

716.5.7.3 Smoke and draft control door labeling requirements. Smoke and draft control doors complying with UL 1784 shall be labeled in accordance with Section 716.5.6.1 and shall show the letter “S” on the fire-rating label of the door. This marking shall indicate that the door and frame assembly are in compliance when listed or labeled gasketing is also installed.

- When doors are required to be approved for smoke and draft control, they require a special label containing the letter “S.” Without this label it is very difficult to assess in the field that the door meets UL 1784 and that listed or labeled gasketing is also required to be installed with the door and frame.

716.5.7.4 Fire door frame labeling requirements. Fire door frames shall be labeled showing the names of the manufacturer and the third-party inspection agency.

- It is required that the fire door frame be labeled with the manufacturer’s name and third-party testing agency to assist in the assessment of the door in the field. The actual rating is not required to be included.

716.5.8 Glazing material. Fire-protection-rated glazing conforming to the opening protection requirements in Section 716.5 shall be permitted in fire door assemblies.

- This section of the code addresses fire protection-rated glazing material in fire protection-rated doors. It applies to glazing in doors, sidelights and transoms, but not to glazing in fire windows, which is covered in Section 716.6. Wired glass is no longer specifically mentioned and, if used, must meet the same test standards as other glazing material (see Table C716.3).

716.5.8.1 Size limitations. Fire-protection-rated glazing shall comply with the size limitations of NFPA 80, and as provided in Sections 716.5.8.1.1 and 716.5.8.1.2.

- NFPA 80 permits fire protection-rated glazing in fire doors with a fire protection rating up to 3 hours. For 1/2, 3/4, 1- and 1 1/2-hour doors, the allowable area is a function of the glazed area tested. One-hour and 1 1/2-hour doors requiring a temperature rise rating are limited to 100 square inches (0.065 m²) or less. While NFPA 80 allows a view panel 10 square inches (0.065 m²) or less in 3-hour fire doors, Table 716.5 does not. The design must meet both NFPA 90 and Table 716.5, whichever is stricter.

716.5.8.1.1 Fire-resistance-rated glazing in door assemblies in fire walls and fire barriers rated greater than 1 hour. Fire-resistance-rated glazing tested to ASTM E 119 or UL 263 and NFPA 252, UL 10B or UL 10C shall be permitted in fire door assemblies located in fire walls and in fire barriers in accordance with Table 716.5 to the maximum size tested and in accordance with their listings.

- Fire-resistance-rated glazing, not fire protection glazing, shall be permitted in fire walls and fire barriers to the maximum size tested and as allowed in Table 716.5. The glazing, if used in a fire door view panel, must be tested to two standards—both ASTM E 119 or UL 263 and NFPA 252 or UL 10.

716.5.8.1.2 Fire-protection-rated glazing in door assemblies in fire walls and fire barriers rated greater than 1 hour. Fire-protection-rated glazing shall be prohibited in fire walls and fire barriers except as provided in Sections 716.5.8.1.2.1 and 716.5.8.1.2.2.

- Fire protection-rated glazing, not fire-resistance-rated glazing, shall not be allowed in fire walls or fire barriers greater than 1 hour except for 100-square-inch (0.065 m²) or less view panels in fire doors in horizontal exits and fire barrier walls. This view panel allowance recognizes the benefit of visual observance in an emergency situation.

716.5.8.1.2.1 Horizontal exits. Fire-protection-rated glazing shall be permitted as vision panels in self-closing swinging fire door assemblies serving as horizontal exits in fire walls where limited to 100 square inches (0.065 m²) with no dimension exceeding 10 inches (0.3 mm).

- Only self-closing swinging fire doors and not all doors in horizontal exits are allowed the limited size view panel.

716.5.8.1.2.2 Fire barriers. Fire-protection-rated glazing shall be permitted in fire doors having a 1 1/2-hour fire protection rating intended for installation in fire barriers, where limited to 100 square inches (0.065 m²).

- Only fire barrier doors required to be 1 1/2-hour fire rated are allowed to have the limited area view panel. Some fire barriers are required to be 3- and 4-hour rated so those doors with the 3-hour fire rating would not be allowed the view panels.

716.5.8.2 Elevator, stairway and ramp protective. Approved fire-protection-rated glazing used in fire door assemblies in elevator, stairways and ramp enclosures shall be so located as to furnish clear vision of the passageway or approach to the elevator, stairway or ramp.

- The purpose of vision panels in exit doors and elevator doors is to permit observation by occupants who
FIRE AND SMOKE PROTECTION FEATURES

may be on the opposite side of the door before opening it. The limitations on the size of panels in Section 716.5.8.1 still apply.

716.5.8.3 Labeling. Fire-protection-rated glazing shall bear a label or other identification showing the name of the manufacturer, the test standard and information required in Section 716.5.8.3.1 that shall be issued by an approved agency and shall be permanently identified on the glazing.

- This provision of the code maintains proper labeling for each piece of fire protection-rated glazing. The label must specify the name or fully identifying logo of the manufacturer, the test standard that was used to evaluate the glass and the rating established by the test.

716.5.8.3.1 Identification. For fire-protection-rated glazing, the label shall bear the following four-part identification: "D - H or NH - T or NT - XXX." "D" indicates that the glazing shall be used in fire door assemblies and that the glazing meets the fire protection requirements of NFPA 252. "H" shall indicate that the glazing meets the hose stream requirements of NFPA 252. "NH" shall indicate that the glazing does not meet the hose stream requirements of the test. "T" shall indicate that the glazing meets the temperature requirements of Section 716.5.5.1. "NT" shall indicate that the glazing does not meet the temperature requirements of Section 716.5.5.1. The placeholder "XXX" shall specify the fire-protection-rating period, in minutes.

- By following the provisions of this section, the glazing utilized in fire door assemblies can be easily identified for verification of its appropriate application. The "D" designation indicates the glazing can be used in a fire-door assembly, with the remaining identifiers providing specific information as to the glazing's capability to meet the hose stream test and temperature limits. Similar identification methods for glazing are found in Section 716.6.8 for fire protection-rated glazing used in fire window assemblies.

716.5.8.4 Safety glazing. Fire-protection-rated glazing installed in fire doors in areas subject to human impact in hazardous locations shall comply with Chapter 24.

- This section provides a cross reference to the safety glazing requirements of Chapter 24, specifically Section 2406. Not only do glass or glazed panels need to be fire-resistance rated, but the glass also must pass the test requirements of CPSC 16 CFR, Part 1201 if it is installed in locations subject to human impact loads. Locations where glazing presents a hazard to occupants upon impact are identified in Section 2406.4. This requirement reduces the hazards of someone falling into a fire-resistance-rated glass panel.

716.5.9 Door closing. Fire doors shall be self- or automatic-closing in accordance with this section. Self-closing chutes shall not fail in a "door open" position in the event of a closer failure.

Exceptions:

1. Fire doors located in common walls separating sleeping units in Group R-1 shall be permitted without automatic- or self-closing devices.

2. The elevator car doors and the associated hoistway enclosure doors at the floor level designated for recall in accordance with Section 3003.2 shall be permitted to remain open during Phase I emergency recall operation.

- In order for fire doors to be effective, they must be in the closed position; therefore, the preferred arrangement is to install self-closing doors. Recognizing that operational practices often require doors to be open for an extended period of time, automatic-closing doors are permitted as long as this opening will not pose a threat to occupant safety and the doors will self-latch. Automatic-closing devices enable the opening to be protected during a fire condition. The basic requirement for closing devices and specific requirements for automatic-closing and self-closing devices are given in NFPA 80 (see Section 716.5). Chute intake doors for refuse and linen chutes must have self closers of a type that will fail in the closed position. If the closer fails in the open position maintenance personnel and occupants using the chutes will be slow to repair or replace the failed part. Failure in the closed position will prompt a timely repair and will not create a hazard until it is repaired.

Exception 1 discusses doors in the separation walls of side-by-side sleeping units in Group R-1 occupancies. This allows two or more sleeping units to be opened to each other so that a suite can be established if desired. If the adjacent rooms are rented by separate people, the doors will generally be closed. If the rooms are rented together, this permits a larger room to be created simply by opening the door. Because most rooms only open to one adjacent room, most configurations would still result in a solid fire partition without any door openings between this suite of rooms and any other sleeping units.

Exception 2 coordinates with the requirements related to elevator recall that are found in Chapter 30. Since the hoistway doors generally provide the shaft opening protection, this exception is needed for this situation.

716.5.9.1 Latch required. Unless otherwise specifically permitted, single fire doors and both leaves of pairs of side-hinged swinging fire doors shall be provided with an active latch bolt that will secure the door when it is closed.

- This section merely reinforces the acceptance criteria of fire test standards for fire doors. A door that does not latch would generally be an ineffective barrier.
against the spread of a fire and would be unable to withstand the pressures of a fire in the adjacent space. Such hardware must be listed for use on fire doors.

716.5.9.1.1 Chute intake door latching. Chute intake doors shall be positive latching, remaining latched and closed in the event of a latch spring failure during a fire emergency.

- Latching devices for chute intake doors must provide a positive latch and, in the event of a latch spring failure, shall remain closed. The proponent of this code change stated that simple technology exists that can accomplish this fail-safe provision.

716.5.9.2 Automatic-closing fire door assemblies. Automatic-closing fire door assemblies shall be self-closing in accordance with NFPA 80.

- NFPA 80 requires doors to be automatic closing with a closing device and a separate hold-release device or hold-open mechanism that closes upon activation of an automatic fire detector acceptable to the building official. This provision simply ensures that when the door is released it will move to the closed position.

716.5.9.3 Smoke-activated doors. Automatic-closing doors installed in the following locations shall be automatic-closing by the actuation of smoke detectors installed in accordance with Section 907.3 or by loss of power to the smoke detector or hold-open device. Doors that are automatic-closing by smoke detection shall not have more than a 10-second delay before the door starts to close after the smoke detector is actuated:

1. Doors installed across a corridor.
2. Doors that protect openings in exits or corridors required to be of fire-resistance-rated construction.
3. Doors that protect openings in walls that are capable of resisting the passage of smoke in accordance with Section 509.4.
4. Doors installed in smoke barriers in accordance with Section 709.5.
5. Doors installed in fire partitions in accordance with Section 708.6.
6. Doors installed in a fire wall in accordance with Section 706.8.
7. Doors installed in shaft enclosures in accordance with Section 713.7.
8. Doors installed in refuse and laundry chutes and access and termination rooms in accordance with Section 713.13. Automatic-closing chute intake doors installed in refuse and laundry chutes shall also meet the requirements of Sections 716.5.9 and 716.5.9.1.1.
9. Doors installed in the walls for compartmentation of underground buildings in accordance with Section 405.4.2.

10. Doors installed in the elevator lobby walls of underground buildings in accordance with Section 405.4.3.
11. Doors installed in smoke partitions in accordance with Section 710.5.2.3.

- Since the integrity of the means of egress or general occupant safety can be compromised by smoke, doors at certain locations are required to be automatic closing upon the detection of smoke if the door is not self-closing. The automatic closer is also to activate upon loss of power to the smoke detector and to the hold-open device. NFPA 72, as referenced in Chapter 9, contains criteria relative to the number and location of detectors necessary for door release service. NFPA 80 also provides criteria for closing devices required for a fire door.

716.5.9.4 Doors in pedestrian ways. Vertical sliding or vertical rolling steel fire doors in openings through which pedestrians travel shall be heat activated or activated by smoke detectors with alarm verification.

- Where vertical sliding or rolling doors are provided as an opening protective through which pedestrian travel is intended, automatic-closing actuation is not permitted via a smoke detector unless alarm verification is provided. Sudden closing of these doors and the potential of false actuation of smoke detectors create a hazard to occupants moving through the opening. Although pedestrian travel is intended in openings regulated by this section, a common oversight is that the vertical rolling or sliding door is not permitted to be considered an egress component, as stated in Section 1008.1.2.

716.5.10 Swinging fire shutters. Where fire shutters of the swinging type are installed in exterior openings, not less than one row in every three vertical rows shall be arranged to be readily opened from the outside, and shall be identified by distinguishing marks or letters not less than 6 inches (152 mm) high.

- The fire department needs access to openings for ventilation purposes and entry; therefore, if an extensive amount of swinging shutters are used, at least one in every three vertical rows must be readily openable from the outside. The operable shutter must also be easily recognized for use by the fire department. The identification is on the exterior.

716.5.11 Rolling fire shutters. Where fire shutters of the rolling type are installed, such shutters shall include approved automatic-closing devices.

- Rolling fire shutters require a detecting device to initiate the closing sequence. The actuation shall be by smoke detectors in locations required by Section 716.5.9.3.
716.6 Fire-protection-rated glazing. Glazing in fire window assemblies shall be fire protection rated in accordance with this section and Table 716.6. Glazing in fire door assemblies shall comply with Section 716.5.8. Fire-protection-rated glazing in fire window assemblies shall be tested in accordance with and shall meet the acceptance criteria of NFPA 257 or UL 9. Fire-protection-rated glazing shall also comply with NFPA 80. Openings in non-fire-resistance-rated exterior wall assemblies that require protection in accordance with Section 705.3, 705.8, 705.8.5 or 705.8.6 shall have a fire protection rating of not less than \( \frac{1}{2} \) hour. Fire-protection-rated glazing in 0.5-hour fire-resistance-rated partitions is permitted to have a 0.33-hour fire protection rating.

- This section covers glazing in fire windows and not fire doors. The appropriate test standards referenced for fire windows (fire protection-rated glazing) are NFPA 257 or UL 9, which are pass/fail tests with a specified time of exposure. It is important to realize that this section only applies to materials that are tested in accordance with the two identified standards and that are intended as an opening protective in a wall that requires openings with a fire protection rating. The distinction between fire protection-rated glazing and a fire-resistance-rated glazing must be understood. Glazing that has a fire-resistance rating is not required to comply with Section 716 if it is tested and installed in accordance with its listing (see Section 716.2). It is required in many openings where fire-protection-rated glazing is not allowed to be installed. Fire windows with fire protection-rated glazing are only allowed in incidental use and occupancy separation fire barrier walls rated at 1 hour or less, fire partitions, smoke barriers and fire-resistance-rated exterior walls. In addition, Sections 1022.4 and 1023.5 would not allow fire windows in exit enclosures and exit passageway enclosures. The basic premise of the referenced standard is that it evaluates the effectiveness of windows when used as opening protective to remain in place during the specified time of exposure. In addition to being subjected to a predetermined fire condition, the assembly is also subjected to a hose stream impact test. The test procedure does not measure or evaluate heat transmission or radiation through the assembly. Table 716.6 gives the fire ratings and the marking requirements for fire windows.

**TABLE 716.6.** See below.

- Table 716.5 prescribes the minimum fire protection ratings for fire windows, relative to the type and fire-resistance rating of the wall. Once the purpose and fire-resistance rating of the wall are identified, the minimum required fire protection rating of windows and the required marking are determined by using the table. The requirements in this table are not to be confused with the ratings for fire doors provided in Table 716.5 since the requirements do differ. For a comparison of the provisions of the two tables see Table C716.3.

716.6.1 Testing under positive pressure. NFPA 257 or UL 9 shall evaluate fire-protection-rated glazing under positive pressure. Within the first 10 minutes of a test, the pressure in the furnace shall be adjusted so at least two-thirds of the test specimen is above the neutral pressure plane, and the neutral pressure plane shall be maintained at that height for the balance of the test.

- Under fire conditions there is likely to be positive pressure acting on the window; therefore, this section requires that tested window assemblies be subjected to positive pressure conditions during the test. This requirement is consistent with standards used for testing window assemblies in the United States and other countries.

NP = Not Permitted.

<sup>a</sup> Not permitted except fire-resistance-rated glazing assemblies tested to ASTM E 119 or UL 263, as specified in Section 716.2.

<sup>b</sup> XXX = The fire rating duration period in minutes, which shall be equal to the fire-resistance rating required for the wall assembly.
716.6.2 Nonsymmetrical glazing systems. Nonsymmetrical fire-protection-rated glazing systems in fire partitions, fire barriers or in exterior walls with a fire separation distance of 5 feet (1524 mm) or less pursuant to Section 705 shall be tested with both faces exposed to the furnace, and the assigned fire protection rating shall be the shortest duration obtained from the two tests conducted in compliance with NFPA 257 or UL 9.

This section requires that glazing systems that by design are not the same on either side need to be tested on both sides. The rating resulting from these tests will be determined from the lower performing side. These requirements are for fire-type barriers (versus smoke) within buildings and when used on an exterior wall with a small separation distance [less than 5 feet (1524 mm)]. The concern here is the same as for nonsymmetrical wall assemblies in Section 703.2.1.

716.6.3 Safety glazing. Fire-protection-rated glazing installed in fire window assemblies in areas subject to human impact in hazardous locations shall comply with Chapter 24.

This section provides a cross reference to the safety glazing requirements of Chapter 24, specifically Section 2406. Not only do glass or glazed panels need to be fire-resistance rated, but the glass also must pass the test requirements of CPSC 16 CFR, Part 1201 if it is installed in locations subject to human impact loads. Locations where glazing presents a hazard to occupants upon impact are identified in Section 2406.4. This requirement reduces the hazards of someone being injured by falling into a fire-resistance-rated glass panel.

716.6.4 Glass and glazing. Glazing in fire window assemblies shall be fire-protection-rated glazing installed in accordance with and complying with the size limitations set forth in NFPA 80.

Nothing in this section prohibits fire-resistance-rated glazing from use in fire window assemblies installed in accordance with their listing. Fire-protection-rated glazing shall be installed in accordance with NFPA 80.

716.6.5 Installation. Fire-protection-rated glazing shall be in the fixed position or be automatic-closing and shall be installed in approved frames.

In order to adequately protect the opening, protection must be in place during a fire event. This is achieved by either having the glazing in a permanently fixed position or having the glazing protective actuated by a detection device.

716.6.6 Window mullions. Metal mullions that exceed a nominal height of 12 feet (3658 mm) shall be protected with materials to afford the same fire-resistance rating as required for the wall construction in which the protective is located.

Fire windows are normally tested in panels not exceeding 1,296 square inches (0.85 m²) and 54 inches (1372 mm) in width or length, respectively. The code does, however, permit panels to be installed adjacent to one another. This section requires that mullions higher than 12 feet (3658 mm) meet the criteria for fire-resistance-rated glazing (ASTM E 119 or UL 263), not fire protection-rated glazing (NFPA 257).

716.6.7 Interior fire window assemblies. Fire-protection-rated glazing used in fire window assemblies located in fire partitions and fire barriers shall be limited to use in assemblies with a maximum fire-resistance rating of 1 hour in accordance with this section.

Since fire protection-rated glazing, has a maximum 3/4-hour fire-resistance rating, fire windows using fire protection-rated glazing may only be used in fire partitions (1-hour rated in accordance with Section 708.3) and fire barriers having a fire-resistance rating of 1 hour. These limitations are indicated in Table 716.6.

716.6.7.1 Where 1/4-hour fire protection window assemblies permitted. Fire-protection-rated glazing requiring 45-minute opening protection in accordance with Table 716.6 shall be limited to fire partitions designed in accordance with Section 708 and fire barriers utilized in the applications set forth in Sections 707.3.6 and 707.3.8 where the fire-resistance rating does not exceed 1 hour. Fire-resistance-rated glazing assemblies tested in accordance with ASTM E 119 or UL 263 shall not be subject to the limitations of this section.

Not all 1-hour fire-resistance-rated walls are allowed to have fire windows with fire-protection-rated glazing. All fire partitions and certain fire barrier walls may have fire protection-rated glazing. Only 1-hour fire-resistance-rated fire barriers in incidental use separations (Section 707.3.7) and mixed occupancy separations (Section 707.3.9) may have fire protection-rated glazing in fire windows. Shaft walls, exit access stairway enclosures, interior exit stairways, exit passage-way enclosures and control area separation walls are considered fire barrier walls, though when rated for 1 hour, are not allowed to have fire windows with fire-protection-rated glazing. Of course, nothing in this section prohibits fire-resistance-rated glazing in fire windows in some of those applications.

716.6.7.2 Area limitations. The total area of the glazing in fire-protection-rated window assemblies shall not exceed 25 percent of the area of a common wall with any room.

The area limitations for interior fire windows vary from those found in Section 707.6 for fire barriers. Openings of all types in fire barriers are limited to 25 percent of the length of the wall while this section bases the limitation on fire windows to the area of the wall; therefore, when dealing with a fire barrier, both the 25-percent length and area would be applicable. When dealing with a fire partition, only the area limitation would apply.

The phrase "common wall" will limit the size to the actual visible wall that is shared and can be seen in
the two rooms. The area of the wall that continues through the interstitial space above a ceiling would not be included when determining the wall size. In addition, if the ceiling height differs on the two sides of the wall, the lowest ceiling height would be used to determine what is considered the "common wall."

716.6.7.3 Where 1/2-hour fire-protection window assemblies permitted. Fire-protection-rated glazing shall be permitted in window assemblies tested to NFPA 257 or UL 9 in smoke barriers and fire partitions requiring 1/2-hour opening protection in accordance with Table 716.6.

- The previous sections dealt with fire partitions and fire barriers, whereas this section addresses smoke barriers and fire partitions requiring only 20-minute opening protective. Fire windows with fire-protection-rated glazing are permitted in such partitions with the ratings and markings shown in Table 716.6.

- This section requires fire protection-rated glazing (see Section 716.6) to be labeled by an approved testing agency. This requirement enables the code user to verify that a fire window has been tested to the correct standard and that the test was properly performed by experienced people with correct equipment. Table 716.6 details the necessary information required on the fire window label. Each glazed panel is to be permanently identified. These descriptive requirements are used to verify that fire window assemblies have been correctly tested. The label on each and every fire window assembly must contain the manufacturer's name, the test standard used and the fire protection rating. The label must be applied at the manufacturer's plant by the third-party inspection agency. As a reminder, fire-resistance-rated glazing is not regulated by this section (see Section 716.2). Labeling requirements for fire-resistance-rated glazing can be found in Section 703.6.

SECTION 717
DUCTS AND AIR TRANSFER OPENINGS

717.1 General. The provisions of this section shall govern the protection of duct penetrations and air transfer openings in assemblies required to be protected and duct penetrations in nonfire-resistance-rated floor assemblies.

- Fire dampers, smoke dampers and combination fire/smoke dampers protect openings created by duct penetrations and transfer openings in assemblies required to be fire-resistance rated. Ceiling radiation dampers protect duct penetrations, which only penetrate the ceiling membrane of a fire-resistance-rated assembly. Penetrations with ducts through nonfire-resistant floors are also regulated by this section. This section includes installation, testing, rating, and actuation requirements in Sections 717.2, 717.3.1, 717.3.2 and 717.3.3, respectively. Section 717.3.1.4 indicates that dampers are to be the label of an approved agency. When dampers are provided, they must be properly maintained and, therefore, must be accessible (see Section 717.4). Section 717.5 indicates the conditions in which dampers are required at penetrations through horizontal assemblies. Duct penetrations and transfer openings through horizontal assemblies, including requirements for ceiling dampers, are regulated in Section 717.6. The provisions of Section 717 are duplicated in Section 607 of the IMC. All the requirements for protection of duct penetrations and transfer openings are found in this section. This section is directly referenced by sections that address vertical and horizontal fire-resistance-rated assemblies, as follows:

717.1.1 Ducts that penetrate fire-resistance-rated assemblies without dampers. Ducts that penetrate fire-resistance-rated assemblies and are not required by this section to have dampers shall comply with the requirements of Sections 714.2 through 714.3.3. Ducts that penetrate horizontal assemblies not required to be contained within a shaft and not required by this section to have dampers shall comply with the requirements of Sections 714.4 through 714.4.2.2.

- This section identifies how duct penetrations are to be properly protected, either in accordance with Section 717 using fire or fire/smoke dampers where required or, if dampers are not required, in accordance with Section 714 with materials that have been tested to either ASTM E 814 or ASTM E 119 or UL 263 to maintain the fire-resistance rating of the fire assembly. This section is coordinated with Section 714.3 (fire-resistance-rated walls) and Section 714.4 (horizontal assemblies). If a duct does not require a damper, the penetration of that duct through a fire-resistance-rated assembly must be protected as a through penetration in accordance with Section 714. If a duct does require a fire damper, smoke damper or combination fire/smoke damper, the through-penetration protection requirements of Section 714 will not apply. The reason is that these dampers are fire tested as a complete assembly installed within a fire-
resistance-rated wall assembly or horizontal assembly. The test and resulting listing will include not only the damper but also all required mounting hardware for the duct at the point where it penetrates the wall or floor. As long as the complete installation details in the listing are complied with, there is no need for any additional protection (e.g., per Section 714) to ensure that the fire-resistance rating of the wall assembly or horizontal assembly is maintained. However, it is possible to pass the fire test and obtain a listing for a fire damper or smoke damper without completely preventing smoke migration outside the duct, such as through the gap between the outside surface of the duct and the inside surface of the hole made to accommodate the duct. This can be quite apparent in some cases, as daylight might be visible from one side of the wall or floor assembly to the other side. This is because the tested dampers generally require a minimum gap to be provided between the damper and the wall or floor it is installed in. Although not required by the code, this gap is sometimes closed with a sealant in order to provide more complete smoke resistance for the wall or floor assembly. It is imperative that an intumescent firestop sealant not be used on the outside of the duct to seal this gap. The expansion pressure of the intumescent sealant can buckle the duct, thus hindering or preventing the proper operation of the damper under fire conditions.

The purpose of this section is to point the user to the annular space protection requirements for ducts that penetrate nonfire-resistance-rated assemblies, when applicable. The referenced section, Section 717.6.3, provides options for protecting these types of penetrations, two of which contain requirements for annular space protection.

717.1.1.1 Ducts that penetrate nonfire-resistance-rated assemblies. The space around a duct penetrating a nonfire-resistance-rated floor assembly shall comply with Section 717.6.3.

- The purpose of this section is to point the user to the annular space protection requirements for ducts that penetrate nonfire-resistance-rated assemblies, when applicable. The referenced section, Section 717.6.3, provides options for protecting these types of penetrations, two of which contain requirements for annular space protection.

717.2 Installation. Fire dampers, smoke dampers, combination fire/smoke dampers and ceiling radiation dampers located within air distribution and smoke control systems shall be installed in accordance with the requirements of this section, the manufacturer’s installation instructions and the dampers’ listing.

- This section performs two regulating functions. First, it requires that dampers be installed in accordance with the manufacturer’s installation instructions and listing. Such instructions will result in an installation that not only protects the penetration when the damper is actuated, but also create a protected opening should the duct collapse. Second, this section introduces Sections 717.2.1 and 717.2.2, which address the relationship of dampers with smoke control systems and hazardous exhaust ducts.

717.2.1 Smoke control system. Where the installation of a fire damper will interfere with the operation of a required smoke control system in accordance with Section 909, approved alternative protection shall be utilized. Where mechanical systems including ducts and dampers utilized for normal building ventilation serve as part of the smoke control system, the expected performance of these systems in smoke control mode shall be addressed in the rational analysis required by Section 909.4.

- Fire dampers are not permitted where they will obstruct or inhibit the proper operation of a required smoke control system. In a smoke control system, fire dampers are replaced with an alternative means of protection subject to the approval of the building official. Alternative protection may be in the form of a fire-resistance-rated shaft enclosure, steel subducts extending at least 22 inches (559 mm) vertically in an exhaust shaft having continuous upward airflow or a fire-resistance-rated horizontal duct enclosure. If a smoke control system is installed that is not required by the code, it is still subject to the same fire damper requirements as a required smoke control system; however, such nonmandated systems would be permitted to employ fire dampers instead of the mandatory alternative protection prescribed in this section for required smoke control systems. A required smoke control system is an important safety system and the code-mandated provisions here combine with Section 909 design requirements to ensure operability. This section does more than simply allow fire dampers to be omitted in required smoke control systems; it mandates the omission of fire dampers where such system operation could be jeopardized. Lastly, this section allows the normal building ventilation system (HVAC) to be employed to serve as the smoke control system, as long as the performance is substantiated.

717.2.2 Hazardous exhaust ducts. Fire dampers for hazardous exhaust duct systems shall comply with the International Mechanical Code.

- This section refers the user to the IMC. In particular, Section 510 of the IMC deals with hazardous exhaust systems. Hazardous exhaust can be emissions including flammable vapors, gases, fumes, mists or dusts, and airborne materials posing a health hazard. These types of duct systems are not allowed by Section 510.6.1 of the IMC to have fire or smoke dampers, but Section 510.6.3 of the IMC requires fire-
resistance-rated duct enclosure construction from the point of penetrations of a fire-resistance-rated wall to the exterior. Section 510.4 of the IMC requires independent systems.

717.3 Damper testing, ratings and actuation. Damper testing, ratings and actuation shall be in accordance with Sections 717.3.1 through 717.3.3.

☐ The purpose of this section is to introduce the requirements for the testing and actuation of fire dampers, smoke dampers, combination fire/smoke dampers and ceiling radiation dampers.

717.3.1 Damper testing. Dampers shall be listed and labeled in accordance with the standards in this section. Fire dampers shall comply with the requirements of UL 555. Only fire dampers labeled for use in dynamic systems shall be installed in heating, ventilation and air-conditioning systems designed to operate with fans on during a fire. Smoke dampers shall comply with the requirements of UL 555S. Combination fire/smoke dampers shall comply with the requirements of both UL 555 and UL 555S. Ceiling radiation dampers shall comply with the requirements of UL 555C or shall be tested as part of a fire-resistance-rated floor/ceiling or roof/ceiling assembly in accordance with ASTM E119 or UL 263.

☐ The purpose of this section is to provide the physical testing requirements for fire dampers, smoke dampers, combination fire/smoke dampers and ceiling radiation dampers. A fire damper is a device designed to close automatically upon detection of heat, to interrupt migratory airflow and to restrict the passage of flame through duct penetrations of rated assemblies. Fire dampers are required to be tested in accordance with UL 555. The criteria for acceptance of fire dampers require that they close and latch automatically, limit movement (warping) to prescribed limitations and remain in the opening for the fire exposure period for which they are rated. In addition to being tested, fire dampers must be labeled and, in accordance with Section 1703.5, require a follow-up service.

Fire dampers are classified by UL 555 for use in static and dynamic airflow conditions. Fire dampers installed in air-distribution systems that remain in operation after smoke or heat from a fire is detected (a dynamic airflow condition) must be labeled for such use. Static fire dampers may not operate properly under dynamic conditions; therefore, fire dampers used in systems designed with dynamic airflow must be tested and labeled for closure under the anticipated airflow and pressure conditions.

The manufacturer’s installation instructions must be followed. Fire dampers are to be installed in the assembly such that an opening created by a duct collapse is properly protected. Dampers are to be installed in accordance with their tested application, either vertically or horizontally. Although the test criteria of UL 555 are not a function of a horizontal versus vertical application, there are specific tests required for spring-operated dampers that are not required for gravity operated types; therefore, the type of damper used requires the building official to determine if it is acceptable for the given application.

Fire dampers are required to have the minimum fire protection rating established in Table 717.3.2.1. A smoke damper is a device installed in a duct, typically in smoke control systems or to protect smoke barrier penetrations, which operates to seal the duct against smoke leakage. Fire dampers tested to UL 555 are not rated for smoke leakage. Fire dampers are activated using a fusible link or other heat-responsive device that activates the damper at a predetermined temperature. Smoke dampers, on the other hand, are tested for leakage in accordance with the requirements of UL 555S and are activated by a smoke detector in the duct or area to be served.

Ceiling radiation dampers, formerly known as ceiling dampers, are designed to limit the radiative heat transfer through an air inlet/outlet opening in the ceiling membrane of a fire-resistance-rated floor/ceiling or roof/ceiling assembly. Ceiling radiation dampers are evaluated either in accordance with UL 555C or as part of the floor/ceiling or roof/ceiling assembly tested to ASTM E119 or UL 263. Ceiling radiation dampers evaluated in accordance with UL 555C are investigated for use in lieu of hinged-door-type dampers commonly specified in the listing of fire-resistance-rated floor/ceiling or roof/ceiling assemblies. UL 555C also provides criteria for the construction of the ceiling dampers. Ceiling radiation dampers investigated as part of the fire-resistance-rated floor/ceiling or roof/ceiling assembly are specified in the listing of such assemblies. The description of the tested assembly will include a description of the ceiling damper and its installation. A fire damper is a device designed to close automatically upon detection of heat, to interrupt migratory airflow and to restrict the passage of flame through duct penetrations of rated assemblies. Since ceiling and fire dampers have different design criteria, a fire damper must not be used in place of a ceiling damper.

717.3.2 Damper rating. Damper ratings shall be in accordance with Sections 717.3.2.1 through 717.3.2.3.

☐ The purpose of this section is to provide direction to the requirements for the ratings of fire dampers (Section 717.3.2.1), smoke dampers (Section 717.3.2.2) and combination fire/smoke dampers (Section 717.3.2.3).
717.3.2.1 Fire damper ratings. Fire dampers shall have the minimum fire protection rating specified in Table 717.3.2.1 for the type of penetration.

- This section primarily serves the purpose of requiring fire damper ratings to be determined in accordance with Table 717.3.2.1. Table 717.3.2.1 sets the minimum damper ratings based upon the type of assemblies being penetrated.

<table>
<thead>
<tr>
<th>TYPE OF PENETRATION</th>
<th>MINIMUM DAMPER RATING (hours)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Less than 3-hour fire-resistance-rated assemblies</td>
<td>1.5</td>
</tr>
<tr>
<td>3-hour or greater fire-resistance-rated assemblies</td>
<td>3</td>
</tr>
</tbody>
</table>

- The table summarizes the required hourly ratings for fire dampers based on the fire-resistance-rated assembly that is being penetrated by the air distribution system. The left-hand column lists the associated hourly ratings of either wall or horizontal assemblies. The code user enters the line item in the left-hand column based on the applicable fire-resistance rating of the element penetrated and reads across to the right column for the appropriate fire damper rating. These fire damper ratings are established based on tests conducted in accordance with UL 555 and represent the ratings necessary to maintain the integrity of the rated wall or horizontal assembly.

717.3.2.2 Smoke damper ratings. Smoke damper leakage ratings shall be Class I or II. Elevated temperature ratings shall not be less than 250°F (121°C).

- In accordance with UL 555S, smoke dampers are marked with a temperature rating starting at 250°F (121°C) and rising in increments of 100°F (56°C). Leakage ratings range from Classes I to III in accordance with the standard and are further identified for tested pressure ranging from 4 inches (102 mm) to 12 inches (305 mm) of water. Class I and II leakage ratings meet the code requirement for the damper to be not less than Class II.

717.3.2.3 Combination fire/smoke damper ratings. Combination fire/smoke dampers shall have the minimum fire protection rating specified for fire dampers in Table 717.3.2.1 for the type of penetration and shall also have a minimum smoke damper rating as specified in Section 717.3.2.2.

- This section primarily serves the purpose of requiring the ratings of combination fire/smoke dampers to comply with the requirements for both fire and smoke dampers, including the fire protection rating, specified in Table 717.3.2.1 and the leakage rating specified in Section 717.3.2.2.

717.3.3 Damper actuation. Damper actuation shall be in accordance with Sections 717.3.3.1 through 717.3.3.4 as applicable.

- The purpose of this section is to provide direction to the requirements for the actuation of fire dampers (Section 717.3.3.1), smoke dampers (Section 717.3.3.2), combination fire/smoke dampers (Section 717.3.3.3) and ceiling radiation dampers (Section 717.3.3.4).

717.3.3.1 Fire damper actuation device. The fire damper actuation device shall meet one of the following requirements:

1. The operating temperature shall be approximately 50°F (10°C) above the normal temperature within the duct system, but not less than 160°F (71°C).

2. The operating temperature shall be not more than 350°F (177°C) where located in a smoke control system complying with Section 909.

- The purpose of this section is to prescribe the actuation (operating temperature) requirements for fire dampers. The thresholds for actuation are based on UL 555. For static systems, UL 555 identifies 160°F (71°C) as the minimum and 215°F (102°C) as the maximum temperature (see Item 1). For dynamic systems, the standard includes a minimum value of 160°F (71°C) and a maximum value of 350°F (177°C) (see Item 2).

717.3.3.2 Smoke damper actuation. The smoke damper shall close upon actuation of a listed smoke detector or detectors installed in accordance with Section 907.3 and one of the following methods, as applicable:

1. Where a smoke damper is installed within a duct, a smoke detector shall be installed in the duct within 5 feet (1524 mm) of the damper with no air outlets or inlets between the detector and the damper. The detector shall be listed for the air velocity, temperature and humidity anticipated at the point where it is installed. Other than in mechanical smoke control systems, dampers shall be closed upon fan shutdown where local smoke detectors require a minimum velocity to operate.

2. Where a smoke damper is installed above smoke barrier doors in a smoke barrier, a spot-type detector listed for releasing service shall be installed on either side of the smoke barrier door opening.

3. Where a smoke damper is installed within an air transfer opening in a wall, a spot-type detector listed for releasing service shall be installed within 5 feet (1524 mm) horizontally of the damper.

4. Where a smoke damper is installed in a corridor wall or ceiling, the damper shall be permitted to be controlled by a smoke detection system installed in the corridor.

5. Where a total-coverage smoke detector system is provided within areas served by a heating, ventilation and air-conditioning (HVAC) system, smoke dampers shall be permitted to be controlled by the smoke detection system.

- This section provides specific requirements to ensure that an installed detector will detect smoke (see Item 1). Additionally, for passive systems (not part of a smoke control system), the location of detectors is critical to their performance. Smoke dampers are
installed in not only duct penetrations, but also transfer openings. A method for properly controlling dampers in such arrangements is provided in Item 3. A smoke detector provided throughout a corridor or an entire area detects smoke more effectively than a duct-type detector. Such detection is necessary for controlling dampers (Items 4 and 5). Smoke dampers may also be operated remotely, especially when used as part of a smoke control system. Combination fire/smoke dampers can be activated by either heat or smoke sensors. Once the primary heat-sensing device has been activated, a remote control system can be used to open the damper to permit its use as a smoke damper in the smoke removal system. Then, if the temperature rises to the damper's maximum degradation test temperature, the secondary heat sensor closes the damper again.

717.3.3.3 Combination fire/smoke damper actuation. Combination fire/smoke damper actuation shall be in accordance with Sections 717.3.3.1 and 717.3.3.2. Combination fire/smoke dampers installed in smoke control system shaft penetrations shall not be activated by local area smoke detection unless it is secondary to the smoke management system controls.

- This section primarily serves the purpose of requiring the actuation of combination fire/smoke dampers to comply with the requirements for both fire and smoke dampers, including the requirements in Sections 717.3.3.1 and 717.3.3.2. Further, when these dampers are used as part of a smoke control system, this section prohibits activation of these dampers by local area smoke detectors because this could render the smoke control system inoperable.

717.3.3.4 Ceiling radiation damper actuation. The operating temperature of a ceiling radiation damper actuation device shall be 50°F (27.8°C) above the normal temperature within the duct system, but not less than 160°F (71°C).

- The purpose of this section is to prescribe the actuation (operating temperature) requirements for ceiling radiation dampers. The thresholds for actuation are similar to those required for fire dampers used in static systems.

717.4 Access and identification. Fire and smoke dampers shall be provided with an approved means of access, which is large enough to permit inspection and maintenance of the damper and its operating parts. The access shall not affect the integrity of fire-resistance-rated assemblies. The access openings shall not reduce the fire-resistance rating of the assembly. Access points shall be permanently identified on the exterior by a label having letters not less than 1/2 inch (12.7 mm) in height reading: FIRE/SMOKE DAMPER, SMOKE DAMPER or FIRE DAMPER. Access doors in ducts shall be tight fitting and suitable for the required duct construction.

- Fire and smoke dampers and combination dampers must be properly maintained so that they will operate as intended. The need to maintain dampers, as well as reset them and replace fusible links after operation, requires that they be accessible as a part of the initial design in the code. The access doors may need to be fire doors in accordance with Section 716, depending on the location of the door, in order to maintain a fire-resistance rating. Access doors in the duct itself do not need a fire protection rating.

717.5 Where required. Fire dampers, smoke dampers and combination fire/smoke dampers shall be provided at the locations prescribed in Sections 717.5.1 through 717.5.7 and 717.6. Where an assembly is required to have both fire dampers and smoke dampers, combination fire/smoke dampers or a fire damper and a smoke damper shall be required.

- In order to maintain the fire-resistance rating of fire and smoke vertical walls, barriers and partitions, code-required dampers must be provided for all duct penetrations. Fire dampers are to be installed in the assembly such that an opening created by a duct collapse is properly protected. The manufacturer's installation instructions, which should indicate how the damper is to be installed, must be followed so that the operation and functioning of the installed assembly will be consistent with that required by the code.

Figure 717.5 shows the difference between where a fire damper is required and where one is not. In this example, the designer has chosen to separate mixed occupancies in accordance with the option of Section 508.4.4. The occupancy separation wall (fire barrier) that is required to be fire-resistant rated is also required to have the duct penetration protected by a fire damper, while the nonrated wall requires no such protection. Occasionally, the visible gap between the outside of the dampered duct and the inside surface of the hole in a wall or floor that accommodates the duct is closed with a sealant. Although not required by the code, this is occasionally done to provide more complete smoke resistance for the wall or floor assembly. The installation of the damper assembly in accordance with the listing and manufacturer's instructions will provide the required fire resistance, even without sealing any apparent gaps between the duct and the hole. It is imperative that an intumescent firestop sealant not be used on the outside of the duct to seal this gap. The expansion pressure of the intumescent sealant can buckle the duct, thus hindering or preventing the proper operation of the damper under fire conditions.

The code requires that a fire damper not be used as a smoke damper unless the location of the installation is appropriate for the dual purpose. The most likely location for this to occur would be where the air distribution system also serves as a smoke control system and a duct penetrates a fire-resistance-rated assembly. Section 717.2.1 requires alternative protection to be provided where fire dampers will interfere with the operation of a smoke control system. A combination fire/smoke damper, such as that described above, may be approved for use as alternative protection.

717.5.1 Fire walls. Ducts and air transfer openings permitted in fire walls in accordance with Section 706.11 shall be pro-
tected with listed fire dampers installed in accordance with their listing.

- Fire walls can create separate buildings within a structure. These multiple buildings may be on a single lot or, in the case of zero lot line construction, the fire wall may be located on the lot line. In the case where the fire wall separates different buildings on different lots, the code does not permit openings (see Sections 706.1.1 and 706.11). In such instances, a duct penetration is not permitted. Where the fire wall is not located on a lot line, the wall is permitted to be penetrated by a duct or transfer opening, provided the opening is protected with a listed fire damper. The fire damper in 3-hour and greater fire-resistance-rated walls must be rated for 3-hours.

**717.5.1.1 Horizontal exits.** A listed smoke damper designed to resist the passage of smoke shall be provided at each point a duct or air transfer opening penetrates a fire wall that serves as a horizontal exit.

- Recognizing that fire walls can jointly serve as horizontal exits, this section requires ducts and air transfer opening penetrations of such walls to be provided with smoke dampers. The purpose of this section is to recognize that horizontal exits are required to resist the passage of smoke as well as fire.

**717.5.2 Fire barriers.** Ducts and air transfer openings of fire barriers shall be protected with approved fire dampers installed in accordance with their listing. Ducts and air transfer openings shall not penetrate enclosures for stairways, ramps and exit passageways except as permitted by Sections 1022.4 and 1023.6, respectively.

**Exception:** Fire dampers are not required at penetrations of fire barriers where any of the following apply:

1. Penetrations are tested in accordance with ASTM E 119 or UL 263 as part of the fire-resistance-rated assembly.

2. Ducts are used as part of an approved smoke control system in accordance with Section 909 and where the use of a fire damper would interfere with the operation of a smoke control system.

3. Such walls are penetrated by ducted HVAC systems, have a required fire-resistance rating of 1 hour or less, are in areas of other than Group H and are in buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2. For the purposes of this exception, a ducted HVAC system shall be a duct system for conveying supply, return or exhaust air as part of the structure's HVAC system. Such a duct system shall be constructed of sheet steel not less than No. 26 gage thickness and shall be continuous from the air-handling appliance or equipment to the air outlet and inlet terminals.

- Fire barriers require fire dampers at duct and transfer openings; however, ducts and transfer openings are not allowed to penetrate stairway and exit passageway enclosures even with fire dampers. Of course, independent stair pressurization ductwork may penetrate the stairway enclosure in accordance with Sections 1022.5 and 1022.6. Penetration of an exit has the potential to allow smoke or flame to be introduced into the enclosure from other parts of the building, effectively blocking the exit path.

Exception 1 states that fire dampers are not required for duct penetrations of fire barriers when the assembly has been tested in accordance with ASTM E 119 or UL 263 without fire dampers and the required fire-resistance rating is obtained. In this case, the penetration assembly has been demonstrated as preserving the fire-resistance rating of the wall assembly.

Exception 2 reinforces the provisions of Section 717.2.1 (see commentary). A fire damper may inter-

**FIRE DAMPERS IN RATED WALL**

---

2012 INTERNATIONAL BUILDING CODE® COMMENTARY 7-109
FIRE AND SMOKE PROTECTION FEATURES

de with the operation of the smoke control system; however, some form of alternative protection must be provided due to the duct penetrating the fire barrier.

Exception 3 states that, in fully sprinklered buildings containing occupancies other than Group H, fire dampers may be omitted in duct penetrations of walls having a fire-resistance rating of 1 hour or less. Such duct systems must be 26 gauge steel continuous from the air handler to the air outlet with no flex duct connectors.

717.5.2.1 Horizontal exits. A listed smoke damper designed to resist the passage of smoke shall be provided at each point a duct or air transfer opening penetrates a fire barrier that serves as a horizontal exit.

- Walls separating buildings into areas of refuge in accordance with Section 1025 are specific types of fire barrier walls. The purpose of this section is to recognize that horizontal exits are required to resist the passage of smoke as well as fire. This section, therefore, requires that smoke dampers be installed at ducts or transfer openings that penetrate a fire barrier wall used as a horizontal exit.

717.5.3 Shaft enclosures. Shaft enclosures that are permitted to be penetrated by ducts and air transfer openings shall be protected with approved fire and smoke dampers installed in accordance with their listing.

Exceptions:

1. Fire dampers are not required at penetrations of shafts where:

   a. Steel exhaust subducts are extended at least 22 inches (559 mm) vertically in exhaust shafts, provided there is a continuous airflow upward to the outside; or

   b. Penetrations are tested in accordance with ASTM E 119 or UL 263 as part of the fire-resistance-rated assembly; or

   c. Ducts are used as part of an approved smoke control system designed and installed in accordance with Section 909 and where the fire damper will interfere with the operation of the smoke control system; or

   d. The penetrations are in parking garage exhaust or supply shafts that are separated from other building shafts by not less than 2-hour fire-resistance-rated construction.

2. In Group B and R occupancies equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1, smoke dampers are not required at penetrations of shafts where:

   a. Kitchen, clothes dryer, bathroom and toilet room exhaust openings are installed with steel exhaust subducts, having a minimum wall thickness of 0.0187-inch (0.4712 mm) (No. 26 gage);

   b. The subducts extend at least 22 inches (559 mm) vertically; and

   c. An exhaust fan is installed at the upper terminus of the shaft that is powered continuously in accordance with the provisions of Section 908.11, so as to maintain a continuous upward airflow to the outside.

3. Smoke dampers are not required at penetration of exhaust or supply shafts in parking garages that are separated from other building shafts by not less than 2-hour fire-resistance-rated construction.

4. Smoke dampers are not required at penetrations of shafts where ducts are used as part of an approved mechanical smoke control system designed in accordance with Section 909 and where the smoke damper will interfere with the operation of the smoke control system.

5. Fire dampers and combination fire/smoke dampers are not required in kitchen and clothes dryer exhaust systems when installed in accordance with the International Mechanical Code.

- This section requires both fire and smoke dampers at duct and air transfer openings in the shaft wall. The fire damper is required due to the penetration of a fire-resistance-rated wall. The smoke damper is required in order to limit the migration of smoke to other parts of the building via the shaft and the chimney effect (see commentary, Section 713.1). The exceptions allow the omission of fire dampers and smoke dampers under certain conditions. Exception 1 addresses fire dampers and Exceptions 2, 3 and 4 address smoke dampers. Exception 4 addresses the interface with smoke control systems as designed in Section 909 and coordinates with Section 717.2.1. Exception 5 addresses both fire and fire/smoke dampers, but not smoke dampers. When applying the exceptions, remember both fire and smoke dampers are required for shaft wall penetrations by ducts. Some exceptions only address one and not the other. Exceptions can be combined.

   Exceptions 1.1 thru 1.4 only exempt fire dampers.

   Exception 1.1 recognizes that the presence of a vertical subduct in a shaft will also offer some degree of fire resistance should the duct outside of the shaft collapse. Steel exhaust ducts that consist of a 22-inch (559 mm) vertical upturn in the shaft need not be protected with a fire damper if there is a continuous upward airflow to the outside. The continuous airflow will create a negative pressure in the shaft as compared to adjacent spaces, thereby minimizing the spread of hot gases from the shaft [see Figure 717.5.3.1(1)].

   Exceptions 2.1 and 2.1 are identical to Exceptions 1 and 2 to Section 717.5.2 (see commentary, Section 717.5.2).

   Exception 1.4 states that fire dampers may also be omitted in exhaust and supply shafts that serve a garage and are separated from all other shafts in the building by a 2-hour fire separation assembly [see Figure 717.5.3.1(2)]. Requiring fire dampers in garage exhaust and supply shafts would not signifi-
cantly prevent the spread of smoke and fire within the garage, since the vehicle ramp from floor to floor is a much greater conduit of smoke and fire in a garage.

Exception 2 is specific to Group B and R occupancies and exempts smoke dampers. Exception 2 has many more conditions than Exception 1.1, but together they can be used to exempt both fire and smoke dampers.

Exception 3 addresses parking garage shafts for exhaust and supply ducts and exempts smoke dampers, whereas Exception 1.4 exempts fire dampers. The conditions for the exception are the same.

Exception 4 is the counterpart to Exception 1.3. One exempts the fire damper and one exempts the smoke damper.

Exception 5 exempts fire dampers and combination fire/smoke dampers from kitchen and clothes dryer exhaust systems that are installed in accordance with the IMC. This is to recognize the hazards associated with obstructing the airflow for these installations. The IMC requires a shaft for multifloor kitchen and clothes dryer exhaust systems and requires 22-inch (559 mm) sub-ducts and special construction in accordance with Section 504.8 of the IMC. The fact that fire dampers and combination fire/smoke dampers are not required does not exempt the requirement for smoke dampers; however, Exception 2 of this section can be used.
FIRE AND SMOKE PROTECTION FEATURES

717.5.4 Fire partitions. Ducts and air transfer openings that penetrate fire partitions shall be protected with listed fire dampers installed in accordance with their listing.

Exceptions: In occupancies other than Group H, fire dampers are not required where any of the following apply:

1. Corridor walls in buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2 and the duct is protected as a through penetration in accordance with Section 714.

2. Tenant partitions in covered and open mall buildings where the walls are not required by provisions elsewhere in the code to extend to the underside of the floor or roof sheathing, slab or deck above.

3. The duct system is constructed of approved materials in accordance with the International Mechanical Code and the duct penetrating the wall complies with all of the following requirements:
   3.1. The duct shall not exceed 100 square inches (0.06 m²).
   3.2. The duct shall be constructed of steel a minimum of 0.0217 inch (0.55 mm) in thickness.
   3.3. The duct shall not have openings that communicate the corridor with adjacent spaces or rooms.
   3.4. The duct shall be installed above a ceiling.
   3.5. The duct shall not terminate at a wall register in the fire-resistance-rated wall.

4. A minimum 12-inch-long (305 mm) by 0.060-inch-thick (1.52 mm) steel sleeve shall be centered in each duct opening. The sleeve shall be secured to both sides of the wall and all four sides of the sleeve with minimum 1/2-inch by 1/4-inch by 0.060-inch (38 mm by 38 mm by 1.52 mm) steel retaining angles. The retaining angles shall be secured to the sleeve and the wall with No. 10 (M5) screws. The annular space between the steel sleeve and the wall opening shall be filled with mineral wool/batting on all sides.

4. Such walls are penetrated by ducted HVAC systems, have a required fire-resistance rating of 1 hour or less, and are in buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2. For the purposes of this exception, a ducted HVAC system shall be a duct system for conveying supply, return or exhaust air as part of the structure’s HVAC system. Such a duct system shall be constructed of sheet steel not less than No. 26 gage thickness and shall be continu-ous from the air-handling appliance or equipment to the air outlet and inlet terminals.

- Fire dampers are required when a duct or air transfer opening penetrates a fire partition and must be listed for the fire rating of the partition and installed in accordance with the listing. Please note that corridor walls, when required to be separated by Section 1018.1, must have duct penetrations or transfer openings protected with smoke dampers unless exempted by Section 717.5.1.1. This section includes four exceptions to the fire damper requirement.

Exception 1 addresses fire-resistance-rated corridor walls. In fully sprinklered buildings corridor wall penetrations by ducts or air transfer openings need not have fire dampers but they still are required to have smoke dampers by Section 717.5.4.1 unless further exempted there. Remember that duct penetrations that are exempted from fire dampers are required by Section 717.1.1 to have through-penetration firestops [see Figure 717.5.4(1)].

Exception 2 coordinates with Exception 4 to Section 708.4 and addresses standard construction designs for mall buildings as they relate to open ceiling spaces. The exception removes an implied requirement for dampers where logic would dictate none is required. This provision recognizes that walls separating tenants in a covered mall are required to be rated but are allowed to stop at unrated ceilings and storefronts, providing no true separation; therefore, it does not make sense to require a damper through the wall. If the tenant separation wall is required to be continuous to a roof deck or rated floor assembly for another purpose, the fire dampers would obviously be required.

Exception 3 states that fire dampers are not required where a steel duct penetrates a wall but does not have openings serving adjacent rooms or spaces [see Figure 717.5.4(2)] This exception has several criteria, one of which is to utilize a steel sleeve with mineral wool batting on all sides. Steel ducts have been shown to have the ability to remain in place during severe fire exposures. With no openings into the corridor to allow for smoke and heat transfer in the protected corridor enclosure, a fire damper is not necessary to attain the required fire performance of the penetration.

Exception 4 is similar to Exception 1. Exception 4 exempts all ducted penetrations of all fire partitions and not just corridor wall penetrations. Exception 4, in addition to the sprinkler provision, requires all steel ducts and does not allow flexible duct connectors. For corridors, Exception 1 is easier. Both exceptions would require through-penetration protection in accordance with Section 717.1.1. Exception 4 is identical to Exception 3 for fire barrier duct penetrations in Section 717.5.2.
717.5.4.1 Corridors. A listed smoke damper designed to resist the passage of smoke shall be provided at each point a duct or air transfer opening penetrates a corridor enclosure required to have smoke and draft control doors in accordance with Section 716.5.3.

Exceptions:

1. Smoke dampers are not required where the building is equipped throughout with an approved smoke control system in accordance with Section 909, and smoke dampers are not necessary for the operation and control of the system.

2. Smoke dampers are not required in corridor penetrations where the duct is constructed of steel not less than 0.019 inch (0.48 mm) in thickness and there are no openings serving the corridor.

◊ All corridors required to have fire-resistance-rated walls are required by Section 716.5.3 to have the required 20-minute doors to be smoke and draft con-
FIRE AND SMOKE PROTECTION FEATURES

trol listed assemblies; therefore, all fire-rated corridor walls penetrated by ducts or air transfer openings must have listed smoke dampers. Protecting the corridors from smoke during a fire incident is important for egress from the buildings.

Exception 1 cites the concern of the damper interfering with the smoke control system (see commentary, Section 717.2.1).

Exception 2 exempts the duct penetration from smoke dampers when a steel duct penetrates the corridor walls and there are no duct outlets or openings serving the corridor.

717.5.5 Smoke barriers. A listed smoke damper designed to resist the passage of smoke shall be provided at each point a duct or air transfer opening penetrates a smoke barrier. Smoke dampers and smoke damper actuation methods shall comply with Section 717.3.3.2.

Exception: Smoke dampers are not required where the openings in ducts are limited to a single smoke compartment and the ducts are constructed of steel.

* Smoke barriers are required for both Group I-2 (see Section 407.5) and I-3 (see Section 408.6) occupancies. See the commentary to Section 709.1 for other applications of smoke barriers. The concept of requiring smoke barriers is to limit the migration of smoke. In fact, Section 709.4 requires that smoke barriers form an effective continuous membrane from outside wall to outside wall and from the floor slab to the floor or roof deck above. This would include continuity through concealed spaces, such as those found above suspended ceilings and interstitial structural and mechanical spaces.

To prevent smoke migration across the smoke barrier where duct penetrations occur, an approved damper designed to resist the passage of smoke is to be provided at each point where a duct penetrates a smoke barrier. The damper closes upon detection of smoke by an approved smoke detector within the duct. If the duct penetration is above a smoke barrier door assembly, smoke detectors for adjacent doors may also be used to operate the damper and the duct detector may be eliminated. A reference to Section 717.3.3.2 is provided for activation mechanisms.

The designer must evaluate the specific conditions of the installation to determine which class of damper should be installed. If a fire damper is required (i.e., the smoke barrier is also a mixed occupancy separation or corridor wall), a combination fire/smoke damper or separate fire and smoke dampers may be installed.

717.5.6 Exterior walls. Ducts and air transfer openings in fire-resistance-rated exterior walls required to have protected openings in accordance with Section 705.10 shall be protected with listed fire dampers installed in accordance with their listing.

The purpose of this section is to recognize that under certain conditions exterior walls are required to be fire-resistance rated. Depending on the fire separation distance, not all fire-resistance-rated exterior walls require protected openings. If protected openings are required by Section 705.10, then fire dampers are required.

717.5.7 Smoke partitions. A listed smoke damper designed to resist the passage of smoke shall be provided at each point that an air transfer opening penetrates a smoke partition. Smoke dampers and smoke damper actuation methods shall comply with Section 717.3.3.2.

Exception: Where the installation of a smoke damper will interfere with the operation of a required smoke control system in accordance with Section 909, approved alternative protection shall be utilized.

The purpose of this section is to recognize that penetrations of smoke partitions by air transfer openings need to resist the transfer of smoke and, therefore, are required to be provided with a smoke damper. This is also consistent with the requirements in Section 710.8. This section also requires the actuation of the damper to comply with Section 717.3.3.2. The exception cites the concern of the damper interfering with the smoke control system (see commentary, Section 717.2.1).

717.6 Horizontal assemblies. Penetrations by ducts and air transfer openings of a floor, floor/ceiling assembly or the ceiling membrane of a roof/ceiling assembly shall be protected by a shaft enclosure that complies with Section 713 or shall comply with Sections 717.6.1 through 717.6.3.

In general, all floor openings that connect two or more stories are to be enclosed in shafts that are constructed in accordance with Section 713. Section 712.1.5 references Section 717.6 for duct openings (penetration). Sections 717.6.1 through 717.6.3 identify conditions where a shaft is not required and either a fire damper (see Section 717.6.1) or ceiling radia
tion damper (see Section 717.6.2.1) is required. There is an exception within Section 717.6.1 that allows the elimination of the fire damper; however, ceiling radiation dampers would be required in some cases (see Section 717.6.2.1).

717.6.1 Through penetrations. In occupancies other than Group I-2 and I-3, a duct constructed of approved materials in accordance with the International Mechanical Code that penetrates a fire-resistance-rated floor/ceiling assembly that connects not more than two stories is permitted without shaft enclosure protection. provided a listed fire damper is installed at the floor line or the duct is protected in accordance with Section 714.4. For air transfer openings, see Section 712.1.8.

Exception: A duct is permitted to penetrate three floors or less without a fire damper at each floor, provided such duct meets all of the following requirements:

1. The duct shall be contained and located within the cavity of a wall and shall be constructed of steel having a minimum wall thickness of 0.0187 inches (0.4712 mm) (No. 26 gage).
2. The duct shall open into only one dwelling or sleeping unit and the duct system shall be continuous from the unit to the exterior of the building.

3. The duct shall not exceed 4-inch (102 mm) nominal diameter and the total area of such ducts shall not exceed 100 square inches (0.665 m²) in any 100 square feet (9.3 m²) of floor area.

4. The annular space around the duct is protected with materials that prevent the passage of flame and hot gases sufficient to ignite cotton waste where subjected to ASTM E 119 or UL 263 time-temperature conditions under a minimum positive pressure differential of 0.01 inch (2.49 Pa) of water at the location of the penetration for the time period equivalent to the fire-resistance rating of the construction penetrated.

5. Grille openings located in a ceiling of a fire-resistance-rated floor/ceiling or roof/ceiling assembly shall be protected with a listed ceiling radiation damper installed in accordance with Section 717.6.2.1.

Penetrations of a fire-resistance-rated horizontal assembly by air ducts are permitted where no more than two stories are connected (i.e., the duct penetrates a single floor) and a fire damper is provided at the floor line. The fire damper must be tested in accordance with UL 555 [see Figure 717.6.1(1)]. A roof assembly penetrated by a duct that is open to the atmosphere is not required to have a fire damper installed at the penetrations because it is considered acceptable for the fire to vent to the outside atmosphere and heat or fire extension will do no harm [see Figure 717.6.1(2)]. However, a ceiling radiation damper would still be needed to protect a roof/ceiling assembly.
assembly per Section 717.6.2, Item 2. As noted, there is an exception to this section that allows the elimination of fire dampers at each floor when the ducts extend through a maximum of three floors. There are several criteria that must be followed to allow this, including:

- Minimum duct thickness (increases time for heat to penetrate and provides more durability) and enclosure within wall cavity.
- Limited to a single sleeping unit or dwelling unit (to reduce the likelihood that one dwelling unit or sleeping unit will be able to endanger another).
- Size of the duct opening (smaller opening means smaller amounts of fire effluents).
- Annular protection (reduces the chance of duct leakage from penetrated walls/barriers).
- Ceiling radiation dampers at grilles in fire-resistant ceilings (maintains ceiling fire resistance).
- All criteria center on limiting the impact of hot gases being present and spreading from one area to another. As noted, Section 712.1.8 addresses air transfer openings.

717.6.2 Membrane penetrations. Ducts and air transfer openings constructed of approved materials in accordance with the International Mechanical Code that penetrate the ceiling membrane of a fire-resistance-rated floor/ceiling or roof/ceiling assembly shall be protected with one of the following:

1. A shaft enclosure in accordance with Section 713.
2. A listed ceiling radiation damper installed at the ceiling line where a duct penetrates the ceiling of a fire-resistance-rated floor/ceiling or roof/ceiling assembly.
3. A listed ceiling radiation damper installed at the ceiling line where a diffuser with no duct attached penetrates the ceiling of a fire-resistance-rated floor/ceiling or roof/ceiling assembly.

- Unless the duct system is protected with a shaft enclosure in accordance with Sections 713 and 714.4, a ceiling radiation damper, as described in Section 717.6.2.1, is to be installed at the line where the ceiling is both penetrated by a noncombustible air duct and is an integral component of the fire-resistance rating.

The requirement for a ceiling radiation damper applies to ductwork that either penetrates the ceiling membrane from above and continues downwards, or where a diffuser with no ductwork attached below penetrates a ceiling membrane. Ceiling diffusers without ducts attached above or below are also covered by this section. Section 717.6.1 contains the requirements for fire dampers where the duct penetrates through the entire assembly [see Figures 717.6.1(1) and Figures 717.6.1(2) for ceiling radiation damper and fire damper locations].

Ceiling radiation dampers are designed to limit the radiative heat transfer through an air inlet or outlet opening in the ceiling membrane of a fire-resistance-rated floor/ceiling or roof/ceiling assembly.

717.6.2.1 Ceiling radiation dampers. Ceiling radiation dampers shall be tested in accordance with Section 717.3.1. Ceiling radiation dampers shall be installed in accordance with the details listed in the fire-resistance-rated assembly and the manufacturer's installation instructions and the listing. Ceiling radiation dampers are not required where either of the following applies:

1. Tests in accordance with ASTM E 119 or UL 263 have shown that ceiling radiation dampers are not necessary in order to maintain the fire-resistance rating of the assembly.

2. Where exhaust duct penetrations are protected in accordance with Section 714.1.2, are located within the cavity of a wall and do not pass through another dwelling unit or tenant space.

- Ceiling radiation dampers, formerly known as ceiling dampers, are evaluated either in accordance with UL 555C or as part of the floor/ceiling or roof/ceiling assembly tested to ASTM E 119 or UL 263. Ceiling radiation dampers evaluated in accordance with UL 555C are investigated for use in lieu of hinged-door-type dampers commonly specified in the listing of fire-resistance-rated floor/ceiling or roof/ceiling assemblies. UL 555C also provides criteria for the construction of the ceiling radiation dampers. If the fire-resistance-rated floor/ceiling or roof/ceiling assembly does not incorporate a hinged-door-type damper, a ceiling radiation damper may not be utilized in the assembly. Ceiling radiation dampers investigated as part of the fire-resistance-rated floor/ceiling or roof/ceiling assembly are specified in the listing of such assemblies. The description of the tested assembly will include a description of the ceiling radiation damper and its installation. Both types of ceiling radiation dampers shall be installed in accordance with the details listed in the fire-resistance-rated assembly and the manufacturer's installation instructions and listing.

The design information section of the UL Fire Resistance Directory also includes two duct outlet protection systems. "Duct Outlet Protection System A" may be used where specified in the fire-resistance-rated floor/ceiling or roof/ceiling assembly. "Duct Outlet Protection System B" may be used in lieu of hinged-door-type dampers commonly specified in the listing of fire-resistance-rated floor/ceiling or roof/ceiling assemblies. These methods meet ASTM E 119 or UL 363.

One exception to the ceiling radiation dampers is for ceiling membrane penetrations by ducts or ceiling diffusers that have been tested in accordance with ASTM E 119 or UL 263 as part of the overall fire-resistance-rated assembly.

Another exception is for exhaust ducts that penetrate a ceiling and: (1) are protected in accordance with Section 714.4.1.2; (2) are located within the cav-
ity of a wall above and (3) do not pass through another dwelling unit or tenant space.

717.6.3 Non-fire-resistance-rated floor assemblies. Duct systems constructed of approved materials in accordance with the International Mechanical Code that penetrate non-fire-resistance-rated floor assemblies shall be protected by any of the following methods:

1. A shaft enclosure in accordance with Section 713.

2. The duct connects not more than two stories, and the annular space around the penetrating duct is protected with an approved noncombustible material that resists the free passage of flame and the products of combustion.

3. The duct connects not more than three stories, and the annular space around the penetrating duct is protected with an approved noncombustible material that resists the free passage of flame and the products of combustion and a fire damper is installed at each floor line.

Exception: Fire dampers are not required in ducts within individual residential dwelling units.

Floor assemblies that are not rated still require isolation in some form based upon the requirements of Section 717.6.3 when duct systems penetrate the assemblies. Three conditions or requirements are listed.

First, the ducts can be part of a shaft enclosure in accordance with Section 713. The shaft construction required in Section 713.4 would be at least 1 hour.

Second, duct systems that connect not more than two stories (penetrate one floor) are permitted, provided the annular space around the duct is sealed with a noncombustible material that will not allow free passage of flame or the smoke. The two-story arrangement does not require a rated damper [see Figure 717.6.3(1)].

Third, when air ducts connect three levels or less and thus penetrate two floors or less, fire dampers must be provided at each floor line. A 1 1/2-hour-rated fire damper (see Table 717.3.2.1) is required even though the floor is not required to have a fire-resistance rating [see Figure 717.6.3(2)]. Fire dampers, unlike door opening protectives with multiple ratings, are only rated for 1 1/2 or 3 hours.

717.7 Flexible ducts and air connectors. Flexible ducts and air connectors shall not pass through any fire-resistance-rated assembly. Flexible air connectors shall not pass through any wall, floor or ceiling.

Flexible air ducts are prohibited from penetrating fire-resistance-rated assemblies. Flexible air connectors are not permitted to pass through any wall, floor or ceiling (fire-resistance rated or not). An adequate seal at the assembly penetration could allow smoke or flame to penetrate the assembly. Flexible air ducts and connectors can be constructed of both combustible and noncombustible components; therefore, the duct’s resistance to the passage of fire could be less than the resistance of the penetrated assembly. All construction assemblies, whether fire-resistance rated or not, provide some inherent resistance to the spread of fire.

Figure 717.6.3(1)
DUCT PENETRATIONS OF NONFIRE-RESISTANCE-RATED ASSEMBLIES
SECTION 718
CONCEALED SPACES

718.1 General. Fireblocking and draftstopping shall be installed in combustible concealed locations in accordance with this section. Fireblocking shall comply with Section 718.2. Draftstopping in floor/ceiling spaces and attic spaces shall comply with Sections 718.3 and 718.4, respectively. The permitted use of combustible materials in concealed spaces of buildings of Type I or II construction shall be limited to the applications indicated in Section 718.5.

The key words in this section are "combustible concealed spaces." This section does not apply to noncombustible construction. During a fire, flame, smoke and gases will spread via the paths of least resistance. Certain assemblies create void spaces, which will not only affect the spread of fire but, since the voids are concealed, will also make access for suppression more difficult.

The code has established two means by which fire spread within void spaces can be controlled: fireblocking and draftstopping. Fireblocking involves the use of building materials to prevent the movement of flame and gases to other areas through concealed spaces. Draftstopping involves the use of building materials to prevent the movement of air, smoke, gases and flames to other areas through large concealed spaces. For example, the protection in an attic space is draftstopping, while the protection in the cavity of a wall assembly is fireblocking.

Section 718.2.1 identifies the materials that are acceptable for use as fireblocks and Section 718.3.1 specifies the acceptable materials for draftstops. Sections 718.2, 718.3 and 718.4 address where fireblocking and draftstopping are required.

Fireblocks and draftstops are to be installed in combustible concealed spaces to prevent the spread of flame, smoke and gases. If a fire condition exists in a concealed space, the fireblocks and draftstops will help contain the fire until it can be suppressed. This section also includes provisions for permitted combustibles in concealed spaces in buildings of Type I and II construction (see Section 718.5 and Section 603.1, Exceptions 1 through 25).

718.2 Fireblocking. In combustible construction, fireblocking shall be installed to cut off concealed draft openings (both vertical and horizontal) and shall form an effective barrier between floors, between a top story and a roof or attic space. Fireblocking shall be installed in the locations specified in Sections 718.2.2 through 718.2.7.

This section merely states the goals associated with fireblocking. The intent of fireblocking is to reduce the ability of a fire, smoke and gases from moving to different parts of the building through combustible concealed spaces. Since there are no test standards for fire-blocking as with firestopping materials, the requirements are prescriptive.
718.2.1 Fireblocking materials. *Fireblocking* shall consist of the following materials:

1. Two-inch (51 mm) nominal lumber.
2. Two thicknesses of 1-inch (25 mm) nominal lumber with broken lap joints.
3. One thickness of 0.719-inch (18.3 mm) wood structural panels with joints backed by 0.719-inch (18.3 mm) wood structural panels.
4. One thickness of 0.75-inch (19.1 mm) particleboard with joints backed by 0.75-inch (19 mm) particleboard.
5. One-half-inch (12.7 mm) gypsum board.
6. One-fourth-inch (6.4 mm) cement-based millboard.
7. Batts or blankets of *mineral wool, mineral fiber* or other *approved* materials installed in such a manner as to be securely retained in place.
8. Cellulose insulation installed as tested for the specific application.

- This approved list of fireblocking materials has not been tested for fire resistance, but is simply deemed as acceptable materials for slowing the spread of flame and products of combustion. Their effectiveness depends on their correct installation, something which must be inspected at the time of construction.

Various insulation materials have been evaluated for use as fireblocking and have been shown to perform well if installed in accordance with their specifications. For insulating material to function well as fireblocking, it must completely fill the area where fireblocking is required so that no unblocked passages exist.

Certain insulating materials have been evaluated for use as fireblocks. The evaluation reports that specify the configuration and attachment for the insulating materials in the construction assemblies are based on tests performed on the assemblies. Although the code does not specify a test standard for fireblocking, these materials have been tested using the ASTM E 119 or UL 263 standard and their performance during the test is compared to the performance of other conventional fireblocking material. Nonrigid materials such as mineral wool, mineral fiber and fiber glass batts or blankets have somewhat limited applications. See Sections 718.2.1.1 and 718.2.1.2 for the limits on these materials. A new material has joined the list as possible fireblocking material—cellulose insulation. The code requires cellulose insulation to be tested for the specific application as fireblocking. Just because a space is filled with cellulose insulation does not guarantee that fireblocking will be accomplished.

718.2.1.1 Batts or blankets of mineral wool or mineral fiber. Batts or blankets of *mineral wool* or *mineral fiber* or other *approved* nonrigid materials shall be permitted for compliance with the 10-foot (3048 mm) horizontal *fireblocking* in walls constructed using parallel rows of studs or staggered studs.

- The use of mineral wool or mineral fiber or other approved nonrigid material is allowed to fulfill the requirement for fireblocking in the horizontal cavities formed by parallel rows of studs or staggered studs. Some type of fireblocking is required at 10 foot (3048 mm) intervals measured horizontally by Section 718.2.2. The code allows these types of batts or blankets, but the installation details must be approved and inspected in the field to verify that all concealed spaces are effectively fireblocked at the required locations. Simply because a space is filled with insulation does not guarantee that fireblocking will be accomplished.

718.2.1.2 Unfaced fiberglass. Unfaced fiberglass batt insulation used as *fireblocking* shall fill the entire cross section of the wall cavity to a minimum height of 16 inches (406 mm) measured vertically. When piping, conduit or similar obstructions are encountered, the insulation shall be packed tightly around the obstruction.

- Unfaced fiberglass is a batt insulation that can be used as fireblocking when installed as described in this section. For fiberglass batt insulation to be effective it must fill the wall cavity at the location being fireblocked not necessarily the full height of the wall. It must be a minimum of 16 inches (406 mm) vertically since it is assumed that this application is to prevent vertical spread of fire.

718.2.1.3 Loose-fill insulation material. Loose-fill insulation material, insulating foam sealants and caulk materials shall not be used as a fireblock unless specifically tested in the form and manner intended for use to demonstrate its ability to remain in place and to retard the spread of fire and hot gases.

- Loose-fill insulation materials are generally not suitable for use as fireblocking because, by their very nature, they are not intended to span an open gap and serve the purpose intended for fireblocking. However, the code does allow for the possibility that some types of materials with some cohesiveness might work; therefore, the code would require testing. This should be full-scale testing using a fire generated in accordance with ASTM E 119 or UL 263.

718.2.1.4 Fireblocking integrity. The integrity of fireblocks shall be maintained.

- The continued integrity of the fireblocking over time is necessary to ensure that it is in place at the time a fire occurs. Some of these materials over time, with repair work or remodeling work being done, will be removed, have holes put in the material or be subject to other activity that will make the material ineffective as a fireblock.

718.2.1.5 Double stud walls. Batts or blankets of mineral or glass fiber or other *approved* nonrigid materials shall be
FIRE AND SMOKE PROTECTION FEATURES

allowed as fireblocking in walls constructed using parallel rows of studs or staggered studs.

- The fireblocking at horizontal intervals of 10 feet (3048 mm) or less in the cavities of double stud or staggered stud walls may be fiberglass, mineral fiber or other approved nonrigid materials (see commentary, Section 718.2.1.1).

**718.2.2 Concealed wall spaces.** Fireblocking shall be provided in concealed spaces of stud walls and partitions, including furred spaces, and parallel rows of studs or staggered studs, as follows:

1. Vertically at the ceiling and floor levels.
2. Horizontally at intervals not exceeding 10 feet (3048 mm).

- The intent of this section is to prevent the spread of fires within walls. Losses in this area have been seen in existing structures of balloon construction, but the requirements apply to platform framing as well. This section requires both vertical and horizontal blocking. Vertical blocking simply requires fireblocking in vertical wall cavities at floors and ceilings; therefore, a tall warehouse-type building may not need any vertical fireblocking. Horizontal blocking, however, would be required every 10 feet (3048 mm). Section 718.2.1 provides the various methods for fireblocking. One method addressed is the use of mineral or glass fiber insulation, which is only allowed for horizontal fireblocking (see commentary, Section 717.2.1.1).

**718.2.3 Connections between horizontal and vertical spaces.** Fireblocking shall be provided at interconnections between concealed vertical stud wall or partition spaces and concealed horizontal spaces created by an assembly of floor joists or trusses, and between concealed vertical and horizontal spaces such as occur at soffits, drop ceilings, cove ceilings and similar locations.

- To prevent fire and smoke from spreading between vertical and horizontal spaces, fireblocks are required [see Figures 718.2.3(1 thru 3)]. If not provided, a concealed fire could spread throughout the floor level because of the interconnection of the concealed combustible wall and ceiling spaces.

In platform framing, where the gypsum wallboard is continued to the top plate of the wall, then typically either the gypsum board or the top plate will serve to cut off the connection between the vertical and horizontal construction. Therefore, with many typical details, no additional fireblocking is needed at this location.

**718.2.4 Stairways.** Fireblocking shall be provided in concealed spaces between stair stringers at the top and bottom of the run. Enclosed spaces under stairs shall also comply with Section 1009.9.3.

- Fireblocks are required at the top and bottom of concealed spaces between stair stringers (see Figure 718.2.4). Similar to fireblocks between horizontal and vertical spaces, fireblocks at the top and bottom of a run will provide a barrier between the floor below the stair and the floor that the stair serves. Additionally, a reference is made to Section 1009.9.3, which requires the interior of the space under stairs to contain 1-hour fire-resistant-rated construction or the stairway to be fire resistant (whichever is greater).
Figure 718.2.3(2)
FIREBLOCKING—DROP CEILINGS

Figure 718.2.3(3)
FIREBLOCKING—COVE CEILING
718.2.5 Ceiling and floor openings. Where required by Section 712.1.7, Exception 1 of Section 714.4.1.2 or Section 714.4.2, fireblocking of the annular space around vents, pipes, ducts, chimneys and fireplaces at ceilings and floor levels shall be installed with a material specifically tested in the form and manner intended for use to demonstrate its ability to remain in place and resist the free passage of flame and the products of combustion.

- Sections 712.1.7 and 714.4 allow penetrations of ceilings and floors to be fireblocked [see Figures 714.4.1(1), 714.4.1.2(2) and 714.4.2.1]. It should be noted that depending on the type of penetration and the number of floors penetrated (or stories connected), a shaft may be required (see Sections 712 and 713).

718.2.5.1 Factory-built chimneys and fireplaces. Factory-built chimneys and fireplaces shall be fireblocked in accordance with UL 103 and UL 127.

- UL 103 and 127 specify that only metal fireblocks and insulation shields are to be used with factory-built chimneys and fireplaces. The IMC contains a reference similar to that made in the UL standards. When fire-resistance-rated floor/ceiling assemblies are penetrated, the higher degree of protection afforded by tested through-penetration protection systems is required.

718.2.6 Exterior wall coverings. Fireblocking shall be installed within concealed spaces of exterior wall coverings and other exterior architectural elements where permitted to be of combustible construction as specified in Section 1406 or where erected with combustible frames. Fireblocking shall be installed at maximum intervals of 20 feet (6096 mm) in either dimension so that there will be no concealed space exceeding 100 square feet (9.3 m²) between fireblocking. Where wood furring strips are used, they shall be of approved wood of natural decay resistance or preservative-treated wood. If noncontinuous, such elements shall have closed ends, with at least 4 inches (102 mm) of separation between sections.

Exceptions:

1. Fireblocking of cornices is not required in single-family dwellings. Fireblocking of cornices of a two-family dwelling is required only at the line of dwelling unit separation.

2. Fireblocking shall not be required where the exterior wall covering is installed on noncombustible framing and the face of the exterior wall covering exposed to the concealed space is covered by one of the following materials:

   2.1. Aluminum having a minimum thickness of 0.019 inch (0.5 mm).

   2.2. Corrosion-resistant steel having a base metal thickness not less than 0.016 inch (0.4 mm) at any point.

   2.3. Other approved noncombustible materials.

3. Fireblocking shall not be required where the exterior wall covering has been tested in accordance with, and complies with the acceptance criteria of, NFPA...
285. The exterior wall covering shall be installed as tested in accordance with NFPA 285.

- Combustible exterior wall finish and exterior architectural elements are required to be fireblocked at a maximum of 20-foot (6096 mm) intervals and a 100-square-foot (9.3 m²) maximum area to prevent the spread of fire or smoke through concealed spaces. Adjacent sections of exterior trim need not be considered as contributing to the 20-foot (6096 mm) limitation if there is a minimum 4-inch (102 mm) separation between sections of exterior trim and the ends are closed. Trim on the building exterior presents the same concern as interior combustible concealed wall spaces and, therefore, requires fireblocking. To increase the long-term durability of wood used on the exterior, a certain level of decay resistance is required.

Exception 1 exempts single-family dwellings from the fireblocking requirement in the eaves or cornices.

Exception 2 exempts aluminum or steel siding installed over noncombustible wall framing.

Exception 3 exempts exterior wall coverings that have been tested and comply with NFPA 285, provided the coverings are installed in accordance with the listing. This exception is compatible to the metal composite material (MCM) wall coverings in Section 1407. Section 1407.10.4 requires the NFPA 285 test also.

718.2.7 Concealed sleeper spaces. Where wood sleepers are used for laying wood flooring on masonry or concrete fire-resistance-rated floors, the space between the floor slab and the underside of the wood flooring shall be filled with an approved material to resist the free passage of flame and products of combustion or fireblocked in such a manner that there will be no open spaces under the flooring that will exceed 100 square feet (9.3 m²) in area and such space shall be filled solidly under permanent partitions so that there is no communication under the flooring between adjoining rooms.

Exceptions:

1. Fireblocking is not required for slab-on-grade floors in gymnasiums.

2. Fireblocking is required only at the juncture of each alternate lane and at the ends of each lane in a bowling facility.

- Concealed spaces created by floor sleepers must be fireblocked into areas no greater than 100 square feet (9.3 m²) or such spaces must be filled with materials capable of resisting flame, smoke or gases (see Figure 718.2.7).

Since floor sleepers may cover large areas, this fireblock or material will restrict a fire from spreading within the concealed space to other areas of the floor. This section is commonly applied when a raised, wood-finish floor surface is installed in Type I or II construction.

718.3 Draftstopping in floors. In combustible construction, draftstopping shall be installed to subdivide floor/ceiling assemblies in the locations prescribed in Sections 718.3.2 through 718.3.3.

- Draftstopping subdivides combustible concealed horizontal spaces, unlike firestopping which subdivides vertical spaces. Draftstopping is required in combustible concealed floor construction in the locations required by Sections 718.3.2 and 718.3.3.

718.3.1 Draftstopping materials. Draftstopping materials shall not be less than 1/2-inch (12.7 mm) gypsum board, 5/8-inch (9.5 mm) wood structural panel, 5/8-inch (9.5 mm) particleboard, 1-inch (25-mm) nominal lumber, cement fiber-
board, batts or blankets of mineral wool or glass fiber, or other approved materials adequately supported. The integrity of draftstops shall be maintained.

- Similar to fireblocks in small concealed spaces, draftstops also act as a barrier to smoke and gases. Because of the large areas that require this barrier, however, the code permits certain types of sheathing material such as 1/4-inch (12.7 mm) gypsum board, 1/8-inch (9.5 mm) plywood and particleboard, 1-inch nominal lumber, cement fiberboard, mineral wool and glass fiber batts or blankets or other approved materials. The draftstop material must be properly supported and capable of remaining in place when subjected to initial fire exposure. It is reasonable to assume that materials that are acceptable for fireblocking purposes (see Section 718.2.1) would perform as well for draftstopping situations, so many items are duplicated here. Although the code does provide an extensive laundry list of accepted materials, it is important to note that the code does allow the use of any other approved material when it is adequately supported. Glass and mineral fiber batts are mentioned as an approved draftstopping material. Since the nonrigid glass or mineral fiber batts are not for insulation, they should be compressed to assure that the void is completely filled. Battts used for insulation cannot be compressed.

718.3.2 Groups R-1, R-2, R-3 and R-4. Draftstopping shall be provided in floor/ceiling spaces in Group R-1 buildings, in Group R-2 buildings with three or more dwelling units, in Group R-3 buildings with two dwelling units and in Group R-4 buildings. Draftstopping shall be located above and in line with the dwelling unit and sleeping unit separations.

Exceptions:

1. Draftstopping is not required in buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1.

2. Draftstopping is not required in buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.2, provided that automatic sprinklers are also installed in the combustible concealed spaces where the draftstopping is being omitted.

- To maintain the integrity of dwelling or sleeping unit separation walls in buildings of Groups R-1, R-2, R-3 and R-4, draftstopping is to be provided when the dwelling, or sleeping-unit separation wall is not continuous to the floor sheathing above. The draftstopping must be installed directly above the dwelling or sleeping unit separation wall (see Figure 718.3.2). The dwelling unit or sleeping unit separation wall (see Section 708.4), plus the draftstopping above, are considered a barrier to the spread of fire and smoke. As such, the draftstop offers some level of protection to the occupants of one dwelling or sleeping unit from a fire occurring in another dwelling or sleeping unit.

The exception indicates that the draftstopping need not be provided if sprinklers are installed above and below the ceiling, since sprinkler activation will control the spread of fire. The sprinkler system must be installed in accordance with Section 903.3.1.1 or
903.3.1.2 and NFPA 13 or 13R. The NFPA 13 sprinkler system (see Section 903.3.1.1) will generally require the sprinklers to be installed within combustible floor spaces unless the space meets the exceptions found within the standard. The NFPA 13R sprinkler system (see Section 903.3.1.2) would generally not require the sprinkler system within the concealed floor space. However, when using the provisions of Exception 2, the NFPA 13R system must be extended into the floor space despite the normal exclusion within the standard. See Section 102.4, which supports that the code requirement will control in this situation.

718.3.3 Other groups. In other groups, draftstopping shall be installed so that horizontal floor areas do not exceed 1,000 square feet (93 m²).

Exception: Draftstopping is not required in buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1.

- Unless the buildings are sprinklered throughout with an NFPA 13 system, draftstopping is to be provided in all groups except Groups R-1, R-2, R-3 and R-4 such that the concealed combustible floor/ceiling space is subdivided into horizontal spaces not exceeding 1,000 square feet (93 m²) (see Figure 718.3.3).

718.4 Draftstopping in attics. In combustible construction, draftstopping shall be installed to subdivide attic spaces and concealed roof spaces in the locations prescribed in Sections 718.4.2 and 718.4.3. Ventilation of concealed roof spaces shall be maintained in accordance with Section 1203.2.

- Fires that spread to attics that are not properly draftstopped often cause considerable damage. For this reason, draftstopping is required in attic and concealed roof spaces in accordance with Sections 718.4.2 and 718.4.3. The text also reminds the code user that, although the space must be compartmented, it still must be ventilated in accordance with the provisions of Chapter 12 in order to eliminate moisture or condensation or to cool the attic.

718.4.1 Draftstopping materials. Materials utilized for draftstopping of attic spaces shall comply with Section 718.3.1.

- See the commentary to Section 718.3.1

718.4.1.1 Openings. Openings in the partitions shall be protected by self-closing doors with automatic latches constructed as required for the partitions.

- Section 1209.2 requires attic access. The placement of draftstopping in the attic may interfere with the ability of the fire department to gain access to all attic spaces. This section requires that if draftstopping is

---

**Figure 718.3.3**

DRAFTSTOPPING—CONCEALED FLOOR SPACES, OTHER GROUP

For SI: 1 square foot = 0.0929 mm².
provided with access openings to adjacent draft-stopped portions of the attic, the openings must be constructed of draftstopping materials and be equipped with self-closing mechanisms in order to ensure that the draftstop will perform its intended function.

718.4.2 Groups R-1 and R-2. Draftstopping shall be provided in attics, mansards, overhangs or other concealed roof spaces of Group R-2 buildings with three or more dwelling units and in all Group R-1 buildings. Draftstopping shall be installed above, and in line with, sleeping unit and dwelling unit separation walls that do not extend to the underside of the roof sheathing above.

Exceptions:

1. Where corridor walls provide a sleeping unit or dwelling unit separation, draftstopping shall only be required above one of the corridor walls.

2. Draftstopping is not required in buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1.

3. In occupancies in Group R-2 that do not exceed four stories above grade plane, the attic space shall be subdivided by draftstops into areas not exceeding 3,000 square feet (279 m²) or above every two dwelling units, whichever is smaller.

4. Draftstopping is not required in buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.2, provided that automatic sprinklers are also installed in the combustible concealed space where the draftstopping is being omitted.

- To maintain the integrity of dwelling- and sleeping-unit separation walls (see commentary, Section 718.3.2), draftstopping is to be provided above dwelling- or sleeping-unit separation walls that do not extend to the roof sheathing [see Figures 718.4.2(1) and 718.4.2(2)]. This provision is limited to Group R-1 and R-2 occupancies. Groups R-3 and R-4 are regulated by Section 718.4.3.

Exception 1 clarifies that for corridor walls that serve as dwelling- or sleeping-unit separations, draftstopping is only required above one of the two corridor walls. It should be noted that this option only applies to roof/attic spaces and not to floors (see Sections 718.3.2 and 708.4).

Exceptions 2 and 4 omit the requirement for draftstopping attics that are sprinklered in accordance with Section 903.3.1.1 (see Exception 2) or 903.3.1.2 (see Exception 4). This exception would require the attic to be sprinklered even though it may not be required by the standard. NFPA 13R typically would not require an attic to be sprinklered. This is consistent with the exceptions to Section 718.3.2 for draftstopping of floor spaces (see commentary, Section 718.3.2).

The draftstopping requirements can be reduced in Group R-2 occupancies of four stories or less by...
Exception 3. This exception allows the area between draftstopping to be increased to 3,000 square feet (279 m²) or above every two dwelling units, whichever is smaller. This provides the opportunity for a simpler draftstopping installation when the draftstops are not required to be in line with the dwelling or sleeping unit separation walls. Group R-2 buildings are required by Section 903.2.8 to be sprinklered; sprinklers reduce the need for attic draftstopping. The four-story restriction will match with the limitations of Section 903.3.1.2 for NFPA 13R sprinkler systems. Therefore, by providing this level of draftstopping, buildings that use the NFPA 13R systems will not need to comply with Exception 4, which is discussed above. If Section 903.3.1.1 (an NFPA 13 sprinkler system) is used, then sprinklers will generally be required within the attic space and Exception 2 (discussed above) would be applicable.

718.4.3 Other groups. Draftstopping shall be installed in attics and concealed roof spaces, such that any horizontal area does not exceed 3,000 square feet (279 m²).

Exception: Draftstopping is not required in buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1.

* Since Group R-3, R-4 and nonresidential buildings are not always subdivided into small tenant spaces, concealed roof spaces and attics are to be subdivided into areas not exceeding 3,000 square feet (279 m²). The exception indicates that draftstopping is not required when the spaces above and below the ceiling are provided coverage by an automatic sprinkler system, in accordance with NFPA 13.

718.5 Combustible materials in concealed spaces in Type I or II construction. Combustible materials shall not be permitted in concealed spaces of buildings of Type I or II construction.

Exceptions:

1. Combustible materials in accordance with Section 603.
2. Combustible materials exposed within plenums complying with Section 602 of the International Mechanical Code.
3. Class A interior finish materials classified in accordance with Section 803.
4. Combustible piping within partitions or shaft enclosures installed in accordance with the provisions of this code.
5. Combustible piping within concealed ceiling spaces installed in accordance with the International Mechanical Code and the International Plumbing Code.
6. Combustible insulation and covering on pipe and tubing, installed in concealed spaces other than plenums, complying with Section 720.7.

* This section is necessary because Section 718 would generally exclude Type I and II buildings from the

![Diagram of Roof with Concealed Space and Draftstopping](image)

**Figure 718.4.2(2)**
DRAFTSTOPPING IN LINE WITH TENANT AND DWELLING UNIT SEPARATION WALLS

---

2012 INTERNATIONAL BUILDING CODE® COMMENTARY 7-127
concealed space draftstopping and fireblocking provisions. The use of combustibles in nonstructural applications is limited to the listed exceptions to prevent fire spread within building elements. The severity of a potential problem increases when combustibles are located within concealed spaces that are inaccessible to manual fire fighting. This section regulates the use of combustibles within concealed spaces of noncombustible buildings. This section is referenced from Exception 24 of Section 603.1.

SECTION 719
FIRE-RESISTANCE REQUIREMENTS FOR PLASTER

719.1 Thickness of plaster. The minimum thickness of gypsum plaster or Portland cement plaster used in a fire-resistance-rated system shall be determined by the prescribed fire tests. The plaster thickness shall be measured from the face of the lath where applied to gypsum lath or metal lath.

- The fire resistance of plaster is dependent on material variations, such as the aggregate mixture (sand content) as well as bonding to the plaster base. The use of wire or wire fabric reinforces the plaster mixes applied to plaster bases and, therefore, ensures increased fire resistance. As such, the makeup of the plastered element is required when evaluating the fire-resistance rating of plaster. Because the type of plaster used affects the fire-resistance rating, it is essential that the tests conducted utilize a plaster mix similar to that which is to be used in actual construction. Depending on the type of plaster, additional tests may not be required. If the plaster is a type that is judged to be equivalent to a tested type (see Section 719.2), additional testing is not required.

Similar to the requirements of Section 714.2.5, it is the thickness of the protective covering that is important. Therefore, the plaster is to be measured from the face of the lath, which reinforces the plaster.

Code users should also be aware that Sections 721 and 722 contain a number of items related to the use of plaster in fire-resistance ratings. Section 720 contains a number of prescriptive assemblies that can be used to obtain a fire-resistance rating. Section 721 contains methods of calculating fire-resistant assemblies and the contribution of plaster to other assemblies. For more information, see Sections 722.2.1.4, 722.3.2 and 722.4.1. Although many people are not familiar with these provisions, they are permitted under Section 703.3 and provide another option for establishing rated assemblies.

719.2 Plaster equivalents. For fire-resistance purposes, 1/2 inch (12.7 mm) of unsanded gypsum plaster shall be deemed equivalent to 3/4 inch (19.1 mm) of one-to-three gypsum sand plaster or 1 inch (25 mm) of Portland cement sand plaster.

This section indicates that prescribed thicknesses of unsanded gypsum plaster, one-to-three sanded gypsum plaster as well as Portland cement sand plaster are considered equivalent in terms of their fire-resistance rating characteristics. Once tests are conducted to determine the fire resistance of an assembly using one of these types, equivalency to the other prescribed types can be determined without subsequent tests.

719.3 Noncombustible furring. In buildings of Type I and II construction, plaster shall be applied directly on concrete or masonry or on approved noncombustible plastering base and furring.

- Buildings of Type I and II construction are required to be predominantly of noncombustible construction. This section requires the plastering base and furring to be noncombustible. The intent of this provision is to not permit a combustible cavity behind the finished plaster, which may be an area for a potentially concealed fire buildup.

719.4 Double reinforcement. Plaster protection more than 1 inch (25 mm) in thickness shall be reinforced with an additional layer of approved lath embedded at least 3/4 inch (19.1 mm) from the outer surface and fixed securely in place.

Exception: Solid plaster partitions or where otherwise determined by fire tests.

- The additional reinforcement is intended to decrease the likelihood of the plaster loosening when subjected to high temperatures. The plaster relies on the lath to provide a finish that is structurally sound. As the thickness of the plaster increases, additional reinforcement is required to hold the plaster in place.

719.5 Plaster alternatives for concrete. In reinforced concrete construction, gypsum plaster or Portland cement plaster is permitted to be substituted for 1/8 inch (12.7 mm) of the required poured concrete protection, except that a minimum thickness of 3/8 inch (9.5 mm) of poured concrete shall be provided in reinforced concrete floors and 1 inch (25 mm) in reinforced concrete columns in addition to the plaster finish. The concrete base shall be prepared in accordance with Section 2510.7.

Concrete elements, such as reinforced slabs and columns, rely in part on the thickness of the element to provide a fire-resistance rating. In order to reduce the concrete thickness, this section permits up to 1/2 inch (12.7 mm) of plaster to be substituted for 1/8 inch (12.7 mm) of concrete without affecting the fire-resistance rating of the element. While plaster can be substituted for concrete for fire-resistance purposes, a minimum amount of concrete is still required to be provided for structural integrity.

SECTION 720
THERMAL- AND SOUND-INSULATING MATERIALS

720.1 General. Insulating materials, including facings such as vapor retarders and vapor-permeable membranes, similar coverings and all layers of single and multilayer reflective foil insulations, shall comply with the requirements of this section. Where a flame spread index or a smoke-developed...
index is specified in this section, such index shall be determined in accordance with ASTM E 84 or UL 723. Any material that is subject to an increase in flame spread index or smoke-developed index beyond the limits herein established through the effects of age, moisture or other atmospheric conditions shall not be permitted.

Exceptions:

1. Fiberboard insulation shall comply with Chapter 23.
2. Foam plastic insulation shall comply with Chapter 26.
3. Duct and pipe insulation and duct and pipe coverings and linings in plenums shall comply with the International Mechanical Code.
4. All layers of single and multilayer reflective plastic core insulation shall comply with Section 2613.

This section addresses the potential fire or flame spread hazards of insulating materials installed in building spaces. Other provisions of the code or companion codes regulate insulating materials used for duct and plenum insulation [see the IMC for energy conservation purposes and the International Energy Conservation Code® (IECC®)] and foam plastic insulation (see Section 2603). Insulating materials can affect fire development and fire spread and are, therefore, regulated accordingly.

This section addresses the various insulating materials that may be installed in building spaces, including insulating bats, blankets, fills (including vapor barriers and vapor-permeable membranes) or other coverings. Fiberboard insulation is regulated by Chapter 23. Cellulose loose-fill insulation is regulated by Section 720.6. Foam plastic insulation is regulated by Chapter 26. The applicable test method is ASTM E 84 or UL 723 (see commentary, Section 803.1).

The requirements of Section 703.2 regarding the potential that adding items into a fire-resistant assembly may reduce the rating of the tested assembly must be considered. The addition of insulation has the potential to either add to or reduce the fire-resistance rating of an assembly. The reduction of ratings is more of a problem when insulation is added into a horizontal assembly.

720.2 Concealed installation. Insulating materials, where concealed as installed in buildings of any type of construction, shall have a flame spread index of not more than 25 and a smoke-developed index of not more than 450.

Exception: Cellulose loose-fill insulation that is not spray applied, complying with the requirements of Section 720.6, shall only be required to meet the smoke-developed index of not more than 450.

Concealed insulation no longer acts as an interior finish unless the covering material is removed or the fire is in the concealed building space. To limit the contribution of the insulation to a fire condition, the material must have a flame spread index of no more than 25 and a smoke-developed index of no more than 450. This is illustrated in Figure 720.2. Cellulose loose-fill insulation is regulated by the U.S. Consumer Product Safety Commission (CPSC) in accordance with Section 720.6. Spray-applied cellulose is regulated by Section 720.3.1 (see commentary, Section 720.4).

720.2.1 Facings. Where such materials are installed in concealed spaces in buildings of Type III, IV or V construction, the flame spread and smoke-developed limitations do not apply to facings, coverings, and layers of reflective foil insulation that are installed behind and in substantial contact with the unexposed surface of the ceiling, wall or floor finish.

Exception: All layers of single and multilayer reflective plastic core insulation shall comply with Section 2613.

In buildings of Type III, IV and V construction, the flame spread indices do not apply to facing material, provided it is installed behind (and in substantial contact with) the unexposed surface of the ceiling, floor or wall finish. For example, when paper-backed insulation is placed directly on top of a ceiling, the paper facing is not required to meet the flame spread index; however, if the same material is applied to the underside of a roof deck and the paper facing is exposed to the attic space, the paper facing must meet the flame spread criteria. The potential for flame spread is greatly diminished when the facings are installed in direct contact with the finish material because of the lack of airspace to support a fire if it were to be exposed to a source of ignition.

The purpose of the vapor retarder being placed on the warm-in-winter side of the building element is to prevent moisture vapor in the warm interior from reaching the dew-point temperature on a cold surface in the roof, wall or floor system. The generally accepted rating of a vapor retarder is 1 perm [57 mg/(s·m²·Pa)]. It is assumed that the permeance of an adequate vapor barrier will not exceed 1 perm [57 mg/(s·m²·Pa)] (see commentary, Section 1203.2).

720.3 Exposed installation. Insulating materials, where exposed as installed in buildings of any type of construction, shall have a flame spread index of not more than 25 and a smoke-developed index of not more than 450.

Exception: Cellulose loose-fill insulation that is not spray applied, complying with the requirements of Section 720.6
shall only be required to meet the smoke-developed index of not more than 450.

- Exposed insulating materials represent the same fire exposure hazard as any other exposed material, such as interior finish. The flame spread index for all applications of insulation materials is limited to 25, compared to 200 for interior finishes installed in rooms or spaces of certain occupancies (see commentary, Chapter 8). As with all interior finishes, the smoke-developed index is limited to 450. Cellulose loose-fill insulation is regulated by the CPSC in accordance with Section 720.6. Spray-applied cellulose is regulated by Section 720.3.1 (see commentary, Section 720.4).

It is important to remember that insulation materials that are open and exposed within an attic or crawl space are still considered as being "exposed" and, therefore, regulated by this section. The general requirements of this section do not differ from the provisions of Section 720.1. The main difference is that the facing materials within concealed installations may be exempt from the flame spread and smoke-developed rating (see Section 720.2.1) while the exposed facings would be limited as stated in this section.

720.3.1 Attic floors. Exposed insulation materials installed on attic floors shall have a critical radiant flux of not less than 0.12 watt per square centimeter when tested in accordance with ASTM E 970.

- ASTM E 970 is a test method that was developed by the insulation industry to evaluate the fire hazard of exposed attic insulation and is referenced in the material standards for insulation. Cellulose loose-fill insulation is required to comply with CPSC 16 CFR, Part 1209 (see Section 720.6), which requires testing by this standard. Spray-applied cellulose insulation that is not subject to the CPSC standard is also subject to the ASTM E 970 testing by virtue of this section.

720.4 Loose-fill insulation. Loose-fill insulation materials that cannot be mounted in the ASTM E 84 or UL 723 apparatus without a screen or artificial support shall comply with the flame spread and smoke-developed limits of Sections 720.2 and 720.3 when tested in accordance with CAN/ULC S102.2.

Exception: Cellulose loose-fill insulation shall not be required to be tested in accordance with CAN/ULC S102.2, provided such insulation complies with the requirements of Section 720.2 or 720.3, as applicable, and Section 720.6.

- The exception serves to make a distinction between cellulose insulation, which is spray applied using a water-mist applicator, and cellulose or other loose-fill insulation, which is poured or blown in place. Spray-applied cellulose insulation can be exposed on vertical and horizontal ceiling-type surfaces so it is treated as any other insulating material in regard to testing. Cellulose loose-fill insulation, which is poured or blown in, is regulated by CPSC requirements (see Section 720.6) and is exempt from the test procedure described in this section.

720.5 Roof insulation. The use of combustible roof insulation not complying with Sections 720.2 and 720.3 shall be permitted in any type of construction provided it is covered with approved roof coverings directly applied thereto.

- Foam plastic roof insulation is required to comply with Chapter 26. This section allows combustible insulation other than foam plastic insulation to be incorporated in the roof assembly without declassifying the type of construction. This provision coordinates with Section 603.1, Item 4.

- Cellulose loose-fill insulation is federally regulated by the CPSC. CPSC 16 CFR, Parts 1209 and 1404, contain various requirements that regulate the product to avoid excessive flammability or significant fire hazards. The smoke-developed index for cellulose loose-fill insulation must be determined by the ASTM E 84 test and must be 450 or less. The intent of this section is that the procedure for the smoke-developed index should be done by an ASTM E 84 test and not by the test procedures specified in Section 720.4.

720.7 Insulation and covering on pipe and tubing. Insulation and covering on pipe and tubing shall have a flame spread index of not more than 25 and a smoke-developed index of not more than 450.

Exception: Insulation and covering on pipe and tubing installed in plenums shall comply with the International Mechanical Code.

- This section maintains the general provision for insulation by requiring a maximum flame spread of 25 and smoke-developed index of 450, as stated in Sections 720.2 and 720.3; however, if exposed in a plenum, the IMC limits the smoke-developed index to 50.

SECTION 721
PRESCRIPTIVE FIRE RESISTANCE

721.1 General. The provisions of this section contain prescriptive details of fire-resistance-rated building elements, components or assemblies. The materials of construction listed in Tables 721.1(1), 721.1(2), and 721.1(3) shall be assumed to have the fire-resistance ratings prescribed therein. Where materials that change the capacity for heat dis-
sipation are incorporated into a fire-resistance-rated assembly, fire test results or other substantiating data shall be made available to the building official to show that the required fire-resistance-rating time period is not reduced.

- Section 703.3 permits the fire-resistance ratings to be determined in a number of ways, including those found in Section 721 (see Section 703.3, Item 2). In this section, there are many prescriptive details for fire-resistance-rated construction, particularly those materials and assemblies listed in Table 721.1(1) for structural parts; Table 721.1(2) for walls and partitions and Table 721.1(3) for floor and roof systems. For the most part, the listed items have been tested in accordance with the fire-resistance ratings indicated. In addition, a similar footnote to all of the tables allows the acceptance of generic assemblies that are listed in GA 600, Fire-Resistance Design Manual. It is important to review all of the applicable footnotes when using a material or assembly from one of the tables.

As stated above, the fire-resistance ratings for the walls and partitions outlined in Table 721.1(2) are based on actual tests. For reinforced concrete walls, it is important to note the type of aggregate used. The difference in aggregates is quite significant for a 4-hour fire-resistance-rated wall, as it amounts to a difference in thickness of almost 2 inches (51 mm). For hollow-unit masonry walls, the thickness required for a particular fire-endurance rating is the equivalent thickness as defined in Section 722.3.1 for concrete masonry and Section 722.4.1.1 for clay masonry.

Table 721.1(3) provides fire-resistance ratings for floor/ceiling and roof/ceiling assemblies. Note n, which exempts unusable space from the flooring and ceiling requirements, is especially important. This exemption is consistent with Section 711.3.3.

Often, materials such as insulation are added to fire-resistance-rated assemblies. The code requires substantiating fire test data to show that when the materials are added, they do not reduce the required fire-endurance time period. As an example, adding insulation to a floor/ceiling assembly may change its capacity to dissipate heat and, particularly for noncombustible assemblies, the fire-resistance rating may be changed.

Although the primary intent of the provision is to cover those cases where thermal insulation is added, the language is intentionally broad so that it applies to any material that might be added to the assembly.

721.1.1 Thickness of protective coverings. The thickness of fire-resistant materials required for protection of structural members shall be not less than that set forth in Table 721.1(1), except as modified in this section. The figures shown shall be the net thickness of the protecting materials and shall not include any hollow space in back of the protection.

- In accordance with this section, the required thickness of insulating material used to provide fire resistance to a structural member cannot be less than the dimension established by Table 721.1(1), except for permitted modifications. An example of the minimum thickness of concrete required for a structural steel column is shown in Figure 721.1.1(1). Figure 721.1.1(2) illustrates the minimum concrete thickness requirements for protecting reinforcing steel in concrete columns, beams, girders and trusses. Refer to Section 704 for additional provisions regarding structural members.

721.1.2 Unit masonry protection. Where required, metal ties shall be embedded in bed joints of unit masonry for protection of steel columns. Such ties shall be as set forth in Table 721.1(1) or be equivalent thereto.

- Items 1-3.1 through 1-3.4 of Table 721.1(1) require horizontal joint reinforcement. This section stipulates that if ties are required to connect the masonry to the steel column, such ties are to be located in the bed joints, which is where the horizontal reinforcement is to be located.

721.1.3 Reinforcement for cast-in-place concrete column protection. Cast-in-place concrete protection for steel col-

![Figure 721.1.1(1)
STEEL COLUMN ENCASED IN CONCRETE](image)

For SI: 1 inch = 25.4 mm.
Columns shall be reinforced at the edges of such members with wire ties of not less than 0.18 inch (4.6 mm) in diameter wound spirally around the columns on a pitch of not more than 8 inches (203 mm) or by equivalent reinforcement.

- In order for a concrete-encased steel column to maintain a fire-resistance rating, it is imperative that the concrete remain in place. Similar to a reinforced concrete column with spiral reinforcement (see Section 721.2.4.3), the ties required by this section are necessary for the concrete to remain in place around the column.

721.1.4 Plaster application. The finish coat is not required for plaster protective coatings where they comply with the design mix and thickness requirements of Tables 721.1(1), 721.1(2) and 721.1(3).

- The thickness of plaster for prescriptive assemblies, such as Item 1-4.1 in Table 721.1(1), Item 12-1.1 in Table 721.1(2) and Item 11-1.1 in Table 721.1(3), does not include the finish coat. Only the scratch coat and brown coat are needed to achieve the indicated fire-resistance ratings in the tables.

721.1.5 Bonded prestressed concrete tendons. For members having a single tendon or more than one tendon installed with equal concrete cover measured from the nearest surface, the cover shall not be less than that set forth in Table 721.1(1). For members having multiple tendons installed with variable concrete cover, the average tendon cover shall not be less than that set forth in Table 721.1(1), provided:

1. The clearance from each tendon to the nearest exposed surface is used to determine the average cover.
2. In no case can the clear cover for individual tendons be less than one-half of that set forth in Table 721.1(1). A minimum cover of \(1/4\) inch (19.1 mm) for slabs and 1 inch (25 mm) for beams is required for any aggregate concrete.

3. For the purpose of establishing a fire-resistance rating, tendons having a clear covering less than that set forth in Table 721.1(1) shall not contribute more than 50 percent of the required ultimate moment capacity for members less than 350 square inches (0.226 m²) in cross-sectional area and 65 percent for larger members. For structural design purposes, however, tendons having a reduced cover are assumed to be fully effective.

- As the ultimate-moment capacity of the member is critical to its behavior under fire conditions, the code requires the reduction for those tendons having cover to be less than that specified by the code. Behavior at service loads, however, is less affected by the heat of a fire; therefore, the code permits those tendons with reduced cover to be fully effective (see Figure 721.1.5).

TABLE 721.1(1). See page 7-135.

- An example of the minimum thickness of concrete required for a structural steel column is shown in Figure 721.1.1(1). As shown, this figure depicts Item 1-1.5 of Table 721.1(1). Figure 721.1.1(2) depicts a reinforced concrete column based on Item 5-1.1 (see commentary, Section 721.1).

TABLE 721.1(2). See page 7-139.

- An example of the minimum thickness of concrete required for a wall is shown in Figure 721.1.2(1). As shown, this figure depicts Item 4-1.1 of Table 721.1(2). Figure 721.1.2(1) depicts a noncombustible stud exterior wall based on Item 15-1.4 (see commentary, Section 721.1).

TABLE 721.1(3). See page 7-147.

- An example of a 1-hour-rated wood floor or roof truss is shown in Figure 721.1.3(1). As shown, this figure depicts Item 21-1.1 (see commentary, Section 721.1).

For SI: 1 inch = 25.4 mm.

For SI: 1 inch = 25.4 mm, 1 square inch = 645.2 mm<sup>2</sup>, 1 cubic foot = 0.0283 m<sup>3</sup>, 1 pound per cubic foot = 16.02 kg/m<sup>3</sup>.

a. Reentrant parts of protected members to be filled solidly.
b. Two layers of equal thickness with a 1/4-inch airspace between.
c. For all of the construction with gypsum wallboard described in Table 721.1(1), gypsum base for veneer plaster of the same size, thickness and core type shall be permitted to be substituted for gypsum wallboard, provided attachment is identical to that specified for the wallboard and the joints on the face layer are reinforced, and the entire surface is covered with a minimum of 1/4-inch gypsum veneer plaster.
d. An approved adhesive qualified under ASTM E 119 or UL 263.
e. Where lightweight or sand-lightweight concrete having an oven-dry weight of 110 pounds per cubic foot or less is used, the tabulated minimum cover shall be permitted to be reduced 25 percent, except that in no case shall the cover be less than 3/4 inch in slabs or 1 1/2 inches in beams or girders.
f. For solid slabs of siliceous aggregate concrete, increase tendon cover 20 percent.
g. Adequate provisions against spalling shall be provided by U-shaped or looped stirrups spaced not to exceed the depth of the member with a clear cover of 1 inch.
h. Prestressed slabs shall have a thickness not less than that required in Table 721.1(3) for the respective fire-resistance time period.
i. Fire coverage and end anchorages shall be as follows: Cover to the prestressing steel at the anchor shall be 1/4 inch greater than that required away from the anchor. Minimum cover to steel-bearing plate shall be 1 inch in beams and 3/4 inch in slabs.
j. For beam widths between 8 inches and 12 inches, cover thickness shall be permitted to be determined by interpolation.
k. Interior spans of continuous slabs, beams and girders shall be permitted to be considered restrained.
l. For use with concrete slabs having a comparable fire endurance where members are framed into the structure in such a manner as to provide equivalent performance to that of monolithic concrete construction.
m. Generic fire-resistance ratings (those not designated as PROPRIETARY<sup>*</sup> in the listing) in GA 600 shall be accepted as if herein listed.
n. No additional insulating material is required on the exposed outside face of the column flange to achieve a 1-hour fire-resistance rating.

</table>

For SI: 1 inch = 25.4 mm, 1 square inch = 645.2 mm², 1 cubic foot = 0.0283 m³.

a. Staples with equivalent holding power and penetration shall be permitted to be used as alternate fasteners to nails for attachment to wood framing.

b. Thickness shown for brick and clay tile is nominal thicknesses unless plastered, in which case thicknesses are net. Thickness shown for concrete masonry and clay masonry is equivalent thickness defined in Section 722.3.1 for concrete masonry and Section 722.4.1.1 for clay masonry. Where all cells are solid grouted or filled with silicone-treated perlite loose-fill insulation; vermiculite loose-fill insulation; or expanded clay, shale or slate lightweight aggregate, the equivalent thickness shall be the thickness of the block or brick using specified dimensions as defined in Chapter 21. Equivalent thickness may also include the thickness of applied plaster and lath or gypsum wallboard, where specified.

c. For units in which the net cross-sectional area of cored brick in any plane parallel to the surface containing the cores is at least 75 percent of the gross cross-sectional area measured in the same plane.

d. Shall be used for nonbearing purposes only.

e. For all of the construction with gypsum wallboard described in this table, gypsum base for veneer plaster of the same size, thickness and core type shall be permitted to be substituted for gypsum wallboard, provided attachment is identical to that specified for the wallboard, and the joints on the face layer are reinforced and the entire surface is covered with a minimum of 1/4-inch gypsum veneer plaster.

f. The fire-resistance time period for concrete masonry units meeting the equivalent thicknesses required for a 2-hour fire-resistance rating in Item 3, and having a thickness of not less than 7 1/4" in 4 hours when cores which are not grouted are filled with silicone-treated perlite loose-fill insulation; vermiculite loose-fill insulation; or expanded clay, shale or slate lightweight aggregate, sand or slag having a maximum particle size of 1/2 inch.

g. The fire-resistance rating of concrete masonry units composed of a combination of aggregate types or where plaster is applied directly to the concrete masonry shall be determined in accordance with ACI 216.1/TMS 0216. Lightweight aggregates shall have a maximum combined density of 65 pounds per cubic foot.

(continued)
TABLE 721.1(2)—continued
RATED FIRE-RESISTANCE PERIODS FOR VARIOUS WALLS AND PARTITIONS a, b, p

h. See also Note h. The equivalent thickness shall be permitted to include the thickness of cement plaster or 1.5 times the thickness of gypsum plaster applied in accordance with the requirements of Chapter 25.

i. Concrete walls shall be reinforced with horizontal and vertical temperature reinforcement as required by Chapter 19.

j. Studs are welded truss wire studs with 0.18 inch (No. 7 B.W. gage) flange wire and 0.18 inch (No. 7 B.W. gage) truss wires.

k. Nailable metal studs consist of two channel studs spot welded back to back with a crimped web forming a nailing groove.

l. Wood structural panels shall be permitted to be installed between the fire protection and the wood studs on either the interior or exterior side of the wood frame assemblies in this table, provided the length of the fasteners used to attach the fire protection is increased by an amount at least equal to the thickness of the wood structural panel.

m. For studs with a slenderness ratio, L/d, greater than 33, the design stress shall be reduced to 78 percent of allowable F\text{c}', For studs with a slenderness ratio, L/d, not exceeding 33, the design stress shall be reduced to 78 percent of the adjusted stress F\text{c}', calculated for studs having a slenderness ratio L/d of 33.

n. For properties of cooler and wallboard nails, see ASTM C 514, ASTM C 547 or ASTM F 1667.

o. Generic fire-resistance ratings (those not designated as PROPRIETARY* in the listing) in the GA 600 shall be accepted as if herein listed.

p. NCMA TEK 5-8A shall be permitted for the design of fire walls.

q. The design stress of studs shall be equal to a maximum of 100 percent of the allowable F\text{c}', calculated in accordance with Section 2306.

---

TABLE 721.1(3)—continued
MINIMUM PROTECTION FOR FLOOR AND ROOF SYSTEMS* q

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound = 0.454 kg, 1 cubic foot = 0.0283 m³.
1 pound per square inch = 6.895 kPa, 1 pound per linear foot = 1.4882 kg/m.
a. Staples with equivalent holding power and penetration shall be permitted to be used as alternate fasteners to nails for attachment to wood framing.
b. When the slab is in an unrestrained condition, minimum reinforcement cover shall not be less than 1/4 inch for 4 hours (silicone aggregate only); 1/8 inch for 4 and 3 hours; 1/6 inch for 2 hours (silicone aggregate only); and 1/4 inch for all other restrained and unrestrained conditions.
c. For all of the construction with gypsum wallboard described in this table, gypsum base for veneer plaster of the same size, thickness and core type shall be permitted to be substituted for gypsum wallboard, provided attachment is identical to that specified for the wallboard, and the joints on the face layer are reinforced and the entire surface is covered with a minimum of 1/4-inch-gypsum veneer plaster.
d. Slab thickness over steel joists measured at the joists for metal lath form and at the top of the form for steel form units.
e. (a) The maximum allowable stress level for H-Series joists shall not exceed 22,000 psi.
(b) The allowable stress for K-Series joists shall not exceed 26,000 psi, the nominal depth of such joist shall not be less than 10 inches and the nominal joist weight shall not be less than 5 pounds per linear foot.
f. Cement plaster with 15 pounds of hydrated lime and 3 pounds of approved additives or admixtures per bag of cement.
g. Gypsum wallboard ceilings attached to steel framing shall be permitted to be suspended with 1/16-inch cold-formed carrying channels spaced 48 inches on center, which are suspended with No. 8 SWG galvanized wire hangers spaced 48 inches on center. Cross-furring channels are tied to the carrying channels with No. 18 SWG galvanized wire hangers spaced 48 inches on center. Cross-furring channels are tied to the carrying channels with No. 18 SWG galvanized wire (double strand) and spaced as required for direct attachment to the framing. This alternative is also applicable to those steel framing assemblies recognized under Note q.
h. Six-inch hollow clay tile with 2-inch concrete slab above.
i. Four-inch hollow clay tile with 1/4-inch concrete slab above.
j. Thickness measured to bottom of steel form units.
k. Five-eighths inch of vermiculite gypsum plaster plus 1/4-inch of approved vermiculite acoustical plastic.
l. Furring channels spaced 12 inches on center.
m. Double wood floor shall be permitted to be either of the following:
   (a) Subfloor of 1-inch nominal boarding, a layer of asbestos paper weighing not less than 14 pounds per 100 square feet and a layer of 1-inch nominal tongue-and-groove finished flooring; or
   (b) Subfloor of 1-inch nominal tongue-and-groove boarding or 15/32-inch wood structural panels with exterior glue and a layer of 1-inch nominal tongue-and-groove finished flooring or 15/32-inch wood structural panel finish flooring or a layer of Type 1 Grade M-1 particleboard not less than 1/4-inch thick.

n. The ceiling shall be permitted to be omitted over unusable space, and flooring shall be permitted to be omitted where unusable space occurs above.
o. For properties of cooler or wallboard rails, see ASTM C 514, ASTM C 547 or ASTM F 1667.
p. Thickness measured on top of steel deck unit.
q. Generic fire-resistance ratings (those not designated as PROPRIETARY* in the listing) in the GA 600 shall be accepted as if herein listed.

SECTION 722
CALCULATED FIRE RESISTANCE

Due to the prescriptive nature of Section 722, this section contains explanatory material, examples and reference materials related to calculating fire-resistance ratings of materials and assemblies. As such, commentary is provided where necessary as the basis for a provision or to illustrate the application of the requirement.

This section provides a number of useful alternatives for establishing compliance with the code. The provisions in this section can be used to calculate the fire-resistance rating for an assembly (concrete, concrete masonry, clay masonry, steel and wood). It also contains provisions that would permit modifications or changes to a tested assembly. For example, the steel assemblies (see Section 722.5) will allow the selection of different sized or shaped members depending on the weight-to-heated-perimeter ratio (see Sections 722.5.2.1.2 and 722.5.2.2). In addition, the amount of spray-applied fire-resistant materials can be modified from a tested assembly to either increase or decrease the coverage dependent on the member and the spray-applied material.

The section also addresses items that are much less exotic and may be helpful in a number of situations. Section 722.6 will provide methods for calculating the fire resistance of wood assemblies, including light-framed walls and floors or heavy timber-exposed members. Section 722.4.1 can be used for masonry walls (including existing conditions) where additional protection such as filled cores or an additional wythe such as a brick veneer is added.

While this section is not often used by many people, those that have used it will find that it is often helpful in solving difficult situations related to the protection of certain assemblies. Therefore, taking the time to become familiar with this section can be very beneficial. The provisions of this section include methods for calculating fire resistance as follows:

Concrete Assemblies:
- Walls—722.2.1
- Floor and roof slabs—722.2.2
- Beams—722.2.3
- Columns—722.2.3

Concrete Masonry:
- Walls—722.3.2
- Lintels—722.3.4
- Columns—722.3.5

Clay Brick and Tile Masonry:
- Walls—722.4.1
- Lintels—722.4.3
- Columns—722.4.4
FIRE AND SMOKE PROTECTION FEATURES

Steel Assemblies:
- Columns using:
  - Gypsum wallboard—722.5.1.2
  - Spray-applied materials—722.5.1.3
  - Concrete or masonry—722.5.1.4
- Beams using:
  - Spray-applied materials—722.5.2.2
- Trusses using:
  - Spray-applied materials—722.5.2.3
Wood Assemblies:
- Walls, floors and roofs—722.6.2
Exposed Wood Members:
- Beams and columns—722.6.3

722.1 General. The provisions of this section contain procedures by which the fire resistance of specific materials or combinations of materials is established by calculations. These procedures apply only to the information contained in this section and shall not be otherwise used. The calculated fire resistance of concrete, concrete masonry and clay masonry assemblies shall be permitted in accordance with ACI 216.1/TMS 0216. The calculated fire resistance of steel assemblies shall be permitted in accordance with Chapter 5 of ASCE 29. The calculated fire resistance of exposed wood members and wood decking shall be permitted in accordance with Chapter 16 of ANSI/AF&PA National Design Specification for Wood Construction (NDS).

- Section 703.3 permits the fire-resistance ratings to be determined in a number of ways, including those found in Section 722 (see Section 703.3, Item 3). The provisions of this section contain procedures by which the fire resistance of specific materials or combinations of materials is established by calculations. These procedures apply only to the information contained in this section and are not to be otherwise used. The calculated fire resistance of concrete, concrete masonry and clay masonry assemblies is also permitted in accordance with ACI 216.1/TMS 0216.1 while steel assemblies can use ASCE 29 (see commentary, Section 703.3).

722.1.1 Definitions. The following terms are defined in Chapter 2:
- This section lists terms that are specifically associated with the subject matter of this chapter. It is important to emphasize that these terms are not exclusively related to this chapter but may or may not also be applicable where the term is used elsewhere in the code.

Definitions of terms can help in the understanding and application of the code requirements. The purpose for including a list within this chapter is to provide more convenient access to terms which may have a specific or limited application within this chapter. For the complete definition and associated commentary, refer back to Chapter 2. Terms that are italicized provide a visual identification throughout the code that a definition exists for that term. The use and application of all defined terms are set forth in Section 201.

CERAMIC FIBER BLANKET.
CONCRETE, CARBONATE AGGREGATE.
CONCRETE, CELLULAR.
CONCRETE, LIGHTWEIGHT AGGREGATE.
CONCRETE, PELITE.
CONCRETE, SAND-LIGHTWEIGHT.
CONCRETE, SILICEOUS AGGREGATE.
CONCRETE, VERMICULITE.
GLASS FIBERBOARD.
MINERAL BOARD.

722.2 Concrete assemblies. The provisions of this section contain procedures by which the fire-resistance ratings of concrete assemblies are established by calculations.

722.2.1 Concrete walls. Cast-in-place and precast concrete walls shall comply with Section 722.2.1.1. Multiwythe concrete walls shall comply with Section 722.2.1.2. Joints between precast panels shall comply with Section 722.2.1.3. Concrete walls with gypsum wallboard or plaster finish shall comply with Section 722.2.1.4.

722.2.1.1 Cast-in-place or precast walls. The minimum equivalent thicknesses of cast-in-place or precast concrete walls for fire-resistance ratings of 1 hour to 4 hours are shown in Table 722.2.1.1. For solid walls with flat vertical surfaces, the equivalent thickness is the same as the actual thickness. The values in Table 722.2.1.1 apply to plain, reinforced or prestressed concrete walls.

- Although there have been few fire tests of concrete walls (other than concrete masonry), there have been many fire tests of concrete slabs tested as floors or roofs. Fire tests of floors or roofs are considered to be more severe than those of walls because of the loading conditions (tension cracks associated with bending moment). In addition, most ASTM E 119 or UL 263 fire tests of floor assemblies have been conducted while the assembly was supported within restraining frames. As concrete assemblies are heated and tend to expand, the expansion is resisted by the restraining frame. These restraining forces are usually much greater than the superimposed loads supported by load-bearing walls; thus, floor or roof assemblies are subjected to both vertical superimposed loads and horizontal restraining loads during fire tests. By contrast, load-bearing walls are subjected only to superimposed loads.

The fire endurance of masonry or concrete walls is nearly always governed by the ASTM E 119 or UL 263 criteria for temperature rise of the unexposed surface (i.e., the "heat transmission" end point). For flat concrete slabs or panels, the heat transmission fire endurance depends primarily on the aggregate type and thickness and is essentially the same for floors as it is for walls.

</tbody>
</table>

For SI: 1 inch = 25.4 mm.

The data in Table 722.2.1.1 was derived from Portland Cement Association (PCA) Bulletin 223, "Fire Endurances of Concrete Slabs as Influenced by Thickness, Aggregate Type, and Moisture," and PCA Publication T-140, Fire Resistance of Reinforced Concrete Floors.

722.2.1.1.1 Hollow-core precast wall panels. For hollow-core precast concrete wall panels in which the cores are of constant cross section throughout the length, calculation of the equivalent thickness by dividing the net cross-sectional area (the gross cross section minus the area of the cores) of the panel by its width shall be permitted.

The method for determining equivalent thickness of masonry units was developed because the cores in masonry units taper. The method is, of course, also applicable to hollow-core precast concrete panels; however, because the cores in hollow-core panels do not taper, the equivalent thickness can be calculated by dividing the net cross-sectional area of the panel by its width.

722.2.1.1.2 Core spaces filled. Where all of the core spaces of hollow-core wall panels are filled with loose-fill material, such as expanded shale, clay, or slag, or vermiculite or perlite, the fire-resistance rating of the wall is the same as that of a solid wall of the same concrete type and of the same overall thickness.

The PCA report "Tests of Fire Resistance and Strength of Walls of Concrete Masonry Units" shows that filling cores of concrete masonry units with loose lightweight aggregates increases the fire endurance to a duration significantly longer than that of solid masonry units of the same total thickness. It is reasonable to assume that the same relationship exists for walls made of hollow-core panels.

722.2.1.3 Tapered cross sections. The thickness of panels with tapered cross sections shall be that determined at a distance 2t or 6 inches (152 mm), whichever is less, from the point of minimum thickness, where t is the minimum thickness.

Some precast concrete wall panel sections (e.g., certain single-tee units) have tapered surfaces so the thickness varies, as shown in code Figure 722.2.2.1.2. In fire tests, it has been customary to monitor the unexposed surface temperature at the location shown in the figure.

722.2.1.1.4 Ribbed or undulating surfaces. The equivalent thickness of panels with ribbed or undulating surfaces shall be determined by one of the following expressions:

\[ t + \left( \frac{A_t}{s} - 1 \right) (t_e - t) \]  

(Equation 7-3)

where:

\[ s \] = Spacing of ribs or undulations.

\[ t \] = Minimum thickness.

\[ t_e \] = Equivalent thickness of the panel calculated as the net cross-sectional area of the panel divided by the width, in which the maximum thickness used in the calculation shall not exceed 2t.

The portion of a ribbed panel that can be used in calculating equivalent thickness, \( t_e \), is shown in Figure 722.2.2.1.3. Note that the procedure outlined gives no credit for stems of double tees or of similar ribbed panels and clearly indicates that the minimum thickness must be used for such sections.

722.2.1.2 Multiwythe walls. For walls that consist of two wythes of different types of concrete, the fire-resistance ratings shall be permitted to be determined from Figure 722.2.1.2.

The graphs in the code Figure 722.2.1.2 were derived from a report entitled "Fire Endurance of Two-Course Floors and Roofs" in the ACI Journal.

722.2.1.2.1 Two or more wythes. The fire-resistance rating for wall panels consisting of two or more wythes shall be permitted to be determined by the formula:

\[ R = (R_1^{0.59} + R_2^{0.59} + ... + R_n^{0.59})^{1.7} \]  

(Equation 7-4)

where:

\[ R \] = The fire endurance of the assembly, minutes.

\[ R_1, R_2, \text{ and } R_n \] = The fire endurances of the individual wythes, minutes. Values of \( R_n^{0.59} \) for use in Equation 7-4 are given in Table 722.2.1.2(1). Calculated fire-resistance ratings are shown in Table 722.2.1.2(2).

Equation 7-4 was developed by the U.S. National Bureau of Standards (NBS) in the early 1940s and first appeared in Appendix B of BMS 92. Verification of the accuracy of the equation is given in "Fire Endurance of Two-Course Floors and Roofs" in the ACI Journal.

This section and the associated tables allow both the determination of the fire endurance of a particular assembly [see Table 722.2.1.2(1)] and what thicknesses are required to achieve a certain fire endurance [see Table 722.2.1.2(2)].

a. Based on Equation 7-4.
722.2.1.2.2 Foam plastic insulation. The fire-resistance ratings of precast concrete wall panels consisting of a layer of foam plastic insulation sandwiched between two wythes of concrete shall be permitted to be determined by use of Equation 7-4. Foam plastic insulation with a total thickness of less than 1 inch (25 mm) shall be disregarded. The \( R^a \) value for thickness of foam plastic insulation of 1 inch (25 mm) or greater, for use in the calculation, is 5 minutes; therefore \( R^a = 2.5 \).

This value was for foam plastic insulation 1-inch (25 mm) thick and greater, determined from a fire test conducted on a panel that consisted of a 2-inch (51 mm) base slab of carbonate aggregate concrete, a 1-inch (25 mm) layer of cellular polystyrene insulation and a 2-inch (51 mm) face slab of carbonate aggregate concrete. The resulting fire endurance was 2 hours. From Equation 7-4, the contribution of the 1-inch (25 mm) layer of foam polystyrene was calculated to be 5 minutes.

Presumably, a comparable \( R \)-value for a 1-inch (25 mm) layer of foam polystyrene would be somewhat greater than for a 1-inch (25 mm) layer of foam polystyrene, but test values are not available. The above value for polystyrene is conservative for foam polystyrene.

Equation 7-4 can be rewritten as:
\[
R^a = (R^{0.59} + R^{0.59} + \ldots + R^{0.59})
\]

This form of the equation is useful in making a quick determination of whether or not an assembly qualifies for a particular classification when used in conjunction with Tables 722.2.1.2(1) and 722.2.1.2(2).

**EXAMPLE:**

**GIVEN:** A sandwich wall panel consists of two 2 1/2-inch (63 mm) wythes of normal-weight concrete with a 2-inch (51 mm) layer of foam polystyrene between them.

**FIND:** Does the panel qualify for a 3-hour fire-resistance rating?

**SOLUTION:** From Table 722.2.1.2(1) in the code, the value of \( R^a = 8.1 + 2.5 + 8.1 = 18.7 \)

From Table 722.2.1.2(2), a 3-hour rating is required to have an \( R^a = 21.41 \).

18.7 < 21.41, thus the wall does not qualify for a 3-hour rating.

722.2.1.3 Joints between precast wall panels. Joints between precast concrete wall panels which are not insulated as required by this section shall be considered as openings in walls. Uninsulated joints shall be included in determining the percentage of openings permitted by Table 705.8. Where openings are not permitted or are required by this code to be protected, the provisions of this section shall be used to determine the amount of joint insulation required. Insulated joints shall not be considered openings for purposes of determining compliance with the allowable percentage of openings in Table 705.8.

722.2.1.3.1 Ceramic fiber joint protection. Figure 722.2.1.3.1 shows thicknesses of ceramic fiber blankets to be used to insulate joints between precast concrete wall panels for various panel thicknesses and for joint widths of 3/8 inch (9.5 mm) and 1 inch (25 mm) for fire-resistance ratings of 1 hour to 4 hours. For joint widths between 3/8 inch (9.5 mm) and 1 inch (25 mm), the thickness of ceramic fiber blanket is allowed to be determined by direct interpolation. Other tested and labeled materials are acceptable in place of ceramic fiber blankets.

Code Figure 722.2.1.3.1 was derived from data in the report entitled "Fire Tests of Joints Between Precast Concrete Wall Units: Effect of Various Joint Treatments" in the PCI Journal.

**EXAMPLE:**

**FIND:** Determine the thickness of a ceramic fiber blanket needed for a 2-hour fire-resistance rating for joints between 5-inch-thick (127 mm) precast concrete wall panels made of siliceous aggregate concrete if the maximum joint width is 3/8-inch (22.2 mm).

**SOLUTION:** Code Figure 722.2.1.3.1 indicates a minimum 0.7-inch (18 mm) thickness of ceramic fiber blanket for 5-inch (127 mm) panels for a 2-hour rating of a 3/8-inch (19.5 mm) wide joint and 2.1 inches (53
mm) for a 1-inch (25 mm) wide joint. By interpolation, the thickness is computed as follows:

\[ t = 2.1 - (2.1 - 0.7) \times (1 - \frac{h}{L}) = 1.93 \text{ inches} \]

Therefore, the required thickness for a 2-hour rating is 1.93 inches (49 mm).

722.2.1.4 Walls with gypsum wallboard or plaster finishes. The fire-resistance rating of cast-in-place or precast concrete walls with finishes of gypsum wallboard or plaster applied to one or both sides shall be permitted to be calculated in accordance with the provisions of this section.

- The information contained in this section is based on fire endurance tests on unit masonry walls with gypsum wallboard and the Supplement to the National Building Code of Canada 1980 (NRCC 17724) by the National Research Council of Canada.

For instance, a wall with a rating of 1 hour that has a 1-inch (25.4 mm) layer of Portland cement-sand plaster applied on metal lath would add 30 minutes to the rating. Therefore, the fire-resistance rating would now be 1 1/2 hours.

722.2.1.4.1 Nonfire-exposed side. Where the finish of gypsum wallboard or plaster is applied to the side of the wall not exposed to fire, the contribution of the finish to the total fire-resistance rating shall be determined as follows: The thickness of the finish shall first be corrected by multiplying the actual thickness of the finish by the applicable factor determined from Table 722.2.1.4(1) based on the type of aggregate in the concrete. The corrected thickness of finish shall then be added to the actual or equivalent thickness of concrete and fire-resistance rating of the concrete and finish determined from Table 722.2.1.1, Figure 722.2.1.2 or Table 722.2.1.2(1).

- The fire resistance of concrete walls is generally determined by temperature rise on the unexposed surface (i.e., the heat transmission end point) (see commentary, Section 722.2.1.1). The time required to reach the heat transmission end point (fire-resistance rating) is primarily dependent upon the thickness of the concrete and the type of aggregate used to make the concrete. When additional finishes are applied to the unexposed side of the wall, the time required to reach the heat transmission end point is delayed and the fire-resistance rating of the wall is thus increased.

The increase in the rating contributed by the finish can be determined by considering the finish as adding to the thickness of concrete; however, since the finish material and concrete may have different insulating properties, the actual thickness of the finish may need to be corrected to be compatible with the type of aggregate used in the concrete. The correction is made by multiplying the actual finish thickness by the factor determined from Table 722.2.1.4(1), and then adding the corrected thickness to the thickness of the concrete. This equivalent thickness is used to determine the fire-resistance rating from Table 722.2.1.1, Figure 722.2.1.2 or Table 722.2.1.2(1) of the code.

**TABLE 722.2.1.4(1). See below.**

- See the commentary to Section 722.2.1.4.1.

722.2.1.4.2 Fire-exposed side. Where gypsum wallboard or plaster is applied to the fire-exposed side of the wall, the contribution of the finish to the total fire-resistance rating shall be determined as follows: The time assigned to the finish as established by Table 722.2.1.4(2) shall be added to the fire-resistance rating determined from Table 722.2.1.1 or Figure 722.2.1.2, or Table 722.2.1.2(1) for the concrete alone, or to the rating determined in Section 722.2.1.4.1 for the concrete and finish on the nonfire-exposed side.

- Where finishes are added to the fire-exposed side of a concrete wall, their contribution to the total fire-resistance rating is based primarily upon the ability of the finish to remain in place, thus affording protection to the concrete wall. Table 722.2.1.4(2) lists the times that have been assigned to finishes on the fire-exposed side of the wall. These time-assigned values are based upon actual fire tests. The time-assigned values are added to the fire-resistance rating of the wall alone or to the rating determined for the wall and any finish on the unexposed side.

**TABLE 722.2.1.4(2). See page 7-163.**

- See the commentary to Section 722.2.1.4.2.

722.2.1.4.3 Nonsymmetrical assemblies. For a wall having no finish on one side or different types or thicknesses of finish on each side, the calculation procedures of Sections 722.2.1.4.1 and 722.2.1.4.2 shall be performed twice, assuming either side of the wall to be the fire-exposed side. The

For SI: 1 inch = 25.4 mm.

^a For Portland cement-sand plaster 1/4 inch or less in thickness and applied directly to the concrete or concrete masonry on the nonfire-exposed side of the wall, the multiplying factor shall be 1.00.

2012 INTERNATIONAL BUILDING CODE® COMMENTARY

7-162
**Fire-resistance rating** of the wall shall not exceed the lower of the two values.

**Exception:** For an exterior wall with a fire separation distance greater than 5 feet (1524 mm) the fire shall be assumed to occur on the interior side only.

- Except for exterior walls having more than 5 feet (1524 mm) of horizontal separation, Section 705.5 requires that walls be rated for exposure to fire from both sides; therefore, two calculations must be performed, which assumes each side of the wall to be the fire-exposed side. Two calculations are not necessary for exterior walls with more than 5 feet (1524 mm) of horizontal separation or for other walls that are symmetrical (i.e., walls having the same type and thickness of finish on each side). The calculated fire-resistance rating of the wall is the lower of the two ratings determined, assuming that each side is the fire-exposed side.

**722.2.1.4.4 Minimum concrete fire-resistance rating.** Where finishes applied to one or both sides of a concrete wall contribute to the fire-resistance rating, the concrete alone shall provide not less than one-half of the total required fire-resistance rating. Additionally, the contribution to the fire resistance of the finish on the nonfire-exposed side of a load-bearing wall shall not exceed one-half the contribution of the concrete alone.

- Where gypsum wallboard or plaster finishes are applied to a concrete wall, the calculated fire-resistance rating for the concrete alone should not be less than one-half the required fire-resistance rating. This limitation is necessary to ensure that the concrete wall is of sufficient thickness to withstand fire exposure.

**EXAMPLE:**

**GIVEN:** An exterior bearing wall of a building of Type IB construction with 4 feet (1216 mm) of horizontal separation is required to have a 2-hour fire-resistance rating. The wall will be cast in place with siliceous aggregate concrete. The interior will be finished with a 7/8-inch (12.7 mm) thickness of gypsum wallboard applied to steel furring members.

**FIND:** What is the minimum thickness of concrete required?

**SOLUTION:**

First calculation: Assume the interior to be the fire-exposed side.

1. From Table 722.2.1.4(2), the 1/2-inch (12.7 mm) gypsum wallboard has a time-assigned value of 15 minutes; therefore, the fire-resistance rating that must be developed by the concrete must not be less than 1 1/4 hours (2 hours - 15 minutes).

2. Since Table 722.2.1.1 does not include a minimum thickness requirement corresponding to 1 1/4 hours, direct interpolation between the val-

For SI: 1 inch = 25.4 mm.

a. The actual thickness of Portland cement-sand plaster, provided it is 3/4 inch or less in thickness, shall be permitted to be included in determining the equivalent thickness of the masonry for use in Table 722.3.2.
ues for 1\(\frac{1}{2}\) and 2 hours is acceptable. The interpolation results in a required thickness of 4.65 inches (118 mm) of concrete.

Second calculation: Assume the exterior to be the fire-exposed side.

1. From Table 722.2.1.4(1), the multiplying factor for gypsum wallboard and siliceous aggregate concrete is 1.25; therefore, the corrected thickness for 1\(\frac{1}{2}\) inch (12.7 mm) of gypsum wallboard is 0.63 inch (16.02 mm) [1.25 inches (32 mm) \times 1\(\frac{1}{2}\) inch (12.7 mm)].

2. Table 722.2.1.1 requires 5 inches (127 mm) of siliceous aggregate concrete for a 2-hour fire-resistance rating; therefore, the actual thickness of concrete required is 4.37 inches (111 mm) [5 inches (127 mm) – 0.63 inches (16 mm)].

3. Since the thickness of concrete required when assuming the interior side to be the fire-exposed side is greater, the minimum concrete thickness required to achieve a 2-hour fire-resistance rating is 4.65 inches (118 mm).

4. Section 722.2.1.4.4 requires that the concrete alone provides no less than one-half the total required rating; thus, the concrete must provide at least a 1-hour rating. From Table 722.2.1.1, it can be seen that only 3.5 inches (89 mm) of siliceous aggregate concrete is required for 1 hour, whereas 4.65 inches (118 mm) will be provided.

For a similar example problem, see the commentary to Section 722.3.2.4.

722.2.1.4.5 Concrete finishes. Finishes on concrete walls that are assumed to contribute to the total fire-resistance rating of the wall shall comply with the installation requirements of Section 722.3.2.5.

- See the commentary to Section 722.3.2.5.

722.2.2 Concrete floor and roof slabs. Reinforced and prestressed floors and roofs shall comply with Section 722.2.2.1. Multicourse floors and roofs shall comply with Sections 722.2.2.2 and 722.2.2.3, respectively.

- The fire test criteria for temperature rise of the unexposed surface and the ability to resist superimposed loads (heat transmission and structural criteria, respectively) must both be considered in determining the fire resistance of floors and roofs. Section 722.2.2 deals with heat transmission and Section 722.2.3 deals with structural criteria.

722.2.2.1 Reinforced and prestressed floors and roofs. The minimum thicknesses of reinforced and prestressed concrete floor or roof slabs for fire-resistance ratings of 1 hour to 4 hours are shown in Table 722.2.2.1.

- The criterion limiting the average temperature rise to 250°F (327°C) and the maximum rise at one point to 325°F (527°C) is often referred to as the “heat transmission end point.” For solid concrete slabs, the heat transmission end point is primarily a function of slab thickness and aggregate type. Other factors that affect heat transmission to a lesser degree are moisture content of the concrete, aggregate size, mortar content and air content. Factors that have very little effect on heat transmission are cement content and strength; type; amount and location of reinforcement, provided these items are within the normal range of usage. The values in Table 722.2.2.1 apply to concrete slabs reinforced with bars or welded wire fabric, as well as to prestressed slabs.

</tbody>
</table>

For SI: 1 inch = 25.4 mm.

- See the commentary to Section 722.2.2.1.

722.2.2.1.1 Hollow-core prestressed slabs. For hollow-core prestressed concrete slabs in which the cores are of constant cross section throughout the length, the equivalent thickness shall be permitted to be obtained by dividing the net cross-sectional area of the slab including grout in the joints, by its width.

- The method for determining equivalent thickness of masonry units was developed because the cores in masonry units taper. The method is, of course, also applicable to hollow-core precast concrete panels; however, because the cores in hollow-core panels do not taper, the equivalent thickness can be calculated by dividing the net cross-sectional area of the panel by its width.

722.2.2.1.2 Slabs with sloping soffits. The thickness of slabs with sloping soffits (see Figure 722.2.2.1.2) shall be determined at a distance 2\(t\) or 6 inches (152 mm), whichever is less, from the point of minimum thickness, where \(t\) is the minimum thickness.

- Some precast concrete wall panel sections (e.g., certain single-tee units) have tapered surfaces, so the
thickness varies, as shown in code Figure 722.2.2.1.2. In fire tests, it is customary to monitor the unexposed surface temperature at the location shown in the figure.

**722.2.2.1.3 Slabs with ribbed soffits.** The thickness of slabs with ribbed or undulating soffits (see Figure 722.2.2.1.3) shall be determined by one of the following expressions, whichever is applicable:

For $s > 4t$, the thickness to be used shall be $t$

For $s \leq 2t$, the thickness to be used shall be $t_e$

For $4t > s > 2t$, the thickness to be used shall be

$$t + \left( \frac{4t}{s} - 1 \right)(t_e - t)$$

(Equation 7-5)

where:

$s$ = Spacing of ribs or undulations.

$t$ = Minimum thickness.

$t_e$ = Equivalent thickness of the slab calculated as the net area of the slab divided by the width, in which the maximum thickness used in the calculation shall not exceed $2t$.

The portion of a ribbed slab that can be used in calculating equivalent thickness, $t_e$, is shown in code Figure 722.2.2.1.3. Note that the procedure does not give credit for joists in one- or two-way joisted floors or in double tees. For such sections, the minimum thickness of the deck slab must be used.

**EXAMPLE:**

**FIND:** Determine the fire-resistance rating of the floor section shown in code Figure 722.2.2.1.3(1) if the units were made of siliceous aggregate concrete.

**SOLUTION:**

$s$ = 12 inches.

$t$ = 4 inches.

Therefore:

$4t > s > 2t$ (16 inches > 12 inches > 8 inches)

$4''(12'') + (5'')(1.6'') + \left( \frac{1}{2}'' \right)(1'')(1.6'')$

$t_e = \frac{12''}{1.6''}$

$t_e = 4.8$ inches < $2t$.

Therefore the thickness to be used, $t_s$:

$t_s = 4'' + \left( \frac{4''}{12} - 1 \right)(4.8'' - 4'')$

$t_s = 4.27$ inches.

From Table 722.2.2.1, using interpolation, the fire-resistance rating of the floor section shown is 1.48 hours or 1 hour, 29 minutes.

**722.2.2.2 Multicourse floors.** The fire-resistance ratings of floors that consist of a base slab of concrete with a topping (overlay) of a different type of concrete shall comply with Figure 722.2.2.2.

- The information in this section is based on the report entitled "Fire Endurance of Two-course Floors and Roofs" in the *ACI Journal*.
722.2.3 Multicourse roofs. The fire-resistance ratings of roofs which consist of a base slab of concrete with a topping (overlay) of an insulating concrete or with an insulating board and built-up roofing shall comply with Figures 722.2.2.3(1) and 722.2.2.3(2).

- The information in this section is based on the report entitled "Fire Endurance of Two-course Floors and Roofs" in the ACI Journal.

722.2.2.3.1 Heat transfer. For the transfer of heat, three-ply built-up roofing contributes 10 minutes to the fire-resistance rating. The fire-resistance rating for concrete assemblies such as those shown in Figure 722.2.2.3(1) shall be increased by 10 minutes. This increase is not applicable to those shown in Figure 722.2.2.3(2).

722.2.2.4 Joints in precast slabs. Joints between adjacent precast concrete slabs need not be considered in calculating the slab thickness provided that a concrete topping at least 1 inch (25 mm) thick is used. Where no concrete topping is used, joints must be grouted to a depth of at least one-third the slab thickness at the joint, but not less than 1 inch (25 mm), or the joints must be made fire resistant by other approved methods.

- Based on data developed by UL, where a concrete topping is not used over precast concrete floors, joints must be grouted. If a concrete topping at least 1 inch thick (25 mm) is used, the joints need not be grouted.

722.2.3 Concrete cover over reinforcement. The minimum thickness of concrete cover over reinforcement in concrete slabs, reinforced beams and prestressed beams shall comply with this section.

- See the commentary to Sections 722.2.3.1 and 722.2.3.2.

722.2.3.1 Slab cover. The minimum thickness of concrete cover to the positive moment reinforcement shall comply with Table 722.2.3(1) for reinforced concrete and Table 722.2.3(2) for prestressed concrete. These tables are applicable for solid or hollow-core one-way or two-way slabs with flat undersurfaces. These tables are applicable to slabs that are either cast in place or precast. For precast prestressed concrete not covered elsewhere, the procedures contained in PCI MNL 124 shall be acceptable.

- The temperature of the tensile reinforcement depends on the thickness of cover and aggregate type. For unrestrained slabs, the values shown in Tables 722.2.3(1) and 722.2.3(2) are the cover thickness needed to keep the tensile reinforcement below 1,100°F (1922°C) and 800°F (1382°C), respectively.
FIRE AND SMOKE PROTECTION FEATURES

For restrained slabs, the temperature of the tensile reinforcement is not as critical, and thus, a minimum cover of \( 3/4 \) inch (19.5 mm) is specified in PCA Bulletin 223, "Fire Endurance of Concrete Slabs as Influenced by Thickness, Aggregate Type and Moisture."

### TABLE 722.2.3.2(1) See below.

- See the commentary to Section 722.2.3.1.
- See the commentary to Section 722.2.3.1.
- See the commentary to Section 722.2.3.2.
- See the commentary to Section 722.2.3.2.
- See the commentary to Section 722.2.3.2.

#### 722.2.3.2 Reinfoced beam cover. The minimum thickness of concrete cover to the positive moment reinforcement (bottom steel) for reinforced concrete beams is shown in Table 722.2.3(3) for fire-resistance ratings of 1 hour to 4 hours.

- For reinforced concrete beams, the critical steel temperature is 1,100°F (1922°C), so the effect of aggregate type is minimal. For prestressed concrete, the comparable temperature is 800°F (1382°C), so aggregate type must be considered. The data in Tables 722.2.3(3) and 722.2.3(4) was derived from the fire tests of a series of beam specimens that ranged in width between 2 and 24 inches (51 and 607 mm). Other variables in the series included aggregate type and amount of reinforcement. Tests were conducted at the PCA. The results of the fire tests of beams conducted at UL were also analyzed. Charts graphically showing the resulting data are shown in Figure A4 of PCI Manual 124, Design for Fire Resistance of Precast Prestressed Concrete.

</tbody>
</table>

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

- Tabulated values for restrained assemblies apply to beams spaced more than 4 feet on center. For restrained beams spaced 4 feet or less on center, minimum cover of \( 3/4 \) inch is adequate for ratings of 4 hours or less.
- For beam widths between the tabulated values, the minimum cover thickness can be determined by direct interpolation.
- The cover for an individual reinforcing bar is the minimum thickness of concrete between the surface of the bar and the fire-exposed surface of the beam. For beams in which several bars are used, the cover for corner bars used in the calculation shall be reduced to one-half of the actual value. The cover for an individual bar must be not less than one-half of the value given in Table 722.2.3(3) nor less than \( 3/4 \) inch.
722.2.3.3 Prestressed beam cover. The minimum thickness of concrete cover to the positive moment prestressing tendons (bottom steel) for restrained and unrestrained prestressed concrete beams and stemmed units shall comply with the values shown in Tables 722.2.3.4(a) and 722.2.3.5 for fire-resistance ratings of 1 hour to 4 hours. Values in Table 722.2.3.4 apply to beams 8 inches (203 mm) or greater in width. Values in Table 722.2.3.5 apply to beams or stems of any width, provided the cross-section area is not less than 40 square inches (25 806 mm²). In case of differences between the values determined from Table 722.2.3.4 or 722.2.3.5, it is permitted to use the smaller value. The concrete cover shall be calculated in accordance with Section 722.2.3.3.1. The minimum concrete cover for nonprestressed reinforcement in prestressed concrete beams shall comply with Section 722.2.3.2.

- See the commentary to Section 721.2.3.2.

</table>

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

a. Tabulated values for restrained assemblies apply to beams spaced more than 4 feet on center. For restrained beams spaced 4 feet or less on center, minimum cover of 1\(\frac{1}{4}\) inch is adequate for 4-hour ratings or less.

b. The cross-sectional area of a stem is permitted to include a portion of the area in the flange, provided the width of the flange used in the calculation does not exceed three times the average width of the stem.

c. U-shaped or hooped stirrups spaced not to exceed the depth of the member and having a minimum cover of 1 inch shall be provided.

2012 INTERNATIONAL BUILDING CODE® COMMENTARY
722.2.4 Concrete columns. Concrete columns shall comply with this section.

- Most building code provisions for reinforced concrete columns are based on two reports: "Fire Tests of Building Columns" of the Associated Factory Mutual Insurance Companies and "Fire Resistance of Concrete Columns" by the NBS. Sizes of the tested columns were 12 inches (305 mm), 16 inches (406 mm) and 18 inches (457 mm). Nearly all of the columns withstood 4-hour fire tests that were essentially conducted in accordance with ASTM E 119 or UL 263. Most of the tests were stopped after 4 hours, but some were continued to 8 hours. The shortest duration was 3 hours. At the time of the tests few, if any, concrete columns were smaller than 12 inches (305 mm), but smaller columns have been in use for many years since then.

- Fire tests conducted in Europe on smaller columns indicate that fire endurance is greater for larger columns.

</tbody>
</table>

For SI: 1 inch = 25 mm.

- The minimum dimension is permitted to be reduced to 8 inches for rectangular columns with two parallel sides at least 36 inches in length.
- The minimum dimension is permitted to be reduced to 10 inches for rectangular columns with two parallel sides at least 36 inches in length.

- Table 722.2.4 reflects the information cited in the reports listed in the commentary to Section 722.2.4 and in the report "Investigations on Building Fires: Part VI: Fire Resistance of Reinforced Concrete Columns" in the National Building Studies Research Paper No. 18. This table is for columns that may be exposed to fire on all four sides. Notes a and b to Table 722.2.4 permit a smaller minimum dimension for columns than required in the table, provided the longer dimension of the column is at least 36 inches (914 mm).

- Minimum size. The minimum overall dimensions of reinforced concrete columns for fire-resistance ratings of 1 hour to 4 hours for exposure to fire on all sides comply with this section.

- Column requirements are based on provisions in ACI 216.1-07/TMS 0216.1-07, Code Requirements for Determining Fire Resistance of Concrete and Masonry Construction Assemblies, the successor to ACI 216.1-97/TMS 0216.1-97.

722.2.4.1 Concrete strength less than or equal to 12,000 psi. For columns made with concrete having a specified compressive strength, \(f'_{c}\), of less than or equal to 12,000 psi (82.7 MPa), the minimum dimension shall comply with Table 722.2.4.

- For concrete with compressive strength less than 12,000 psi (82.7 MPa), the minimum dimensions necessary to achieve certain fire-resistance ratings are given by Table 722.2.4. Concrete compressive strengths used in building construction are normally in the range of 4,000 to 6,000 psi (27.6 to 41.4 MPa) so this section and Table 722.2.4 are operative most of the time in determining fire-resistance ratings for concrete.

722.2.4.1.2 Concrete strength greater than 12,000 psi. For columns made with concrete having a specified compressive strength, \(f'_{c}\), greater than 12,000 psi (82.7 MPa), for fire-resistance ratings of 1 hour to 4 hours the minimum dimension shall be 24 inches (610 mm).

- Concrete with a compressive strength greater than 12,000 psi (82.7 MPa) is very rarely used in building construction. The concrete is very stiff, with a very low water-to-cement ratio, and therefore is very difficult to work with. Because it contains very small air pockets and voids, the material conducts heat relatively quickly when compared to more common concrete with compressive strengths in the 4,000 to 6,000 psi (27.6 to 41.4 MPa) range. Therefore, the minimum thickness necessary to achieve a fire-resistance rating of 1 to 4 hours is considerably higher.

722.2.4.2 Minimum cover for R/C columns. The minimum thickness of concrete cover to the main longitudinal reinforcement in columns, regardless of the type of aggregate used in the concrete and the specified compressive strength of concrete, \(f'_{c}\), shall not be less than 1 inch (25 mm) times the number of hours of required fire resistance or 2 inches (51 mm), whichever is less.

- The minimum concrete cover refers to the main longitudinal reinforcement, not ties or spirals.

722.2.4.3 Tie and spiral reinforcement. For concrete columns made with concrete having a specified compressive strength, \(f'_{c}\), greater than 12,000 psi (82.7 MPa), tie and spiral reinforcement shall comply with the following:

1. The free ends of rectangular ties shall terminate with a 135-degree (2.4 rad) standard tie hook.
2. The free ends of circular ties shall terminate with a 90-degree (1.6 rad) standard tie hook.
3. The free ends of spirals, including at lap splices, shall terminate with a 90-degree (1.6 rad) standard tie hook.

The hook extension at the free end of ties and spirals shall be the larger of six bar diameters and the extension required by Section 7.1.3 of ACI 318. Hooks shall project into the core of the column.

- The intent of the provisions in this section is to prevent ties or spirals from disengaging from the longitudinal reinforcement should the concrete cover over the ties or spirals be lost during a fire. The section expands on the provisions found in ACI 216.1/TMS...
0216.1 by addressing spiral reinforcement, which is typically used for lateral reinforcement in round columns.

722.2.4.4 Columns built into walls. The minimum dimensions of Table 722.2.4 do not apply to a reinforced concrete column that is built into a concrete or masonry wall provided all of the following are met:

1. The fire-resistance rating for the wall is equal to or greater than the required rating of the column;
2. The main longitudinal reinforcing in the column has cover not less than that required by Section 722.2.4.2; and
3. Openings in the wall are protected in accordance with Table 716.5.

Where openings in the wall are not protected as required by Section 716.5, the minimum dimension of columns required to have a fire-resistance rating of 3 hours or less shall be 8 inches (203 mm), and 10 inches (254 mm) for columns required to have a fire-resistance rating of 4 hours, regardless of the type of aggregate used in the concrete.

Table 722.2.4 does not apply to columns built into concrete or masonry walls that meet all three of the conditions in this section.

722.2.4.5 Precast cover units for steel columns. See Section 722.5.1.4.

722.3 Concrete masonry. The provisions of this section contain procedures by which the fire-resistance ratings of concrete masonry are established by calculations.

722.3.1 Equivalent thickness. The equivalent thickness of concrete masonry construction shall be determined in accordance with the provisions of this section.

722.3.1.1 Concrete masonry unit plus finishes. The equivalent thickness of concrete masonry assemblies, $T_{eq}$, shall be computed as the sum of the equivalent thickness of the concrete masonry unit, $T_c$, as determined by Section 722.3.1.2, 722.3.1.3 or 722.3.1.4, plus the equivalent thickness of finishes, $T_f$, determined in accordance with Section 722.3.2:

$$T_{eq} = T_c + T_f$$

(Equation 7-6)

722.3.1.2 Ungrooved or partially grooved construction. $T_c$ shall be the value obtained for the concrete masonry unit determined in accordance with ASTM C 140.

722.3.1.3 Solid grooved construction. The equivalent thickness, $T_c$, of solid grooved concrete masonry units is the actual thickness of the unit.

722.3.1.4 Airspaces and cells filled with loose-fill material. The equivalent thickness of completely filled hollow concrete masonry is the actual thickness of the unit when loose-fill materials are: sand, pea gravel, crushed stone, or slag that meet ASTM C 33 requirements; pumice, scoria, expanded shale, expanded clay, expanded slate, expanded slag, expanded fly ash, or cinders that comply with ASTM C 331; or perlite or vermiculite meeting the requirements of ASTM C 549 and ASTM C 516, respectively.

722.3.2 Concrete masonry walls. The fire-resistance rating of walls and partitions constructed of concrete masonry units shall be determined from Table 722.3.2. The rating shall be based on the equivalent thickness of the masonry and type of aggregate used.

- It has been accepted practice to determine the fire-resistance rating of concrete masonry walls based on the type of aggregate used to manufacture them and the equivalent thickness of solid material in the wall. Equivalent thicknesses shown in Table 722.3.2 have been developed and refined through actual fire testing.

To determine the minimum equivalent thickness, Section 722.3.1.2 references ASTM C 140.

**EXAMPLE:**

**FIND:** Determine the equivalent thickness of a standard 8-inch by 8-inch by 16-inch (203 mm by 203 mm by 406 mm) concrete masonry unit. The unit is normal weight with sand and gravel aggregate.

**SOLUTION:** The equivalent thickness is actually the average thickness of the solid material in the unit. The equivalent thickness is determined by the following:

$$T_e = 1728 \frac{A}{L \times H}$$

where:

$T_e$ = Equivalent thickness, in.
$A$ = Net volume of unit, ft$^3$.
$L$ = Length of unit, in.
$H$ = Height of unit, in.

Net volume, $A$, is determined by the following equation:

$$A = \frac{C}{D}$$

where:

$C$ = Dry weight of unit, pounds.
$D$ = Density of unit, pounds per cubic foot.

From data furnished by the manufacturer, the dry unit weight is 44 pounds (20 kg) and the density is 135 pounds per cubic foot (pcf) (2115 kg/m$^3$).

$$T_e = \frac{(1.728 \text{ in.}^3/\text{ft.}^3)(0.326 \text{ ft.}^3)}{(15.625 \text{ in.})(7.625 \text{ in.})}$$

$T_e = 4.73$ inches (120 mm).

The fire-resistance rating for this type of unit with siliceous gravel aggregate can now be determined from Table 722.3.2. In this case, the fire-resistance rating will fall between 2.25 and 2.5 hours.

**TABLE 722.3.2.** See page 7-171.

- See the commentary to Section 722.3.2.

722.3.2.1 Finish on nonfire-exposed side. Where plaster or gypsum wallboard is applied to the side of the wall not exposed to fire, the contribution of the finish to the total fire-resistance rating shall be determined as follows: The thickness of gypsum wallboard or plaster shall be corrected by multiplying the actual thickness of the finish by applicable
FIRE AND SMOKE PROTECTION FEATURES

factor determined from Table 722.2.1.4(1). This corrected thickness of finish shall be added to the equivalent thickness of the fire-resistance rating of the wall alone or to the rating determined for the wall and finish determined from Table 722.3.2.

The information contained in this section is based on Fire Endurance Tests on Unit Masonry Walls with Gypsum Wallboard and The Supplement to the National Building Code of Canada 1980 by the National Research Council of Canada.

The fire resistance of concrete masonry walls is generally determined by temperature rise on the unexposed surface (i.e., the "heat transmission" end point). The time required to reach the heat transmission end point (fire-resistance rating) is primarily dependent upon the equivalent thickness of the masonry and the type of aggregate used to make the concrete. When additional finishes are applied to the unexposed side of the wall, the time required to reach the heat transmission end point is increased; thus, the fire-resistance rating of the wall is increased. The increase in the rating contributed by the finish can be determined by considering the finish as an addition to the equivalent thickness of masonry; however, since the finish material and masonry may have different insulating properties, the actual thickness of the finish must be multiplied by a correction factor to be compatible with the type of aggregate used in the concrete. The correction is made by multiplying the actual finish thickness by the factor determined from Table 722.2.1.4(1), then adding the modified thickness to the equivalent thickness of masonry. This combined equivalent thickness is used to determine the fire-resistance rating from Table 722.3.2.

**722.3.2.2 Finish on fire-exposed side.** Where plaster or gypsum wallboard is applied to the fire-exposed side of the wall, the contribution of the finish to the total fire-resistance rating shall be determined as follows: The time assigned to the finish as established by Table 722.2.1.4(2) shall be added to the fire-resistance rating determined in Section 722.3.2 for the masonry alone, or in Section 722.3.2.1 for the masonry and finish on the nonfire-exposed side.

Where finishes are added to the fire-exposed side of a concrete masonry wall, their contribution to the total fire-resistance rating is based primarily upon their ability to remain in place, thus affording protection to the masonry wall. Table 722.2.1.4(2) lists the times that have been assigned to finishes on the fire-exposed side of the wall. These time-assigned values are based upon actual fire tests. The time-assigned values are added to the fire-resistance rating of the wall alone or to the rating determined for the wall and any finish on the unexposed side.

**722.3.2.3 Nonsymmetrical assemblies.** For a wall having no finish on one side or having different types or thicknesses of finish on each side, the calculation procedures of this section shall be performed twice, assuming either side of the wall to be the fire-exposed side. The fire-resistance rating of the wall shall not exceed the lower of the two values calculated.

Exception: For exterior walls with a fire separation distance greater than 5 feet (1524 mm) the fire shall be assumed to occur on the interior side only.

Except for exterior walls having more than 5 feet (1524 mm) of FSD, Section 704.5 requires that walls be rated for exposure to fire from both sides; therefore, two calculations must be performed, which assumes each side to be the fire-exposed side. Two calculations are not necessary for exterior walls with an FSD of more than 5 feet (1524 mm) or for other walls that are symmetrical (i.e., walls having the same type and thickness of finish on each side). The calculated fire-resistance rating must not exceed the lower of the two ratings determined, assuming that each side is the fire-exposed side.

**722.3.2.4 Minimum concrete masonry fire-resistance rating.** Where the finish applied to a concrete masonry wall contributes to its fire-resistance rating, the masonry alone shall provide not less than one-half the total required fire-resistance rating.

Where gypsum wallboard or plaster finishes are applied to a concrete masonry wall, the calculated fire-resistance rating for the concrete alone should be not less than one-half the required fire-resistance rating. This limitation is necessary to ensure that the masonry wall is of sufficient thickness to withstand fire exposure.

<table>

<td>1.9</td>
</tr>
<tr>
<td>Calcareous or siliceous gravel</td>
<td>2.0</td>
</tr>
</tbody>
</table>

For SI: 1 inch = 25.4 mm.

a. Values between those shown in the table can be determined by direct interpolation.

b. Where combustible members are framed into the wall, the thickness of solid material between the end of each member and the opposite face of the wall, or between members set in from opposite sides, shall not be less than 93 percent of the thickness shown in the table.

c. Requirements of ASTM C 55, ASTM C 73, ASTM C 90 or ASTM C 744 shall apply.

d. Minimum required equivalent thickness corresponding to the hourly fire-resistance rating for units with a combination of aggregate shall be determined by linear interpolation based on the percent by volume of each aggregate used in manufacture.
EXAMPLE:

GIVEN: A wall required to have a 4-hour fire-resistance rating will be constructed with concrete masonry units of expanded shale aggregate. The wall will be finished on each side with a layer of \( \frac{1}{2} \)\text{inch} (12.7 \text{ mm}) gypsum wallboard.

FIND: What is the minimum equivalent thickness of concrete masonry required?

SOLUTION: Since the wall has the same type and thickness of finish on each side, only one calculation is required.

1. The \( \frac{1}{2} \)\text{inch} (12.7 \text{ mm}) gypsum wallboard on the fire-exposed side has a time-assigned value of 15 minutes in accordance with Table 722.2.1.4(2).

2. Therefore, the fire resistance required to be provided by the masonry and gypsum wallboard on the unexposed side is 3 hours and 45 minutes (4 hours - 15 minutes).

3. From Table 722.2.1.4(1), the corrected thickness of gypsum wallboard on the unexposed side is \( \frac{1}{2} \)\text{inch} (12.7 \text{ mm}) (1.00 \times \frac{1}{2} \text{inch}).

4. From Table 722.3.2, the minimum equivalent thickness of masonry, including the corrected thickness of gypsum wallboard, required for a rating of 3 hours and 45 minutes is 4.9 inches (124 mm).

5. Therefore, the equivalent thickness of masonry required is 4.4 inches (112 mm) [4.9 inches (124 mm) - \( \frac{1}{2} \)\text{inch} (12.7 mm)].

6. From Table 722.3.2, it can be determined that 4.4 inches (112 mm) expanded shale aggregate concrete masonry will provide a fire resistance of 3 hours; therefore, the requirement that the masonry alone provide at least one-half of the total required rating is satisfied.

For a similar example problem, see the commentary to Section 722.2.1.4.

722.3.2.5 Attachment of finishes. Installation of finishes shall be as follows:

1. Gypsum wallboard and gypsum lath applied to concrete masonry or concrete walls shall be secured to wood or steel furring members spaced not more than 16 inches (406 mm) on center (o.c.).

2. Gypsum wallboard shall be installed with the long dimension parallel to the furring members and shall have all joints finished.

3. Other aspects of the installation of finishes shall comply with the applicable provisions of Chapters 7 and 25.

722.3.3 Multiwythe masonry walls. The fire-resistance rating of wall assemblies constructed of multiple wythes of masonry materials shall be permitted to be based on the fire-resistance rating period of each wythe and the continuous airspace between each wythe in accordance with the following formula:

\[
R_A = \left( R_1^{0.59} + R_2^{0.59} + \ldots + R_n^{0.59} + A_1 + A_2 + \ldots + A_n \right)^{1.7}
\]

(Equation 7-7)

where:

- \( R_0 = \) Fire-resistance rating of the assembly (hours).
- \( R_1, R_2, \ldots, R_n = \) Fire-resistance rating of wythes for 1, 2, \( \ldots, n \) (hours), respectively.
- \( A_1, A_2, \ldots, A_n = 0.30 \) factor for each continuous airspace for 1, 2, \( \ldots, n \), respectively, having a depth of \( \frac{1}{2} \)\text{inch} (12.7 \text{ mm}) or more between wythes.

This calculation method was first published in Report BMS 92 of the NBS.

722.3.4 Concrete masonry lintels. Fire-resistance ratings for concrete masonry lintels shall be determined based on the nominal thickness of the lintel and the minimum thickness of concrete masonry or concrete, or any combination thereof, covering the main reinforcing bars, as determined according to Table 722.3.4, or by approved alternate methods.

<table>
<thead>
<tr>

For SI: 1 inch = 25.4 mm.

722.4 Clay brick and tile masonry. The provisions of this section contain procedures by which the fire-resistance ratings of clay brick and tile masonry are established by calculation.

722.4.1 Masonry walls. The fire-resistance rating of masonry walls shall be based upon the equivalent thickness as calculated in accordance with this section. The calculation shall take into account finishes applied to the wall and airspaces between wythes in multiwythe construction.

722.4.1.1 Equivalent thickness. The fire-resistance ratings of walls or partitions constructed of solid or hollow clay masonry units shall be determined from Table 722.4.1(1) or...
722.4.1(2). The equivalent thickness of the clay masonry unit shall be determined by Equation 7-8 when using Table 722.4.1(1). The fire-resistance rating determined from Table 722.4.1(1) shall be permitted to be used in the calculated fire-resistance rating procedure in Section 722.4.2.

\[ T_e = \sqrt{V_n / LH} \]  
(Equation 7-8)

where:

- \( T_e \) = The equivalent thickness of the clay masonry unit (inches).
- \( V_n \) = The net volume of the clay masonry unit (in cubic inches)\(^{1}\).
- \( L \) = The specified length of the clay masonry unit (inches).
- \( H \) = The specified height of the clay masonry unit (inches).

\( \nabla \) It has been accepted practice to determine the fire-resistance ratings of clay masonry walls by the ASTM E 119 or UL 263 test method. In fact, Table 722.4.1(1) is based on tests performed by various laboratories in conformance with ASTM E 119 or UL 263. Most notable are the NBS, Ohio State University Experiment Station and the University of California at Berkeley. New methods, however, have been developed to evaluate the fire resistance of clay masonry by the equivalent thickness method, similar to concrete masonry. This approach was used in conjunction with extensive testing previously performed on clay masonry to develop Table 722.4.1(1).

722.4.1.1.1 Hollow clay units. The equivalent thickness, \( T_e \), shall be the value obtained for hollow clay units as determined in accordance with Equation 7-8. The net volume, \( V_n \), of the units shall be determined using the gross volume and percentage of void area determined in accordance with ASTM C 67.

722.4.1.1.2 Solid grouted clay units. The equivalent thickness of solid grouted clay masonry units shall be taken as the actual thickness of the units.

722.4.1.1.3 Units with filled cores. The equivalent thickness of the hollow clay masonry units is the actual thickness of the unit when completely filled with loose-fill materials of: sand, pea gravel, crushed stone, or slag that meet ASTM C 33 requirements; pumice, scoria, expanded shale, expanded clay, expanded slate, expanded slag, expanded fly ash, or cinders.

For SI: 1 inch = 25.4 mm.
in compliance with ASTM C 331; or perlite or vermiculite meeting the requirements of ASTM C 549 and ASTM C 516, respectively.

**722.4.1.2 Plaster finishes.** Where plaster is applied to the wall, the total fire-resistance rating shall be determined by the formula:

\[ R = (R_{n,59} + pl)^{1.7} \]  
(Equation 7-9)

where:

- \( R \) = The fire-resistance rating of the assembly (hours).
- \( R_{n} \) = The fire-resistance rating of the individual wall (hours).
- \( pl \) = Coefficient for thickness of plaster.

Values for \( R_{n,59} \) for use in Equation 7-9 are given in Table 722.4.1(3). Coefficients for thickness of plaster shall be selected from Table 722.4.1(4) based on the actual thickness of plaster applied to the wall or partition and whether one or two sides of the wall are plastered.

The variables for use in Equation 7-9 for determining the fire-resistance rating of plastered clay masonry walls are based on BMS 92, *Fire Resistance Classifications of Building Construction* of the NBS. These values were derived from fire test results. The average thickness of plaster applied in the series of tests ranged from \( \frac{1}{2} \) inch (12.7 mm) to \( \frac{3}{4} \) inch (19.1 mm). The thickness for which the coefficients of plaster in Table 722.4.1(4) are given are those most likely to be applied to a clay masonry wall. Ratings for other thicknesses provided can be obtained by substituting the appropriate coefficients in the formula.

A test of four hollow concrete unit walls shows the effect of one coat of plaster on the fire-exposed side to be about the same as for one coat of plaster on the unexposed side. Tests have not been made with plaster on the unexposed side of only clay hollow walls; however, the ratings resulting from Equation 7-9 for clay or tile masonry walls for plaster on one side are believed to have a sufficient margin of safety to be applicable to either the exposed or unexposed side of the wall.

**EXAMPLE:**

**GIVEN:** A 4-inch (102 mm) solid brick wall is required to have a 3-hour fire-resistance rating with clay masonry units.

**FIND:** The thickness of one side of plaster required to attain a 3-hour rating.

**SOLUTION:**

1. From Table 722.4.1(1), a 2-hour solid brick wall is 3.8 inches (99 mm) of equivalent thickness and a 3-hour wall is 4.9 inches (124 mm). Through interpolation (Note a), a 4-inch (102 mm) wall is approximately a 131-minute (2.18 hours) fire rating.

2. From Table 722.4.1(4), plaster has a coefficient of 0.3 for \( \frac{1}{2} \) inch thick (12.7 mm) plaster, 0.37 for \( \frac{3}{8} \) inch thick (15.9 mm) plaster or 0.45 for \( \frac{3}{4} \) inch (19.1 mm) thick plaster.

3. From Equation 7-9:

\[ R = (R_{n,59} + pl)^{1.7} \]

where:

- \( R = 3 \)
- \( R_{n} = 2.18 \)
- \( 3 = [(2.18)^{0.59} + pl]^{1.7} \)
- \( 1.91 = 1.584 + pl \)
- \( pl = .326. \)

4. Therefore, one coat of \( \frac{3}{4} \) inch-thick (15.9 mm) sanded gypsum plaster on a 4-inch (102 mm) solid brick masonry wall would result in a 3-hour fire-resistance rating.

722.4.1.3 Multiwythe walls with airspace. Where a continuous airspace separates multiple wythes of the wall or partition, the total fire-resistance rating shall be determined by the formula:

\[
R = (R_1^{0.59} + R_2^{0.59} + \ldots + R_w^{0.59} + as)^{1.7} \quad (\text{Equation 7-10})
\]

where:
- \( \hat{R} \) = The fire-resistance rating of the assembly (hours).
- \( R_1, R_2 \) and \( R_w \) = The fire-resistance rating of the individual wythes (hours).
- \( as \) = Coefficient for continuous airspace.

Values for \( R_w^{0.59} \) for use in Equation 7-10 are given in Table 722.4.1(3). The coefficient for each continuous airspace of \( \frac{1}{2} \) inch to \( 3\frac{1}{2} \) inches (12.7 to 89 mm) separating two individual wythes shall be 0.3.

Tests have shown that a continuous airspace separating two wythes of masonry can also increase the fire-resistance rating of a clay masonry wall. According to BMS 92 of the NBS, the coefficient for continuous airspace (as) between \( \frac{1}{2} \) inch (12.7 mm) and \( 3\frac{1}{2} \) inches (89 mm) is 0.3. Equation 7-10 provides the formula for calculating the fire-resistance ratings involving an airspace if the fire-resistance rating of the wythes separated by the airspace is known. The fire-resistance ratings for various wythes can be obtained from Tables 722.4.1(1) and 722.4.1(2). The procedure for using Equation 7-10 is the same as Equation 7-9, except that a coefficient for airspace (as) is substituted for the coefficient of plaster (p).

722.4.1.4 Nonsymmetrical assemblies. For a wall having no finish on one side or having different types or thicknesses of finish on each side, the calculation procedures of this section shall be performed twice, assuming either side to be the fire-exposed side of the wall. The fire resistance of the wall shall not exceed the lower of the two values determined.

Exception: For exterior walls with a fire separation distance greater than 5 feet (1524 mm), the fire shall be assumed to occur on the interior side only.

- Except for exterior walls having an FSD of more than 5 feet (1524 mm), Section 704.5 requires that walls be rated for exposure to fire from both sides; therefore, two calculation procedures must be performed, which assumes each side to be the fire-exposed side. Two calculations are not necessary for exterior walls with an FSD of more than 5 feet (1524 mm) or for other walls that are symmetrical (i.e., having the same type and thickness of finish on each side). The calculated fire-resistance rating must not exceed the lower of the two values determined, assuming that each side is the fire-exposed side.

722.4.2 Multiwythe walls. The fire-resistance rating for walls or partitions consisting of two or more dissimilar wythes shall be permitted to be determined by the formula:

\[
\hat{R} = (R_1^{0.59} + R_2^{0.59} + \ldots + R_n^{0.59})^{1.7} \quad (\text{Equation 7-11})
\]

where:
- \( \hat{R} \) = The fire-resistance rating of the assembly (hours).
- \( R_1, R_2 \) and \( R_n \) = The fire-resistance rating of the individual wythes (hours).

Values for \( R_n^{0.59} \) for use in Equation 7-11 are given in Table 722.4.1(3).

 Typically, the fire-resistance-rating period for clay masonry walls is determined by the temperature rise on the unexposed side of the wall. This criterion is what Equation 7-11 is based on. According to the general theory of heat transmission, if walls of the same material are exposed to a heat source that maintains a constant surface temperature on the exposed side and the unexposed side is protected against heat loss, the time in which a given temperature will be attained on the unexposed side will vary as the square of the wall thickness does.

In the standard ASTM E 119 or UL 263 test, which involves specified conditions of temperature measurement and a fire that increases the temperature at the exposed surface of the wall as the test proceeds, the time required to attain a given temperature rise on the unexposed side will differ when the temperature on the exposed side remains constant at the initial exposure temperature for any period. A degree of correlation between test results and calculations can be obtained by assuming the variation to be according to a lower power of \( n \) than the second. The fire resistance of the wall can then be expressed by the formula:

\[
\hat{R} = (CV)^n
\]

where:
- \( \hat{R} \) = Fire-resistance period;
- \( C \) = Coefficient depending on the material, design of the wall and the units of measurement of \( R \) and \( V \);
- \( V \) = Volume of solid material per unit area of wall surface; and
- \( n \) = Exponent depending on the rate of increase of temperature at the exposed face of the wall.

For walls of a given material and design, it was found that an increase of 50 percent in volume of solid material per unit area of wall surface resulted in a 100-percent increase in the fire-resistance period. This correlates to a value of 1.7 for \( n \). A value of \( n \) less than 2 is expected, since an increasing temperature on the exposed surface would tend to shorten the fire-resistance rating of walls that would qualify for a higher rating.
FIRE AND SMOKE PROTECTION FEATURES

The fire-resistance rating of a wall may be expressed in terms of the fire-resistance rating of the conjoined wythes or laminae of the wall as follows:

\[ R_i = (C_i V_i)^{n_i} \]
\[ R_j = (C_j V_j)^{n_j} \]
\[ R_n = (C_n V_n)^{n_n} \]

where \( R_i, R_j \) and \( R_n \) are the fire resistances of each conjoined wythe.

The fire-resistance period of the composite wall will be:

\[ R = \left( \sum_{i=1}^{n} C_i V_i \right)^{n_0} \]
\[ R = (C_1 V_1 + C_2 V_2 + \ldots + C_n V_n)^{n_0} \]

Substituting for \( C_i V_i, C_j V_j \) and \( C_n V_n \) from the above relations yields:

\[ R = (R_1^{1/n_0} + R_2^{1/n_0} + \ldots + R_n^{1/n_0})^{n_0} \]

Substituting 1.7 for \( n_0 \) and 0.59 for \( 1/n_0 \) the general formula becomes:

\[ R = (R_1^{0.59} + R_2^{0.59} + \ldots + R_n^{0.59})^{1.7} \]

Equation 7-11 was developed by the NBS in the early 1940s and first appeared in Appendix B of BMS 92. It is noted that the fire-resistance rating has been expressed in terms of the fire-resistance rating of the component laminae of the wall, which need not be of the same material and design.

722.4.2.1 Multiwythe walls of different material. For walls that consist of two or more wythes of different materials (concrete or concrete masonry units) in combination with clay masonry units, the fire-resistance rating of the different materials shall be permitted to be determined from Table 722.2.1.1 for concrete; Table 722.3.2 for concrete masonry units or Table 722.4.1(1) or 722.4.1(2) for clay and tile masonry units.

- A multiwythe wall (i.e., a wall consisting of two or more dissimilar materials) has a greater fire-resistance rating than a simple summation of the fire-endurance rating of the various layers. Equation 7-11 permits a calculated fire-resistance rating if the fire-resistance endurance rating is known for each dissimilar material. This section lists the applicable tables from Section 722 that can be used in conjunction with clay masonry walls to determine the total fire-resistance rating of a multiwythe wall composed of a combination of concrete, concrete masonry or clay masonry units.

722.4.3 Reinforced clay masonry lintels. Fire-resistance ratings for clay masonry lintels shall be determined based on the nominal width of the lintel and the minimum covering for the longitudinal reinforcement in accordance with Table 722.4.1(5).

722.4.4 Reinforced clay masonry columns. The fire-resistance ratings shall be determined based on the last plan dimension of the column in accordance with Table 722.4.1(6). The minimum cover for longitudinal reinforcement shall be 2 inches (51 mm).

722.5 Steel assemblies. The provisions of this section contain procedures by which the fire-resistance ratings of steel assemblies are established by calculations.

722.5.1 Structural steel columns. The fire-resistance ratings of steel columns shall be based on the size of the element and the type of protection provided in accordance with this section.

![Figure 722.5.1(1) Determination of the Heated Perimeter of Structural Steel Columns](image)

722.5.1.1 General. These procedures establish a basis for determining the fire resistance of column assemblies as a function of the thickness of fire-resistant material and the weight, \( W \), and heated perimeter, \( D \), of steel columns. As used in these sections, \( W \) is the average weight of a structural steel column in pounds per linear foot. The heated perimeter, \( D \), is the inside perimeter of the fire-resistant material in inches as illustrated in Figure 722.5.1(1).

722.5.1.1.2 Embedments. In the absence of substantiating fire-endurance test results, ducts, conduit, piping, and similar mechanical, electrical, and plumbing installations shall not be embedded in any required fire-resistant materials.

722.5.1.3 Weight-to-perimeter ratio. Table 722.5.1(1) contains weight-to-heated-perimeter ratios (\( W/D \)) for both contour and box fire-resistant profiles, for the wide flange shapes most often used as columns. For different fire-resistant protection profiles or column cross sections, the weight-to-heated-perimeter ratios (\( W/D \)) shall be determined in accordance with the definitions given in this section.

722.5.1.2 Gypsum wallboard protection. The fire resistance of structural steel columns with weight-to-heated-perimeter ratios (\( W/D \)) less than or equal to 3.65 and which are protected with Type X gypsum wallboard shall be permitted to be determined from the following expression:

\[ R = 130 \left[ \frac{h(W/D)^{0.75}}{2} \right] \]  

(Equation 7-12)

where:

- \( R \) = Fire resistance (minutes).
FIRE AND SMOKE PROTECTION FEATURES

\[ h = \text{Total thickness of gypsum wallboard (inches).} \]
\[ D = \text{Heated perimeter of the structural steel column (inches).} \]
\[ W' = \text{Total weight of the structural steel column and gypsum wallboard protection (pounds per linear foot).} \]
\[ W'' = W + 50hD/144. \]

722.5.1.2.1 Attachment. The gypsum wallboard shall be supported as illustrated in either Figure 722.5.1.(2) for fire-resistance ratings of 4 hours or less, or Figure 722.5.1.(3) for fire-resistance ratings of 3 hours or less.

EXAMPLE:

GIVEN: A W/12 x 136 column protected by 1/2-inch (12.7 mm) Type X gypsum wallboard as shown in Figure 722.5.1.2.1.

- SNAP-LOCK
- PITTSBURGH SEAM
- LAP

Corner Joint Details (A)

FIGURE 722.5.1.(2)
GYPSUM WALLBOARD PROTECTED STRUCTURAL STEEL COLUMNS WITH SHEET STEEL COLUMN COVERS

For SI: 1 inch = 25.4 mm, 1 foot = 305 mm.

1. Structural steel column, either wide flange or tubular shapes.
2. Type X gypsum wallboard in accordance with ASTM C 1396. For single-layer applications, the wallboard shall be applied vertically with no horizontal joints. For multiple-layer applications, horizontal joints are permitted at a minimum spacing of 8 feet, provided that the joints in successive layers are staggered at least 12 inches. The total required thickness of wallboard shall be determined on the basis of the specified fire-resistance rating and the weight-to-heated-perimeter ratio (W/D) of the column. For fire-resistance ratings of 2 hours or less, one of the required layers of gypsum wallboard may be applied to the exterior of the sheet steel column covers with 1-inch long Type S screws spaced 1 inch from the wallboard edge and 8 inches on center. For such installations, 0.014-inch minimum thickness galvanized steel corner beads with 1/2-inch legs shall be attached to the wallboard with Type S screws spaced 12 inches on center.
3. For fire-resistance ratings of 3 hours or less, the column covers shall be fabricated from 0.0239-inch minimum thickness galvanized or stainless steel. For 4-hour fire-resistance ratings, the column covers shall be fabricated from 0.0239-inch minimum thickness stainless steel. The column covers shall be erected with the Snap Lock or Pittsburgh joint details.
For fire-resistance ratings of 2 hours or less, column covers fabricated from 0.0239-inch minimum thickness galvanized or stainless steel shall be permitted to be erected with lap joints. The lap joints shall be permitted to be located anywhere around the perimeter of the column cover. The lap joints shall be secured with 1/2-inch-long No. 8 sheet metal screws spaced 12 inches on center.

The column covers shall be provided with a minimum expansion clearance of 1/32 inch per linear foot between the ends of the cover and any restraining construction.

FIND: The fire-resistance rating of the column.

SOLUTION:

1. The heated perimeter \( D = 2(12.4 \text{ inches} + 13.4 \text{ inches}) = 51.6 \text{ inches} (1311 \text{ mm}). \)
2. \( W' = 136 + (50)(0.5)(51.6)/144 = 144.96. \)
3. \( W'' = 144.96 / 51.62 = 2.81. \)
4. \( R = 130(0.5)(2.81)/2^{0.75} = 99.7 \text{ minutes (1.66 hours)}. \)
5. Alternatively, from Table 722.5.1(1), the W/D ratio for a W/12 x 136 is tabulated as 2.63. From Figure 722.5.1.(4) using a W/D ratio of 2.63 and

FIGURE 722.5.1.(3)
GYPSUM WALLBOARD PROTECTED STRUCTURAL STEEL COLUMNS WITH STEEL STUD/ScreW ATTACHMENT SYSTEM

For SI: 1 inch = 25.4 mm, 1 foot = 305 mm.

1. Structural steel column, either wide flange or tubular shapes.
2. 1 1/2-inch deep studs fabricated from 0.0179-inch minimum thickness galvanized steel with 1 1/16 or 1 3/4-inch legs. The length of the steel studs shall be 1/2 inch less than the height of the assembly.
3. Type X gypsum wallboard in accordance with ASTM C 1396. For single-layer applications, the wallboard shall be applied vertically with no horizontal joints. For multiple-layer applications, horizontal joints are permitted at a minimum spacing of 8 feet, provided that the joints in successive layers are staggered at least 12 inches. The total required thickness of wallboard shall be determined on the basis of the specified fire-resistance rating and the weight-to-heated-perimeter ratio (W/D) of the column.
4. Galvanized 0.0149-inch minimum thickness steel corner beads with 1/2-inch legs attached to the wallboard with 1-inch-long Type S screws spaced 12 inches on center.
5. No. 18 SWG steel tie wires spaced 24 inches on center.
6. Sheet metal angles with 2-inch legs fabricated from 0.0221-inch minimum thickness galvanized steel.
7. Type S screws, 1 inch long, shall be used for attaching the first layer of wallboard to the steel studs and the third layer to the sheet metal angles at 24 inches on center. Type S screws 1 1/2-inch long shall be used for attaching the second layer of wallboard to the steel studs and the fourth layer to the sheet metal angles at 12 inches on center. Type S screws 2 1/4 inches long shall be used for attaching the third layer of wallboard to the steel studs at 12 inches on center.
1/2-inch (12.7 mm) gypsum wallboard, an R-value of approximately 1.6 hours is obtained.

**722.5.1.2.2 Gypsum wallboard equivalent to concrete.** The determination of the fire resistance of structural steel columns from Figure 722.5.1(4) is permitted for various thicknesses of gypsum wallboard as a function of the weight-to-heated-perimeter ratio (W/D) of the column. For structural steel columns with weight-to-heated-perimeter ratios (W/D) greater than 3.65, the thickness of gypsum wallboard required for specified fire-resistance ratings shall be the same as the thickness determined for a W14 x 233 wide flange shape.

**722.5.1.3 Sprayed fire-resistant materials.** The fire resistance of wide-flange structural steel columns protected with sprayed fire-resistant materials, as illustrated in Figure 722.5.1(5), shall be permitted to be determined from the following expression:

\[
R = \left[ C_1 \left( \frac{W}{D} \right) + C_2 \right] h
\]

(Equation 7-13)

where:

- \( R \) = Fire resistance (minutes).
- \( h \) = Thickness of sprayed fire-resistant material (inches).

For SI: 1 inch = 25.4 mm. 1 pound per linear foot/inch = 0.059 kg/m/mm.

**FIGURE 722.5.1(4)**

FIRE RESISTANCE OF STRUCTURAL STEEL COLUMNS PROTECTED WITH VARIOUS THICKNESSES OF TYPE X GYPSUM WALLBOARD

a. The W/D ratios for typical wide flange columns are listed in Table 721.5.1(1). For other column shapes, the W/D ratios shall be determined in accordance with Section 722.5.1.1.

**FIGURE 721.5.1(5)**

WIDE FLANGE STRUCTURE STEEL COLUMNS WITH SPRAYED FIRE-RESISTANT MATERIALS

**Figure 722.5.1.2.1**

EXAMPLE—STEEL COLUMN PROTECTED WITH WALLBOARD

For SI: 1 inch = 25.4 mm.
$D$ = Heated perimeter of the structural steel column (inches).

$C_1$ and $C_2$ = Material-dependent constants.

$W$ = Weight of structural steel columns (pounds per linear foot).

The fire resistance of structural steel columns protected with intumescent or mastic fire-resistant coatings shall be determined on the basis of fire-resistance tests in accordance with Section 703.2.

- This section sets forth procedures for determining the fire resistance of structural steel columns protected with spray-applied cementitious or mineral fiber fire protection materials. These procedures do not apply to intumescent or mastic fire-resistant coatings, which must be tested in accordance with the requirements found in Section 703.2. These procedures are based upon an empirical equation, which includes two material-dependent constants. As a result, in order to apply this equation, the values of these two constants must be determined for specific fire protection materials. The purpose of this section is to provide guidance for the determination of these constants so that the resulting equation will be reasonably accurate, and yet slightly conservative, over the range of column shapes for the test data that is available.

Two different techniques are available for determining the two constants. The first requires a knowledge of thermal conductivity and specific heat of the fire protection material at elevated temperatures. Data of this nature is both difficult and expensive to obtain with any reasonable degree of accuracy. As a result, this technique will probably not be widely used, and accordingly, it will not be described in this section.

The second technique involves the use of Equation 7-13 as a means for interpolating between ASTM E 119 or UL 263 fire endurance test results on different structural steel columns. Since this technique will undoubtedly be the most widely used, it is described in detail in this section. It is, however, important to recognize that a wide variety of both large- and small-scale tests can be used to accurately determine the required constants. Inherent in Equation 7-13 is the fact that the ratio of fire endurance time to the thickness of fire protection material ($R/h$) varies linearly as a function of the increasing $W/D$ ratio of the protected steel column. These concepts are graphically illustrated in the example that follows. It has been found that this assumption is reasonably accurate for lightweight [density less than 50 pcf (801 kg/m³)] spray-applied materials.

If ASTM E 119 or UL 263 fire endurance test results are available for a specific fire protection material on two different structural steel column shapes, the constants $C_1$ and $C_2$ can be determined directly. The resulting equation can then be used to determine the thickness of fire protection material required for any specified fire endurance rating when applied to structural steel columns with $W/D$ ratios between the largest and smallest column for the actual test results that are available.

To determine the constants, at least four ASTM E 119 or UL 263 fire endurance tests or a combination of two ASTM E 119 or UL 263 fire endurance tests and six small-scale tests [3-foot-long (914 mm) specimens] are conducted. If the results of the small-scale tests are used, at least two of the test assemblies are necessary to duplicate the ASTM E 119 or UL 263 test assemblies for the purpose of establishing correlation. Regardless of the combination of small- and large-scale tests selected, at least two tests are conducted on the largest and two on the smallest columns to establish the limits of applicability to the resulting equation. The constants $C_1$ and $C_2$ are to be determined on the basis of the lowest ratios of fire endurance time to fire protection thickness ($R/h$) for these columns.

In addition, the test data need to be evaluated with respect to the assumption that the ratio of fire endurance to fire protection thickness ($R/h$) is reasonably constant for a given column shape [(W/D) ratio]. The tests conducted on columns of the same shape are designed so that the resulting fire endurance times are approximately 1$1/2$ and 3$1/2$ hours. In evaluating the $R/h$ ratios resulting from tests on the same column shape, differences in the range of 10 percent are typical. Differences greater than 20 percent may, however, suggest that Equation 7-13 is not applicable to the specific fire protection material under consideration, and further examination of the test data is warranted.

EXAMPLE:

**GIVEN:** The fire endurance test data given in Figure 722.5.1.3.

**FIND:** The thickness of a spray-applied cementitious material required for a 3-hour rating on a W12 × 136.

**SOLUTION:**

1. Determine $C_1$ and $C_2$. From the end points of the graph:

   - $R/h = 75$ for a $W/D$ ratio of 0.6 and
   - $R/h = 200$ for a $W/D$ ratio of 2.5.

   From this, two equations with two unknowns are created:

   $75 = C_1 (0.6) + C_2$

   $200 = C_1 (2.5) + C_2$

   Solving these equations, $C_1 = 20$ and $C_2 = 50$.

   Then, $R/h = 50/C_1 + 20/C_2$.
Solving these results in: \( C_1 = 65.79 \); \( C_2 = 35.53 \) and Equation 7-13, with \( h \) in the denominator, becomes:
\[
R/h = 65.79 \times (W/D) + 35.53.
\]

2. From Table 722.5.1(1), a \( W/12 \times 136 \) has a \( W/D \) ratio of 1.82.

3. The required fire resistance is 180 minutes. Calculating for \( h \) yields:
\[
180 = [(65.79)(1.82) + 35.53]h
\]
\[
h = 1.16 \text{ inches (29 mm).}
\]

Therefore, the required thickness of the spray-applied material is 1.16 inches (29 mm).

**722.5.1.3.1 Material-dependent constants.** The material-dependent constants, \( C_1 \) and \( C_2 \), shall be determined for specific fire-resistant materials on the basis of standard fire endurance tests in accordance with Section 703.2. Unless evidence is submitted to the building official substantiating a broader application, this expression shall be limited to determining the fire resistance of structural steel columns with weight-to-heated-perimeter ratios \((W/D)\) between the largest and smallest columns for which standard fire-resistance test results are available.

**722.5.1.3.2 Identification.** Sprayed fire-resistant materials shall be identified by density and thickness required for a given fire-resistance rating.

**722.5.1.4 Concrete-protected columns.** The fire resistance of structural steel columns protected with concrete, as illustrated in Figure 722.5.1(6) (a) and (b), shall be permitted to be determined from the following expression:
\[
R = R_e(1 + 0.03d)
\]
(Equation 7-14)

where:
\[
R_e = 10 \times (W/D)^{0.7} + 17 \times (h^{0.4}/k)^{0.3} \times \frac{1}{[1 + 26 \times (H/r_c h (L + h))^{0.8}]}
\]

As used in these expressions:

- \( R \) = Fire endurance at equilibrium moisture conditions (minutes).
- \( R_e \) = Fire endurance at zero moisture content (minutes).
- \( m \) = Equilibrium moisture content of the concrete by volume (percent).

![Fire Endurance Test Result](image)

**CONCRETE PROTECTED STRUCTURAL STEEL COLUMNS**

- (a) Precast Concrete Column Covers
- (b) Concrete Encased Structural Tube
- (c) Concrete Encased Wide-Flange Shape

a. When the inside perimeter of the concrete protection is not square, \( L \) shall be taken as the average of \( L_1 \) and \( L_2 \). When the thickness of concrete cover is not constant, \( h \) shall be taken as the average of \( h_1 \) and \( h_2 \).

b. Joints shall be protected with a minimum 1 inch thickness of ceramic fiber blanket but in no case less than one-half the thickness of the column cover (see Section 722.2.1.3).
W = Average weight of the steel column (pounds per linear foot).

D = Heated perimeter of the steel column (inches).

h = Thickness of the concrete cover (inches).

k_c = Ambient temperature thermal conductivity of the concrete (Btu/hr ft °F).

H = Ambient temperature thermal capacity of the steel column = 0.11W (Btu/ft °F).

\( \rho_c = \) Concrete density (pounds per cubic foot).

\( c_c = \) Ambient temperature specific heat of concrete (Btu/lb °F).

L = Interior dimension of one side of a square concrete box protection (inches).

**EXAMPLE:**

**GIVEN:** A W8 \( \times 28 \) steel column encased in lightweight concrete \([\text{density} = 110 \text{pcf (1762 kg/m}^3])\) shown in Figure 722.5.1(4), with all reentrant spaces filled with concrete cover 1.25 inches (32 mm) and a moisture content of 5 percent. The web thickness is 0.285 inches.

**FIND:** The fire-resistance rating.

**SOLUTION:**

\[ D = 4(6.535) + 2(8.06) - 2(0.285) = 41.69 \text{ inches (1059 mm).} \]

\[ W/D = 28 \text{ lb/ft}/41.69^2 = 0.67 \text{ lb/ft} \cdot \text{in}. \]

\[ h = 1.25 \text{ inches (32 mm).} \]

\[ k_c = 0.35 \text{ Btu/hr} \cdot \text{°F}. \]

\[ c_c = 0.20 \text{ Btu/lb} \cdot \text{°F}. \]

\[ \rho_c = 110 \text{ pcf (1762 kg/m}^3). \]

\[ L = (6.535 + 8.06)/2 = 7.30 \text{ inches (185 mm).} \]

\[ A_s = 8.25 \text{ square inches (.005 m}^2). \]

\[ H = 11(28) + [(110)(.20)/144][(6.535)(8.06) - 8.25] = 9.87 \]

\[ R_0 = 10(0.67)^{0.7} + 17[(1.25)^{1.6}]/[(0.35)^{0.2}]^{0.8} \]

\[ 1 + 26\left[\frac{9.87}{(110)(0.2)(1.25)(7.3 + 1.25)}\right]^{0.8} \]

\[ R_0 = 99 \text{ minutes.} \]

Therefore,

\[ R = 99[1 + 0.33(5)] = 114 \text{ minutes.} \]

For comparison purposes, the minimum cover requirement for a W8 \( \times 28 \) steel column from Table 722.5.1(8) is 1 inch (25 mm) for a 1 1/2-hour rating. The column does not quite meet the required fire rating for a 2-hour column since 1.5 inches (38 mm) is required; therefore, the fire resistance of the column is 1 1/2 hours.

722.5.1.4.1 Reentrant space filled. For wide-flange steel columns completely encased in concrete with all reentrant spaces filled [Figure 722.5.1(6)(c)], the thermal capacity of the concrete within the reentrant spaces shall be permitted to be added to the thermal capacity of the steel column, as follows:

\[ H = 0.11W \times \left( \frac{\rho_c c_c}{144} \right) (b_r - A_s) \]

(Equation 7-15)

where:

\[ b_r = \text{Flange width of the steel column (inches).} \]

\[ d = \text{Depth of the steel column (inches).} \]

\[ A_s = \text{Cross-sectional area of the steel column (square inches).} \]

722.5.1.4.2 Concrete properties unknown. If specific data on the properties of concrete are not available, the values given in Table 722.5.1(2) are permitted.

722.5.1.4.3 Minimum concrete cover. For structural steel column encased in concrete with all reentrant spaces filled, Figure 722.5.1(6)(c) and Tables 722.5.1(7) and 722.5.1(8) indicate the thickness of concrete cover required for various fire-resistance ratings for typical wide-flange sections. The thicknesses of concrete indicated in these tables also apply to structural steel columns larger than those listed.

722.5.1.4.4 Minimum precast concrete cover. For structural steel columns protected with precast concrete column covers as shown in Figure 722.5.1(6)(a), Tables 722.5.1(9) and 722.5.1(10) indicate the thickness of the column covers required for various fire-resistance ratings for typical wide-flange shapes. The thicknesses of concrete given in these tables also apply to structural steel columns larger than those listed.

722.5.1.4.5 Masonry protection. The fire resistance of structural steel columns protected with concrete masonry units or clay masonry units as illustrated in Figure 722.5.1(7), shall be permitted to be determined from the following expression:

\[ R = 0.17 \left( \frac{W}{D} \right)^{0.7} + \left[ 0.285 \left( \frac{T_e}{K} \right)^{0.6} \left( 1.0 + 42.7 \left( \frac{A_s}{d_m} \right) \left( \frac{0.25p + T_e}{0.8} \right) \right) \right] \]

(Equation 7-16)

where:

\[ R = \text{Fire-resistance rating of column assembly (hours).} \]

\[ W = \text{Average weight of steel column (pounds per foot).} \]

\[ D = \text{Heated perimeter of steel column (inches) [see Figure 722.5.1(7)].} \]

\[ T_e = \text{Equivalent thickness of concrete or clay masonry unit (inches) [see Table 722.3.2 Note a or Section 722.4.1].} \]

\[ K = \text{Thermal conductivity of concrete or clay masonry unit (Btu/hr} \cdot \text{ft} \cdot \text{°F) [see Table 722.5.1(3)].} \]

\[ A_s = \text{Cross-sectional area of steel column (square inches).} \]

\[ d_m = \text{Density of the concrete or clay masonry unit (pounds per cubic foot).} \]

\[ p = \text{Inner perimeter of concrete or clay masonry protection (inches) [see Figure 722.5.1(7)].} \]
FIRE AND SMOKE PROTECTION FEATURES

722.5.1.4.6 Equivalent concrete masonry thickness. For structural steel columns protected with concrete masonry, Table 722.5.1(5) gives the equivalent thickness of concrete masonry required for various fire-resistance ratings for typical column shapes. For structural steel columns protected with clay masonry, Table 722.5.1(6) gives the equivalent thickness of concrete masonry required for various fire-resistance ratings for typical column shapes.

722.5.2 Structural steel beams and girders. The fire-resistance ratings of steel beams and girders shall be based upon the size of the element and the type of protection provided in accordance with this section.

722.5.2.1 Determination of fire resistance. These procedures establish a basis for determining the fire resistance of structural steel beams and girders which differ in size from that specified in approved fire-resistant-rated assemblies as a function of the thickness of fire-resistant material and the weight (W) and heated perimeter (D) of the beam or girder. As used in these sections, W is the average weight of a structural steel member in pounds per linear foot (psf). The heated perimeter, D, is the inside perimeter of the fire-resistant material in inches as illustrated in Figure 722.5.2.

722.5.2.1.1 Weight-to-heated perimeter. The weight-to-heated-perimeter ratios (W/D), for both contour and box fire-resistant protection profiles, for the wide flange shapes most often used as beams or girders are given in Table 722.5.1(4). For different shapes, the weight-to-heated-perimeter ratios (W/D) shall be determined in accordance with the definitions given in this section.

722.5.2.1.2 Beam and girder substitutions. Except as provided for in Section 722.5.2.2, structural steel beams in approved fire-resistant-rated assemblies shall be considered the minimum permissible size. Other beam or girder shapes shall be permitted to be substituted provided that the weight-to-heated-perimeter ratio (W/D) of the substitute beam is equal to or greater than that of the beam specified in the approved assembly.

This section defines a general rule for the substitution of different steel beam and girder shapes in all fire-resistant assemblies. In the past, the substitution of larger beams has been permitted based upon the thickness of web and flange elements. Extensive research at UL has proven that the heat transfer to a protected steel beam or girder is a direct function of the W/D ratio. As a result, beam substitutions should be based upon W/D ratios, as defined in this section. The significance of the thickness of web and flange elements is inherently included in the determination of W/D ratios. Figure 722.5.2 illustrates the procedure for determining heated perimeters (D), and Table 722.5.1(4) provides W/D ratios for the most commonly used wide flange beam and girder shapes.

For SI: 1 inch = 25.4 mm.

*The tabulated thicknesses are based upon the assumed properties of structural lightweight concrete given in Table 722.5.1(2).*
722.5.2.2 Sprayed fire-resistant materials. The provisions in this section apply to structural steel beams and girders protected with sprayed fire-resistant materials. Larger or smaller beam and girder shapes shall be permitted to be substituted for beams specified in approved unrestrained or restrained fire-resistance-rated assemblies, provided that the thickness of the fire-resistant material is adjusted in accordance with the following expression:

\[
h_2 = h_1 \left( \left( \frac{W_1}{D_1} \right) + 0.60 \right) \left( \left( \frac{W_2}{D_2} \right) + 0.60 \right)
\]

(Equation 7-17)

where:

- \( h = \) Thickness of sprayed fire-resistant material in inches.
- \( W = \) Weight of the structural steel beam or girder in pounds per linear foot.
- \( D = \) Heated perimeter of the structural steel beam in inches.

Subscript 1 refers to the beam and fire-resistant material thickness in the approved assembly.

Subscript 2 refers to the substitute beam or girder and the required thickness of fire-resistant material.

The fire resistance of structural steel beams and girders protected with intumescent or mastic fire-resistant coatings shall be determined on the basis of fire-resistance tests in accordance with Section 703.2.

This section defines an equation for adjusting the thickness of spray-applied cementitious and mineral fiber materials as a function of \( W/D \) ratios. This equation was developed by UL, and appropriate limitations have been included. The minimum \( W/D \) ratio of 0.37 in Section 722.5.2.2.1 will prevent the use of this equation for determining the fire resistance of very small shapes that have not been tested. The \( \frac{3}{8} \) inch (9.5 mm) minimum thickness of protection is a practical limit based upon the most commonly used spray-applied fire protection materials.

EXAMPLE:

GIVEN: Determine the thickness of spray-applied fire protection required to provide a 2-hour fire-resistance rating for a W12 × 16 beam to be substituted for a W8 × 15 beam requiring 1.44 inches (37 mm) of protection for the same rating.

SOLUTION:

From Table 722.5.1(4):

\[
\begin{align*}
W_1/D_1 & = 0.54 \text{ for W8 × 15} \\
W_2/D_2 & = 0.45 \text{ for W12 × 16} \\
h_1 & = 1.44 \text{ inches.} \\
\end{align*}
\]

\[
h_2 = \frac{0.54 + 0.60}{0.45 + 0.60} + 1.44 = 1.56 \text{ inches (39 mm).}
\]

It is noted within this section that intumescent or mastic fire-resistant coatings are required to be tested in accordance with the requirements of Section 703.2.

722.5.2.2.1 Minimum thickness. The use of Equation 7-17 is subject to the following conditions:

1. The weight-to-heated-perimeter ratio for the substitute beam or girder \( W_2/D_2 \) shall not be less than 0.37.
2. The thickness of fire protection materials calculated for the substitute beam or girder \( T_2 \) shall not be less than \( \frac{3}{8} \) inch (9.5 mm).
3. The unrestrained or restrained beam rating shall not be less than 1 hour.
4. When used to adjust the material thickness for a restrained beam, the use of this procedure is limited to steel sections classified as compact in accordance with the AISC Specification for Structural Steel Buildings, (AISC 360-05).

This section describes the application of spray-applied fire protection to structural steel trusses when each truss element is individually protected with spray-applied materials. The thickness of protection is determined using the column equation specified in Section 722.5.1.3. For trusses, the column equation is more technically correct than the beam equation, since it requires greater thicknesses of protection than the beam equation. Most truss elements can be exposed to fire on all sides simultaneously. As a result, the heated perimeter of truss elements should be determined in the same manner as for columns. However, an exception is included for top chord elements that directly support floor or roof construction. The heated perimeter of such elements should be determined in the same manner as for beams and girders.

This section notes that intumescent and mastic fire-resistant materials must be tested in accordance with the requirements in Section 703.2.
722.6 Wood assemblies. The provisions of this section contain procedures by which the fire-resistance ratings of wood assemblies are established by calculations.

- The information contained in this section is based on Technical Paper No. 222 of the Division of Building Research Council of Canada entitled “Fire Endurance of Light Framed and Miscellaneous Assemblies” and NBS Report BMS 92. The fire-resistance rating is equal to the sum of the time assigned to the membranes [see Table 722.6.2(1)], the time assigned to the framing members [see Table 722.6.2(2)] and the time assigned for additional contribution by other protective measures, such as insulation [see Table 722.6.2(5)]. The membrane on the unexposed side is not included in the calculations. It is assumed that once the structural members fail, the entire assembly fails. The time assigned to the individual membranes is individual contributions to the overall fire-resistance rating of the complete assembly. The assigned time is not to be confused with the fire-resistance rating of the membranes. Fire-resistance rating takes into account the rise in temperature on the unexposed side of the membrane. Times that have been assigned to membranes on the fire-exposed side of the assembly are based on their ability to remain in place during fire tests.

- The fire-resistance rating of wood-frame assemblies is equal to the sum of the time assigned to the various components (membranes) on the fire-exposed side and the structural members. Interior walls and partitions; exterior walls within 5 feet (1524 mm) of a lot line or assumed lot line and some shaft walls must be designed for fire resistance by assuming that either side of the wall is exposed to fire.

- Mineral fiber insulation provides additional protection to wood studs by shielding the studs from exposure to the furnace, thus delaying the time of collapse. The use of reinforcement in the membrane exposed to fire also adds to the fire resistance by extending the time to failure. Special care must be taken to ensure that all insulation materials used in conjunction with this method satisfy the weight criteria of Table 722.6.2(5).

- The following are examples of how to use this section:

**EXAMPLE 1:**

**GIVEN:** The exterior wall assembly shown in Figure 722.6 having a layer of 15/32-inch (12 mm) wood structural panel bonded with exterior glue covered with a layer of 13/32-inch (15.8 mm) gypsum wallboard and attached to studs spaced at 16 inches (406 mm) on center (o.c.).

**FIND:** Does the wall assembly qualify as a 1-hour fire-resistant wall assembly?

**SOLUTION:** From Tables 722.6.2(1) and 722.6.2(2):

<table>
<thead>
<tr>
<th>Wood structural panel</th>
<th>10 minutes.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gypsum wallboard</td>
<td>30 minutes</td>
</tr>
</tbody>
</table>

Wood studs = 20 minutes.
Total = 60 minutes.

Therefore, the wall does qualify as a 1-hour wall. If the wall is an interior wall, both sides would be required to be fire protected with at least 40 minutes of membrane coverings (60 minutes - 20 minutes for wood frame).

---

![Diagram of wall assembly](image)

**FIRE EXPOSED SIDE**

For SI: 1 inch = 25.4 mm.

**Figure 722.6**

**EXAMPLE—WOOD STUD WALL WITH WALLBOARD**

**TABLE 722.6.2(1)**

<table>
<thead>
<tr>
<th>DESCRIPTION OF FINISH</th>
<th>TIME(minutes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>13/16-inch wood structural panel bonded with exterior glue</td>
<td>5</td>
</tr>
<tr>
<td>11/32-inch wood structural panel bonded with exterior glue</td>
<td>10</td>
</tr>
<tr>
<td>15/32-inch wood structural panel bonded with exterior glue</td>
<td>15</td>
</tr>
<tr>
<td>1/8-inch gypsum wallboard</td>
<td>10</td>
</tr>
<tr>
<td>1/8-inch gypsum wallboard</td>
<td>15</td>
</tr>
<tr>
<td>3/16-inch gypsum wallboard</td>
<td>30</td>
</tr>
<tr>
<td>1/4-inch Type X gypsum wallboard</td>
<td>25</td>
</tr>
<tr>
<td>3/8-inch Type X gypsum wallboard</td>
<td>40</td>
</tr>
<tr>
<td>Double 1/8-inch gypsum wallboard</td>
<td>25</td>
</tr>
<tr>
<td>1/8-inch + 1/4-inch gypsum wallboard</td>
<td>35</td>
</tr>
<tr>
<td>Double 1/4-inch gypsum wallboard</td>
<td>40</td>
</tr>
</tbody>
</table>

For SI: 1 inch = 25.4 mm.

a. These values apply only when membranes are installed on framing members which are spaced 16 inches o.c. or less.

b. Gypsum wallboard installed over framing or furring shall be installed so that all edges are supported, except 1/8-inch Type X gypsum wallboard shall be permitted to be installed horizontally with the horizontal joints staggered 24 inches each side and unsupported but finished.

c. On wood frame floor/ceiling or roof/ceiling assemblies, gypsum board shall be installed with the long dimension perpendicular to framing members and shall have all joints finished.

d. The membrane on the unexposed side shall not be included in determining the fire resistance of the assembly. When dissimilar membranes are used on a wall assembly, the calculation shall be made from the least fire-resistant (weaker) side.

e. The time assigned is not a finished rating.
It should be noted that Section 722.6.2.3 requires the exterior side to be protected in accordance with Table 722.6.2(3) or any membrane that is assigned a time of at least 15 minutes as listed in Table 722.6.2(1).

It should also be noted that if the wall cavities between the studs are filled with mineral fiber batts weighing no less than that specified in Table 722.6.2(5), the 3/8-inch (12 mm) plywood membrane layer could be eliminated because the insulation adds 15 minutes of fire resistance, as indicated in Section 722.6.2.5 and Table 722.6.2(5). Thus, adding the contribution times for the 3/8-inch (15.9 mm) gypsum board, the wood framing and the insulation (30 minutes + 20 minutes + 15 minutes), the resultant rating for the wall would be 65 minutes and meet a 1-hour fire-resistance rating.

<td><strong>DESCRIPTION OF ADDITIONAL PROTECTION</strong></td>
</tr>
<tr>
<td>Add to the fire-resistance rating of wood stud walls if the spaces between the studs are completely filled with glass fiber mineral wool batts weighing not less than 2 pounds per cubic foot (0.6 pound per square foot of wall surface) or rockwool or slag material wool batts weighing not less than 3.3 pounds per cubic foot (1 pound per square foot of wall surface), or cellulose insulation having a nominal density not less than 2.5 pounds per cubic foot.</td>
</tr>
</tbody>
</table>

For SI: 1 pound/cubic foot = 16.0185 kg/m³.
EXAMPLE 2:

GIVEN: A floor/ceiling assembly using wood joists spaced at 16 inches (406 mm) o.c., protected on the bottom side (ceiling side) with two layers of $1/4$-inch (12.7 mm) Type X gypsum wallboard and protected on the upper side (floor side) with a $1/8$-inch (12 mm) plywood subfloor, a $1/2$-inch (15.9 mm) panel-type underlayment and carpet.

FIND: Does the floor/ceiling assembly meet the requirements of a 1-hour fire-resistance-rated assembly?

SOLUTION: Referring to Sections 722.6.2.1 and 722.6.2.4, Table 722.6.2(1) indicates that the time contribution for each layer of $1/4$-inch (12.7 mm) Type X gypsum wallboard is 25 minutes. The time of contribution for wood joists 16 inches (406 mm) o.c. is listed in Table 722.6.2(2) as 10 minutes. By adding the two layers of gypsum board ($2 \times 25$ minutes) to the wood frame (10 minutes), a fire-resistance rating of 60 minutes, or 1 hour, can be obtained. It should be noted that Section 722.6.2.4 requires the upper membrane to be specified as in Table 722.6.2(4) or any membrane that has a time of contribution of at least 15 minutes as listed in Table 722.6.2(1).

If the above example had been a roof/ceiling assembly, the upper membrane would have been treated the same. If the proposed assembly is a ceiling with an attic above, Section 722.6.2.4 notes the exception to Section 711.3.3, which allows the elimination of the upper membrane.

The fastening requirements for assemblies developed by Section 722.6 should be in accordance with Chapter 23 as stated in Section 722.6.2.6.

722.6.1 General. This section contains procedures for calculating the fire-resistance ratings of walls, floor/ceiling and roof/ceiling assemblies based in part on the standard method of testing referenced in Section 703.2.

722.6.1.1 Maximum fire-resistance rating. Fire resistance ratings calculated for assemblies using the methods in Section 722.6 shall be limited to a maximum of 1 hour.

722.6.1.2 Dissimilar membranes. Where dissimilar membranes are used on a wall assembly, the calculation shall be made from the least fire-resistant (weaker) side.

All wood assemblies by which the fire-resistance rating is calculated must have a membrane on each side; however, the calculation shall be made from the least fire-resistant side.

722.6.2 Walls, floors and roofs. These procedures apply to both load-bearing and nonload-bearing assemblies.

722.6.2.1 Fire-resistance rating of wood frame assemblies. The fire-resistance rating of a wood frame assembly is equal to the sum of the time assigned to the membrane on the fire-exposed side, the time assigned to the framing members and the time assigned for additional contribution by other protective measures such as insulation. The membrane on the unexposed side shall not be included in determining the fire resistance of the assembly.

722.6.2.2 Time assigned to membranes. Table 722.6.2(1) indicates the time assigned to membranes on the fire-exposed side.

722.6.2.3 Exterior walls. For an exterior wall with a fire separation distance greater than 10 feet (3048 mm), the wall is assigned a rating dependant on the interior membrane and the framing as described in Tables 722.6.2(1) and 722.6.2(2). The membrane on the outside of the nonfire-exposed side of exterior walls with a fire separation distance greater than 10 feet (3048 mm) may consist of sheathing, sheathing paper and siding as described in Table 722.6.2(3).

722.6.2.4 Floors and roofs. In the case of a floor or roof, the standard test provides only for testing for fire exposure from below. Except as noted in Section 703.3, Item 5, floor or roof assemblies of wood framing shall have an upper membrane consisting of a subfloor and finished floor conforming to Table 722.6.2(4) or any other membrane that has a contribution to fire resistance of at least 15 minutes in Table 722.6.2(1).

722.6.2.5 Additional protection. Table 722.6.2(5) indicates the time increments to be added to the fire resistance where glass fiber, rockwool, slag mineral wool or cellulose insulation is incorporated in the assembly.

722.6.2.6 Fastening. Fastening of wood frame assemblies and the fastening of membranes to the wood framing members shall be done in accordance with Chapter 23.

722.6.3 Design of fire-resistant exposed wood members. The fire-resistance rating, in minutes, of timber beams and columns with a minimum nominal dimension of 6 inches (152 mm) is equal to:

Beams: $2.54Zd [4 - (b/b)] for beams which may be exposed to fire on four sides.

Columns: $2.54Zd [3 - (d/2b)] for columns which may be exposed to fire on four sides.

where:

$\begin{align*}
  b &= \text{The breadth (width) of a beam or larger side of a column before exposure to fire (inches).} \\
  d &= \text{The depth of a beam or smaller side of a column before exposure to fire (inches).} \\
  Z &= \text{Load factor, based on Figure 722.6.3(1).}
\end{align*}$

(Equation 7-18)

(Equation 7-19)

(Equation 7-20)

(Equation 7-21)
722.6.3.1 Equation 7-21. Equation 7-21 applies only where the unexposed face represents the smaller side of the column. If a column is recessed into a wall, its full dimension shall be used for the purpose of these calculations.

722.6.3.2 Allowable loads. Allowable loads on beams and columns are determined using design values given in AF&PA NDS.

722.6.3.3 Fastener protection. Where minimum 1-hour fire resistance is required, connectors and fasteners shall be protected from fire exposure by 11/4 inches (38 mm) of wood, or other approved covering or coating for a 1-hour rating. Typical details for commonly used fasteners and connectors are shown in AITC Technical Note 7.

722.6.3.4 Minimum size. Wood members are limited to dimensions of 6 inches (152 mm) nominal or greater. Glued-laminated timber beams utilize standard laminating combinations except that a core lamination is removed. The tension zone is moved inward and the equivalent of an extra nominal 2-inch-thick (51 mm) outer tension lamination is added.

Chapter 8: Interior Finishes

General Comments
Past fire experience has shown that interior finish and decorative materials are key elements in the development and spread of fire. In some cases, as with Boston’s devastating Cocoanut Grove fire in 1942, interior decorations were the first materials ignited. In many other cases, the interior finish materials became involved in the early stages of fire and contributed to its early growth and spread.

The provisions of Chapter 8 require materials used as interior finishes and decorations to have a flame spread index or meet certain flame propagation criteria based on the relative fire hazard associated with the occupancy.

The performance of the material is evaluated based on test standards. The design professional or permit applicant is responsible for determining and providing documentation on the flame spread potential and ability to propagate flames of a material in order to support the permit application. The building official then evaluates the information supplied to ascertain that compliance with the applicable code provisions has been achieved. It is also critical that a field inspection verifies that the material is installed in accordance with the approved documents and the code.

Purpose
This chapter contains the performance requirements for controlling fire growth within buildings by restricting interior finish materials and decorative materials.

SECTION 801 GENERAL

801.1 Scope. Provisions of this chapter shall govern the use of materials used as interior finishes, trim and decorative materials.

- This chapter contains requirements for materials used as interior finish, trim or decorative materials. These materials must conform to the flame spread index limitations, the heat release and flashover limitations or flame propagation limitations established by this chapter. This chapter is similar to Chapter 8 of the International Fire Code® (IFC®) in intent but is focused only on new construction and only on interior finish, trim and a limited amount of decorative materials. The IFC addresses both new and existing buildings and also some key building contents.

801.2 Interior wall and ceiling finish. The provisions of Section 803 shall limit the allowable fire performance and smoke development of interior wall and ceiling finish materials based on occupancy classification.

- The provisions of this chapter require materials used as interior finishes to have limited flame spread and smoke-developed indexes (or a limited heat and smoke release), based on the relative fire hazard and occupant vulnerability associated with the occupancy classification. Section 803 provides the necessary performance of wall and ceiling finishes required in test standards based upon the occupancy classification. The primary test standard is ASTM E 84 or UL 723).

801.3 Interior floor finish. The provisions of Section 804 shall limit the allowable fire performance of interior floor finish materials based on occupancy classification.

- Just as for wall and ceiling finish materials, Chapter 8 provides limitations on flame propagation for materials used as floor finish. Section 804 provides the test requirements and criteria for floor finish materials.

[F] 801.4 Decorative materials and trim. Decorative materials and trim shall be restricted by combustibility and the flame propagation performance criteria of NFPA 701, in accordance with Section 806.

- This section is specific to decorative materials and trim, and their specific hazards versus the interior finish within a space. Section 806 addresses the tests for these materials, such as NFPA 701, which provides an indication of the potential for flame propagation of materials such as draperies. Additionally, materials, such as foam plastic used as interior trim, are limited in their combustibility through size, density and coverage limits (see commentary, Section 806).

801.5 Applicability. For buildings in flood hazard areas as established in Section 1612.3, interior finishes, trim and decorative materials below the elevation required by Section 1612 shall be flood-damage-resistant materials.

- All building materials located below the design flood elevation (DFE), including interior finishes, trim and decorative materials, must be resistant to flood damage. Many elevated buildings located in designated flood hazard areas have enclosed lower areas.
"Flood damage-resistant materials" are defined in Section 202 as "any construction material capable of withstanding direct and prolonged contact with floodwaters without sustaining any damage that requires more than cosmetic repair." The term "prolonged contact" means at least 72 hours, and the term "cosmetic repair" means cleaning the affected surfaces with commercially available cleaners and repainting as necessary. For further guidance, refer to FEMA FIA-TB #2, Flood-resistant Material Requirements for Buildings Located in Special Flood Hazard Areas; FEMA FIA-TB #7, Wet Floodproofing Requirements for Structures Located in Special Flood Hazard Areas; and FEMA FIA-TB #8, Corrosion Protection for Metal Connectors in Coastal Areas for Structures Located in Special Flood Hazard Areas.

801.6 Application. Combustible materials shall be permitted to be used as finish for walls, ceilings, floors and other interior surfaces of buildings.

- This section simply points out that this chapter allows combustible materials as interior finish. This would include the finish of walls that are required to be "non-combustible" due to the building's type of construction or other code requirements. This is supported by the provisions of Section 603.1, which allows limited combustible materials in Type I and II construction. Item 5 of Section 603.1 lists interior floor finish and interior finish, trim and millwork, such as doors, door frames, window sashes and frames, as allowable combustible materials. The majority of materials that are used as finish materials are combustible in nature; however, all materials in regulated environments are required to exhibit maximum flame spread and smoke-developed indexes or an equivalent performance on heat and smoke release in an appropriate room-corner fire test. Section 803 clarifies the limits on such materials by limiting the flame spread index and smoke-developed index of such materials in certain portions of the building based upon the occupancy.

801.7 Windows. Show windows in the exterior walls of the first story above grade plane shall be permitted to be of wood or of unprotected metal framing.

- First-story windows used as display spaces are exempt from finish requirements. These areas are subject to frequent redecoration; however, the enforcement of finish requirements would be impractical. The exemption is limited to the first story above grade plane, which is considered to provide ready access for the fire department from the exterior for effective manual fire suppression efforts.

801.8 Foam plastics. Foam plastics shall not be used as interior finish except as provided in Section 803. Foam plastics shall not be used as interior trim except as provided in Section 806.3 or 2604.2. This section shall apply both to exposed foam plastics and to foam plastics used in conjunction with a textile or vinyl facing or cover.

- This section establishes that foam plastic materials are not permitted to be used as interior finish materials unless the foam plastic complies with Section 2603.4, 2603.10 or 2604. Sections 2603.4 and 2603.4.1 generally require that foam plastic materials be covered by an approved thermal barrier, such as 0.5-inch (12.7 mm) gypsum wallboard. When covered in this manner, the foam plastic is no longer the interior finish material. Section 2603.10 provides a means by which foam plastics can be installed without a thermal barrier. A thermal barrier is not required when foam plastic insulation has met the following two criteria: (1) it has been tested in accordance with FM 4880, UL 1040 or UL 1715 or with NFPA 286 (with the pass/fail criteria of Section 803.1.2.1) and (2) the foam plastic meets the flame spread requirements of Section 803 (see commentary, Section 2603.10).

The reference to Section 2604 is for the use of foam plastic as trim.

Sections 806.3 and 2604.2 do allow the use of a limited amount of foam plastic as interior trim when certain criteria is met. The IFC contains the same allowance for interior trim (see commentary, Section 806.3). It should be noted that the IFC further regulates some building contents with regard to foam plastic. More specifically, Section 807.4.2.1 of the IFC places maximum heat release rate criteria on foam plastic used for decorative purposes, stage scenery or exhibit booths when tested in accordance with UL 1975. This code typically does not regulate building contents.

SECTION 802 DEFINITIONS

802.1 Definitions. The following terms are defined in Chapter 2:

- Definitions facilitate the understanding of code provisions and minimize potential confusion. To that end, this section lists definitions of terms associated with interior finishes. Note that these definitions are found in Chapter 2. The use and application of defined terms, as well as undefined terms, are set forth in Section 201.

EXPANDED VINYL. WALL COVERING.
FLAME SPREAD.
FLAME SPREAD INDEX.

INTERIOR FLOOR-WALL BASE.
SECTION 803
WALL AND CEILING FINISHES

803.1 General. Interior wall and ceiling finish materials shall be classified for fire performance and smoke development in accordance with Section 803.1.1 or 803.1.2, except as shown in Sections 803.2 through 803.13. Materials tested in accordance with Section 803.1.2 shall not be required to be tested in accordance with Section 803.1.1.

Wall and ceiling interior finish and trim materials are required to have limits on flame spread and smoke-developed indexes as prescribed in Section 803.9 based upon occupancy. ASTM E 84 or UL 723 is one of the tests available to demonstrate compliance with the requirements of Section 803. This test method has been around since 1944 [see Figure 803.1(1)]. This is the primary method used, but NFPA 286 is an alternate optional test that is discussed in the commentary for Section 803.1.2. ASTM E 84 is intended to determine the relative burning behavior of materials on exposed surfaces, such as walls and ceilings, by visually observing the flame spread along the test specimen [see Figure 803.1(2)]. Flame spread and smoke-developed indexes are then reported. The test method is not appropriate for materials that are not capable of supporting themselves or of being supported in the test tunnel. There may also be concerns with materials that drip, melt or delaminate and with very thin materials. A distinction is made, therefore, for textiles, expanded vinyl wall or ceiling coverings and foam plastic insulation materials (see Sections 803.6, 803.7 and 806.3).

ASTM E 84 establishes a flame spread index based on the area under a curve when the actual flame spread distance is plotted as a function of time. The code has divided the acceptable range of flame spread indexes (0-200) into three classes: Class A (0-25), Class B (26-75) and Class C (76-200). For all three classes the code has established a common acceptable range of smoke-developed index: 0-450. An indication of relative fire performance is as follows: an inorganic reinforced-cement board has a flame spread index of zero, while select grade red oak wood flooring has a flame spread index of 100. Not to preclude more detailed information resulting from an ASTM E 84 test report, Table 803.1.(3) identifies the typical flame spread properties of certain building materials.

803.1.1 Interior wall and ceiling finish materials. Interior wall and ceiling finish materials shall be classified in accordance with ASTM E 84 or UL 723. Such interior finish materials shall be grouped in the following classes in accordance with their flame spread and smoke-developed indexes.

- Class A: Flame spread index 0-25; smoke-developed index 0-450.
- Class B: Flame spread index 26-75; smoke-developed index 0-450.
- Class C: Flame spread index 76-200; smoke-developed index 0-450.

Exception: Materials tested in accordance with Section 803.1.2.

Wall and ceiling interior finish and trim materials are required to have limits on flame spread and smoke-developed indexes as prescribed in Section 803.9, based upon occupancy. ASTM E 84 (or UL 723) is one of the tests available to demonstrate compliance with the requirements of Section 803. This test...
method has been around since 1944 [see Figure 803.1.1(i)]. This is the primary method used; but, as noted earlier, NFPA 286 is an alternative test, which is discussed in the commentary for Section 803.1.2. ASTM E 84 is intended to determine the relative burning behavior of materials on exposed surfaces, such as ceilings and walls, by visually observing the flame spread along the test specimen [see Figure 803.1.2]. Flame spread and smoke-developed indexes are then reported. The test method is not appropriate for materials that are not capable of supporting themselves or of being supported in the test tunnel. There may also be concerns with materials that drip, melt or delaminate and that are very thin. A distinction is made, therefore, for textile wall or ceiling covering, expanded vinyl wall or ceiling coverings and foam plastic insulation materials (see Sections 803.5, 803.6, 803.7 and 803.8).

ASTM E 84 establishes a flame spread index based on the area under a curve when the actual flame spread distance is plotted as a function of time. The code has divided the acceptable range of flame spread indexes (0-200) into three classes: Class A (0-25), Class B (26-75) and Class C (76-200). For all three classes the code has established a common acceptable range of smoke-developed index of 0-450. An indication of relative fire performance is as follows: an inorganic reinforced-cement board has a flame spread and smoke-developed index of zero, while select grade red oak wood flooring has a flame spread and smoke-developed index of 100. Not to preclude more detailed information resulting from an ASTM E 84 test report, Figure 803.1.1 identifies the typical flame spread properties of certain building materials.

Table 803.1.3
TYPICAL FLAME SPREAD OF COMMON MATERIALS

803.1.2 Room corner test for interior wall or ceiling finish materials. Interior wall or ceiling finish materials shall be permitted to be tested in accordance with NFPA 286. Interior wall or ceiling finish materials tested in accordance with NFPA 286 shall comply with Section 803.1.2.1.

- The alternative test method for determining compliance for interior wall and ceiling finish and trim, other than textiles, is found in test standard NFPA 286. This test is known as a "room-corner" fire test and is similar to that referenced for textile wall coverings in Section 803.1.3.2 (NFPA 265) [see Figures 803.1.2(1) and 803.1.2(2)]. In this test, materials are mounted covering three walls of the compartment (excluding the wall containing the door) and the ceiling. In the case where testing is only for ceiling finish properties, the sample only needs to be mounted on the ceiling. Then a fire source consisting of a gas burner is placed in one corner, flush against both walls (furthest from the doorway) of the compartment with the following exposure conditions:
  - 40 kilowatts (kW) for 5 minutes, then
  - 160 kW for 10 minutes.

The test then measures heat release and smoke release through the collection of the fire effluents and measurement of oxygen concentrations in the exhaust duct. Heat release is calculated by the oxygen consumption principle, which has shown that heat release is a function of the decrease in oxygen concentration in the fire effluents. Thus, exhaust duct measurements include temperatures, pressures and smoke values for use in the calculations. Temperatures and heat fluxes are also measured in the room. This generally provides a more realistic understanding of the fire hazard associated with the materials.

The NFPA 286 test method does not contain pass/fail criteria; however, the code provides such criteria in Section 803.1.2.1.
803.1.2 Acceptance criteria for NFPA 286. The interior finish shall comply with the following:

1. During the 40 kW exposure, flames shall not spread to the ceiling.
2. The flame shall not spread to the outer extremity of the sample on any wall or ceiling.
3. Flashover, as defined in NFPA 286, shall not occur.
4. The peak heat release rate throughout the test shall not exceed 800 kW.
5. The total smoke released throughout the test shall not exceed 1,000 m².

As noted in Section 803.1.2, there are two levels of exposure during an NFPA 286 fire test in order to better represent a growing fire: 40 kW fire size for 5 minutes and 160 kW for 10 minutes. The 40 kW exposure represents the beginning of a fire where the initial spread is critical; therefore, the stated criteria is that the fire cannot spread to the ceiling. The 160 kW exposure is obviously a more intense fire situation and the criteria relates to preventing flashover (as defined by NFPA 286) and the extent of flame spread throughout the entire test assembly. There is also a total smoke production criterion of 1,000 m². It should be noted that the criteria used in NFPA 265 and NFPA 286 to determine if flashover has occurred would include any two of the following:

- Heat release exceeds 1 megawatt (MW).
- Heat flux at the floor exceeds 20 kW/m².
- Average upper layer temperature exceeds 1112° F (600°C).
- Flames exit the doorway. Auto ignition of paper target on the floor occurs.

It should be noted that the code has additional criteria when applying NFPA 286 to new buildings, which is a maximum peak heat release rate of 800 kW. The reasoning for this criterion relates to the fact that some poorer performing materials can achieve compliance with the flashover criteria but could have a higher peak heat release rate. Generally, the current criteria without the 800-kW limit will catch poorer performing materials. The 800-kW peak heat release rate limit is applicable to new buildings only, in accordance with the criteria in Section 803.2.1.

803.1.3 Room corner test for textile wall coverings and expanded vinyl wall coverings. Textile wall coverings and expanded vinyl wall coverings shall meet the criteria of Section 803.1.3 when tested in the manner intended for use in accordance with the Method B protocol of NFPA 265 using the product-mounting system, including adhesive.

- This particular section allows textile materials and expanded vinyl wall coverings when tested in accordance with Method B protocol of NFPA 265. NFPA 265 is known as a full-scale “room-corner” fire test. Past research conducted with this kind of configuration has shown that flame spread indexes produced by ASTM E 84 may not reliably predict the fire behavior of textile wall coverings. A more reliable test procedure was developed at the University of California and involved the use of a room-corner fire test with a gas diffusion burner(s). The research findings are described in a report from the University of California Fire Research Laboratory titled, “Room Fire Experiments of Textile Wall Coverings.” The NFPA 265 test method is only slightly different from NFPA 286. NFPA 286 is more severe in three ways:

1. The gas diffusion burner is used to expose the material on the wall in the room. The fire test starts with a heat release rate exposure of 40 kW for the first 5 minutes in both tests, but is then followed by 150 kW for 10 minutes in NFPA 265 and by 160 kW for 10 minutes in NFPA 286.
2. The gas burner is placed 2 inches (51 mm) away from each of the walls in NFPA 265, whereas, it is placed flush against both walls in NFPA 286.
3. The test sample is mounted on the walls only in accordance with NFPA 265, while it is mounted
both on the walls and ceiling in accordance with NFPA 286.

A key result of the difference in intensity and location of the gas burner is that the burner flame does not reach the ceiling during the 150 kW exposure (while it does reach the ceiling during the 160 kW exposure in NPA 286). Therefore, NFPA 265 is not considered to be suitable for testing ceiling coverings.

Based on the use of test Method B from NFPA 265, the sample must meet the criteria of Section 803.1.3.1. This test helps to determine the contribution of textile wall coverings to overall fire growth and spread in a compartment fire. This test also exposes the textile to an ignition source while mounted on the wall. It should be noted that the IFC allows the use of test Method A or B in NFPA 265. The testing requirements in the IFC apply specifically to existing buildings. In the Method A test protocol, 2-foot-wide (610 mm) strips of the material are mounted on the two walls closest to the corner with the burner, whereas, in the Method B test protocol, the sample is mounted completely covering three walls (except for the wall containing the door); therefore, Method B test protocol is more severe. As noted, these textiles are exposed to a prescribed heat release rate of 40 kW for 5 minutes, which is then followed by a heat release rate of 150 kW for 10 minutes.

803.1.3.1 Acceptance criteria for NFPA 265. The interior finish shall comply with the following:
1. During the 40 kW exposure, flames shall not spread to the ceiling.
2. The flame shall not spread to the outer extremities of the samples on the 8-foot by 12-foot (203 by 305 mm) walls.
3. Flashover, as defined in NFPA 265, shall not occur.
4. The total smoke released throughout the test shall not exceed 1,000 m³.

To pass the Method B test protocol of NFPA 265, there are several criteria, including avoiding flashover, as defined in the standard. See the commentary to Section 803.1.3, which discusses limitations on the flame spread of the sample in both the 40 kW and 160 kW exposure and limits the total smoke released to 1000 m³, just as in NFPA 266.

803.1.4 Acceptance criteria for textile and expanded vinyl wall or ceiling coverings tested to ASTM E 84 or UL 723. Textile wall and ceiling coverings and expanded vinyl wall and ceiling coverings shall have a Class A flame spread index in accordance with ASTM E 84 or UL 723 and be protected by an automatic sprinkler system installed in accordance with Section 803.3.1.1 or 803.3.1.2. Test specimen preparation and mounting shall be in accordance with ASTM E 2404.

Textile wall coverings and expanded vinyl wall coverings dramatically increase the fuel load in a room. As such, additional protection is required as a safety factor for rooms finished with these types of material. ASTM E 84 alone is not considered a sufficient test of the flame spread properties of textile wall coverings because they are too thin when tested, and thus sprinklers would be required in addition to a Class A flame spread rating as a safety factor.

803.2 Thickness exemption. Materials having a thickness less than 0.036 inch (0.9 mm) applied directly to the surface of walls or ceilings shall not be required to be tested.

Thin materials used as interior finish, such as wallpaper, are exempt from the testing requirements of this section. These materials represent a very low fuel load and minimal risk of significant flame spread.

803.3 Heavy timber exemption. Exposed portions of structural members complying with the requirements for buildings of Type IV construction in Section 602.4 shall not be subject to interior finish requirements.

This section is simply intended to clarify the code regarding heavy timber, which is commonly exposed to the interior without any interior finish. The concerns over the contribution of heavy timber members of a structure are dealt with in the general requirements of Chapter 6 and other provisions of the code that allow heavy timber.

803.4 Foam plastics. Foam plastics shall not be used as interior finish except as provided in Section 2603.10. This section shall apply both to exposed foam plastics and to foam plastics used in conjunction with a textile or vinyl facing or cover.

This section is simply intended to serve as a reminder that the provisions of Chapter 26 apply when the material is foam plastic. The special approval provisions of Section 2603.10 would be required in order to allow a foam plastic to be used in an exposed interior application. The special approval involves testing in accordance with NFPA 286, which is also used for acceptance of other materials in this section.

803.5 Textile wall coverings. Where used as interior wall finish materials, textile wall coverings, including materials having woven or nonwoven, napped, tufted, looped or similar surface and carpet and similar textile materials, shall be tested in the manner intended for use, using the product mounting system, including adhesive, and shall comply with the requirements of Section 803.1.2, 803.1.3 or 803.1.4.

The concern that this section addresses for mounting or attaching any interior finish is that the materials or method of attachment will not cause a significant increase in the flame spread characteristics of the interior finish material. For textiles and expanded vinyl wall coverings, the variety of adhesives and mounting methods are such that the entire system needs to be tested in the Steiner tunnel tests or the room-corner test specified in Section 803.1.3 or 803.1.4.

803.6 Textile ceiling coverings. Where used as interior ceiling finish materials, textile ceiling coverings, including materials having woven or nonwoven, napped, tufted, looped or similar surface and carpet and similar textile materials, shall be tested in the manner intended for use, using the product...
mounting system, including adhesive, and shall comply with the requirements of Section 803.1.2 or 803.1.4.

- The concern that this section addresses for mounting or attaching any interior finish is that the materials or method of attachment will not cause a significant increase in the flame spread characteristics of the interior finish material. For textiles and expanded vinyl wall coverings, the variety of adhesives and mounting methods are such that the entire system needs to be tested in the Steiner tunnel tests or the room-corner test specified in Section 803.1.3 or 803.1.4.

803.7 Expanded vinyl wall coverings. Where used as interior wall finish materials, expanded vinyl wall coverings shall be tested in the manner intended for use, using the product mounting system, including adhesive, and shall comply with the requirements of Section 803.1.2, 803.1.3 or 803.1.4.

- The concern that this section addresses for mounting or attaching any interior finish is that the materials or method of attachment will not cause a significant increase in the flame spread characteristics of the interior finish material. For textiles and expanded vinyl wall coverings, the variety of adhesives and mounting methods are such that the entire system needs to be tested in the Steiner tunnel tests or the room-corner test specified in Section 803.1.3 or 803.1.4.

803.8 Expanded vinyl ceiling coverings. Where used as interior ceiling finish materials, expanded vinyl ceiling coverings shall be tested in the manner intended for use, using the product mounting system, including adhesive, and shall comply with the requirements of Section 803.1.2 or 803.1.4.

- The concern that this section addresses for mounting or attaching any interior finish is that the materials or method of attachment will not cause a significant increase in the flame spread characteristics of the interior finish material. For textiles and expanded vinyl wall coverings, the variety of adhesives and mounting methods are such that the entire system needs to be tested in the Steiner tunnel tests or the room-corner test specified in Section 803.1.3 or 803.1.4.

803.9 Interior finish requirements based on group. Interior wall and ceiling finish shall have a flame spread index not greater than that specified in Table 803.9 for the group and location designated. Interior wall and ceiling finish materials tested in accordance with NFPA 286 and meeting the acceptance criteria of Section 803.1.2.1, shall be permitted to be used where a Class A classification in accordance with ASTM E 84 or UL 723 is required.

- The requirements for flame spread indexes for interior finish materials applied to walls and ceilings are contained in Table 803.9 (see Sections 804 and 805 for floor finish requirements). The referenced test for determining flame spread indexes is ASTM E 84 or UL 723, which establishes a relative measurement of flame spread across the surface of the material. The classifications used in Table 803.9 are defined in Section 803.1. See the commentary to Section 803.1 for additional information on the uses and limitations of the test procedure. This section also allows the use of NFPA 286 as noted in the exception to Section 803.1 and Section 803.2 (without the exception). Section 803.5, in particular, states that materials that pass NFPA 286 in accordance with the pass/fail criteria in Section 803.2.1 can be used as an alternative to ASTM E 84. Passing NFPA 286 means that the material would be considered equivalent to Class A. In other words, it can be used as a replacement for all categories, as Class A is the most restrictive (see commentary, Section 803.1.2 for more detail on the test).

When evaluating test reports, the method of application and substrate material are considered. For example, adhesives that soften at moderate temperatures will allow wall or ceiling finishes to drop or peel. This not only increases the susceptibility of the material to ignition but also exposes the substrate material. The substrate material can also affect the interior finish rating of the surface material. It is not uncommon for a thin, combustible finish applied to a noncombustible material to obtain a low flame spread index, while the same material applied to a combustible substrate or applied without a substrate could exhibit a significantly high tendency to spread flame.

TABLE 803.9. See page 8-8.

- This table prescribes the minimum requirements for interior finishes applied to walls and ceilings. Class A material has the most restrictive flame spread index and Class C has the least restrictive flame spread index; therefore, the use of a Class A material in an area that requires a minimum Class B material is always allowed. Likewise, when the table requires Class C materials, Classes A and B can also be used.

The requirements are based on the use of the space. To determine the applicable criteria, first determine whether the space is an exit stairway, ramp or passageway; a corridor, exit access stairway or ramp; or a room or enclosed space. For definitions of these various spaces, see Chapter 2. For the minimum requirements for these spaces, see Chapter 10.

Interior finishes in spaces that are not separated from a corridor (for example, waiting areas in business or health care facilities) must comply with the requirements for a corridor space. As shown in the table, the code places more emphasis on the allowable flame spread index for exits than for enclosed rooms because of the critical nature and relative importance that is placed on maintaining the integrity of exits to evacuate the building.

Numerous notes amend the basic requirements of Table 803.9. Notes through I apply only where they are specifically referenced in the table.

For SI: 1 inch = 25.4 mm, 1 square foot = 0.0929m<sup>2</sup>.

- a. Class C interior finish materials shall be permitted for wainscoting or paneling of not more than 1,000 square feet of applied surface area in the grade lobby where applied directly to a noncombustible base or over furring strips applied to a noncombustible base and fireblocked as required by Section 803.11.1.
- b. In other than Group I-2 occupancies in buildings less than three stories above grade plane of other than Group I-3, Class B interior finish for nonsprinklered buildings and Class C interior finish for sprinklered buildings shall be permitted in interior exit stairways and ramps.
- c. Requirements for rooms and enclosed spaces shall be based upon spaces enclosed by partitions. Where a fire-resistance rating is required for structural elements, the enclosing partitions shall extend from the floor to the ceiling. Partitions that do not comply with this shall be considered enclosing spaces and the rooms or spaces on both sides shall be considered one. In determining the applicable requirements for rooms and enclosed spaces, the specific occupancy thereof shall be the governing factor regardless of the group classification of the building or structure.
- d. Lobby areas in Group A-1, A-2 and A-3 occupancies shall not be less than Class B materials.
- e. Class C interior finish materials shall be permitted in places of assembly with an occupant load of 300 persons or less.
- f. For places of religious worship, wood used for ornamental purposes, trusses, paneling or chancel furnishing shall be permitted.
- g. Class B material is required where the building exceeds two stories.
- h. Class C interior finish materials shall be permitted in administrative spaces.
- i. Class C interior finish materials shall be permitted in rooms with a capacity of four persons or less.
- j. Class B materials shall be permitted as wainscoting extending not more than 48 inches above the finished floor in corridors and exit access stairways and ramps.
- k. Finish materials as provided for in other sections of this code.
- l. Applies when protected by an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2.

### 803.10 Stability

*Interior finish* materials regulated by this chapter shall be applied or otherwise fastened in such a manner that such materials will not readily become detached where subjected to room temperatures of 200°F (93°C) for not less than 30 minutes.

- Interior finishes are not to become detached under exposure to elevated temperatures [200°F (93°C)] for 30 minutes. There is not a standard test method yet developed to evaluate this requirement. Other sections of the code, however, offer some additional guidance. For example, the performance of the method of attachment of finish materials during a fire-resistance test will usually be an adequate indication of performance. Section 2506 contains requirements for gypsum wallboard that is not part of a fire-resistance-rated assembly. Interior finishes that become detached may add to the spread of fire, as well as create a hazard for fire fighters.

### 803.11 Application of interior finish materials to fire-resistance-rated or noncombustible building elements

Where *interior finish* materials are applied on walls, ceilings or structural elements required to have a fire-resistance rating or to be of noncombustible construction, they shall comply with the provisions of this section.

- Where an assembly is required to have a fire-resistance rating or be of noncombustible materials, interior finish materials are required to be applied in accordance with Sections 803.4.1 through 803.4.4. These methods are to prevent other types of fire...
spread onto the exposed surface through the use of fireblocking and similar methods.

803.11.1 Direct attachment and furred construction. Where walls and ceilings are required by any provision in this code to be of fire-resistance-rated or noncombustible construction, the interior finish material shall be applied directly against such construction or to furring strips not exceeding 1\(\frac{3}{4}\) inches (44 mm), applied directly against such surfaces.

- Interior finish materials are required to be applied directly to the exposed surface of structural elements or to the furring attached to such surfaces. By applying the finish directly to the surface, the potential for the back side to contribute to a fire is diminished and, as a result, the effects on the fire-resistance rating and the creation of combustible cavities in noncombustible walls are minimized.

803.11.1.1 Furred construction. If the interior finish material is applied to furring strips, the intervening spaces between such furring strips shall comply with one of the following:

1. Be filled with material that is inorganic or noncombustible;
2. Be filled with material that meets the requirements of a Class A material in accordance with Section 803.1.1 or 803.1.2; or
3. Be fireblocked at a maximum of 8 feet (2438 mm) in every direction in accordance with Section 718.

- Interior finishes are allowed to be applied to furring strips under specific limitations. All concealed spaces created by furring are to be fireblocked at a maximum of 8-foot (2438 mm) intervals in any direction. Likewise, fireblocks in furred construction also diminish the likelihood of fire involvement between the finish and the interior wall surface. The use of wood nailing strips is intended to be limited to that which is necessary for the installation of finish and trim materials. As such, the amount of combustible material is restricted so that the performance of the element to which it is attached will not be adversely affected. It should be noted that the type of construction classification of the building is not intended to regulate the combustibility of the interior finish materials. The fire performance characteristics of the interior finish materials are regulated by Section 803.1.

803.11.2 Set-out construction. Where walls and ceilings are required to be of fire-resistance-rated or noncombustible construction and walls are set out or ceilings are dropped distances greater than specified in Section 803.11.1, Class A finish materials, in accordance with Section 803.1.1 or 803.1.2, shall be used.

Exceptions:

1. Where interior finish materials are protected on both sides by an automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2.

2. Where interior finish materials are attached to noncombustible backing or furring strips installed as specified in Section 803.11.1.1.

- Where walls and ceilings are required to be of fire-resistance-rated or noncombustible construction and walls are set out or ceilings are dropped distances greater than specified in Section 803.11.1, finish materials with the most restrictive flame spread index (Class A) shall be used. Exceptions 1 and 2 describe alternatives to providing the Class A finish material. The first is to provide the protection afforded by an automatic sprinkler system. Note that this protection is required on each side of the finish material. The second is to secure the finish to noncombustible backing or furring strips in accordance with Section 803.11.1.1 (see Figure 803.11.2).

---

**Figure 803.11.2**

For SI: 1 inch = 25.4 mm.

803.11.2.1 Hangers and assembly members. The hangers and assembly members of such dropped ceilings that are below the horizontal fire-resistance rated floor or roof assemblies shall be of noncombustible materials. The construction of each set-out wall and horizontal fire-resistance rated floor or roof assembly shall be of fire-resistance-rated construction as required elsewhere in this code.

Exception: In Types III and V construction, fire-retardant-treated wood shall be permitted for use as hangers and assembly members of dropped ceilings.

- The hangers and assembly members of dropped ceilings that are below the main ceiling line are required
to be noncombustible materials to ensure that the ceiling will remain in place for some time if a fire occurs. The exception allows fire-retardant-treated wood (FRTW) in Type III and V construction. This is consistent with other provisions in the code dealing with options to noncombustible materials used in Type III and V construction.

803.11.3 Heavy timber construction. Wall and ceiling finishes of all classes as permitted in this chapter that are installed directly against the wood decking or planking of Type IV construction or to wood furring strips applied directly to the wood decking or planking shall be fireblocked as specified in Section 803.11.1.1.

Attachment directly to heavy timber decking or planking eliminates concealed spaces (see Section 803.3). Furring strips of any depth are allowed when concealed spaces are treated according to Section 803.11.1.1. Again, the intent is to reduce the likelihood of fire spread between these spaces.

803.11.4 Materials. An interior wall or ceiling finish material that is not more than 1/4 inch (6.4 mm) thick shall be applied directly onto the wall, ceiling or structural element without the use of furring strips and shall not be suspended away from the building element to which it is applied.

Exceptions:

1. Noncombustible interior finish materials.
2. Materials that meet the requirements of Class A materials in accordance with Section 803.1.1 or 803.1.2 where the qualifying tests were made with the material furred out from the noncombustible backing shall be permitted to be used with furring strips.
3. Materials that meet the requirements of Class A materials in accordance with Section 803.1.1 or 803.1.2 where the qualifying tests were made with the material suspended away from the noncombustible backing shall be permitted to be used suspended away from the building element.

Combustible materials that have a maximum thickness of 0.25 inch (6.4 mm) are required to be applied directly against a noncombustible backing and not to an added substrate or furred away from the backing, which may significantly increase the spread of fire (see Figure 803.11.4). Exception 1 allows noncombustible interior finish materials to be furred away from the noncombustible backing. Exceptions 2 and 3 allow materials that perform in tests similar to directly attached materials when furred or suspended from a noncombustible backing, respectively.

803.12 High-density Polyethylene (HDPE) and Polypropylene (PP). Where high-density polyethylene or polypropylene is used as an interior finish it shall comply with Section 803.1.2.

High-density polyethylene (HDPE) and polypropylene (PP) are thermoplastic materials that, when burned, give off considerable energy and produce flammable liquid fires. Recent full-scale room-corner tests using NFPA 286 have demonstrated a significant hazard with some of these (HDPE) materials. Extensive flammable liquid fires occurred during the tests. The Steiner tunnel test, however, is not a suitable measure of the performance of this material because the calculation of flame spread index does not take into account the unique hazards known for this material; therefore, these materials are required to be tested in a full-scale room-corner test in accordance with Section 803.1.2.

803.13 Site-fabricated stretch systems. Where used as interior wall or interior ceiling finish materials, site-fabricated stretch systems containing all three components described in the definition in Section 802 shall be tested in the manner intended for use, and shall comply with the requirements of Section 803.1.1 or 803.1.2. If the materials are tested in accordance with ASTM E 84 or UL 723, specimen preparation and mounting shall be in accordance with ASTM E 2573.

The ASTM E 05 committee on fire standards has issued a standard practice, ASTM E 2573, for specimen preparation and mounting of site-fabricated stretch systems. Until now, there was no correct mandatory way to test these systems. These systems are now being used extensively because they can stretch to cover decorative walls and ceilings with unusual looks and shapes. The systems consist of three parts: a fabric (or vinyl), a frame and an infill core.
material. The testing has often been done on each component separately, which is inappropriate and unsafe, instead of testing the composite system.

SECTION 804
INTERIOR FLOOR FINISH

804.1 General. Interior floor finish and floor covering materials shall comply with Sections 804.2 through 804.4.2.

Exception: Floor finishes and coverings of a traditional type, such as wood, vinyl, linoleum or terrazzo, and resilient floor covering materials that are not comprised of fibers.

This section regulates the design and installation of floor finish and floor covering materials. Traditional floor coverings, such as wood, vinyl, terrazzo and other resilient floor covering material, must be exempt from this section. Smooth surface floor coverings generally contribute minimally to a fire. The focus is more upon textile floor coverings, such as carpets.

804.2 Classification. Interior floor finish and floor covering materials required by Section 804.4.2 to be of Class I or II materials shall be classified in accordance with NFPA 253. The classification referred to herein corresponds to the classifications determined by NFPA 253 as follows: Class I, 0.45 watts/cm² or greater; Class II, 0.22 watts/cm² or greater.

The use of a classification system eliminates the need to state the actual critical radiant flux value for a product to meet the identification requirements of Section 804. Over the years, a classification system has been found to be much easier for the industry to follow and still provides the building official with the information required to verify compliance. The test required to measure the combustibility of floor coverings is NFPA 253. This standard is a radiant panel test, which basically simulates materials subjected to heat from a fire above. The primary concern with flooring is related to the spread of a fire that has already been ignited within a space or room to a different room. Figure 804.2 shows the test apparatus. The critical heat flux indicates the threshold value above which flame spread occurs in the testing environment.

804.3 Testing and identification. Interior floor finish and floor covering materials shall be tested by an agency in accordance with NFPA 253 and identified by a hang tag or other suitable method so as to identify the manufacturer or supplier and style, and shall indicate the interior floor finish or floor covering classification according to Section 804.2. Carpet-type floor coverings shall be tested as proposed for use, including underlayment. Test reports confirming the information provided in the manufacturer’s product identification shall be furnished to the building official upon request.

The only method to ascertain that a floor meets the criteria of this section is to request a copy of the test report for the specific material being installed; therefore, it is critical that the carpeting be properly identified in order to verify that acceptable materials are being provided in the appropriate locations. The identification is to be provided on the material itself since a manufacturer’s designation is required.

804.4 Interior floor finish requirements. Interior floor covering materials shall comply with Sections 804.4.1 and 804.4.2 and interior floor finish materials shall comply with Section 804.4.2.

Regardless of occupancy, all interior floor covering materials need to comply with one of two test requirements as indicated in Section 804.4.1, both of which deal with ignition performance of the floor covering. The finish flooring requirements for means of egress components, such as enclosed exit stairways and ramps, exit passageways, corridors and spaces open to the corridor, are regarded as more critical than other building floor surfaces. As such, these finishes and coverings are also required to comply with the minimum critical radiant flux provisions in Section 804.4.2.

804.4.1 Test requirement. In all occupancies, interior floor covering materials shall comply with the requirements of the DOC FF-1 “pill test” (CPSC 16 CFR Part 1630) or with ASTM D 2859.

This section contains two test methods for interior floor covering materials: DOC FF-1 and ASTM D 2859. All carpeting greater than 24 square feet (2.2 m²) in area sold in the United States is required by

Figure 804.2
RADIANT FLOOR PANEL TEST (NFPA 253)
federal law to pass DOC FF-1 as a minimum. DOC FF-1, also referred to as the "Methenamine Pill Test," was developed as a means of preventing the distribution of highly flammable soft-floor coverings within the United States. ASTM D 2859 has been determined to be equivalent to DOC FF-1 and can be used as an alternative test method. Both test methods essentially evaluate the performance of the floor covering when subject to a cigarette-type ignition by using a small methenamine tablet.

804.4.2 Minimum critical radiant flux. In all occupancies, interior floor finish and floor covering materials in enclosures for stairways and ramps, exit passageways, corridors and rooms or spaces not separated from corridors by partitions extending from the floor to the underside of the ceiling shall withstand a minimum critical radiant flux. The minimum critical radiant flux shall not be less than Class I in Groups I-1, I-2 and I-3 and not less than Class II in Groups A, B, E, H, I-4, M, R-1, R-2 and S.

Exception: Where a building is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2, Class II materials are permitted in any area where Class I materials are required, and materials complying with DOC FF-1 "pill test" (CPSC 16 CFR Part 1630) or with ASTM D 2859 are permitted in any area where Class II materials are required.

This section prescribes the minimum requirements for interior floor finish materials that are used in enclosed exit stairways and ramps, or passageways and corridors and rooms or spaces open to the corridor. The criteria are based on the occupancy classification and the relationship of the space to the egress system. Similar to Table 803.9, the occupancy classification designation is meant to apply to the actual occupancy of the space and not necessarily the overall building classification.

Classifications I and II, as used in this section, are defined in Section 804.2 and are based on the results of the NFPA 253 test procedure.

Recognizing the ability of automatic sprinkler systems to control a fire and the minimal contribution of interior floor finishes to the early stages of fire growth, the exception allows the required interior floor finish ratings to be reduced when an automatic sprinkler system is provided throughout the building. The reference to Section 903.3.1.1 or 903.3.1.2 clarifies that the system is to be installed in accordance with NFPA 13 or 13R. In cases where Class II materials are required and an automatic sprinkler system is provided, the minimum requirement is that the material meet either the DOC FF-1 or the ASTM D 2859 test criteria. For a discussion of these two methods, see the commentary to Section 804.4.1.

SECTION 805
COMBUSTIBLE MATERIALS IN TYPES I AND II CONSTRUCTION

805.1 Application. Combustible materials installed on or embedded in floors of buildings of Type I or II construction shall comply with Sections 805.1.1 through 805.1.3.

Exception: Stages and platforms constructed in accordance with Sections 410.3 and 410.4, respectively.

This section provides several methods of allowing combustible materials in the floors of Type I or II construction. Generally, the focus is on fire spread in concealed spaces. If not properly addressed, combustible floor surfaces may eventually contribute to a fire within a concealed space. Sections 410.3 and 410.4 permit wood flooring in stages.

805.1.1 Subfloor construction. Floor sleepers, bucks and nailing blocks shall not be constructed of combustible materials, unless the space between the fire-resistance-rated floor assembly and the flooring is either solidly filled with noncombustible materials or fireblocked in accordance with Section 718, provided that each open space shall not extend under or through permanent partitions or walls.

Sleepers, bucks and nailing blocks are permitted to be of combustible materials only where the void space is filled with a noncombustible material or is fireblocked in accordance with Section 718. Section 718 permits a maximum concealed space area of 100 square feet (9.3 m²). In either case, the open spaces cannot extend under or through permanent partitions or walls. The purpose of the fill or fireblocking is to reduce the impact of a fire in a concealed combustible space in the floor. Likewise, fire spread around partitions or walls through the concealed space in the floor is also intended to be prevented.

805.1.2 Wood finish flooring. Wood finish flooring is permitted to be attached directly to the embedded or fireblocked wood sleepers and shall be permitted where cemented directly to the top surface of fire-resistance-rated floor assemblies or directly to a wood subfloor attached to sleepers as provided for in Section 805.1.1.

Wood floor finish materials may be applied directly to the wood sleepers, provided that the space is protected in accordance with Section 805.1.1. Wood floor finish materials may also be applied directly to the top surface of a fire-resistance-rated assembly or directly to a wood subfloor that is attached to sleepers that are either fireblocked or provide noncombustible fill between the sleepers in accordance with Section 805.1.1.

805.1.3 Insulating boards. Combustible insulating boards not more than 1/2 inch (12.7 mm) thick and covered with finish flooring are permitted where attached directly to a non-
combustible floor assembly or to wood subflooring attached to sleepers as provided for in Section 805.1.1.

- The addition of combustible insulating boards with a maximum thickness of 0.5 inch (12.7 mm) will not significantly increase the fuel load when applied as prescribed by this section or attached to sleepers as provided for in Section 805.1.1.

In all occupancies, interior floor finish in exit enclosures, exit passageways, exit access corridors and rooms or spaces not separated from exit access corridors by full-height partitions extending from the floor to the underside of the ceiling must withstand a minimum critical radiant flux as specified in Section 804.4.2. The focus surrounding the critical radiant flux is combustibility and potential for flame spread of the exposed materials. Section 805 focuses upon fire spread through concealed spaces created by floors.

SECTION 806
DECORATIVE MATERIALS AND TRIM

[F] 806.1 General requirements. In occupancies in Groups A, E, I and R-1 and dormitories in Group R-2, curtains, draperies, hangings and other decorative materials suspended from walls or ceilings shall meet the flame propagation performance criteria of NFPA 701 in accordance with Section 806.2 or be noncombustible.

Exceptions:

1. Curtains, draperies, hangings and other decorative materials suspended from walls of sleeping units and dwelling units in dormitories in Group R-2 protected by an approved automatic sprinkler system installed in accordance with Section 903.3.1 and such materials are limited to not more than 50 percent of the aggregate area of walls.

2. Decorative materials, including, but not limited to, photographs and paintings in dormitories in Group R-2 where such materials are of limited quantities such that a hazard of fire development or spread is not present.

In Groups I-1 and I-2, combustible decorative materials shall meet the flame propagation criteria of NFPA 701 unless the decorative materials, including, but not limited to, photographs and paintings, are of such limited quantities that a hazard of fire development or spread is not present. In Group I-3, combustible decorative materials are prohibited.

Fixed or movable walls and partitions, paneling, wall pads and crash pads applied structurally or for decoration, acoustical correction, surface insulation or other purposes shall be considered interior finish if they cover 10 percent or more of the wall or of the ceiling area, and shall not be considered decorative materials or furnishings.

In Group B and M occupancies, fabric partitions suspended from the ceiling and not supported by the floor shall meet the flame propagation performance criteria in accordance with Section 806.2 and NFPA 701 or shall be noncombustible.

- The requirements in this section apply to decorative materials installed in Group A, E, I and R-1 occupancies and dormitories in Group R-2 occupancies. The list of groups is based on the number of persons and the condition or capabilities of the occupants to evacuate quickly in an emergency. Decorative materials must be noncombustible or meet the flame propagation performance criteria of Section 806.2 and NFPA 701.

The requirements for Groups I-1 and I-2 become more stringent because of the nature of the occupants and activities in these types of facilities. Combustible materials in these facilities must meet the flame propagation performance criteria of NFPA 701, but a limited amount of decorative materials, such as photographs and paintings, need not be flame retardant. No amount of combustible decorative materials are permitted in Group I-3 facilities.

In any occupancy classification when a movable wall, partition, paneling, wall pads or crash pads cover larger areas, they need to be dealt with as interior finishes instead of as decorative materials. Such areas would not be considered decorative materials if the area covered is greater than 10 percent of the wall or ceiling area. This is clarified in the third paragraph of this section.

This section also clarifies that in Group B and M occupancies fabric partitions suspended from the ceiling, but not physically contacting the floor; should be treated as decorative materials similar to curtains or draperies and comply with the flame propagation performance criteria of NFPA 701.

[F] 806.1.1 Noncombustible materials. The permissible amount of noncombustible decorative material shall not be limited.

- Where decorative materials are classified as noncombustible, it is presumed that they will contribute little, if at all, to the growth and spread of fire; therefore, the quantity of noncombustible decorative materials is not limited.

[F] 806.1.2 Combustible decorative materials. The permissible amount of decorative materials meeting the flame propagation performance criteria of NFPA 701 shall not exceed 10 percent of the specific wall or ceiling area to which it is attached.

Exceptions:

1. In auditoriums in Group A, the permissible amount of decorative material meeting the flame propagation performance criteria of NFPA 701 shall not exceed 75 percent of the aggregate wall area where the building is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 and where the material is installed in accordance with Section 803.11.
2. The amount of fabric partitions suspended from the ceiling and not supported by the floor in Group B and M occupancies shall not be limited.

Meeting the flame propagation performance criteria of NFPA 701 does not mean that materials will not burn, only that they are going to spread flame relatively slowly. These materials are, therefore, limited to a maximum of 10 percent of the total wall and ceiling area of the space under consideration. Unlike incidental trim, decorative materials are not necessarily distributed evenly throughout the room. Additionally, consideration of the long-term maintenance of the materials, including possible periodic retreatment, should be taken into account.

There are two exceptions to the 10-percent limitation in Section 806.1.2. Exception 1 is for Group A auditoriums that would allow 75-percent coverage of the walls and ceilings (instead of the limit of 10 percent) if the space is sprinklered in accordance with NFPA 13 and the material is applied in accordance with Section 803.4. Exception 2 correlates with the general requirements in Section 806.1 and further emphasizes that an unlimited amount of fabric ceiling partitions are allowed as long as they meet the flame propagation performance of NFPA 701.

[F] 806.2 Acceptance criteria and reports. Where required by Section 806.1, decorative materials shall be tested by an agency and meet the flame propagation performance criteria of NFPA 701 or such materials shall be noncombustible. Reports of test results shall be prepared in accordance with NFPA 701 and furnished to the building official upon request.

The standard test method to be used to evaluate the ability of a material to propagate flame is NFPA 701, which contains two test methods. Test 1 is a less severe test than Test 2 and uses smaller test specimens. Test 1 is intended for lighter weight materials and single layer fabrics; the limit is a linear density of 700 g/m² (21 oz/yd²). Test 2 is a more severe test than Test 1 and uses larger test specimens. It is intended for higher density materials and multilayered fabrics. It also applies to vinyl-coated fabric blackout linings and lined draperies using any density, because they have been shown to give misleading results using Test 1. NFPA 701 sets out the types of materials, including fabrics, that should be tested using each method.

Essentially, NFPA 701 provides a mechanism to distinguish between materials that allow flames to spread quickly and those that do not when using a small fire exposure.

Materials tested only to NFPA 701 are not permitted for use as interior finish materials, but instead are generally used as shades, swags, curtains and other similar materials. These tests are used to determine whether materials propagate flame beyond the area exposed to the ignition source. They are not intended to indicate whether the material tested will resist the propagation of flame under fire exposures more extreme than the test conditions.

[F] 806.3 Foam plastic. Foam plastic used as trim in any occupancy shall comply with Section 2604.2.

This section establishes that some dense foam plastic materials may be used as interior trim if the thickness, width and area of coverage are specifically limited as required in Section 2604.2.

Section 2604.2 provides the following maximum values: 0.5-inch (12.7 mm) thickness, 8-inch (203 mm) width and 10 percent of the aggregate wall and ceiling area. Section 2604.2 also establishes a minimum density for foam permitted for use as trim: 20 pounds per cubic foot (320 kg/m³). Minimum instead of maximum density is specified because the denser the foam plastic material, the less likely it is that it will generate misleading ASTM E 84 test results due to having insufficient material for fire testing of the foam [see Figures 806.5(1) and 806.5(2)].

This section specifically calls out a numerical flame spread index limit of 75 for foam plastic used as trim, which is a Class B flame spread index. No thermal barrier is required for the use of foam plastic as trim and the smoke-developed index is not limited. It should be noted that Section 803.7.3 of the IFC, which regulates the use of foam plastic trim for existing construction, has essentially identical requirements to those found in this section. Neither this section nor Section 2603.4.1.11 requires a thermal barrier for interior trim.

[F] 806.4 Pyroxylin plastic. Imitation leather or other material consisting of or coated with a pyroxylin or similarly hazardous base shall not be used in Group A occupancies.

Use of pyroxylin plastics, also known as cellulose nitrate plastics, as imitation leather (or coated to imitation leather) is strictly prohibited in Group A occupancies because of the normally high occupant loads of such occupancies. This type of material is very hazardous because it has the potential to develop explosive atmospheres with high heat emission and it will begin decomposition at temperatures starting at 300°F (149°C). In actual fact, cellulose nitrate use has generally declined considerably because it tends to become somewhat unstable and is easily ignitable. Specifically, use of cellulose nitrate for motion picture film was discontinued in 1951.

[F] 806.5 Interior trim. Material, other than foam plastic used as interior trim, shall have a minimum Class C flame spread and smoke-developed index when tested in accordance with ASTM E 84 or UL 723, as described in Section 803.1.1. Combustible trim, excluding handrails and guardrails, shall not exceed 10 percent of the specific wall or ceiling area in which it is attached.

In occupancies of any group, unless otherwise noted in the code, the minimum classification of all trim must be at least Class C. Additionally, combustible trim may not exceed 10 percent of the area of the aggregate wall or ceiling area. The 10-percent calculation does not need to include handrails and guardrails. Although a Class C rating may be lower than the
rating required for a particular building or facility, this quantity of combustible material will not significantly increase the fuel load and flame spread hazards [see Figures 806.5(1) and 806.5(2)].

[F] 806.6 Interior floor-wall base. Interior floor-wall base that is 6 inches (152 mm) or less in height shall be tested in accordance with Section 804.2 and shall not be less than Class II. Where a Class I floor finish is required, the floor-wall base shall be Class I.

Exception: Interior trim materials that comply with Section 806.5.

Section 806.6 addresses the issue of testing and regulation of interior floor-wall base trim materials. In many cases, the floor covering material is just seamlessly turned up or used at the intersection of the floor and the wall and thus it becomes the floor-wall base trim.

In the 2006 code, these materials could have been considered interior trim in accordance with Sections 804.1 and 806.5 and would have been required to be tested in accordance with ASTM E 84 or UL 723, even though the floor covering may have been required to be tested in accordance with NFPA 253. Based on the small amount of material used, it is very difficult to test these materials in a reliable manner, upside down in the ASTM E 84 test method. Because of their location, at the floor line, floor-wall base materials are not likely to be involved in a fire until the floor covering is also involved, usually at room flashover. Thus, it is reasonable that floor-wall base materials meet the same criteria as floor coverings. The section specifies that floor-wall base materials 6 inches (152 mm) or less in height be tested in accordance with NFPA 253, and the proposal provides requirements for this application.

SECTION 807
INSULATION

807.1 Insulation. Thermal and acoustical insulation shall comply with Section 720.

This section simply references Section 720 for the requirements for insulation materials and clarifies that these materials can be used when they meet the requirements of that section.

SECTION 808
ACOUSTICAL CEILING SYSTEMS

808.1 Acoustical ceiling systems. The quality, design, fabrication and erection of metal suspension systems for acoustical tile and lay-in panel ceilings in buildings or structures shall conform with generally accepted engineering practice, the provisions of this chapter and other applicable requirements of this code.

This section regulates the design and installation of metal suspension systems for acoustical tile and acoustical lay-in panel ceilings. Suspended ceiling systems basically consist of a grid of metal channels

![Diagram of ceiling system]

Wall area: 2 walls (20 x 12) + 2 walls (10 x 12) = 720 sq. ft. 10% of walls = 720 x 0.10 = 72 sq. ft.
Decorative trim coverage = 72 sq. ft.
Ceiling 20 x 10 = 200 sq. ft. 10% of ceiling = 200 x 0.10 = 20
Decorative trim coverage = 20 sq. ft.

For SI: 1 foot = 304.8 mm,
1 square foot = 0.0929 m².

Figure 806.5(1)
TRIM COVERAGE AREA

![Diagram of trim coverage]

For SI: 1 inch = 25.4 mm,
1 pound per square foot = 47.88 Pa.
or T-bars suspended by steel hangers (wires, rods or flats) from the structure above. Light fixtures, air diffusers and acoustical panels may be placed between the metal framing members.

808.1.1 Materials and installation. Acoustical materials complying with the interior finish requirements of Section 803 shall be installed in accordance with the manufacturer's recommendations and applicable provisions for applying interior finish.

- Acoustical materials used in metal suspension systems are regulated for the purpose of limiting flame spread and smoke development in the occupancies shown in Table 803.9.

  Metal suspension system components for acoustical ceilings that might be subjected to the severe environmental conditions of high humidity (fog) or salt spray may have coatings ranked according to their ability to protect the components from deterioration. The installation of metal suspension systems in any exterior application must be considered as an installation in a severe environment (see ASTM C 635).

808.1.1.1 Suspended acoustical ceilings. Suspended acoustical ceiling systems shall be installed in accordance with the provisions of ASTM C 635 and ASTM C 636.

- ASTM C 635 covers metal ceiling suspension systems used primarily to support acoustical tile or acoustical lay-in panels. Suspension systems have three structural classifications, as described below:
  - Light-duty systems—Used primarily for residential and light commercial structures where ceiling loads other than acoustical tile or lay-in panels are not anticipated.
  - Intermediate-duty systems—Used primarily for ordinary commercial structures where some ceiling loads, due to light fixtures and air diffusers, are anticipated.
  - Heavy-duty systems—Used primarily for commercial structures in which the quantities and weights of ceiling fixtures (lights, air diffusers, etc.) are greater than those for an ordinary commercial structure.

- ASTM C 636 covers the installation of suspension systems for acoustical tile and lay-in panels.

While the practices described in this standard have equal application to fire-resistance-rated suspension systems, additional requirements may be imposed to obtain the fire endurance classification of particular floor/ceiling or roof/ceiling assemblies (see Section 808.1.1.2).

808.1.1.2 Fire-resistance-rated construction. Acoustical ceiling systems that are part of fire-resistance-rated construction shall be installed in the same manner used in the assembly tested and shall comply with the provisions of Chapter 7.

- A suspended acoustical ceiling system by itself does not possess a fire-resistance rating. Acoustical ceiling systems are part of an assembly that has a specified fire-resistance rating. Acoustical lay-in panels must remain in place for the tested assembly to be effective.

Bibliography

The following resource materials are referenced in this chapter or are relevant to the subject matter addressed in this chapter.

Chapter 9: Fire Protection Systems

General Comments
The provisions required by Chapter 9 are just one aspect of the overall fire protection system of a building or structure. All fire protection requirements contained in the code must be considered as a package or overall system. Noncompliance with any part of the overall system may cause other parts of the system to fail. Failure to install the systems in accordance with code provisions may result in an increased loss of life and property due to a reduction in the level of protection provided.

It is important that every effort be made to verify the proper design and installation of a given fire protection system, especially those that result in construction alternatives and other code trade-offs.

The requirements found in Chapter 9 can be considered active fire safety provisions. They are provisions directed at containing and abating the fire once it has erupted. This chapter is almost a direct copy of Chapter 9 in the International Fire Code® (IFC®). The IFC, however, contains specific provisions that are only applicable to existing buildings. The IFC also contains periodic testing criteria that are not duplicated in this chapter. Proper testing, inspection and maintenance of the various systems, however, are critical to establish the reliability of the system. Additionally, Chapter 9 references and adopts numerous National Fire Protection Association (NFPA) standards, including the acceptance testing criteria within the standard. The referenced standards will also contain more specific design and installation criteria than are found in this chapter. As noted in Section 102.4, where differences occur between code provisions and the referenced standard, the code provisions apply.

Purpose
Fire protection systems may serve one or more purposes in providing adequate protection from fire and hazardous material exposure. The purpose of Chapter 9 is to prescribe the minimum requirements for an active system or systems of fire protection to perform the following functions: to detect a fire; to alert the occupants or fire department of a fire emergency; to control smoke and to control or extinguish the fire. Generally, the requirements are based on the occupancy and height and area of the building, as these are the factors that most affect fire-fighting capabilities and the relative hazard of a specific space or area.

SECTION 901 GENERAL

901.1 Scope. The provisions of this chapter shall specify where fire protection systems are required and shall apply to the design, installation and operation of fire protection systems.

Chapter 9 contains requirements for fire protection systems that may be provided in a building. These include automatic suppression systems; standpipe systems; fire alarm and detection systems; smoke control systems; smoke and heat vents and portable fire extinguishers and emergency alarm systems. Besides indicating the conditions under which respective systems are required, this chapter contains the design, installation, maintenance and operational criteria for fire protection systems. While the chapter requires proper maintenance for the reliability of the systems, the actual maintenance provisions (periodic testing, inspections and maintenance) are found in the IFC.

This chapter also addresses the requirements for fire command centers, fire department connections, fire pumps and emergency radio systems. These features all directly relate to the proper function of fire protection systems.

901.2 Fire protection systems. Fire protection systems shall be installed, repaired, operated and maintained in accordance with this code and the International Fire Code.

Any fire protection system for which an exception or reduction to the provisions of this code has been granted shall be considered to be a required system.

Exception: Any fire protection system or portion thereof not required by this code shall be permitted to be installed for partial or complete protection provided that such system meets the requirements of this code.

The fire protection system is an integral component of the protection features of the building and is required to be properly installed, repaired, operated and maintained in accordance with the code and the IFC. Improperly installed or maintained systems can negate any anticipated protection and, in fact, create a hazard in itself.

While the code may not require a protection system...
for a specific building or portion thereof, due to its occupancy, the fire protection system would still be considered a required system if some other code trade-off, exception or reduction was taken based on the installation of the fire protection system. For example, a typical small office building may not require an automatic sprinkler system solely due to its Group B occupancy classification; however, if an exit access corridor fire-resistance-rating reduction is taken in accordance with Table 1018.1 for buildings equipped throughout with an NFPA 13 sprinkler system, that sprinkler system would be considered a required system.

The exception acknowledges that a building owner or designer may elect to install a fire protection system that is not required by the code. Even though such a system is not required, it must comply with the applicable provisions of this chapter and the IFC. This requirement is predicated on the concept that any fire protection system not installed in accordance with the code is intrinsically lacking because it could give a false impression of properly installed protection.

For example, if a building owner chooses to provide sprinkler protection in a certain area and such protection is not required by the code, the system must be installed in accordance with the applicable NFPA sprinkler standard (13, 13R or 13D) and other applicable requirements of the code, such as water supply and supervision. The extent of the protection thus provided would not be regulated.

**901.3 Modifications.** No person shall remove or modify any fire protection system installed or maintained under the provisions of this code or the International Fire Code without approval by the building official.

- This section emphasizes the principle that systems installed and maintained in compliance with the codes and standards in effect at the time they were placed in service must remain in an operative condition at all times. Protection must not be diminished in any existing building except for the purpose of conducting tests, maintenance or repairs. The length of service interruptions should be kept to a minimum. The building official must be notified of any service interruptions and should carefully evaluate the continued operation or occupancy of buildings and structures where protection is interrupted.

**901.4 Threads.** Threads provided for fire department connections to sprinkler systems, standpipes, yard hydrants or any other fire hose connection shall be compatible with the connections used by the local fire department.

- Incompatible fire service threads have been a major problem throughout the history of modern fire suppression. Efforts to standardize fire service threads in the United States began as early as 1898. Following the Great Baltimore Fire of 1904, NFPA adopted a national standard for fire hose thread with diameters 2\(\frac{1}{2}\) inches (64 mm) and larger; however, to this day many jurisdictions continue to use their own (historic) thread standards. A number of jurisdictions have pioneered the use of nontreaded, quarter-turn or "Storz" fire hose couplings in place of the national and local traditional thread standards.

**901.5 Acceptance tests.** Fire protection systems shall be tested in accordance with the requirements of this code and the International Fire Code. When required, the tests shall be conducted in the presence of the building official. Tests required by this code, the International Fire Code and the standards listed in this code shall be conducted at the expense of the owner or the owner's representative. It shall be unlawful to occupy portions of a structure until the required fire protection systems within that portion of the structure have been tested and approved.

- All fire protection systems are to be subjected to an acceptance test to determine that the system will operate in the manner required by the code. Acceptance tests are usually part of the final inspection procedures required by Section 1103.310. Specific acceptance test procedures are provided in other sections as well as the referenced standards. In most instances, the acceptance test procedures require 100-percent operation of the testable system components to determine that they are functioning as required. Often, the design professional may require additional testing to verify that the system operates as designed, which may be beyond the code requirements.

The inclusion of the requirement for acceptance tests in the code is not intended to assign responsibility for witnessing the tests. The responsibility to witness the acceptance test is an administrative issue that each municipality must address. Because the acceptance test is critical during design and construction and is a requirement of occupancy, the requirement is located in the code. The section also clarifies that it is the owner's responsibility to conduct the test and the role of the building official to witness—not conduct—the test. Typically, the owner will assign the responsibility to the installing contractor.

Access to all flow test connections, valves and points of fluid discharge required by other sections is to be provided at locations acceptable to the building official. Consideration should be given to the location of sprinkler system inspector test connections and the main drain valves, as well as to the valves necessary to test standpipe and fire pump installations.

Consideration should also be given to the discharge of water from the various test connections for aqueous systems that should be arranged to discharge to the outside or to a drain with sufficient capacity to handle the anticipated water flow. If the test connection is piped to the outside, then protection should be furnished to prevent unnecessary damage to the property by providing splash blocks or similar protection. When the building drainage system is used, the indirect waste provisions of Chapter 7 of the International Plumbing Code® (IPC®) are to apply.
Partial occupancy of any structure should not be permitted unless all fire protection systems for the occupied areas have been tested and approved. Even so, the code assumes that full protection for all areas will be provided as expeditiously as possible. The installation of many fire protection systems and the associated code trade-offs permitted for a given occupancy assume complete building protection, not just in the occupied areas. Final approval of all partial occupancy conditions is subject to the building official.

901.6 Supervisory service. Where required, fire protection systems shall be monitored by an approved supervising station in accordance with NFPA 72.

- All required fire protection systems are to be supervised as a means of determining at any time that the system is operational. Acceptable methods of supervision are provided in NFPA 72.

901.6.1 Automatic sprinkler systems. Automatic sprinkler systems shall be monitored by an approved supervising station.

Exceptions:

1. A supervising station is not required for automatic sprinkler systems protecting one- and two-family dwellings.

2. Limited area systems serving fewer than 20 sprinklers.

- This section highlights that automatic sprinkler systems must be monitored by an approved supervising station. All water supply control valves and waterflow switches are required to be electrically supervised as indicated in Section 903.4. A central station, remote supervising station or proprietary supervising station are approved services recognized in NFPA 72 (see commentary, Section 903.4.1).

Automatic sprinkler systems in one- and two-family dwellings are typically designed in accordance with NFPA 13D, which does not require electrical supervision (see Exception 1). Limited area sprinkler systems are generally supervised by their connection to the domestic water service (see Exception 2). As such, limited area sprinkler systems with fewer than 20 sprinkler heads are not required to have local alarms or a fire department connection.

901.6.2 Fire alarm systems. Fire alarm systems required by the provisions of Section 907.2 of this code and Sections 907.2 and 907.9 of the International Fire Code shall be monitored by an approved supervising station in accordance with Section 907.6.5.

Exceptions:

1. Single- and multiple-station smoke alarms required by Section 907.2.11.

2. Smoke detectors in Group I-3 occupancies.

3. Supervisory service is not required for automatic sprinkler systems in one- and two-family dwellings.

- Fire alarm systems are required to automatically transmit an alarm and any trouble signals to the fire department through one of the approved methods in NFPA 72. This includes systems in new buildings where required by Section 907.2 of both the code and the IFC and in existing buildings where required by Section 907.3 of the IFC.

Exception 1 exempts single- and multiple-station smoke alarms from being supervised due to the potential for unwanted false alarms. Similarly, due to the concern over unwanted alarms, smoke detectors in Group I-3 occupancies need only sound an approved alarm signal, which automatically notifies staff (see Section 907.2.6.3.1). Smoke detectors in Group I-3 occupancies are typically subject to misuse and abuse. Frequent unwanted alarms would negate the effectiveness of the system (see Exception 2).

Exception 3 clarifies that sprinkler systems in one- and two-family dwellings are not part of a dedicated fire alarm system and are typically designed in accordance with NFPA 13D, which does not require electrical supervision.

901.6.3 Group H. Supervision and monitoring of emergency alarm, detection and automatic fire-extinguishing systems in Group H occupancies shall be in accordance with the International Fire Code.

- Given the varied nature and quantity of hazardous materials that could be present, all emergency alarm, detection and automatic fire-extinguishing systems in Group H occupancies are required to be both supervised and monitored by an approved supervising station. Section 5004.10 of the IFC correlates with this section and further allows the building official to approve an on-site monitoring system. Many companies that routinely deal with hazardous materials employ their own fire brigades and have emergency response procedures in place.

901.7 Fire areas. Where buildings, or portions thereof, are divided into fire areas so as not to exceed the limits established for requiring a fire protection system in accordance with this chapter, such fire areas shall be separated by fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both, having a fire-resistance rating of not less than that determined in accordance with Section 707.3.10.

- This section provides specific guidance on how a building needs to be divided into fire areas in order to avoid requiring a fire protection system to be installed. A single occupancy group would require fire barriers or horizontal assemblies in order to create multiple fire areas (see Table 707.3.10), each having an area below the threshold for fire protection system installation.
[F] 901.8 Pump and riser room size. Fire pump and automatic sprinkler system riser rooms shall be designed with adequate space for all equipment necessary for the installation, as defined by the manufacturer, with sufficient working room around the stationary equipment. Clearances around equipment to elements of permanent construction, including other installed equipment and appliances, shall be sufficient to allow inspection, service, repair or replacement without removing such elements of permanent construction or disabling the function of a required fire-resistance-rated assembly. Fire pump and automatic sprinkler system riser rooms shall be provided with a door(s) and unobstructed passageway large enough to allow removal of the largest piece of equipment.

Section 901.8 establishes new requirements to ensure that rooms housing fire protection system risers or fire pumps and their components have adequate space to facilitate their maintenance. This section does not require the construction of a room to house fire protection systems; however, if a room is provided, this section requires that it be adequately sized to allow for maintenance.

Instead of prescribing arbitrary dimensions, this provision bases the room area on clearances specified by the equipment manufacturers to ensure adequate space is available for its installation or removal. The design must provide enough area so that walls, finish materials and doors are not required to be removed during maintenance activities. The provision also prescribes that the size of the door serving a riser or pump room is of a size to accommodate the removal of the largest piece of equipment.

Given that the design of fire protection systems generally commences during the period that building construction drawings and specifications are being reviewed by the jurisdiction, it will be especially important for the building's designer to establish dialogue with the fire protection system contractor early in the design process to ensure that the room and at least one door can accommodate the largest equipment and provide the space needed for maintenance.

SECTION 902
DEFINITIONS

902.1 Definitions. The following terms are defined in Chapter 2:

Definitions of terms can help in the understanding and application of the code requirements. This section directs the code user to Chapter 2 for the proper application of the indicated terms used in this chapter. Terms may be defined in Chapter 2, in another International Code® as indicated in Section 201.3 or the dictionary meaning may be all that is needed (see also commentary, Sections 201 through 201.4).

Certain requirements in the code are based on code provisions in the IFC, International Mechanical Code (IMC) and IPC. A review of definitions included in those codes will aid in the understanding of many of the requirements contained in the code.

SECTION 903
AUTOMATIC SPRINKLER SYSTEMS

General. Automatic sprinkler systems shall comply with this section.

This section identifies the conditions requiring an automatic sprinkler system for all occupancies. The need for an automatic sprinkler system may depend on not only the occupancy but also the occupant load, fuel load, height and area of the building as well as fire-fighting capabilities. Section 903.2 addresses all occupancy conditions requiring an automatic sprinkler system. Section 903.3 contains the installation requirements for all sprinkler systems in addition to the requirements of NFPA 13, NFPA 13R and NFPA 13D. The supervision and alarm requirements for sprinkler systems are contained in Section 903.4, whereas Section 903.5 refers to the IFC, which references testing and maintenance requirements for sprinkler systems found in Section 901 and NFPA 25.

Unless specifically allowed by the code, residential sprinkler systems installed in accordance with NFPA 13R or NFPA 13D are not recognized for reductions or exceptions permitted by other sections of the code. NFPA 13 systems provide the level of protection associated with adequate fire suppression for all occupancies. NFPA 13R and NFPA 13D systems are intended more to provide adequate time for egress but not necessarily for complete suppression of the fire. Figure 903.2 lists examples of where the various sprinkler standards differ in application.

The area values contained in this section are intended to apply to fire areas, which are comprised of all floor areas bounded by fire barriers, fire walls or exterior walls. The minimum required fire-resistance rating of fire barrier assemblies that define a fire area is specified in Table 707.3.10. Because the areas are defined as fire areas, fire barriers, horizontal assemblies, fire walls or exterior walls are the only acceptable means of subdividing a building into smaller areas instead of installing an automatic sprinkler system. Where fire barrier and exterior walls define multiple fire areas within a single building, a fire wall defines separate buildings within one structure. Also note that some of the threshold limitations result in a requirement to install an automatic sprinkler system throughout the building while others may require only specific fire areas to be sprinklered.

Another important point is that one fire area may include floor areas in more than one story of a building (see the commentary to the definition of “Fire area” in Section 202).

The application of mixed occupancies and fire areas must be carefully researched. Often the required separation between occupancies for the purposes of applying the separated mixed-use option in Section 508.4 will result in a separation that is less than what is required to define the boundaries of a fire area. It is possible to have two different occupancies within a given fire area, treated as separated uses but with code requirements applicable to both, since they are not separated by the rating required for fire areas.

Alternative protection. Alternative automatic fire-extinguishing systems complying with Section 904 shall be permitted in lieu of automatic sprinkler protection where recognized by the applicable standard and approved by the fire code official.

This section permits the use of an alternative automatic fire-extinguishing system when approved by the fire code official as a means of compliance with the occupancy requirements of Section 903. Although the use of an alternative extinguishing system allowed by Section 904, such as a carbon dioxide system or clean-agent system, would satisfy the requirements of Section 903.2, it would not be considered an acceptable alternative for the purposes of exceptions, reductions or other code alternatives that would be applicable if an automatic sprinkler system were installed.

Note: Thresholds located in Section 903.2 unless noted. See also Table 903.2.11.6 for additional required suppression systems.

For SI: 1 foot = 304.8 mm, 1 square foot = 0.0929 m².

Figure 903.2
SUMMARY OF OCCUPANCY-RELATED AUTOMATIC SPRINKLER THRESHOLDS
[F] 903.2 Where required. Approved automatic sprinkler systems in new buildings and structures shall be provided in the locations described in Sections 903.2.1 through 903.2.12.

Exception: Spaces or areas in telecommunications buildings used exclusively for telecommunications equipment, associated electrical power distribution equipment, batteries and standby engines, provided those spaces or areas are equipped throughout with an automatic smoke detection system in accordance with Section 907.2 and are separated from the remainder of the building by not less than 1-hour fire barriers constructed in accordance with Section 707 or not less than 2-hour horizontal assemblies constructed in accordance with Section 711, or both.

Sections 903.2.1 through 903.2.12 identify the conditions requiring an automatic sprinkler system (see Figure 903.2). The type of sprinkler system must be one that is permitted for the specific occupancy condition. An NFPA 13R sprinkler system, for example, may not be installed to satisfy the sprinkler threshold requirements for a mercantile occupancy (see Section 903.2.7). As indicated in Section 903.3.1.2, the use of an NFPA 13R sprinkler system is limited to Group R occupancies not exceeding four stories in height.

Where the thresholds for sprinkler protection include the number of occupants and the fire area, it is important to remember that the proper application is the determination of the hazard present. If the actual fire area is less than the fire area threshold but the total occupant load exceeds the occupant load threshold, it is still necessary to determine whether or not the occupant load of that occupancy is present. For example, if the occupant load threshold is 300 for a given occupancy, it is necessary to determine that there are 300 occupants of that occupancy classification. Just because the fire area has an occupant load exceeding the occupant threshold does not in itself indicate that sprinkler protection is required. The code requires automatic sprinkler protection when the occupant load for the specific occupancy exceeds the established threshold. In applying the occupant load thresholds, it is important to note that they are to be evaluated and applied per occupancy and not as an aggregate of all occupancies that may be present in the building.

There is one exception for those spaces or areas used exclusively for telecommunications equipment. The telecommunications industry has continually stressed the need for the continuity of telephone service, and the ability to maintain this service is of prime importance. This service is a vital link between the community and the various life safety services, including fire, police and emergency medical services. The integrity of this communications service can be jeopardized not only by fire, but also by water, from whatever the source.

It must be emphasized that the exception applies only to those spaces or areas that are used exclusively for telecommunications equipment. Historically, those spaces have a low incidence of fire events. Fires in telecommunications equipment are difficult to start and, if started, grow slowly, thus permitting early detection. Such fires are typically of the smoldering type, do not spread beyond the immediate area and generally self-extinguish.

Note, however, that this exception requires a fire-resistance-rated separation from other portions of the building and that the building cannot qualify for any code trade-offs for fully sprinklered buildings.

[F] 903.2.1 Group A. An automatic sprinkler system shall be provided throughout buildings and portions thereof used as Group A occupancies as provided in this section. For Group A-1, A-2, A-3 and A-4 occupancies, the automatic sprinkler system shall be provided throughout the floor area where the Group A-1, A-2, A-3 or A-4 occupancy is located, and in all floors from the Group A occupancy to, and including, the nearest level of exit discharge serving the Group A occupancy. For Group A-5 occupancies, the automatic sprinkler system shall be provided in the spaces indicated in Section 903.2.1.5.

Group A occupancies are characterized by a significant number of people who are not familiar with their surroundings. The requirement for a suppression system reflects the additional time needed for egress. The protection is also intended to extend to the occupants of the assembly group from unobserved fires in other building areas located between the floor level containing the assembly occupancy and the level of exit discharge serving such occupancies. The only exception to the coverage is for Group A-5 occupancies that are open to the atmosphere. Such occupancies require only certain aspects to be sprinklered, such as certain concession stands and other enclosed use areas (see commentary, Section 903.2.1.5).

The requirement for sprinklers is based on the location and function of the space. It is not dependent on whether or not the area is provided with exterior walls. IFC Committee Interpretation No. 25-05 to this section discusses this issue and states, in part, that "where no surrounding exterior walls are provided along the perimeter of the building, the building area is used to identify and determine applicable fire area." Outdoor areas such as pavilions and patios may have no walls but will have an occupant load and other factors that identify the assembly occupancy as such. If any of the thresholds are reached requiring sprinkler protection, then sprinkler protection must be provided whether there are exterior walls or not.

[F] 903.2.1.1 Group A-1. An automatic sprinkler system shall be provided for Group A-1 occupancies where one of the following conditions exists:

1. The fire area exceeds 12,000 square feet (1115 m²);
2. The fire area has an occupant load of 300 or more;
3. The fire area is located on a floor other than a level of exit discharge serving such occupancies; or
4. The fire area contains a multiplex theater complex.

Group A-1 occupancies are identified as assembly occupancies with fixed seating, such as theaters. In addition to the high occupant load associated with these types of facilities, egress is further complicated by the possibility of low lighting levels customary during performances. The fuel load in these buildings is usually of a type and quantity that would support fairly rapid fire development and sustained duration.

Theaters with stages pose a greater hazard. Sections 410.6 and 410.7 require stages to be equipped with an automatic sprinkler system and standpipe system, respectively. The proscenium opening must also be protected. These features compensate for the additional hazards associated with stages in Group A-1 occupancies.

This section lists four conditions that require installing a suppression system in a Group A-1 occupancy. Condition 1 requires that, if any one fire area of Group A-1 exceeds 12,000 square feet (1115 m²), the automatic fire suppression system is to be installed throughout the entire story or floor level where a Group A-1 occupancy is located, regardless of whether the building is divided into more than one fire area. However, if all the fire areas are less than 12,000 square feet (1115 m²) (and less than the other thresholds), then sprinklers would not be required. Compartmentalization into multiple fire areas in compliance with Chapter 7 is deemed an adequate alternative to sprinkler protection.

Condition 2 establishes the minimum number of occupants for which a suppression system is considered necessary. The determination of the actual occupant load must be based on Section 1004.

Condition 3 accounts for occupant egress delay when traversing a stairway requiring a sprinkler system, regardless of the size of occupant load. In such cases alternative emergency escape elements such as windows may not be available, making the suppression needs all the greater. It is not necessary for the occupant load to exceed 300 on a level other than the level of exit discharge serving such occupancy. Any number of Group A-1 occupants on the alternative level would be cause to apply the requirement for sprinklers. The text does not make reference to "story" but uses the term "floor," which could include mezzanines and basements.

Condition 4 states that a sprinkler system is required for multiplex theater complexes to account for the delay associated with the notification of adjacent compartmentalized spaces where the occupants may not be immediately aware of an emergency.

[F] 903.2.1.2 Group A-2. An automatic sprinkler system shall be provided for Group A-2 occupancies where one of the following conditions exists:
1. The fire area exceeds 5,000 square feet (464.5 m²);
2. The fire area has an occupant load of 100 or more;
3. The fire area is located on a floor other than a level of exit discharge serving such occupancies.

Group A-2 assembly occupancies are intended for food or drink consumption, such as banquet halls, nightclubs and restaurants. Occupancies in Group A-2 involve life safety factors such as a high occupant density, flexible fuel loading, movable furnishings and limited lighting; therefore, they must be protected with an automatic sprinkler system under any of the listed conditions.

In the case of an assembly use, the purpose of the automatic sprinkler system is to provide life safety from fire as well as preserving property. By requiring fire suppression in areas through which the occupants may egress, including the level of exit discharge serving such occupancies, the possibility of unobserved fire development affecting occupant egress is minimized.

The 5,000-square-foot (464 m²) threshold for the automatic sprinkler system reflects the higher degree of life safety hazard associated with Group A-2 occupancies. As alluded to earlier, Group A-2 occupancies could have low lighting levels, loud music, late hours of operation, dense seating with ill-defined aisles and alcoholic beverage service. These factors in combination could delay fire recognition, confuse occupant response and increase egress time.

Although the calculated occupant load for a 5,000 square-foot (465 m²) space at 15 square feet (1.4 m²) per occupant would be over 100, the occupant load threshold in Condition 2 is meant to reflect the concern for safety in these higher density occupancies. Although the major reason for establishing the occupant threshold at 100 was due to several recent nightclub incidents, the requirement is not limited to nightclubs or banquet facilities but to all Group A-2 occupancies. Any restaurant with an occupant load greater than 100 would require sprinkler protection as well. This includes fast food facilities with no low lighting or alcohol sales. The similar intent of Condition 3 is addressed in the commentary to Section 903.2.1.1.

[F] 903.2.1.3 Group A-3. An automatic sprinkler system shall be provided for Group A-3 occupancies where one of the following conditions exists:
1. The fire area exceeds 12,000 square feet (1115 m²);
2. The fire area has an occupant load of 300 or more; or
3. The fire area is located on a floor other than a level of exit discharge serving such occupancies.

Group A-3 occupancies are assembly occupancies intended for worship, recreation or amusement and other assembly uses not classified elsewhere in Group A, such as churches, museums and libraries. While Group A-3 occupancies could potentially have a high occupant load, they normally do not have the same potential combination of life safety hazards...
associated with Group A-2 occupancies. As with most assembly occupancies, however, most of the occupants are typically not completely familiar with their surroundings. When any of the three listed conditions are applicable, an automatic sprinkler system is required throughout the fire area containing the Group A-3 occupancy and in all floors between the Group A occupancy and exit discharge that serves that occupancy (see commentary, Sections 903.2.1 and 903.2.1.1).

[F] 903.2.1.4 Group A-4. An automatic sprinkler system shall be provided for Group A-4 occupancies where one of the following conditions exists:

1. The fire area exceeds 12,000 square feet (1115 m²);  
2. The fire area has an occupant load of 300 or more; or  
3. The fire area is located on a floor other than a level of exit discharge serving such occupancies.

- Group A-4 occupancies are assembly uses intended for viewing of indoor sporting events and activities such as arenas, skating rinks and swimming pools. The occupant load density may be high depending on the extent and style of seating, such as bleachers or fixed seats, and the potential for standing-room viewing.

When any of the three listed conditions are applicable, an automatic sprinkler system is required throughout the fire area containing the Group A-4 occupancy and in all floors between the Group A occupancy and exit discharge (see commentary, Sections 903.2.1 and 903.2.1.1).

[F] 903.2.1.5 Group A-5. An automatic sprinkler system shall be provided for Group A-5 occupancies in the following areas: concession stands, retail areas, press boxes and other accessory use areas in excess of 1,000 square feet (93 m²).

- Group A-5 occupancies are assembly uses intended for viewing of outdoor activities. This occupancy classification could include amusement park structures, grandstands and open stadiums. A sprinkler system is not required in the open area of Group A-5 occupancies because the buildings would not accumulate smoke and hot gases. A fire in open areas would also be obvious to all spectators.

Enclosed areas such as retail areas, press boxes and concession stands require sprinklers if they are in excess of 1,000 square feet (93 m²). The 1,000-square-foot (93 m²) accessory use area is not intended to be an aggregate condition but rather per space. Thus, a press box that is 2,500 square feet (232 m²) in area would need to be subdivided into areas less than 1,000 square feet (93 m²) each in order to be below the threshold for sprinklers. There is no specific requirement for the separation of these spaces. It is assumed, however, that the separation would be a solid barrier of some type but without a required fire-resistance rating.

The provision is meant to mirror that in Section 1028.6.2.3, which exempts press boxes and storage facilities less than 1,000 square feet (93 m²) in area from sprinkler requirements in smoke-protected assembly seating areas.

[F] 903.2.2 Ambulatory care facilities. An automatic sprinkler system shall be installed throughout the entire floor containing an ambulatory care facility where either of the following conditions exist at any time:

1. Four or more care recipients are incapable of self-preservation, whether rendered incapable by staff or staff has accepted responsibility for care recipients already incapable.

2. One or more care recipients that are incapable of self-preservation are located at other than the level of exit discharge serving such a facility.

In buildings where ambulatory care is provided on levels other than the level of exit discharge, an automatic sprinkler system shall be installed throughout the entire floor where such care is provided as well as all floors below, and all floors between the level of ambulatory care and the nearest level of exit discharge, including the level of exit discharge.

- Ambulatory care facilities are Group B occupancies, which have an enhanced set of requirements that account for the fact that patients may be incapable of self-preservation and require rescue by other occupants or fire personnel. There are several aspects to the enhanced features, including smoke compartments, sprinklers and fire alarms. More specifically, the requirements for sprinklers are based on the presence of four or more care recipients at any given time that are incapable of self-preservation or any number of care recipients that are incapable of self-preservation located on a floor other than the level of exit discharge that serves the ambulatory care facility. The sprinkler requirement is limited to the floor area that contains the Group B ambulatory care facility and any floors between the ambulatory care facility and level of exit discharge (see commentary, Section 422).

[F] 903.2.3 Group E. An automatic sprinkler system shall be provided for Group E occupancies as follows:

1. Throughout all Group E fire areas greater than 12,000 square feet (1115 m²) in area.

2. Throughout every portion of educational buildings below the lowest level of exit discharge serving that portion of the building.  

Exception: An automatic sprinkler system is not required in any area below the lowest level of exit discharge serving that area where every classroom throughout the building has at least one exterior exit door at ground level.

- Group E occupancies are limited to educational purposes through the 12th grade and day care centers serving children older than 2 years of age. The 12,000-square-foot (1115 m²) fire area threshold for the sprinkler system was established to allow smaller schools and day care centers to be nonsprinklered to
minimize the economic impact on these facilities. The 12,000-square-foot (1115 m²) threshold is similar to that used for several other occupancies, such as Group M occupancies.

Sprinklers would also be required in portions of the building located below the level of egress discharge serving that occupancy. However, there is an exception that would allow the omission of the automatic sprinkler system for the Group E fire area if there is a direct exit to the exterior from each classroom at ground level. The occupants must be able to go from the classroom directly to the outside without passing through intervening corridors, passageways or interior exit stairways.

[F] 903.2.4 Group F-1. An automatic sprinkler system shall be provided throughout all buildings containing a Group F-1 occupancy where one of the following conditions exists:

1. A Group F-1 fire area exceeds 12,000 square feet (1115 m²).
2. A Group F-1 fire area is located more than three stories above grade plane.
3. The combined area of all Group F-1 fire areas on all floors, including any mezzanines, exceeds 24,000 square feet (2230 m²).
4. A Group F-1 occupancy used for the manufacture of upholstered furniture or mattresses exceeds 2,500 square feet (232 m²).

Group F-1 occupancies must meet several different conditions as to when the fire area or occupancy must be sprinklered. The first three conditions are related to the difficulty of manually suppressing a fire involving a large area. Therefore, occupancies of Group F-1 must be protected throughout with an automatic sprinkler system if the fire area is in excess of 12,000 square feet (1115 m²), if the total of all fire areas is in excess of 24,000 square feet (2230 m²) or if the fire area is located more than three stories above grade plane. This is one of the few locations in the code where the total floor area of the building is aggregated for application of a code requirement. The stipulated conditions for when an automatic sprinkler system is required also apply to Group M (see Section 903.2.7) and S-1 (see Section 903.2.9) occupancies. Condition 4 for sprinklering a Group F-1 occupancy relates to the requirement for Group F-1 occupancies in excess of 2,500 square feet (232 m²) that are used for the manufacture of upholstered furniture or mattresses. Note that this requirement is based simply upon the square footage of the Group F-1 occupancy and is not related to fire areas. Upholstered furniture has the potential for rapid growing and high-heat-release fires. This hazard is increased substantially when there are numerous upholstered furniture or mattresses being manufactured. Such fires put the occupants and emergency responders at risk. This requirement exists regardless of whether the upholstered furniture has passed any fire-retardant tests. See the commentary for Section 903.2.7 for more discussion on the subject of upholstered furniture.

The following examples illustrate how the criteria of this section are intended to be applied:

- If a building contains a single fire area of Group F-1 and the fire area is 13,000 square feet (1208 m²), an automatic sprinkler system is required throughout the entire building; however, if this fire area is separated into two fire areas and neither is in excess of 12,000 square feet (1115 m²), an automatic fire sprinkler system is not required. To be considered separate fire areas, the areas must be separated by fire barriers or horizontal assemblies having a fire-resistance rating as required in Table 707.3.10.

- If a 30,000-square-foot (2787 m²) Group F-1 building was equally divided into separate fire areas of 10,000 square feet (929 m²) each, an automatic sprinkler system would still be required throughout the entire building. Because the aggregate area of all fire areas exceeds 24,000 square feet (2230 m²), additional compartmentation will not eliminate the need for an automatic sprinkler system. However, the use of a fire wall to separate the structure into two buildings would reduce the aggregate area of each building to less than 24,000 square feet (2230 m²) and each fire area to less than 12,000 square feet (1115 m²), which would offset the need for an automatic sprinkler system.

[F] 903.2.4.1 Woodworking operations. An automatic sprinkler system shall be provided throughout all Group F-1 occupancy fire areas that contain woodworking operations in excess of 2,500 square feet (232 m²) in area which generate finely divided combustible waste or use finely divided combustible materials.

Because of the potential amount of combustible dust that could be generated during woodworking operations, an automatic sprinkler system is required throughout a fire area when it contains a woodworking operation that exceeds 2,500 square feet (232 m²) in area. Facilities where woodworking operations take place, such as cabinet making, are considered Group F-1 occupancies. The intent of the phrase "finely divided combustible waste" is to describe particle concentrations that are in the explosive range (see Chapter 22 of the IFC for discussion of dust-producing operations).

The extent of sprinkler coverage is only intended to be for the Group F-1 occupancy involved in the woodworking activity. If the fire area is larger than 2,500 square feet (232 m²) but the woodworking area is 2,500 square feet (232 m²) or less, sprinklers are not required. It is not the intent to require the installation of sprinklers throughout the building but rather in the fire area where the hazard may be present.
FIRE PROTECTION SYSTEMS

[F] 903.2.5 Group H. *Automatic sprinkler systems* shall be provided in high-hazard occupancies as required in Sections 903.2.5.1 through 903.2.5.3.

- Group H occupancies are those intended for the manufacturing, processing or storage of hazardous materials that constitute a physical or health hazard. To be considered a Group H occupancy, the amount of hazardous materials is assumed to be in excess of the maximum allowable quantities permitted by Tables 307.1(1) and 307.1(2).

[F] 903.2.5.1 General. An *automatic sprinkler system* shall be installed in Group H occupancies.

- This section requires an automatic sprinkler system in all Group H occupancies. Even though in some instances the hazard associated with the occupancy may be one that is not a fire hazard, an automatic sprinkler system is still required to minimize the potential for fire spreading to the high-hazard use; that is, the sprinklers protect the high-hazard area from fire outside the area. This section does not prohibit the use of an alternative automatic fire-extinguishing system in accordance with Section 904. When a water-based system is not compatible with the hazardous materials involved and thus creates a dangerous condition, an alternative fire-extinguishing system should be used. For example, combustible metals, such as magnesium and titanium, have a serious record of involvement with fire and are typically not compatible with water (see commentary, Chapter 59 of the IFC).

   Where control areas are used to regulate the quantity of hazardous material within a building, the building is not considered a Group H occupancy. Unless a building would be required by some other code provision to be protected with sprinklers, control areas can be used to control the allowable quantities of hazardous materials in a building so as to not warrant a Group H classification and its mandatory sprinkler requirements.

[F] 903.2.5.2 Group H-5. An *automatic sprinkler system* shall be installed throughout buildings containing Group H-5 occupancies. The design of the sprinkler system shall not be less than that required by this code for the occupancy hazard classifications in accordance with Table 903.2.5.2. Where the design area of the sprinkler system consists of a *corridor* protected by one row of sprinklers, the maximum number of sprinklers required to be calculated is 13.

- Group H-5 occupancies are structures that are typically used as semiconductor fabrication facilities and comparable research laboratory facilities that use hazardous production materials (HPM). Many of the materials used in semiconductor fabrication present unique hazards. Many of the materials are toxic, while some are corrosive, water reactive or pyrophoric. Fire protection for these facilities is aimed at preventing incidents from escalating and producing secondary threats beyond a fire, such as the release of corrosive or toxic materials. Because of the nature of Group H-5 facilities, the overall amount of hazardous materials can far exceed the maximum allowable quantities given in Tables 307.1(1) and 307.1(2). Although the amount of HPM material is restricted in fabrication areas, the quantities of HPM in storage rooms normally will be in excess of those allowed by the tables. Additional requirements for Group H-5 facilities are located in Chapter 27 of the IFC and Section 415.10 of the code.

   This section also specifies the sprinkler design criteria, based on NFPA 13, for various areas in a Group H-5 occupancy (see commentary, Table 903.2.5.2). When the corridor design area sprinkler option is used, a maximum of 13 sprinklers must be calculated. This exceeds the requirements of NFPA 13 for typical egress corridors, which require a maximum of either five or seven calculated sprinklers, depending on the extent of protected openings in the corridor. The increased number of calculated corridor sprinklers is based on the additional hazard associated with the movement of hazardous materials in corridors of Group H-5 facilities.

- Table 903.2.5.2 designates the appropriate occupancy hazard classification for the various areas within a Group H-5 facility. The listed occupancy hazard classifications correspond to specific sprinkler system design criteria in NFPA 13, Ordinary Hazard Group 2 occupancies, for example, require a minimum design density of 0.20 gpm/ft² (8.1 L/min/m²) with a minimum design area of 1,500 square feet (139 m²). An Extra Hazard Group 2 occupancy, in turn, requires a minimum design density of 0.40 gpm/ft² (16.3 L/min/m²) with a minimum operating area of 2,500 square feet (232 m²). The increased overall sprinkler demand for Extra Hazard Group 2 occupancies is based on the potential use and handling of substantial amounts of hazardous materials, such as flammable or combustible liquids.

[F] 903.2.5.3 Pyroxylin plastics. An *automatic sprinkler system* shall be provided in buildings, or portions thereof, where cellulose nitrate film or pyroxylin plastics are manufactured, stored or handled in quantities exceeding 100 pounds (45 kg).

- Cellulose nitrate (pyroxylin) plastics pose unusual and substantial fire risks. Pyroxylin plastics are the most dangerous and unstable of all plastic compounds. The chemically bound oxygen in their structure permits them to burn vigorously in the absence of atmospheric oxygen. Although these compounds produce approximately the same amount of energy...
as paper when they burn, pyroxylin plastics burn at a rate as much as 15 times greater than comparable common combustibles. When burning, these materials release highly flammable and toxic combustion byproducts. Consequently, cellulose nitrate fires are very difficult to control. Although this section specifies a sprinkler threshold quantity of 100 pounds, the need for additional fire protection should be considered for pyroxylin plastics in any amount.

Although the code includes cellulose nitrate "film" in its requirements, cellulose nitrate motion picture film has not been used in the United States since the 1950s. All motion picture film produced since that time is what is typically called "safety film." Consequently, the only application for this section relative to motion picture film is where it may be used in laboratories or storage vaults that are dedicated to film restoration and archives. The protection of these facilities is addressed in Sections 306.2 and 6504.2, both in the IFC.

[F] 903.2.6 Group I. An automatic sprinkler system shall be provided throughout buildings with a Group I fire area.

Exceptions:

1. An automatic sprinkler system installed in accordance with Section 903.3.1.2 shall be permitted in Group I-1 facilities.

2. An automatic sprinkler system installed in accordance with Section 903.3.1.3 shall be allowed in Group I-1 facilities when in compliance with all of the following:
   2.1. A hydraulic design information sign is located on the system riser;
   2.2. Exception 1 of Section 903.4 is not applied; and
   2.3. Systems shall be maintained in accordance with the requirements of Section 903.3.1.2.

3. An automatic sprinkler system is not required where day care facilities are at the level of exit discharge and where every room where care is provided has at least one exterior exit door.

4. In buildings where Group I-4 day care is provided on levels other than the level of exit discharge, an automatic sprinkler system in accordance with Section 903.3.1.1 shall be installed on the entire floor where care is provided and all floors between the level of care and the level of exit discharge, all floors below the level of exit discharge, other than areas classified as an open parking garage.

The Group I occupancy is divided into four individual occupancy classifications based on the degree of detention, supervision and physical mobility of the occupants. The evacuation difficulties associated with the building occupants creates the need to incorporate a defend-in-place philosophy of fire protection in occupancies of Group I. For this reason, all such occupancies are to be protected with an automatic sprinkler system.

Of particular note, this Section encompasses all Group I-3 occupancies where more than five persons are detained. There has been considerable controversy concerning the use of automatic sprinklers in detention and correctional occupancies. Special design considerations can be taken into account to alleviate the perceived problems with sprinklers in sleeping units. Sprinklers that reduce the likelihood of vandalism as well as the potential to hang oneself are commercially available. Knowledgeable designers can incorporate certain design features to increase reliability and decrease the likelihood of damage to the system.

Group I-4 occupancies would include either adult-only care facilities or occupancies that provide personal care for more than five children 2½ years of age or less on a less than 24-hour basis. Because the degree of assistance and the time needed for egress cannot be gauged, an automatic sprinkler system is required.

There are four exceptions to this section. Exception 1 permits Group I-1 occupancies to be protected throughout with an NFPA 13R system instead of an NFPA 13 system.

Exception 2 allows the use of an NFPA 13D sprinkler system instead of a standard NFPA 13 sprinkler system, but with several conditions specified. The conditions noted basically relate the system more closely to an NFPA 13R system with requirements for monitoring and maintenance and availability documents describing the hydraulic design for the system. The exception recognizes the perceived mobility of the occupants in a Group I-1 facility as well as the basic life-safety intent to protect the main occupiable areas. However, use of this exception would result in the building not qualifying as a fully sprinklered building in accordance with NFPA 13 for any applicable code alternatives.

Exception 3 exempts sprinkler systems completely if the day care center is at the level of exit discharge and every room has at least one exterior exit door. Note that day cares to which this section applies are considered by Section 308.6.1 to be Group E occupancies. An automatic sprinkler system would not be required unless dictated by the requirements in Section 903.2.2 (see the commentary for Section 308.6.1).

Exception 4 is also related to day cares that are still classified as Group I-4 by nature of the location in the building. In that case, an NFPA 13 system would be required on the floor where the center is located and all floors between and including the level of exit discharge. This is less stringent than the main requirement in Section 903.2.6 that requires the entire building to be sprinklered. As defined in Section 202, a Group I-4 child care facility located at the level of exit discharge and accommodating no more than 100 children, with each child care room having an exit directly to the exterior, would be classified as a Group E occupancy.
[F] 903.2.7 Group M. An automatic sprinkler system shall be provided throughout buildings containing a Group M occupancy where one of the following conditions exists:

1. A Group M fire area exceeds 12,000 square feet (1115 m²).
2. A Group M fire area is located more than three stories above grade plane.
3. The combined area of all Group M fire areas on all floors, including any mezzanines, exceeds 24,000 square feet (2230 m²).
4. A Group M occupancy used for the display and sale of upholstered furniture or mattresses exceeds 5,000 square feet (464 m²).

The sprinkler threshold requirements for Group M occupancies are identical to those of Group F-1 and S-1 occupancies (see commentary, Section 903.2.4). The one exception is that Group M occupancies are provided with an increased area for display of upholstered furniture and mattresses of 5,000 square feet (464 m²) versus 2,500 square feet (232 m²) required for Group F-1 and S-1 occupancies. As noted in the commentary for Group F-1 occupancies, upholstered furniture and mattresses have the potential for rapid growing and high-heat-release fires. This hazard is increased substantially when there are numerous upholstered furniture items or mattresses on display. Such fires put the occupants and emergency responders at risk. This requirement exists regardless of whether the upholstered furniture has passed any fire-retardant tests.

The code does not specifically address what constitutes upholstered furniture, but by simple dictionary definition, upholstered furniture has seats covered with padding, springs, webbing and fabric or leather covers. The code does not make any distinction between levels of padding and upholstery provided on furniture, which was intentional. The proponent’s reason statement for code change F135-07/08 stated, in part, that “the American Home Furnishings Alliance (AHFA) and the National Home Furnishings Association (NHFA) have examined proposals for exempting vendors of certain constructions of furniture and concluded that such exemptions would be impractical for local code officials to enforce. This is the case because the internal construction of furniture cannot be established reliably without deconstructing it.”

Note that, as with Group F-1 occupancies, the criteria is written such that any Group M occupancy, not the fire area, over 5,000 square feet (464 m²) used for the display and sale of upholstered furniture and mattresses shall be sprinklered throughout. This is regardless of how much upholstered furniture and mattresses are actually available for purchase.

Automatic sprinkler systems for mercantile occupancies are typically designed for an Ordinary Hazard Group 2 classification in accordance with NFPA 13. If high-piled storage (see Section 903.2.7.1) is anticipated; however, additional levels of fire protection may be required. Also, some merchandize in mercantile occupancies, such as aerosols, rubber tires, paints and certain plastic commodities, even at limited storage heights, are considered beyond the standard Class I through IV commodity classification assumed for mercantile occupancies in NFPA 13 and may warrant additional fire protection.

[F] 903.2.7.1 High-piled storage. An automatic sprinkler system shall be provided in accordance with the International Fire Code in all buildings of Group M where storage of merchandise is in high-piled or rack storage arrays.

- Regardless of the size of the Group M fire area, an automatic sprinkler system may be required in a high-piled storage area. High-piled storage includes piled, palletized, bin box, shelf or rack storage of Class I through IV commodities to a height greater than 12 feet (3658 mm) and certain high-hazard commodities greater than 6 feet (1829 mm). Chapter 23 of the IFC provides a package of requirements that may include sprinkler protection depending upon the size of the high-piled storage area. The design standard for the sprinkler protection of high-piled storage is NFPA 13, which addresses the many different types and configurations of high-piled storage.

[F] 903.2.8 Group R. An automatic sprinkler system installed in accordance with Section 903.3 shall be provided throughout all buildings with a Group R fire area.

- This section requires sprinklers in any building that contains a Group R fire area. This includes uses such as hotels, apartment buildings, group homes and dormitories. There are no minimum criteria and no exceptions.

It should be noted that buildings constructed under the International Residential Code® (IRC®) are not included in Group R and would not, therefore, be subject to these particular requirements. However, the 2009 IRC requires sprinklers in all new townhouses and, beginning January 1, 2011, in all new one- and two-family dwellings. The IRC is a stand-alone code for the construction of detached one- and two-family dwellings and multiple single-family dwellings (townhouses) no more than three stories in height with a separate means of egress and addresses the requirements for sprinklers in a different way. That is, all of the provisions for new construction that affect those buildings are to be covered exclusively by the IRC and are not to be covered by another International Code. Buildings that do not fall within the scope of the IRC would be classified in Group R and be subject to these provisions. This is stated clearly in IFC Committee Interpretation No. 29-03.

With respect to life safety, the need for a sprinkler system is dependent on the occupants’ proximity to the fire and the ability to respond to a fire emergency. Group R occupancies could contain occupants who may require assistance to evacuate, such as infants, those with a disability or who may simply be asleep.
While the presence of a sprinkler system cannot always protect occupants in residential buildings who are aware of the ignition and either do not respond or respond inappropriately, it can prevent fatalities outside of the area of fire origin regardless of the occupants' response. Section 903.3.2 requires quick-response or residential sprinklers in all Group R occupancies. Full-scale fire tests have demonstrated the ability of quick-response and residential sprinklers to maintain tenability from flaming fires in the room of fire origin.

Where a different occupancy is located in a building with a residential occupancy, the provisions of this section still apply and the entire building is required to be provided with an automatic sprinkler system regardless of the type of mixed-use condition considered. This is consistent with the mixed-use provisions in Chapter 5.

[F] 903.2.8.1 Group R-3 or R-4 congregate residences. An automatic sprinkler system installed in accordance with Section 903.3.1.3 shall be permitted in Group R-3 or R-4 congregate residences with 16 or fewer residents.

- This section allows Group R-3 and R-4 congregate residences to use an NFPA 13D system. This would not be appropriate for all Group R occupancies, but only for small congregate residences. While not technically a single-family dwelling, such occupancies are permitted to use NFPA 13D systems. This is consistent with NFPA 13D requirements and was permitted specifically for Group R-4 in the 2000 edition of the International Building Code® (IBC®). This would also be consistent with Fair Housing Act (FHA) court cases based on nondiscrimination for group homes.

[F] 903.2.8.2 Care facilities. An automatic sprinkler system installed in accordance with Section 903.3.1.3 shall be permitted in care facilities with 5 or fewer individuals in a single-family dwelling.

- This section is similar to Section 903.2.8.1 and allows the use of an NFPA 13D system in place of an NFPA 13 or 13R system. In this case, it is specific to smaller care facilities with five or fewer residents. Again, while not technically a single-family dwelling, they are very similar in nature based upon the type and actual use of the building.

[F] 903.2.9 Group S-1. An automatic sprinkler system shall be provided throughout all buildings containing a Group S-1 occupancy where one of the following conditions exists:

1. A Group S-1 fire area exceeds 12,000 square feet (1115 m²).

2. A Group S-1 fire area is located more than three stories above grade plane.

3. The combined area of all Group S-1 fire areas on all floors, including any mezzanines, exceeds 24,000 square feet (2230 m²).

4. A Group S-1 fire area used for the storage of commercial trucks or buses where the fire area exceeds 5,000 square feet (464 m²).

5. A Group S-1 occupancy used for the storage of upholstered furniture or mattresses exceeds 2,500 square feet (232 m²).

- An automatic sprinkler system must be provided throughout all buildings where the fire area containing a Group S-1 occupancy exceeds 12,000 square feet (1115 m²), where more than three stories in height, where the combined fire area on all floors, including mezzanines, exceeds 24,000 square feet (2230 m²) or where the Group S-1 fire area used for the storage of commercial trucks or buses exceeds 5,000 square feet (464 m²).

The first three sprinkler threshold requirements for Group S-1 occupancies are identical to those of Groups F-1 and M (see commentary, Sections 903.2.4 and 903.2.7). Group S-1 occupancies, such as warehouses and self-storage buildings, are assumed to be used for the storage of combustible materials. While high-piled storage does not change the Group S-1 occupancy classification, sprinkler protection, if required, may have to comply with the additional requirements of Chapter 23 of the IFC. High-piled stock or rack storage in any occupancy must comply with the code. The fourth sprinkler threshold is the same as for Group F-1 except that, in this case, upholstered furniture and mattresses are being stored and not manufactured. Group M has a similar threshold, but is required for larger occupancies containing such items with an area of 5,000 square feet (464 m²) versus what is required for Groups S-1 and F-1 of 2,500 square feet (232 m²). See the commentary for Group M and Group F-1 definitions for more discussion on this issue. Again, it is important to note that the threshold is based upon the square footage of the occupancy and not upon the size of the fire area. Also, the code does not discern between the storage of one mattress or many. The requirements are based solely on the square footage of the occupancies containing upholstered furniture or mattresses.

[F] 903.2.9.1 Repair garages. An automatic sprinkler system shall be provided throughout all buildings used as repair garages in accordance with Section 406, as shown:

1. Buildings having two or more stories above grade plane, including basements, with a fire area containing a repair garage exceeding 10,000 square feet (929 m²).

2. Buildings no more than one story above grade plane, with a fire area containing a repair garage exceeding 12,000 square feet (1115 m²).

4. A Group S-1 fire area used for the repair of commercial trucks or buses where the fire area exceeds 5,000 square feet (464 m²).

- Automatic sprinklers may be required in repair garages, depending on the quantity of combustibles present, their location and floor area. In addition any Group S-1 fire area intended for the repair of com-
mercial buses or trucks that exceeds 5,000 square feet (464 m²) would require sprinklers. This is the same criteria as Group S-1 occupancies and Group S-2 enclosed parking garages storing commercial buses and trucks. Repair garages may contain significant quantities of flammable liquids and other combustible materials. These occupancies are typically considered Ordinary Hazard Group 2 occupancies as defined in NFPA 13. Portions of repair garages used for parts cleaning using flammable or combustible liquids may require automatic sprinkler protection. If quantities of hazardous materials exceed the limitations in Section 307 for maximum allowable quantities per control area, the repair garage would be reclassified as a Group H occupancy.

[F] 903.2.9.2 Bulk storage of tires. Buildings and structures where the area for the storage of tires exceeds 20,000 cubic feet (566 m³) shall be equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1.

- This section specifies when an automatic sprinkler system is required for the bulk storage of tires based on the volume of the storage area as opposed to a specific number of tires. Even in fully sprinklered buildings, tire fires pose significant problems to fire departments. Tire fires produce thick smoke and are difficult to extinguish by sprinklers alone. NFPA 13 contains specific fire protection requirements for the storage of rubber tires.

- Whether the volume of tires is divided into different fire areas or not is irrelevant to the application of this section. If the total for all areas where tires are stored is great enough that the resultant storage volume exceeds 20,000 cubic feet (566 m³), the building must be sprinklered throughout. See the commentary to Section 202 definition of “Tires, bulk storage of” for further information.

[F] 903.2.10 Group S-2 enclosed parking garages. An automatic sprinkler system shall be provided throughout buildings classified as enclosed parking garages in accordance with Section 406.4 as follows:

1. Where the fire area of the enclosed parking garage exceeds 12,000 square feet (1115 m²); or

2. Where the enclosed parking garage is located beneath other groups.

Exception: Enclosed parking garages located beneath Group R-3 occupancies.

- Fire records have shown that fires in parking structures typically fully involve only a single automobile with minor damage to adjacent vehicles. An enclosed parking garage, however, does not allow the dissipation of smoke and hot gases as readily as an open parking structure, which is also considered a Group S-2 occupancy. If the enclosed parking garage has a fire area greater than 12,000 square feet (1115 m²) or is located beneath another occupancy group, the enclosed parking garage must be protected with an automatic sprinkler system. This requirement that the enclosed parking garage located beneath other occupancy groups is required to be sprinklered is based on the potential for a fire to develop undetected, which would endanger the occupants of the other occupancy. The 12,000-square-foot (1115 m²) threshold is similar to other occupancies such as Groups M and S-1.

- It should be noted that while open parking garages are considered a Group S-2 occupancy, they are not required by the provisions of this section to be equipped with an automatic sprinkler system.

- The exception exempts enclosed garages in buildings where the garages are located below a Group R-3 occupancy. The exception is essentially moot since the code requires all buildings with a Group R occupancy to be sprinklered throughout. Because the entire building with the residential occupancy is required to be sprinklered according to Section 903.2.8, the garage would be sprinklered as well. It should be noted that if the Group R-3 occupancy was protected with an NFPA 13D system, the enclosed parking garage would not require sprinklers.

[F] 903.2.10.1 Commercial parking garages. An automatic sprinkler system shall be provided throughout buildings used for storage of commercial trucks or buses where the fire area exceeds 5,000 square feet (464 m²).

- Because of the larger-sized vehicles involved in commercial parking structures, such as trucks or buses, a more stringent sprinkler threshold is required. Bus garages may also be located adjacent to passenger terminals (Group A-3) that have a substantial occupant load. Commercial parking requires only a single vehicle in order to be classified as commercial parking.

The criterion for sprinkler protection is based on the size of the fire area and not the size of the commercial parking. If the commercial parking involves only 1,000 square feet (93 m²) but the fire area exceeds 5,000 square feet (464 m²), sprinkler protection is required.

[F] 903.2.11 Specific building areas and hazards. In all occupancies other than Group U, an automatic sprinkler system shall be installed for building design or hazards in the locations set forth in Sections 903.2.11.1 through 903.2.11.6.

- Sections 903.2.11.1 through 903.2.11.2 specify certain conditions under which an automatic sprinkler system is required, even in otherwise nonsprinklered buildings. As indicated, the listed conditions in the noted sections are applicable to all occupancies except Group U. Most structures that qualify as Group U do not typically have the type of conditions stipulated in Sections 903.2.11.1 through 903.2.11.1.3.

[F] 903.2.11.1 Stories without openings. An automatic sprinkler system shall be installed throughout all stories,
Including basements, of all buildings where the floor area exceeds 1,500 square feet (139.4 m²) and where there is not provided at least one of the following types of exterior wall openings:

1. Openings below grade that lead directly to ground level by an exterior stairway complying with Section 1009 or an outside ramp complying with Section 1010. Openings shall be located in each 50 linear feet (15 240 mm), or fraction thereof, of exterior wall in the story on at least one side. The required openings shall be distributed such that the lineal distance between adjacent openings does not exceed 50 feet (15 240 mm).

2. Openings entirely above the adjoining ground level totaling at least 20 square feet (1.86 m²) in each 50 linear feet (15 240 mm), or fraction thereof, of exterior wall in the story on at least one side. The required openings shall be distributed such that the lineal distance between adjacent openings does not exceed 50 feet (15 240 mm). The height of the bottom of the clear opening shall not exceed 44 inches (1118 mm) measured from the floor.

Because of both the lack of openings in exterior walls for access by the fire department for fire fighting and rescue and the problems associated with venting the products of combustion during fire suppression operations, all stories, including any basements of buildings that do not have adequate openings as defined in this section, must be equipped with an automatic sprinkler system. This section applies to stories without sufficient exterior openings where the floor area exceeds 1,500 square feet (139 m²) and where the building is not otherwise required to be fully sprinklered. The requirement for an automatic sprinkler system in this section applies only to the affected area and does not mandate sprinkler protection throughout the entire building.

Stories without openings, as defined in this section, are stories that do not have at least 20 square feet (1.9 m²) of opening leading directly to ground level in each 50 lineal feet (15 240 mm) or fraction thereof on at least one side. Since exterior doors will provide openings of 20 square feet (1.9 m²), or slightly less in some occupancies, exterior stairways and ramps in each 50 lineal feet (15 240 mm) are considered acceptable.

This section specifically states that the required openings be distributed such that the lineal distance between adjacent openings does not exceed 50 feet (15 240 mm). If the openings in the exterior wall are located without regard to the location of the adjacent openings, it is possible that segments of the exterior wall will not have the required access to the interior of the building for fire-fighting purposes. Any arrangement of required stairways, ramps or openings that results in a portion of the wall 50 feet (15 240 mm) or more in length with no openings to the exterior does not meet the intent of the code that access be provided in each 50 lineal feet (15 240 mm) (see Figure 903.2.11.1).

There is a further restriction on openings that are entirely above grade. More specifically, to support fire-fighting operations the openings need to be accessible and usable. Therefore, item 2 specifies that the maximum sill height be 44 inches (1118 mm) above the floor. This height is consistent with the height provided for emergency escape and rescue windows in Section 1029.3.

One application of this section has been addressed in the 2009 edition of the International Code Interpretations book and deals with automotive service shops that have below-grade service areas where employees perform oil changes and other minor maintenance services. The below-grade areas are typically open to the grade-level service bays via openings providing access to the underside of the vehicles without requiring the vehicle to be lifted into the air. Inasmuch as the below-grade space has no openings directly to the exterior, the question was asked if it would be regulated as a windowless story and thus be required to be equipped with an automatic fire suppression system in accordance with Section 903.2.11.1.

The answer to that question is no. Due to the openness between the adjacent service levels, the below-grade area would be more appropriately regulated similar to a mezzanine rather than a story. A mezzanine is not regulated as a separate story but rather as part of the same story that it serves. Therefore, if the below-grade service level is in compliance with the applicable provisions of Section 505, the windowless story provisions of Section 903.2.11.1 would be evaluated based on the exterior wall openings of the main level and not the service mezzanine below. The direct interconnections between the two adjacent floor levels by multiple service openings provide access to the lower service area for fire-fighting and rescue operations. As such, it would not be regulated as a windowless story.

The requirement to sprinkle the basement is independent of mixed-use conditions. Whether the basement is separated or nonseparated is irrelevant to the need for sprinkler protection, nor does the requirement to provide sprinklers in the basement imply that sprinklers must be provided elsewhere. This requirement is applicable to the basement or any story without openings irrespective of other code provisions.

These provisions are also not based upon the size of a fire area but rather upon the size of the basement. Thus, subdividing the basement into multiple fire areas would have no effect on the requirement. However, one benefit of the multiple fire areas could be that each fire area could have a separate limited area sprinkler system with less than 20 sprinklers.

[F] 903.2.11.1.1 Opening dimensions and access. Openings shall have a minimum dimension of not less than 30 inches (762 mm). Such openings shall be accessible to the fire department from the exterior and shall not be obstructed in a
manner that fire fighting or rescue cannot be accomplished from the exterior.

- To qualify, an opening must not be less than 30 inches (762 mm) in least dimension and must be accessible to the fire department from the exterior. The minimum opening dimension gives fire department personnel access to the interior of the story or basement for fire-fighting and rescue operations and provides openings that are large enough to vent the products of combustion.

[F] 903.2.11.1.2 Openings on one side only. Where openings in a story are provided on only one side and the opposite wall of such story is more than 75 feet (22 860 mm) from such openings, the story shall be equipped throughout with an approved automatic sprinkler system, or openings as specified above shall be provided on at least two sides of the story.

- If openings are provided on only one side, an automatic sprinkler system would still be required if the opposite wall of the story is more than 75 feet (22 860 mm) from existing openings. An alternative to providing the automatic sprinkler system would be to design openings on at least two sides of the exterior of the building. As long as the story being considered is not a basement, the openings on two sides can be greater than 75 feet (22 860 mm) from any portion of the floor. In basements, if any portion is more than 75 feet (22 860 mm) from the openings, the entire basement must be equipped with an automatic sprinkler system, as indicated in Section 903.2.11.1.3. Providing openings on more than one wall allows cross ventilation to vent the products of combustion [see Figures 903.2.11.1(1-4)].

[F] 903.2.11.1.3 Basements. Where any portion of a basement is located more than 75 feet (22 860 mm) from openings required by Section 903.2.11.1, or where walls, partitions or other obstructions are installed that restrict the application of water from hose streams, the basement shall be equipped throughout with an approved automatic sprinkler system.

- The 75-foot (22 860 mm) distance is intended to be measured in the line of travel—not in a straight line perpendicular to the wall. Where obstructions, such as walls or other partitions, are present in a basement, the walls and partitions enclosing any room or space must have openings that provide an equivalent degree of fire department access to that provided by the openings prescribed in Section 903.2.11.1 for exterior walls. When obstructions such as walls or partitions are installed in the basement, the ability to apply hose streams through these openings and reach the basement area is reduced or eliminated. The configuration and clear-opening requirements become useless when an interior wall or other obstruction is placed inside the basement. In that case, it is reasonable to require automatic fire sprinklers to provide adequate protection in the basement. If an equivalent degree of fire department access to all portions of the floor area is not provided, the basement would require an automatic sprinkler system.

[F] 903.2.11.2 Rubbish and linen chutes. An automatic sprinkler system shall be installed at the top of rubbish and linen chutes and in their terminal rooms. Chutes shall have additional sprinkler heads installed at alternate floors and at the lowest intake. Where a rubbish chute extends through a building more than one floor below the lowest intake, the extension shall have sprinklers installed that are recessed from the drop area of the chute and protected from freezing in accordance with Section 903.3.1.1. Such sprinklers shall be installed at alternate floors, beginning with the second level below the last intake and ending with the floor above the discharge. Chute sprinklers shall be accessible for servicing.

- Gravity rubbish and linen chutes can present a significant hazard to building occupants if they are not properly installed and protected. Generally, these systems are installed in high-occupancy buildings where the occupants will be sleeping or in capable of self-rescue, such as in Group R-1, R-2 and I-2 occupancies. Secondly, for occupant convenience, openings to the chutes are commonly provided in areas accessible to the public and, in older buildings, the chute opening may be located in an exit access corridor. In comparison to other building shafts, gravity rubbish and linen chutes always contain fuel. As bags of waste debris or linen fall through the chute, they can deposit fluids such as waste cooking oil, which adheres to the shaft surface. This waste material and other debris provide fuel that can support and accelerate vertical fire spread. The greatest accumulation of fuel will be in the termination room; however, a significant amount of fuel that covers the interior surface area of the chute will be found in the sections of chutes closest to the collection or termination room. Therefore, it is important that the automatic sprinklers be properly placed and protected so they are available in the event of a fire in the termination room and if equipped, the waste compaction equipment.

Installation of gravity chutes for rubbish or linen requires compliance with the code and the IFC. Under the code, permanent rubbish and linen chutes are constructed inside of a fire-resistance-rated shaft assembly with a minimum 1-hour fire-resistance rating in buildings less than four stories in height; in buildings four or more stories in height, the fire-resistance rating is increased to 2 hours by Section 713.4. The design of the shaft system and its openings must also comply with the requirements in Sections 713.11 and 713.13, which require the termination room receiving the discharged material to be separated from the building by a fire-resistance rating equivalent to that of the shaft that it serves.

In Group I-2 occupancies, Exception 2 of Section 713.13 requires that gravity rubbish or linen chutes comply with the requirements in Chapter 5 of NFPA 82. The requirements in NFPA 82 are essentially equivalent to the shaft and fire-resistant construction provisions in Chapter 7 of the code. When dealing with Group I-2 occupancies, code users should be aware of the requirement to comply with NFPA 82.

Section 713.13.6 requires the installation of an automatic sprinkler system in rubbish and linen chutes to comply with the requirements of Section 903.2.11.2. Section 903.2.11.2 correlates with the requirements in Chapter 21 of NFPA 13. Chapter 21 of NFPA 13 contains the special occupancy requirements for all buildings, including gravity waste and linen chutes. The provisions align the code and IFC requirements with those in NFPA 82 and NFPA 13.

A critical term in this section is "extension." The word was selected to address chutes installed in buildings of pedestal construction or other designs in which the fire-resistant construction shaft and chute pass through a less hazardous occupancy, such as a Group S-2 parking garage, or other floors that do not have access to the shaft. In these cases, chute openings are generally not provided. As a result, this section now contains a specific provision that may impose a requirement for sprinklers in the portion of the chute that serves as an extension beyond the last intake and the termination room or discharge area.

Because objects will be falling through the chute, the code requires the chute sprinklers to be recessed and protected from impact. Sprinklers are not required at every story housing a chute. The code requires automatic sprinklers at the top of the chute and at its termination. In addition, sprinkler heads are required at alternate floors within the chute, with a head being installed at the floor level with the lowest intake point into the chute. Previously, these additional sprinkler heads were only required where the shaft extended through three or more floors. These revisions, plus the previously discussed requirements for extensions, may result in additional sprinkler heads within some shafts as compared to the previous requirements.

Sprinklers in chutes that are in locations subject to freezing require freeze protection in accordance with the requirements of Section 903.3.1.1 and, therefore, the NFPA 13 standard. This can be accomplished using a dry-pendant sprinkler or constructing or installing a dry-pipe sprinkler system.

[F] 903.2.11.3 Buildings 55 feet or more in height. An automatic sprinkler system shall be installed throughout buildings with a floor level having an occupant load of 30 or more that is located 55 feet (16 764 mm) or more above the lowest level of fire department vehicle access.

Exceptions:

1. Airport control towers.
2. Open parking structures.
3. Occupancies in Group F-2.

- Because of the difficulties associated with manual suppression of a fire in buildings in excess of 55 feet (16 764 mm) in height, an automatic sprinkler system is required throughout the building regardless of occupancy. Buildings that qualify for a sprinkler system under Section 903.2.11.3 are not necessarily high-rise buildings as defined in Section 202.
The listed exceptions are occupancies that, based on height only, do not require an automatic sprinkler system. Airport control towers and open parking structures are also exempt from the high-rise provisions of Section 403. Although an automatic sprinkler system is not required in open parking structures, a sprinkler system may still be needed, depending on the building construction type and the area and number of parking tiers (see Table 406.3.5).

[F] 903.2.11.4 Ducts conveying hazardous exhausts. Where required by the International Mechanical Code, automatic sprinklers shall be provided in ducts conveying hazardous exhaust, or flammable or combustible materials.

Exception: Ducts in which the largest cross-sectional diameter of the duct is less than 10 inches (254 mm).

Section 510 of the IMC addresses the requirements for hazardous exhaust systems. To protect against the spread of fire within a hazardous exhaust system and to prevent a duct fire from involving the building, an automatic sprinkler system must be installed to protect the exhaust duct system. Where materials conveyed in the ducts are not compatible with water, alternative extinguishing agents should be used. The fire suppression requirement is intended to apply to exhaust systems having an actual fire hazard. An automatic sprinkler system in the duct would be of little value for an exhaust system that conveys only nonflammable or noncombustible materials, fumes, vapors or gases.

The exception recognizes the reduced hazard associated with smaller ducts and the impracticality of installing sprinkler protection. Another exception in the IMC indicates that laboratory hoods that meet specific provisions of the IMC are not required to be suppressed. Because the IMC is more specific in this regard, it should be consulted for the proper application of the exception.

[F] 903.2.11.5 Commercial cooking operations. An automatic sprinkler system shall be installed in commercial kitchen exhaust hood and duct system where an automatic sprinkler system is used to comply with Section 904.

An automatic suppression system is required for commercial kitchen exhaust hood and duct systems where required by Section 609 of the IFC or by the IMC to have a Type I hood. Type I hoods are required for commercial cooking equipment that produces grease-laden vapors or smoke. Section 904.11 recognizes that alternative extinguishing systems other than an automatic sprinkler system may be used. Where an automatic sprinkler system is used for commercial cooking operations, it must comply with the requirements identified in Section 904.11.4.

[F] 903.2.11.6 Other required suppression systems. In addition to the requirements of Section 903.2, the provisions indicated in Table 903.2.11.6 also require the installation of a fire suppression system for certain buildings and areas.

In addition to Section 903.2, requirements for automatic fire suppression systems are also found elsewhere in the code as indicated in Table 903.2.11.6.

Table 903.2.11.6 identifies other sections of the code that require an automatic fire suppression system based on the specific occupancy or use because of the unique hazards of such use or occupancy. The table does not identify the various sections of the code that contain design alternatives based on the use of an automatic fire suppression system, typically an automatic sprinkler system.

[F] 903.2.12 During construction. Automatic sprinkler systems required during construction, alteration and demolition operations shall be provided in accordance with Chapter 33 of the International Fire Code.

Chapter 33 of the code and Chapter 14 of the IFC address fire safety requirements during construction, alteration or demolition work. Working sprinkler systems should remain operative at all times unless it is absolutely necessary to shut down the system because of the proposed work. All sprinkler system impairments should be rectified as quickly as possible unless specific prior approval has been obtained from the fire code official. Buildings with a required sprinkler system should not be occupied unless the sprinkler system has been installed and tested consistent with Section 901.5. If the system must be placed out of service, the requirements of Section...
901.7 of the IFC are necessary to address the temporary impairment to the fire protection system.

[F] 903.3 Installation requirements. Automatic sprinkler systems shall be designed and installed in accordance with Sections 903.3.1.2 and 903.3.1.3 and other chapters of this code, as applicable.

- Automatic sprinkler systems are to be installed to comply with the code and NFPA 13, 13R or 13D. As provided for in Section 102.4, where differences occur between the code and NFPA 13, 13R or 13D, the code applies. The fire code official also has the authority to approve the type of sprinkler system to be installed. See Figure 903.3.1 for typical design parameters for each type of sprinkler system.

This section also provides a pointer to other sections of the code that might provide more specific or detailed sprinkler requirements such as those found in Chapter 4 of the code.

Figure 903.3.1.1
TYPICAL WET PIPE SYSTEM
1. Information required on shop drawings includes:
   — Name of owner and occupant
   — Location, including street address
   — Point of compass
   — Graphic indication of scale
   — Ceiling construction
   — Full-height cross section
   — Location of fire walls
   — Location of partitions
   — Occupancy of each area or room
   — Location and size of blind spaces and closets
   — Any questionable small enclosures in which no sprinklers are to be installed
   — Size of city main in street, pressure and whether dead end or circulation and, if dead end, direction and distance to nearest circulating main, city main test results
   — Other source of water supply, with pressure or elevation
   — Make, type and orifice size of sprinkler
   — Temperature rating and location of high-temperature sprinklers
   — Limitations on extended coverage sprinklers or other special sprinkler types
   — Number of sprinklers on each riser and on each system by floors and total area by each system on each floor
   — Make, type, model and size of alarm or dry pipe valve
   — Make, type, model and size of preaction or deluge valve
   — Type and location of alarm belts
   — Backflow prevention method and details
   — Total number of sprinklers on each dry pipe system or preaction deluge system
   — Approximate capacity in gallons or each dry pipe system
   — Setting for pressure-reducing valves
     — Pipe size, type, and schedule of wall thickness
     — Cutting lengths of pipe (or center-to-center dimensions)
     — Type of fittings, riser nipples and size, and all welds and bends
     — Type and location of hangers, inserts and sleeves
     — Calculations of loads and details for sway bracing
     — All control valves, checks, drain pipes, flushing, and test pipes
     — Size and location of standpipe risers and hose outlets
     — Small hand-hose equipment
     — Underground pipe size, length, location, weight, material, point of connection to city main; the type of valves, meters and valve pits; and the depth that top of the pipe is laid below grade
     — Size and location of hydrants along with hose-houses
     — Size and location of fire department connections
     — When the equipment is to be installed as an addition to an old group of sprinklers without additional feed from the yard system, enough of the old system shall be indicated on the plans to show the total number of sprinklers to be supplied and to make all connections clear
     — Information to be provided on the hydraulic nameplate
     — Name, address and phone number of contractor and sprinkler designer
     — Hydraulic reference points shall be shown by a number and/or letter designation and shall correspond with comparable reference points shown on the hydraulic calculation sheets
     — System design criteria showing the minimum rate of water application (density), the design area of water application and the water required for hose streams both inside and outside
     — Actual calculated requirements showing the total quantity of water and the pressure required at a common reference point for each system
     — Elevation data showing elevations of sprinklers, junction points and supply or reference points
     — Protected wall openings if room design method is used

2. Information required on calculations includes:
   — Location
   — Name of owner and occupant
   — Building identification
   — Description of hazard
   — Name and address of contractor and designer
   — Name of approving agency

3. System design requirements include:
   — Design area of water application
   — Minimum rate of water application (density)
   — Area of sprinkler coverage
   — Hazard or commodity classification
   — Building height
   — Storage height
   — Storage method
   — Total water requirements, as calculated, including allowance for hose demand water supply information and allowance for in-rack sprinklers
   — Location and elevation static and residual test gauge with relation to the riser reference point
   — Size and location of hydrants used for flow test data
   — Flow location
   — Static pressure, psi
   — Residual pressure, psi
   — Flow, gpm
   — Date
   — Time
   — Test conducted by whom
   — Sketch to accompany gridded system calculations to indicate flow quantities and directions for lines with sprinklers operated in the remote area

4. Additional information necessary for complete review includes:
   — Sprinkler description and discharge constant (K-value)
   — Hydraulic reference points
   — Flow, gpm
   — Pipe diameter (actual internal diameter)
   — Pipe length
   — Equivalent pipe length for fittings and components
   — Friction loss in psi per foot of pipe
   — Total friction loss between reference points
   — Elevation difference between reference points
   — Required pressure in psi at each reference point
   — Velocity pressures and normal pressure if included in calculations
   — Notes to indicate starting points, reference to other sheets or classification of dates
   — Information on antifreeze solution (type and quantity)
   — Water treatment system information including reason for treatment and program details

5. Included with the submittal must be a graph sheet showing water supply curves and system requirements including:
   — Hose demand plotted on semilogarithmic graph paper so as to present a graphic summary of the complete hydraulic calculations
   — Sprinkler system demand including in-rack sprinklers (if applicable)
NFPA 13 sprinkler systems. Where the provisions of this code require that a building or portion thereof be equipped throughout with an automatic sprinkler system in accordance with this section, sprinklers shall be installed throughout in accordance with NFPA 13 except as provided in Section 903.3.1.1.1.

NFPA 13 contains the minimum requirements for the design and installation of automatic water sprinkler systems and exposure protection sprinkler systems. The requirements contained in the standard include the character and adequacy of the water supply and the selection of sprinklers, piping, valves and all of the materials and accessories. The standard does not include requirements for installation of private fire service mains and their appurtenances; installation of fire pumps or construction and installation of gravity and pressure tanks and towers.

NFPA 13 defines seven classifications or types of water sprinkler systems: wet pipe (see Figure 903.3.1.1), dry pipe; preaction or deluge; combined dry pipe and preaction; antifreeze systems; sprinkler systems that are designed for a special purpose and outside sprinklers for exposure protection. While numerous variables must be considered in selecting the proper type of sprinkler system, the wet-pipe sprinkler system is recognized as the most effective and efficient. The wet-pipe system is also the most reliable type of sprinkler system, because water under pressure is available at the sprinkler. Therefore, wet-pipe sprinkler systems are recommended wherever possible.

The extent of coverage and distribution of sprinklers is based on the NFPA 13 standard. Numerous conditions exist in the standard where sprinklers are specifically required and also where they may or may not be located. Once it is determined that the sprinkler system is to be in accordance with NFPA 13, that standard must be reviewed for installation details. For example, exterior spaces such as combustible canopies are required to be equipped with sprinklers according to Section 8.15.7 of NFPA 13 where the canopy extends for a distance of 4 feet (1219 mm) or more. A 3-foot (914 mm) combustible canopy would not require sprinklers nor would a 6-foot (1829 mm) canopy constructed of noncombustible materials, provided there is no combustible storage under the canopy.

Because installation is required to be in accordance with NFPA 13, if the standard allows for the omission of sprinklers in any location, then the building is still considered as sprinklered throughout. For example, Section 8.15.8.1.1 of NFPA 13 allows sprinklers to be omitted from bathrooms in certain circumstances. If sprinklers are not provided in the bathrooms due to the conditions stipulated in NFPA 13, the building would still be considered as sprinklered throughout in accordance with the code, NFPA 13 and the IFC.

Exceptions for the use of NFPA 13R and 13D systems are addressed throughout the code when exceptions based upon the use of sprinklers are provided. More specifically, if the use of these other standards is appropriate it will be noted within the exception. For a building to be considered "equipped throughout" with an NFPA 13 sprinkler system, complete protection must be provided in accordance with the referenced standard, subject to the exempt locations indicated in Section 903.3.1.1.1.

NFPA 13.3.1.1.1 Exempt locations. Automatic sprinklers shall not be required in the following rooms or areas where such rooms or areas are protected with an approved automatic fire detection system in accordance with Section 907.2 that will respond to visible or invisible particles of combustion. Sprinklers shall not be omitted from any room merely because it is damp, of fire-resistance-rated construction or contains electrical equipment.

1. Any room where the application of water, or flame and water, constitutes a serious life or fire hazard.
2. Any room or space where sprinklers are considered undesirable because of the nature of the contents, when approved by the fire code official.
3. Generator and transformer rooms separated from the remainder of the building by walls and floor/ceiling or roof/ceiling assemblies having a fire-resistance rating of not less than 2 hours.
4. Rooms or areas that are of noncombustible construction with wholly noncombustible contents.
5. Fire service access elevator machine rooms and machinery spaces.
6. Machine rooms and machinery spaces associated with occupant evacuation elevators designed in accordance with Section 3008.

This section allows the omission of sprinkler protection in certain locations if an approved automatic fire detection system is installed. Buildings in compliance with one of the four listed conditions would still be considered fully sprinklered throughout in compliance with the code and NFPA 13 and thus are eligible for all applicable code alternatives, exceptions or reductions. Elimination of the sprinkler system in a sensitive area is subject to the approval of the fire code official.

Condition 1 addresses restrictions where the application of water could create a hazardous condition. For example, sprinkler protection is to be avoided where it is not compatible with certain stored materials (i.e., some water-reactive hazardous materials such as calcium carbide). Combustible metals, such as magnesium and aluminum, may burn so intensely that the use of water to attempt fire control will only intensify the reaction.

It is not the intent of Condition 2 to omit sprinklers solely because of a potential for water damage. A desire to not sprinkle a certain area (such as a computer room or operating room) does not fall within the limitations of the exception unless there is something unique about the space that would result in water being incompatible. A computer room can be adequately pro-
tected using an automatic sprinkler system or an alternative gaseous suppression agent system or a combination of these systems. The intent of Condition 2 is to consider whether or not the contents would react adversely to the application of water. It is important to note that the fire code official must approve the use of this item. Note also that with respect to computer rooms, NFPA 75—(Protection of Information Technology Equipment) (not a referenced standard) recognizes automatic sprinklers as the primary fire protection system for computer rooms.

Condition 3 recognizes the low fuel load and low occupancy hazards associated with generator and transformer rooms and, therefore, allows the omission of sprinkler protection if the rooms are separated from adjacent areas by 2-hour fire-resistance-rated construction. This condition assumes the room is not used for any combustible storage. This condition is similar to Section 8.15.10.3 of NFPA 13, which exempts electrical equipment rooms from sprinkler protection, provided the room is dedicated to the use of dry-type electrical equipment, is constructed as a 2-hour fire-resistance-rated enclosure and is not used for combustible storage.

Condition 4 requires the construction of the room or area, as well as the contents, to be noncombustible. An example would be an area in an unprotected steel frame building (Type IIb construction) used for steel or concrete block storage. Neither involves any significant combustible packaging or sources of ignition, and few combustibles are present (see Figure 903.3.1).

Condition 5 addresses the concern for elevator machinery rooms and machinery spaces associated with fire service access elevators as required for buildings with occupied floors greater than 120 feet (36.58 m) from the lowest level of fire department access by Sections 403.6.1 and 3007. These elevators need to work during fire situations and their operation cannot be threatened by the activation of a sprinkler in a machine room or space that may affect the operation of the elevator. Fire service access elevators are required to be continuously monitored at the fire command center in accordance with Section 3007.6.

Condition 6, similar to Condition 5, exempts sprinklers from the machine rooms and machinery spaces for occupant evacuation elevators. Like fire service access elevators, these elevators need to work during fire situations and their operation cannot be threatened by the activation of a sprinkler in a machine room or machinery spaces. Such elevators are required to be monitored at the fire command center in accordance with Section 3008.8.

FIRE PROTECTION SYSTEMS

Sprinkler systems designed in accordance with NFPA 13R are intended to prevent flashover (total involvement) in the room of fire origin and to improve the chance for occupants to escape or be evacuated. The design criteria in NFPA 13R are similar to those in NFPA 13 except that sprinklers may be omitted from areas in which fatal fires in residential occupancies do not typically originate (bathrooms, closets, attics, porches, garages and concealed spaces).

A common question is whether a mixed occupancy building which contains a Group R occupancy could still use NFPA 13R for the design. If one of the mixed use occupancies would require a sprinkler system throughout the building in accordance with NFPA 13, then a 13R system would not be allowed. If, however, the only reason a sprinkler system is being installed is because there is a Group R fire area within the building, then an NFPA 13R system would be an appropriate design choice. The areas that are not classified as Group R would require protection in accordance with NFPA 13.

It must be noted that although the building would be considered sprinklered throughout in accordance with NFPA 13R, not all of the code sprinkler alternatives could be applied. Any alternative that requires the installation of an NFPA 13 system would not be applicable if a portion of the building utilizes an NFPA 13R system.

The code provisions that allow for an increase in building height according to Section 504.2 do not compound this section. NFPA 13R is applicable to buildings that are up to four stories in height. If the design of a residential building intends to take advantage of the sprinkler height increase so that the building is five stories or more, the sprinkler system must be an NFPA 13 system. Because this section limits the height to four stories, that is the maximum height for a building that can utilize an NFPA 13R system. This is consistent with the scoping provisions in the NFPA 13R standard.

The limitation of four stories in height is to be measured with respect to the established grade plane, which is consistent with IFC Interpretation No. 43-03. As such, a basement would not be considered a story above grade for purposes of determining the applicability of this section.

[F] 903.3.1.2 NFPA 13R sprinkler systems. Automatic sprinkler systems in Group R occupancies up to and including four stories in height shall be permitted to be installed throughout in accordance with NFPA 13R.

NFPA 13R contains design and installation requirements for a sprinkler system to aid in the detection and control of fires in low-rise (four stories or less) residential occupancies.

[F] 903.3.1.2.1 Balconies and decks. Sprinkler protection shall be provided for exterior balconies, decks and ground floor patios of dwelling units where the building is of Type V construction, provided there is a roof or deck above. Sidewall sprinklers that are used to protect such areas shall be permitted to be located such that their deflectors are within 1 inch (25 mm) to 6 inches (152 mm) below the structural members and a maximum distance of 14 inches (356 mm) below the deck of the exterior balconies and decks that are constructed of open wood joist construction.

Balconies, decks and patios in buildings of Type V construction and used for Group R occupancies are required to have sprinkler protection when there is a roof or deck above. This is in addition to the require-
ments of NFPA 13R, which primarily addresses the life safety of occupants and not property protection. The intent is to address hazards such as grilling and similar activities. Since NFPA 13R does not require such coverage, there is potential that a fire on a balcony could grow much too large for the system within the building to handle. The concern is that a potential exterior balcony fire could spread to unprotected floor/ceiling assemblies and attic spaces and result in major property damage. Section 308.1.4 of the IFC specifically addresses restrictions on open flame cooking devices used on combustible balconies. Note that sprinklers are not intended to be provided in closets found on such balconies.

Regardless of whether the exterior walking surface is attached to the building and called a balcony or is a freestanding structure such as a deck or patio the concern for fire ignition in the area adjacent to the exterior wall is the same. Sidewall sprinklers should be selected based on the area of coverage and climate. If the potential for freezing exists, a dry sidewalk sprinkler should be used. Where the overhanging deck or balcony is extensive, an extended coverage sprinkler should be selected.

[F] 903.3.1.3 NFPA 13D sprinkler systems. Automatic sprinkler systems installed in one- and two-family dwellings, Group R-3 and R-4 congregate residences and townhouses shall be permitted to be installed throughout in accordance with NFPA 13D.

- NFPA 13D contains design and installation requirements for a sprinkler system to aid in the detection and control of fires in one- and two-family dwellings, mobile homes and townhouses. This section also specifically allows the use of an NFPA 13D system for small congregate living facilities (Groups R-4 and R-3, respectively). This is consistent with the NFPA 13D requirements and is also consistent with FHA court cases based on nondiscrimination for group homes.

Similar to NFPA 13R, sprinkler systems designed in accordance with NFPA 13D are intended to prevent flashover (total involvement) in the room of fire origin and to improve the chance for occupants to escape or be evacuated. Although the allowable omission of sprinklers in certain areas of the dwelling unit in NFPA 13D is similar to that in NFPA 13R, the water supply requirements are less restrictive. NFPA 13D uses a two-head sprinkler design with a 10-minute duration requirement, while NFPA 13R uses a four-head sprinkler design with a 30-minute duration requirement. The decreased water supply requirement emphasizes the main intent of NFPA 13D to control the fire and maintain tenability during evacuation of the residence.

Since the fire code official has the authority to approve the type of sprinkler system, this Section may be used to prevent the use of a specific type of sprinkler system that may be inappropriate for a particular type of occupancy.

[F] 903.3.2 Quick-response and residential sprinklers. Where automatic sprinkler systems are required by this code, quick-response or residential automatic sprinklers shall be installed in the following areas in accordance with Section 903.3.1 and their listings:

1. Throughout all spaces within a smoke compartment containing care recipient sleeping units in Group I-2 in accordance with this code.

2. Throughout all spaces within a smoke compartment containing treatment rooms in ambulatory care facilities.

3. Dwelling units and sleeping units in Group I-1 and R occupancies.

4. Light-hazard occupancies as defined in NFPA 13.

- This section requires the use of either listed quick-response or residential automatic sprinklers, depending on the type of sprinkler system required to achieve faster and more effective suppression in certain areas. Residential sprinklers are required in all types of residential buildings that would permit the use of an NFPA 13R or 13D sprinkler system.

Quick-response and residential sprinklers are similar in nature. They use a lighter material for the operating mechanism, thus reducing the heat lag in the element. The faster the heat can be absorbed, the sooner the sprinkler will begin to discharge water. Quick-response sprinklers have shown that they operate up to 25 percent faster than traditional sprinklers and create conditions in the room of origin that significantly increase the tenability of the environment. In tests performed by Factory Mutual (FM) for the Federal Emergency Management Agency (FEMA), the gas temperature in the room of origin was 550°F (288°C) with quick-response sprinklers, while it was 1,470°F (799°C) for conventional sprinklers at the time of sprinkler activation. More importantly, while the carbon monoxide (CO) level was 1,860 ppm for conventional sprinklers, the CO level when tested with quick-response sprinklers was only around 350 ppm. Comparatively, the National Institute of Occupational Safety and Health (NIOSH) considers the IDLH (immediately dangerous to life and health) level of CO to be 1,200 ppm. Thus, quick-response sprinklers have been shown to add significantly to the life safety effects of standard sprinkler systems.

Condition 1 requires the use of approved quick-response or residential sprinklers in smoke compartments containing care recipient sleeping units in Group I-2 occupancies. Even though properly operating standard sprinklers are effective, the extent of fire growth and smoke production that can occur before sprinkler activation creates the need for early warning to enable faster response by care providers and initiation of egress that is critical in occupancies containing persons incapable of self-preservation. The faster response time associated with quick-response or residential sprinklers increases the probability that the
sprinklers will actuate before the care recipient’s life would be threatened by a fire in his or her room.

Condition 2 requires the use of approved quick-response or residential sprinklers in smoke compartments containing treatment rooms in ambulatory care facilities. The justification is the same as that for Condition 1. When there is a potential for care recipients to be incapable of self-preservation, the use of residential sprinklers or quick-response sprinklers is critical.

Because of the kind of occupants sleeping in Group R and I-1 occupancies, as indicated in Condition 3, a faster responding type of sprinkler is desirable. Similar to the first condition, because occupants will be sleeping, the use of quick-response sprinklers creates additional safety by reducing sprinkler response time, thereby increasing the time available for egress and allowing for the time necessary for occupants to wake up and recognize the emergency event.

Condition 4 recognizes light-hazard occupancies in accordance with NFPA 13. These could include restaurants, schools, office buildings, places of religious worship and similar occupancies where the fire load and potential heat release of combustible contents are low.

[F] 903.3.3 Obstructed locations. Automatic sprinklers shall be installed with due regard to obstructions that will delay activation or obstruct the water distribution pattern. Automatic sprinklers shall be installed in or under covered kiosks, displays, booths, concession stands, or equipment that exceeds 4 feet (1219 mm) in width. Not less than a 3-foot (914 mm) clearance shall be maintained between automatic sprinklers and the top of piles of combustible fibers.

Exception: Kitchen equipment under exhaust hoods protected with a fire-extinguishing system in accordance with Section 904.

To provide adequate sprinkler coverage, sprinkler protection must be extended under any obstruction that exceeds 4 feet (1219 mm) in width. Large air ducts are another common obstruction where sprinklers are routinely extended beneath the duct. The 3-foot (914 mm) storage clearance requirement for combustible fibers is caused by their potential high heat release. Most storage conditions require only a minimum 18-inch (457 mm) storage clearance to combustibles, depending on the type of sprinklers used and their actual storage conditions.

The exception recognizes that an alternative extinguishing system is permitted for commercial cooking systems in place of sprinkler protection for exhaust hoods that may be more than 4 feet (1219 mm) wide.

The application of this section is more critical to the ongoing use of the space. The obstruction conditions, therefore, should have already been addressed during plan review and installation inspection. This section gives the fire official and building owner adequate information to avoid the most typical obstruction-related issues in terms of proper sprinkler coverage.

[F] 903.3.4 Actuation. Automatic sprinkler systems shall be automatically actuated unless specifically provided for in this code.

The intent of this section is to eliminate the need for occupant intervention during a fire. As such, it is assumed that it will not be necessary for a person to manually open a valve or perform some other physical activity in order to allow the sprinkler system to activate.

Wet-pipe and dry-pipe sprinkler systems, for example, are essentially fail-safe systems in the sense that, if the system is in proper operating condition, it will operate once a sprinkler fuses. Dry systems have an inherent time lag for water to reach the sprinkler; therefore, the response is not as fast as for a wet-pipe system. Other types of sprinkler systems, such as preaction and deluge, rely on the actuation of a detection system to operate the sprinkler valve.

[F] 903.3.5 Water supplies. Water supplies for automatic sprinkler systems shall comply with this section and the standards referenced in Section 903.3.1. The potable water supply shall be protected against backflow in accordance with the requirements of this section and the International Plumbing Code.

To be effective, all sprinkler systems must have an adequate supply of water. The criteria for an acceptable water supply are contained in the standards referenced in Section 903.3.1. For example, NFPA 13 contains criteria for different types of water supplies as well as the methods to determine the pressure, flow capabilities and capacity necessary to get the intended performance from a sprinkler system. An acceptable water supply could consist of a reliable municipal supply, a gravity tank or a fire pump with a pressure tank or a combination of these.

This section also establishes the requirements for protecting the potable water system against a nonpotable source, such as stagnant water retained within the sprinkler piping. As stated in Section 608.16.4 of the IPC, an approved double check valve device or reduced pressure principle backflow preventer is required.

[F] 903.3.5.1 Domestic services. Where the domestic service provides the water supply for the automatic sprinkler system, the supply shall be in accordance with this section.

This section establishes the scope of domestic services for limited area sprinkler systems and residential combination services.

[F] 903.3.5.1.1 Limited area sprinkler systems. Limited area sprinkler systems serving fewer than 20 sprinklers on any single connection are permitted to be connected to the domestic service where a wet automatic standpipe is not available. Limited area sprinkler systems connected to
domestic water supplies shall comply with each of the following requirements:

1. Valves shall not be installed between the domestic water riser control valve and the sprinklers.

   Exception: An approved indicating control valve supervised in the open position in accordance with Section 903.4.

2. The domestic service shall be capable of supplying the simultaneous domestic demand and the sprinkler demand required to be hydraulically calculated by NFPA 13, NFPA 13D or NFPA 13R.

   ❖ The use of limited area sprinkler systems is restricted to cases in which the code requires a limited number of sprinklers and not a complete automatic sprinkler system. For example, limited area sprinkler systems may be used to protect stages; storage and workshop areas; stories, including basements, without openings; painting rooms; trash rooms and chutes; furnace rooms; kitchens and hazardous exhaust systems and incidental accessory occupancies as regulated in Section 508.2.5. When a wet automatic standpipe is not available, limited-area sprinkler systems may be connected to the domestic water supply.

   The water supply to the sprinkler system is to be controlled only by the same valve that controls the domestic water supply to the building; no shutoff valves are permitted in the sprinkler system piping. These restrictions increase the likelihood that the sprinkler system will be operational should a fire occur. Likewise, if the sprinkler system needs restoration after having operated in response to a fire or needs repairs requiring that the water supply be shut off, this section increases the probability that the system will be restored quickly, because having the domestic water supply to the entire building shut off is an inconvenience to occupants that they will not tolerate for very long.

   The exception recognizes the value of standard sprinkler valve supervision complying with Section 903.4 as providing the level of system reliability contemplated by this section.

   Documentation, usually in the form of hydraulic calculations, must be submitted demonstrating that the domestic water system is adequate to supply the sprinkler demand in addition to the peak domestic demand. The domestic demand would normally be determined as stated in the IPC.

[F] 903.3.5.1.2 Residential combination services. A single combination water supply shall be allowed provided that the domestic demand is added to the sprinkler demand as required by NFPA 13R.

   ❖ NFPA 13R permits a common supply main to a building to serve both the sprinkler system and domestic services if the domestic demand is added to the sprinkler demand. NFPA 13R systems do not provide the same level of property protection as NFPA 13 systems.

[F] 903.3.5.2 Secondary water supply. An automatic secondary on-site water supply having a capacity not less than the hydraulically calculated sprinkler demand, including the hose stream requirement, shall be provided for high-rise buildings assigned to Seismic Design Category C, D, E or F as determined by the International Building Code. An additional fire pump shall not be required for the secondary water supply unless needed to provide the minimum design intake pressure at the suction side of the fire pump supplying the automatic sprinkler system. The secondary water supply shall have a duration of not less than 30 minutes as determined by the occupancy hazard classification in accordance with NFPA 13.

   Exception: Existing buildings.

   ❖ The intent of this section is that a secondary water supply be provided on the high-rise building site in order to provide a high level of functional reliability for the fire protection systems in the event a seismic event disables the primary water supply for high-rise buildings assigned to Seismic Design Category C, D, B or F. The categories are described in Section 1613.5.

   The text’s specific wording that the secondary supply be “on-site” rather than “to the site” would preclude the use, for example, of a second connection to the municipal supply remote from the primary connection to the municipal supply to achieve compliance with this requirement. It should be noted, however, that the fire code official has the authority to modify the provisions of the code in accordance with Section 104.10 should there be practical difficulties preventing precise compliance with the text.

   The required amount of water is equal to the hydraulically calculated sprinkler demand plus hose stream demand for a minimum 30-minute period dependent upon the appropriate occupancy hazard classification in NFPA 13.

   Note that the beginning of Section 903.3.5.2 requires that the secondary water supply be automatic; in other words, switchover to the secondary water source cannot occur manually. This is consistent with the definitions of “Automatic sprinkler system” and “Classes of standpipe systems” in that both systems are required to be connected to a reliable water supply.

   Generally, this section does not automatically require a second fire pump, but, if necessary, an additional pump may be required. A second pump would be necessary if the secondary water supply does not provide the necessary water pressure for intake into the primary fire pump.

   The exception recognizes the infeasibility of requiring a secondary water supply in existing high-rise buildings.

[F] 903.3.6 Hose threads. Fire hose threads and fittings used in connection with automatic sprinkler systems shall be as prescribed by the fire code official.

   ❖ The threads on connections and fittings that the fire department will use to connect a hose must be com-
patible with the fire department threads.

Design documents must specify the type of thread to be used in order to be compatible with the local fire department equipment after consultation and coordination with the fire code official. The criteria typically apply to fire department connections for sprinkler and standpipe systems, standpipe hose connections, yard hydrants and wall hydrants.

The majority of fire departments in the United States use the American National Fire Hose Connection Screw Thread also commonly known as NST and NS. NFPA 1963 gives the screw thread dimensions and the thread size of threaded connections, with nominal sizes ranging from $3/4$ inch (19 mm) to 6 inches (152 mm) for the NS thread. Although efforts to standardize fire hose threads began after the Boston conflagration in 1872, there are still many different screw threads, some of which give the appearance of compatibility with the NH thread. While NFPA 1963 may be used as a guide, the code does not require that any particular standard be used. Rather, it is important that the fire code official be consulted for the appropriate thread selection. The intent is that the threads match those of the local department identically so that adapters are not required within the fire department's own district.

[F] 903.4 Sprinkler system supervision and alarms. All valves controlling the water supply for automatic sprinkler systems, pumps, tanks, water levels and temperatures, critical air pressures and water flow switches on all sprinkler systems shall be electrically supervised by a listed fire alarm control unit.

Exceptions:

1. Automatic sprinkler systems protecting one- and two-family dwellings.

2. Limited area systems serving fewer than 20 sprinklers.

3. Automatic sprinkler systems installed in accordance with NFPA 13R where a common supply main is used to supply both domestic water and the automatic sprinkler system, and a separate shutoff valve for the automatic sprinkler system is not provided.

4. Jockey pump control valves that are sealed or locked in the open position.

5. Control valves to commercial kitchen hoods, paint spray booths or dip tanks that are sealed or locked in the open position.

6. Valves controlling the fuel supply to fire pump engines that are sealed or locked in the open position.

7. Trim valves to pressure switches in dry storage and deluge sprinkler systems that are sealed or locked in the open position.

The reliability data on automatic sprinkler systems clearly indicate that a closed valve is the leading cause of sprinkler system failure. There are also a number of other critical elements that contribute to successful sprinkler system operation, including, but not limited to, pumps, water tanks and air pressure maintenance devices; therefore, this section requires that the various critical elements that contribute to an available water supply and to the function of the sprinkler system be electrically supervised.

Automatic sprinkler systems in one- and two-family dwellings are typically designed to comply with NFPA 13D, which does not require electrical supervision (see Exception 1).

Limited area sprinkler systems are generally supervised by their connection to the domestic water service (see Exception 2). Compliance with the exception means that none of the following alarm provisions are applicable to limited area systems. Consequently, limited area sprinkler systems do not require local alarms or supervision. Electrical supervision is required only if a control valve is installed between the riser control valve and the sprinkler system piping.

Similar to limited area sprinkler systems, electrical supervision is not required for NFPA 13R residential combination services when a shutoff valve is not installed (see Exception 3). NFPA 13R sprinkler systems are supervised in that the only way to shut off the sprinkler system is to also shut off the domestic water supply.

The valves discussed in Exceptions 4 through 7 can be sealed or locked in the open position because they do not control the sprinkler system water supply.

[F] 903.4.1 Monitoring. Alarm, supervisory and trouble signals shall be distinctly different and shall be automatically transmitted to an approved supervising station or, when approved by the fire code official, shall sound an audible signal at a constantly attended location.

Exceptions:

1. Underground key or hub valves in roadway boxes provided by the municipality or public utility are not required to be monitored.

2. Backflow prevention device test valves located in limited area sprinkler system supply piping shall be locked in the open position. In occupancies required to be equipped with a fire alarm system, the backflow preventer valves shall be electrically supervised by a tamper switch installed in accordance with NFPA 72 and separately annunciated.

Automatic sprinkler systems must be supervised as a means of determining that the system is operational. A valve supervisory switch operating as a normally open or normally closed switch is usually used. NFPA 72 does not permit valve supervisory switches to be connected to the same zone circuit as the water flow switch unless it is specifically arranged to actuate a signal that is distinctive from the circuit trouble condition signal.

Required sprinkler systems are to be monitored by an approved supervising service to comply with
NFPA 72. Types of supervising stations recognized in NFPA 72 include central stations, remote supervising stations or proprietary supervising stations.

A central station is an independent off-site facility operated and maintained by personnel whose primary business is to furnish, maintain, record and supervise a signaling system. A proprietary system is similar to a central station system; however, a proprietary system is typically an on-site facility monitoring a number of buildings on the same site for the same owner. A remote station system has an alarm signal that is transmitted to a remote location acceptable to the authority having jurisdiction and that is attended 24 hours a day. The receiving equipment is usually located at a fire station, police station, regional emergency communications center or telephone answering service. An alternative use to the three previous supervising methods is an audible signal that can be transmitted to a constantly attended location approved by the fire code official.

Exception 1 recognizes that underground key or hub valves in roadway boxes are not normally supervised or required to be supervised by this section or NFPA 13.

Exception 2 acknowledges that local water utilities and environmental authorities in many instances require, by local ordinances, that backflow prevention devices be installed in limited-area sprinkler system piping. To make the testing and maintenance of backflow prevention devices easier, test valves are installed on each side of the device. These valves are typically indicating-type valves and can function as shutoff valves for the sprinkler system, and therefore require some level of supervision.

Because these infrequently used valves may be the only feature of protection requiring supervision in occupancies not otherwise required to be equipped with a fire alarm system, Exception 2 permits these valves to be locked in the open position; however, if the occupancy is protected by a fire alarm system, these valves must be equipped with approved valve supervisory devices connected to the fire alarm control panel on a separate (supervisory) zone so that the supervisory signal is transmitted to the designated receiving station. Installation and testing of backflow preventers in sprinkler systems are regulated in Sections 312.10 (testing) and 608.16.4 (devices) of the IPC.

[F] 903.4.2 Alarms. An approved audible device, located on the exterior of the building in an approved location, shall be connected to each automatic sprinkler system. Such sprinkler water-flow alarm devices shall be activated by water flow equivalent to the flow of a single sprinkler of the smallest orifice size installed in the system. Where a fire alarm system is installed, actuation of the automatic sprinkler system shall actuate the building fire alarm system.

- The audible alarm, sometimes referred to as the "outside ringer" or "water-motor gong," sounds when the sprinkler system has activated. The alarm device may be electrically operated or it may be a true water-motor gong operated by a paddle-wheel-type attachment to the sprinkler system riser that responds to the flow of water in the piping. Though no longer the alarm device of choice, water-motor gongs do have the advantage of not being subject to power failures within or outside the protected building (see Sections 6.9 and 8.17 of NFPA 13 for further information on these devices). The alarm must be installed on the exterior of the building in a location approved by the fire code official. This location is often in close proximity to the fire department connection (FDC), serving a collateral function of helping the responding fire apparatus engineer more promptly locate the FDC.

The alarm is not intended to be an evacuation alarm. The requirement is also not intended to be an indirect requirement for a fire alarm system. Unless a fire alarm system is required by some other code provision, only the exterior alarm device is required. However, when a fire alarm system is installed, the sprinkler system must also be interconnected with the fire alarm system so that when the sprinkler system actuates, it sounds the evacuation alarms required for the fire alarm system.

The primary purpose of the exterior alarm is to notify people outside the building that the sprinkler system is in operation. Originally, it was to act as a supplemental alert so that passersby could notify the fire department of the condition. However, because the code now requires electronic supervision of sprinkler systems, that function is mostly moot. The exterior notification now primarily serves the function of alerting the arriving fire department of which building or sprinkler system is in operation before staging firefighting activities for the building.

[F] 903.4.3 Floor control valves. Approved supervising indicating control valves shall be provided at the point of connection to the riser on each floor in high-rise buildings.

- In high-rise buildings, sprinkler control valves with supervisory initiating devices must be installed at the point of connection to the riser on each floor. Sprinkler control valves on each floor are intended to permit servicing activated systems without impairing the water supply to large portions of the building.

[F] 903.5 Testing and maintenance. Sprinkler systems shall be tested and maintained in accordance with the International Fire Code.

- Section 901 contains requirements for the testing and maintenance of sprinkler systems. Acceptance tests are necessary to verify that the system performs as intended by design and by the code. Periodic testing and maintenance are essential to verify that the level of protection designed into the building will be operational whenever a fire occurs. Water-based extinguishing systems must be tested and maintained as required by NFPA 25.
SECTION 904
ALTERNATIVE AUTOMATIC
FIRE-EXTINGUISHING SYSTEMS

[F] 904.1 General. Automatic fire-extinguishing systems, other than automatic sprinkler systems, shall be designed, installed, inspected, tested and maintained in accordance with the provisions of this section and the applicable referenced standards.

- Section 904 covers alternative fire-extinguishing systems that use extinguishing agents other than water. Alternative automatic fire-extinguishing systems include wet-chemical, dry-chemical, foam, carbon dioxide, halon and clean-agent suppression systems. In addition to the provisions of Section 904, the indicated referenced standards include specific installation, maintenance and testing requirements for all systems.

[F] 904.2 Where required. Automatic fire-extinguishing systems installed as an alternative to the required automatic sprinkler systems of Section 903 shall be approved by the fire code official. Automatic fire-extinguishing systems shall not be considered alternatives for the purposes of exceptions or reductions allowed by other requirements of this code.

- One of the main considerations in selecting an extinguishing agent should be the compatibility of the agent with the hazard. The fire code official is responsible for approving an alternative extinguishing agent. The approval should be based on the compatibility of the agent with the hazard and the potential effectiveness of the agent to suppress a fire involving the hazards present.

The code places limitations on alternative systems in that they may not be credited toward a building being equipped throughout with an automatic sprinkler system where the sprinkler system is an alternative to a code requirement.

[F] 904.2.1 Commercial hood and duct systems. Each required commercial kitchen exhaust hood and duct system required by Section 609 of the International Fire Code or Chapter 5 of the International Mechanical Code to have a Type I hood shall be protected with an approved automatic fire-extinguishing system installed in accordance with this code.

- This section requires an effective suppression system to combat fire on the cooking surfaces of grease-producing appliances and within the hood and exhaust system of a commercial kitchen installation. Type I hoods, including the duct system, must be protected with an approved automatic fire-extinguishing system because they are used for handling grease-laden vapors or smoke, whereas Type II hoods handle fumes, steam, heat and odors. Type I hoods are typically required for commercial food heat-processing equipment, such as deep fryers, griddles, charbroilers, broilers and open burner stoves and ranges. For additional guidance on the requirements for Type I and II hoods, see the commentary to Section 507 of the IMC.

[F] 904.3 Installation. Automatic fire-extinguishing systems shall be installed in accordance with this section.

- The installation of automatic fire-extinguishing systems must comply with the requirements of Sections 904.3.1 through 904.3.5 in addition to the installation criteria contained in the referenced standard for the proposed type of alternative extinguishing system.

[F] 904.3.1 Electrical wiring. Electrical wiring shall be in accordance with NFPA 70.

- NFPA 70 regulates the design and installation of electrical systems and equipment. All electrical work must also be in compliance with any specific electrical classifications and conditions contained in the referenced standards for each type of system.

Chapter 27 of the code and Section 605 of the IFC contain provisions that also reference NFPA 70. Those sections also contain additional information that must be applied when addressing electrical issues.

[F] 904.3.2 Actuation. Automatic fire-extinguishing systems shall be automatically actuated and provided with a manual means of actuation in accordance with Section 904.11.1. Where more than one hazard could be simultaneously involved in fire due to their proximity, all hazards shall be protected by a single system designed to protect all hazards that could become involved.

Exception: Multiple systems shall be permitted to be installed if they are designed to operate simultaneously.

- Section 904.3.2 requires alternative fire-extinguishing systems to be designed for automatic activation. Activation commonly occurs when a heat, fire or smoke detection system operates. In Type I commercial kitchen hoods, Section 904.11 requires a manual and automatic means of actuating the fire-extinguishing system. Designing a fire-extinguishing system to only operate upon manual actuation is prohibited by the code and many of the NFPA fire protection system standards.

The requirements for fire-extinguishing system actuation correlate with the requirements of NFPA 17 and NFPA 17A. The requirement prescribes that when a hazard is protected by two or more fire-extinguishing systems, all of the systems must be designed to operate simultaneously. The reason for the revision is that a typical alternative automatic fire-extinguishing system has a limited amount of fire-extinguishing agent. The amount of agent that is available is based on the area or volume of the hazard and the fire behavior of the fuel. Because the amount of agent is limited, the simultaneous operation of all the fire-extinguishing systems ensures that enough agent is applied to extinguish the fire and prevent its spread from the area of origin.

It is fairly common for a single hazard to be protected by two or more alternative automatic fire-extinguishing systems. For example, protection of a spray booth used for the application of flammable finishes using dry chemical commonly requires two or three
FIRE PROTECTION SYSTEMS

alternative automatic fire-extinguishing systems. The reason is that many dry-chemical and all wet-chemical systems are preengineered systems. Utilizing listed nozzles, preengineered systems are designed and constructed based on the manufacturer's installation requirements. Because these systems are assembled using listed nozzles and extinguishing agents, one system may not be able to protect the spraying space and exhaust plenum. As a result, two or more systems may be required as a provision of an extinguishing system's listing to protect certain hazards.

Another example is commercial kitchen cooking operations. Consider a flat grill broiler and a deep fat fryer located beneath the same Type I hood. It is quite common for each of these commercial cooking appliances to be protected by separate automatic fire-extinguishing systems. Based on the revision to Section 904.3.2, both extinguishing systems must simultaneously operate in the event a fire involves either of the example appliances (see commentary, Section 904.11.1).

[F] 904.3.3 System interlocking. Automatic equipment interlocks with fuel shutoffs, ventilation controls, door closers, window shutters, conveyor openings, smoke and heat vents and other features necessary for proper operation of the fire-extinguishing system shall be provided as required by the design and installation standard utilized for the hazard.

- Shutting off fuel supplies will eliminate potential ignition sources in the protected area. Automatic door and window closers and dampers for forced-air ventilation systems are intended to maintain the desired concentration level of the extinguishing agent in the protected area. See the commentary for Section 904.11.2 for information on system interconnections in commercial cooking fire-extinguishing systems.

[F] 904.3.4 Alarms and warning signs. Where alarms are required to indicate the operation of automatic fire-extinguishing systems, distinctive audible and visible alarms and warning signs shall be provided to warn of pending agent discharge. Where exposure to automatic-extinguishing agents poses a hazard to persons and a delay is required to ensure the evacuation of occupants before agent discharge, a separate warning signal shall be provided to alert occupants once agent discharge has begun. Audible signals shall be in accordance with Section 907.5.2.

- Safeguards are necessary to prevent injury or death to personnel in areas where the atmosphere will be made hazardous by oxygen depletion due to agent discharge in a confined space. The "where alarms are required" phrase is referring to requirements that will be found in the referenced installation standards indicated in Sections 904.5 through 904.11, as applicable. Predischarge alarms that will operate on fire detection system activation must be installed within and at entrances to the affected areas.

Where required by the appropriate installation standard, an extinguishing agent discharge delay feature shall also be provided to allow evacuation of personnel prior to agent discharge. Warning and instructional signs are also to be posted, preferably at the entrances to and within the protected area. See Section 4.5.6.1 of NFPA 12 for additional information on carbon dioxide system alarms, Section 4.3.5 of NFPA 12A for additional information on Halon system alarms and Section 4.3.5 of NFPA 2001 for additional information on clean agent system alarms.

[F] 904.3.5 Monitoring. Where a building fire alarm system is installed, automatic fire-extinguishing systems shall be monitored by the building fire alarm system in accordance with NFPA 72.

- Automatic fire-extinguishing systems need not be electrically supervised unless the building is equipped with a fire alarm system. This section recognizes the fact that a fire alarm system is not required in all buildings. However, because most alternative fire-extinguishing systems require the space to be evacuated before the system is discharged, they are equipped with evacuation alarms. Interconnection of the fire-extinguishing system evacuation alarm with the building evacuation alarm results in an increased level of hazard notification for the occupants in addition to the electrical supervision of the fire-extinguishing system.

[F] 904.4 Inspection and testing. Automatic fire-extinguishing systems shall be inspected and tested in accordance with the provisions of this section prior to acceptance.

- The completed installation must be tested and inspected to determine that the system has been installed in compliance with the code and will function as required. Full-scale acceptance tests must be conducted as required by the applicable referenced standard.

[F] 904.4.1 Inspection. Prior to conducting final acceptance tests, the following items shall be inspected:

1. Hazard specification for consistency with design hazard.
2. Type, location and spacing of automatic- and manual-initiating devices.
3. Size, placement and position of nozzles or discharge orifices.
4. Location and identification of audible and visible alarm devices.
5. Identification of devices with proper designations.
6. Operating instructions.

- This section identifies those items that need to be verified or visually inspected prior to the final acceptance tests. All equipment should be listed, approved and installed in accordance with the manufacturer's recommendations.

[F] 904.4.2 Alarm testing. Notification appliances, connections to fire alarm systems and connections to approved
supervising stations shall be tested in accordance with this section and Section 907 to verify proper operation.

- Components of fire-extinguishing systems related to alarm devices and their supervision must be tested before the system is approved. Alarm devices must be tested to satisfy the requirements of NFPA 72.

[F] 904.4.2.1 Audible and visible signals. The audibility and visibility of notification appliances signaling agent discharge or system operation, where required, shall be verified.

- This section requires verification upon completion of the system installation of the audibility and visibility of notification appliances in the area affected by the extinguishing agent discharge of the alternative automatic fire extinguishing system.

[F] 904.4.3 Monitor testing. Connections to protected premises and supervising station fire alarm systems shall be tested to verify proper identification and retransmission of alarms from automatic fire-extinguishing systems.

- Where monitoring of fire-extinguishing systems is required, such as by Section 904.3.5, all connections related to the supervision of the system must be tested to verify they are in proper working order.

[F] 904.5 Wet-chemical systems. Wet-chemical extinguishing systems shall be installed, maintained, periodically inspected and tested in accordance with NFPA 17A and their listing.

- NFPA 17A contains minimum requirements for the design, installation, operation, testing and maintenance of wet-chemical preengineered extinguishing systems. Equipment that is typically protected with wet-chemical extinguishing systems includes restaurant, commercial and institutional hoods; plenums; ducts and associated cooking equipment. Strict compliance with the manufacturer’s installation instructions is vital for a viable installation.

- Wet-chemical solutions used in extinguishing systems are relatively harmless and there is usually no lasting significant effect on a person’s skin, respiratory system or clothing. These solutions may produce a mild, temporary irritation but the symptoms will usually disappear when contact is eliminated.

[F] 904.6 Dry-chemical systems. Dry-chemical extinguishing systems shall be installed, maintained, periodically inspected and tested in accordance with NFPA 17 and their listing.

- NFPA 17 contains the minimum requirements for the design, installation, testing, inspection, approval, operation and maintenance of dry-chemical extinguishing systems.

- The fire code official has the authority to approve the type of dry-chemical extinguishing system to be used. NFPA 17 identifies three types of dry-chemical extinguishing systems: total flooding, local application and hand hose-line systems. Only total flooding and local application systems are considered automatic extinguishing systems.

- The types of hazards and equipment that can be protected with dry-chemical extinguishing systems include: flammable and combustible liquids and combustible gases; combustible solids, which melt when involved in a fire; electrical hazards, such as transformers or oil circuit breakers; textile operations subject to flash surface fires; ordinary combustibles such as wood, paper or cloth and restaurant and commercial hoods, ducts and associated cooking appliance hazards, such as deep fat fryers and some plastics, depending on the type of material and configuration.

- Total flooding dry-chemical extinguishing systems are used only where there is a permanent enclosure surrounding the hazard that is adequate to enable the required concentration to be built up. The total area of unclosable openings must not exceed 15 percent of the total area of the sides, top and bottom of the enclosure. Consideration must be given to eliminating the probable sources of re-ignition within the enclosure because the extinguishing action of dry-chemical systems is transient.

- Local application of dry-chemical extinguishing systems is to be used for extinguishing fires where the hazard is not enclosed or where the enclosure does not conform to the requirements for total flooding systems. Local application systems have successfully protected hazards involving flammable or combustible liquids, gases and shallow solids, such as paint deposits.

- NFPA 17 also discusses pre-engineered dry-chemical systems consisting of components designed to be installed in accordance with pretested limitations as tested and labeled by a testing agency. Pre-engineered systems must be installed within the limitations that have been established by the testing agency and may include total flooding, local application or a combination of both types of systems.

- The type of dry chemical used in the extinguishing system is a function of the hazard to be protected. The type of dry chemical used in a system should not be changed unless it has been proven changeable by a testing laboratory, is recommended by the manufacturer of the equipment and is acceptable to the fire code official for the hazard being protected. Additional guidance on the use of various dry-chemical agents can be found in NFPA 17.

[F] 904.7 Foam systems. Foam-extinguishing systems shall be installed, maintained, periodically inspected and tested in accordance with NFPA 11 and NFPA 16 and their listing.

- NFPA 11 covers the characteristics of foam-producing materials used for fire protection and the requirements for design, installation, operation, testing and maintenance of equipment and systems, including those used in combination with other fire-extinguishing agents. The minimum requirements are covered for flammable and combustible liquid hazards in local areas within buildings, storage tanks and indoor and outdoor processing areas.

- Low-expansion foam is defined as an aggregation of air-filled bubbles resulting from the mechanical
expansion of a foam solution by air with a foam-to-solution volume ratio of less than 20:1. It is most often used to protect flammable and combustible liquid hazards. Also, low-expansion foam may be used for heat radiation protection. Combined-agent systems involve the application of low-expansion foam to a hazard simultaneously or sequentially with dry-chemical powder.

NFPA 11 gives minimum requirements for the installation, design, operation, testing and maintenance of medium- and high-expansion foam systems. Medium-expansion foam is defined as an aggregation of air-filled bubbles resulting from the mechanical expansion of a foam solution by air or other gases with a foam-to-volume solution volume ratio of 20:1 to 200:1. High-expansion foam has a foam-to-solution volume ratio of 200:1 to approximately 1,000:1.

Medium-expansion foam may be used on solid fuel and liquid fuel fires where some degree of in-depth coverage is necessary (for example, for the total flooding of small, enclosed or partially enclosed volumes, such as engine test cells, transformer rooms, etc.). High-expansion foam is most suitable for filling volumes in which fires exit at various levels. For example, high-expansion foam can be used effectively against high-rack storage fires in enclosures such as in underground passages, where it may be dangerous to send personnel to control fires involving liquefied natural gas (LNG) and liquefied petroleum gas (LPG), and to provide vapor dispersion control for LNG and ammonia spills. High-expansion foam is particularly suited for indoor fires in confined spaces, since it is highly susceptible to wind and lack-of-confinement effects.

NFPA 16 contains the minimum requirements for open-head deluge-type foam-water sprinkler systems and foam-water spray systems. The systems are especially applicable to the protection of most flammable liquid hazards and have been used successfully to protect aircraft hangars and truck loading racks.

[F] 904.8 Carbon dioxide systems. Carbon dioxide extinguishing systems shall be installed, maintained, periodically inspected and tested in accordance with NFPA 12 and their listing.

NFPA 12 provides minimum requirements for the design, installation, testing, inspection, approval, operation and maintenance of carbon dioxide extinguishing systems.

Carbon dioxide extinguishing systems are useful in extinguishing fires in specific hazards or equipment in occupancies where an inert electrically nonconductive medium is essential or desirable and where cleanup of other extinguishing agents, such as dry-chemical residue, presents a problem. Carbon dioxide systems have satisfactorily protected the following: flammable liquids; electrical hazards, such as transformers, oil switches, rotating equipment and electronic equipment; engines using gasoline and other flammable liquid fuels; ordinary combustibles, such as paper, wood and textiles and hazardous solids.

The fire code official has the authority to approve the type of carbon dioxide system to be installed. NFPA 12 defines four types of carbon dioxide systems: total flooding, local application, hand hose lines and standpipe and mobile supply systems. Only total flooding and local application systems are automatic suppression systems.

Total-flooding systems may be used where there is a permanent enclosure around the hazard that is adequate to allow the required concentration to be built up and maintained for the required period of time, which varies for different hazards. Examples of hazards that have been successfully protected by total flooding systems include rooms, vaults, enclosed machines, ducts, ovens and containers and their contents.

Local application systems may be used for extinguishing surface fires in flammable liquids, gases and shallow solids where the hazard is not enclosed or the enclosure does not conform to the requirements for a total-flooding system. Examples of hazards that have been successfully protected by local application systems include dip tanks, quench tanks, spray booths, oil-filled electric transformers and vapor vents.

[F] 904.9 Halon systems. Halogenated extinguishing systems shall be installed, maintained, periodically inspected and tested in accordance with NFPA 12A and their listing.

NFPA 12A contains minimum requirements for the design, installation, testing, inspection, approval, operation and maintenance of Halon 1301 extinguishing systems. Halon 1301 fire-extinguishing systems are useful in specific hazards, equipment or occupancies where an electrically nonconductive medium is essential or desirable and where cleanup of other extinguishing agents presents a problem.

Halon 1301 systems have satisfactorily protected gaseous and liquid flammable materials; electrical hazards, such as transformers, oil switches and rotating equipment; engines using gasoline and other flammable fuels; ordinary combustibles, such as paper, wood and textiles and hazardous solids. Halon 1301 systems have also satisfactorily protected electronic computers, data processing equipment and control rooms.

The fire code official has the authority to approve the type of halogenated extinguishing system to be installed. NFPA 12A defines two types of halogenated extinguishing systems: total flooding and local application. Total-flooding systems may be used where there is a fixed enclosure around the hazard that is adequate to enable the required halon concentration to be built up and maintained for the required period of time to enable the effective extinguishing of the fire. Total-flooding systems may provide fire protection for rooms, vaults, enclosed machines, ovens, containers, storage tanks and bins.

Local application systems are used where there is
not a fixed enclosure around the hazard or where the fixed enclosure around the hazard is not adequate to enable an extinguishing concentration to be built up and maintained in the space. Hazards that may be successfully protected by local application systems include dip tanks, quench tanks, spray booths, oil-filled electric transformers and vapor vents.

Two other considerations in selecting the proper extinguishing system are ambient temperature and the personnel hazards associated with the agent. The ambient temperature of the enclosure for a total-flooding system must be above 70°F (21°C) for halon 1301 systems. Special consideration must also be given to the use of halon systems when the temperatures are in excess of 900°F (482°C) because halon will readily decompose at such temperatures and the products of decomposition can be extremely irritating if inhaled, even in small amounts.

Halon 1301 total-flooding systems must not be used in concentrations greater than 10 percent in normally occupied areas. Where personnel cannot vacate the area within 1 minute, Halon 1301 total-flooding systems must not be used in normally occupied areas with concentrations greater than 7 percent. Halon 1301 total-flooding systems may be used with concentrations of up to 15 percent if the area is not normally occupied and the area can be evacuated within 30 seconds.

The use of halogenated extinguishing systems has become a concern with respect to the potential environmental effects of halon. Halogenated fire-extinguishing agents have been identified as a source of emissions, resulting in the depletion of the stratospheric ozone layer and, in accordance with the Montreal Protocol, the ceasing of its production in January 1994. Therefore, the supply of halon is limited and new supplies of halogenated extinguishing agents will not be available in the future. Existing supplies of halon can, however, continue to be used in existing, undischarged systems or to recharge discharged systems. This newfound need for halon supplies has given rise to new industries geared to the ranking, recycling and reclamation of existing halon supplies. Alternative "clean agent" extinguishing agents have been developed to replace halogenated agents (see Section 904.10).

[F] 904.10 Clean-agent systems. Clean-agent fire-extinguishing systems shall be installed, maintained, periodically inspected and tested in accordance with NFPA 2001 and their listing.

- NFPA 2001 contains minimum requirements for the design, installation, testing, inspection and operation of clean-agent fire-extinguishing systems. A clean agent is an electrically nonconducting suppression agent that is volatile or gaseous at discharge and does not leave a residue on evaporation. Clean-agent fire-extinguishing systems are installed in locations that are enclosed and have openings in the protected area that can be sealed on activation of the alarm to provide effective clean-agent concentra-

tions. A clean-agent fire-extinguishing system should not be installed in locations that cannot be sealed unless testing has shown that adequate concentrations can be developed and maintained.

The two categories of clean agents are halocarbon compounds and inert gas agents. Halocarbon compounds include bromine, carbon, chlorine, fluorine, hydrogen and iodine. Halocarbon compounds suppress fires by a combination of breaking the chemical chain reaction of the fire, reducing the oxygen supporting the fire and reducing the ambient temperature of the fire origin to reduce the propagation of the fire. Inert gas agents contain primary components consisting of helium, neon, argon or a combination of these. Inert gases work by reducing the oxygen concentration around the fire origin to a level that does not support combustion.

Clean-agent fire-extinguishing systems were developed in response to the demise of halon as an acceptable fire-extinguishing agent because of its harmful effect on the environment. Although the original hope for a halon substitute was that these new clean agents could be directly and proportionally substituted for halon agents in existing systems (drop in replacements), research has shown that clean agents are less efficient in extinguishing fires than are the halons they were intended to replace and require approximately 60 percent more agent by weight and volume in storage to do the same job. Additionally, the physical and chemical characteristics of clean agents differ sufficiently from halon to require different nozzles in addition to the need for larger storage vessels. Existing piping systems should be salvaged for use with clean agents only if they are carefully evaluated and determined to be hydraulically compatible with the flow characteristics of the new agent.

This section also relies on strict adherence to the system manufacturer's design and installation instructions for code compliance. As with many of the alternative fire suppression systems covered in this chapter, clean-agent systems are, for the most part, subjected by their manufacturers to a testing and listing program conducted by an approved testing agency. In such testing and listing programs, the clean agent is listed for use with specific equipment and equipment is listed for use with specific clean agents. The resultant listings include reference to the manufacturer's installation manuals, thereby giving the fire code official another valuable resource for reviewing and approving clean-agent systems.

Although clean agents have found a limited market for local application uses, such as a replacement for Halon 1211 in portable fire extinguishers, their primary application is in total-flooding systems, and they are available in both engineered and preengineered configurations.

Engineered clean-agent systems are specifically designed for protection of a particular hazard, whereas preengineered systems are designed to operate within predetermined limitations up to the
noted maximums, thus allowing broader applicability to a variety of hazard applications. Total flooding systems are used where there is a fixed enclosure around the hazard that is adequate to enable the required clean-agent concentration to build up and be maintained within the space long enough to extinguish the fire. Such applications can include vaults, ovens, containers, tanks, computer rooms, paint lockers or enclosed machinery. In selecting the clean agent to be used in a given application, careful consideration must be given to whether the protected area is a normally occupied space, because different agents have different levels of concentration at which they may be a health hazard to occupants of the area.

The fire code official has the authority to approve the type of clean-agent system to be installed and should become familiar with the unique characteristics and hazards of clean-agent extinguishing systems using all available resources on the subject.

[F] 904.11 Commercial cooking systems. The automatic fire-extinguishing system for commercial cooking systems shall be of a type recognized for protection of commercial cooking equipment and exhaust systems of the type and arrangement protected. Preengineered automatic dry- and wet-chemical extinguishing systems shall be tested in accordance with UL 300 and listed and labeled for the intended application. Other types of automatic fire-extinguishing systems shall be listed and labeled for specific use as protection for commercial cooking operations. The system shall be installed in accordance with this code, its listing and the manufacturer's installation instructions. Automatic fire-extinguishing systems of the following types shall be installed in accordance with the referenced standard indicated, as follows:

1. Carbon dioxide extinguishing systems, NFPA 12.
3. Foam-water sprinkler system or foam-water spray systems, NFPA 16.
4. Dry-chemical extinguishing systems, NFPA 17.
5. Wet-chemical extinguishing systems, NFPA 17A.

Exception: Factory-built commercial cooking recirculating systems that are tested in accordance with UL 710B and listed, labeled and installed in accordance with Section 304.1 of the International Mechanical Code.

The history of commercial kitchen exhaust systems shows that the mixture of flammable grease and effluents carried by such systems and the potential for the cooking equipment to act as an ignition source contribute to a higher level of hazard for kitchen exhaust systems than is normally found in many other exhaust systems. Furthermore, fire in a grease exhaust duct can produce temperatures of 2,000°F (1093°C) or more and heat radiating from the duct can ignite nearby combustibles. As a result, the code requires exhaust systems serving grease-producing equipment to include fire suppression to protect the cooking surfaces, hood, filters and exhaust duct to confine a fire to the hood and duct system, thus reducing the likelihood of it spreading to the structure.

In addition to the general requirements of this section, five industry standards are referenced for the installation of fire-extinguishing systems protecting commercial food heat-processing equipment and kitchen exhaust systems. Design professionals should specify and design fire-extinguishing systems to comply with these referenced standards. Only the installation of fire-extinguishing systems is regulated by these references. Where preengineered automatic dry- and wet-chemical extinguishing systems are installed, they must be listed and labeled for the specific cooking operation and tested in accordance with UL 300. Design and construction requirements for the specific types of fire-extinguishing systems are found in the respective sections of the referenced standards.

Regulatory requirements for the approval and installation of fire-extinguishing systems are the same as the approval required for all mechanical equipment and appliances. This section, therefore, requires extinguishing systems to be listed and labeled by an approved agency and installed in accordance with their listing and the manufacturer's installation instructions.

The exception allows factory-built commercial cooking recirculating systems to be installed if they have been tested and listed in accordance with UL 710B. It is important that they be installed in accordance with the manufacturer's installation instructions so that the listing requirements are met. An improper installation could result in hazardous vapors being discharged back into the kitchen.

Commercial cooking recirculating systems consist of an electric cooking appliance and an integral or matched packaged hood assembly. The hood assembly consists of a fan, collection hood, grease filter, fire damper, fire-extinguishing system and air filter, such as an electrostatic precipitator. These systems are tested for fire safety and emissions. The grease vapor (condensible particulate matter) in the effluent at the system discharge is not allowed to exceed a concentration of 5.0 mg/m³. Recirculating systems are not used with fuel-fired appliances because the filtering systems do not remove combustion products. Kitchens require ventilation in accordance with Chapter 4 of the IMC.

Although the provisions in Section 904.11 address many of the specifics for commercial kitchens, additional information regarding commercial cooking suppression systems is located in Sections 904.2 and 904.3. This information is supplemental to that and should be considered together in developing the design for commercial cooking suppression systems.

[F] 904.11.1 Manual system operation. A manual actuation device shall be located at or near a means of egress from the cooking area a minimum of 10 feet (3048 mm) and a maximum of 20 feet (6096 mm) from the kitchen exhaust system.
The manual actuation device shall be installed not more than 48 inches (1200 mm) or less than 42 inches (1067 mm) above the floor and shall clearly identify the hazard protected. The manual actuation shall require a maximum force of 40 pounds (178 N) and a maximum movement of 14 inches (356 mm) to actuate the fire suppression system.

Exception: Automatic sprinkler systems shall not be required to be equipped with manual actuation means.

The manual device, usually a pull station, mechanically activates the suppression system. The typical system uses a mechanical circuit of cables under tension to hold the system in the armed (cocked) mode. Melting of a fusible link or actuation of a manual pull station causes the cable to lose tension, which, in turn, starts the discharge of the suppression agent. The manual actuation device must be readily and easily usable by the building occupants; therefore, the device must not require excessive force or range of movement to cause actuation.

In order to allow the actuation device to be used most effectively, the specified mounting height is intended to be consistent with the NFPA 17A standards and be handicapped accessible. This includes the requirement to identify the actuation device with the hazard protected. Where multiple kitchen appliances are provided, properly identifying which device relates to which appliance is very important. Required signage should be readily visible in the hazard area and capable of conveying information quickly and concisely.

Manual actuation is not required for automatic sprinkler systems because the typical system design will employ closed heads and wet system piping. A manual actuation valve would serve no purpose because sprinkler heads are already supplied with pressurized water and will discharge water only when the individual fusible elements open the heads.

[F] 904.11.2 System interconnection. The actuation of the fire suppression system shall automatically shut down the fuel or electrical power supply to the cooking equipment. The fuel and electrical supply reset shall be manual.

The actuation of any fire suppression system must automatically shut off all sources of fuel or power to all cooking equipment located beneath the exhaust hood protected by the suppression system. This requirement is intended to shut off all heat sources that could reignite or intensify a fire. Shutting off a fuel and power supply to cooking appliances will eliminate an ignition source and allow the cooking surfaces to cool down. This shutdown is accomplished with mechanical or electrical interconnections between the suppression system and a shutoff valve or switch located on the fuel or electrical supply.

Common fuel shutoff valves include mechanical-type gas valves and electrical solenoid-type gas valves. Contactor-type switches or shunt-trip circuit breakers can be used for electrically heated appliances. The fuel or electric source must not be automatically restored after the suppression system has been actuated.

Chemical-type fire-extinguishing systems discharge for only a limited time and can discharge only once before recharge and reset; therefore, precautions must be taken to prevent a fire from reigniting. After a fire is detected and the initial suppressant discharge begins, the fuel and power supply will be locked out, thereby preventing the operation of the appliances until all systems are again ready for operation. Fuel and power supply shutoff must be manually restored by resetting a mechanical linkage or holding (latching)-type circuit.

[F] 904.11.3 Carbon dioxide systems. When carbon dioxide systems are used, there shall be a nozzle at the top of the ventilating duct. Additional nozzles that are symmetrically arranged to give uniform distribution shall be installed within vertical ducts exceeding 20 feet (6096 mm) and horizontal ducts exceeding 50 feet (15 240 mm). Dampers shall be installed at either the top or the bottom of the duct and shall be arranged to operate automatically upon activation of the fire-extinguishing system. Where the damper is installed at the top of the duct, the top nozzle shall be immediately below the damper. Automatic carbon dioxide fire-extinguishing systems shall be sufficiently sized to protect against all hazards venting through a common duct simultaneously.

This section states specific design requirements for nozzle locations, dampers and ducts for carbon dioxide extinguishing systems that may be used to protect commercial cooking systems. These requirements are intended to supersede similar, more general provisions in NFPA 12. Because carbon dioxide (CO₂) is a gaseous suppressant, dampers are required in the ductwork to define the atmosphere where the fire event would be. A specific concentration of CO₂ is necessary and dampers are required to define and contain the suppressant. The discharge cools exposed surfaces in addition to depriving the fire of oxygen. Although not mentioned specifically in this section, the applicable provisions of NFPA 12 should also be applied because the system is a CO₂ system as referenced in Section 904.8.

[F] 904.11.3.1 Ventilation system. Commercial-type cooking equipment protected by an automatic carbon dioxide-extinguishing system shall be arranged to shut off the ventilation system upon activation.

Shutting down the ventilation system upon activation of the CO₂ extinguishing system maintains the desired concentration of carbon dioxide to suppress the fire. Leakage of gas from the protected area should be kept to a minimum. Where leakage is anticipated, additional quantities of carbon dioxide must be provided to compensate for any losses.

[F] 904.11.4 Special provisions for automatic sprinkler systems. Automatic sprinkler systems protecting commercial-type cooking equipment shall be supplied from a separate,
readily accessible, indicating-type control valve that is identified.

- This section requires a separate control valve in the water line to the sprinklers protecting the cooking and ventilating system. The additional valve allows the flexibility to shut off the system for repairs or for cleanups after sprinkler discharge without taking the entire system out of service.

[F] 904.11.4.1 Listed sprinklers. Sprinklers used for the protection of fryers shall be tested in accordance with UL 199E, listed for that application and installed in accordance with their listing.

- Sprinklers specifically listed for such use must be used when protecting deep-fat fryers. These specially listed sprinklers use finer water droplets than standard spray sprinklers. The water spray lowers the temperature below a point where the fire can sustain itself and reduces the possibility of expanding the fire. UL 199E addresses these special sprinklers and includes performance tests for deep-fat fryer extinguishment and also deep-fat fryer cooking temperature splash. The selection of inappropriate sprinklers for deep-fat fryer protection can increase the hazards during water application rather than suppressing the fire.

SECTION 905 STANDPIPE SYSTEMS

[F] 905.1 General. Standpipe systems shall be provided in new buildings and structures in accordance with this section. Fire hose threads used in connection with standpipe systems shall be approved and shall be compatible with fire department hose threads. The location of fire department hose connections shall be approved. In buildings used for high-piled combustible storage, fire protection shall be in accordance with the International Fire Code.

- Standpipe systems are required in buildings to provide a quick, convenient water source for fire department use where hose lines would otherwise be impractical, such as in high-rise buildings. Standpipe systems can also be used prior to deployment of hose lines from fire department apparatus. The requirements for standpipe systems are based on practical requirements of typical fire-fighting operations and the nationally recognized standard NFPA 14.

The threads on connections to which the fire department may connect a hose must be compatible with the fire department hose threads (see commentary, Section 903.3.6). Chapter 23 of the IFC requires a Class I standpipe system in exit passageways of buildings used for high-piled storage. Note that if a building containing high-piled storage does not contain an exit passageway, then standpipes would not be required. High-piled storage involves the solid-piled, bin box, palletized or rack storage of Class I through IV commodities over 12 feet (3658 mm) high. High-hazard commodities stored higher than 6 feet (1829 mm) are also considered high piled.

[F] 905.2 Installation standard. Standpipe systems shall be installed in accordance with this section and NFPA 14.

- This section requires the installation of standpipe systems to comply with the applicable provisions of NFPA 14 in addition to Section 905. NFPA 14 contains the minimum requirements for the installation of standpipe and hose systems for buildings and structures. The standard addresses additional requirements not addressed in the code, such as pressure limitations, minimum flow rates, piping specifications, hose connection details, valves, fittings, hangers and the testing and inspection of standpipes. The periodic inspection, testing and maintenance of standpipe systems must comply with NFPA 25.

Section 905 and NFPA 14 recognize three classes of standpipe systems: Class I, II or III. The type of system required depends on building height, building area, type of occupancy and the extent of automatic sprinkler protection. Section 905 also recognizes five types of standpipe systems: automatic dry, automatic wet, manual dry, manual wet and semiautomatic dry. The use of each type of system is limited to the building conditions and locations identified in Section 905.3. The classes and types of standpipe systems are defined in Section 202.

[F] 905.3 Required installations. Standpipe systems shall be installed where required by Sections 905.3.1 through 905.3.8. Standpipe systems are allowed to be combined with automatic sprinkler systems.

Exception: Standpipe systems are not required in Group R-3 occupancies.

- Standpipe systems are installed in buildings based on the occupancy, fire department accessibility and special conditions that may require manual fire suppression exceeding the capacity of a fire extinguisher. Standpipe systems are most commonly required for buildings that exceed the height threshold requirement in Section 905.3.1 or the area threshold requirement in Section 905.3.2. Specific occupancies such as covered and open mall buildings, stages and underground buildings, because of their use or occupancy, also require a standpipe system.

This section also states that a standpipe system does not have to be separate from an installed sprinkler system. It is common practice in multistory buildings for the standpipe system risers to also serve as risers for the automatic sprinkler systems.

In these instances, precautions need to be taken so that the operation of one system will not interfere with the operation of the other system. Therefore, control valves for the sprinkler system must be installed where the sprinklers are connected to the standpipe riser at each floor level. This allows the standpipe system to remain operational, even if the
sprinkler system is shut off at the floor control valve. The exception recognizes that standpipe systems in Group R-3 occupancies would be of minimal value to the fire department and would send the wrong message to the occupants of a dwelling unit. In the case of multiple single-family dwellings, each dwelling unit has a separate entrance and is separated from the other units by 1-hour fire partitions. These conditions permit ready access to fires and also provide for a degree of fire containment through compartmentation, which is not always present in other occupancies.

[F] 905.3.1 Height. Class III standpipe systems shall be installed throughout buildings where the floor level of the highest story is located more than 30 feet (9144 mm) above the lowest level of fire department vehicle access, or where the floor level of the lowest story is located more than 30 feet (9144 mm) below the highest level of fire department vehicle access.

Exceptions:

1. Class I standpipes are allowed in buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2.
2. Class I manual standpipes are allowed in open parking garages where the highest floor is located not more than 150 feet (45 720 mm) above the lowest level of fire department vehicle access.
3. Class I manual dry standpipes are allowed in open parking garages that are subject to freezing temperatures, provided that the hose connections are located as required for Class II standpipes in accordance with Section 905.5.

4. Class I standpipes are allowed in basements equipped throughout with an automatic sprinkler system.
5. In determining the lowest level of fire department vehicle access, it shall not be required to consider:
   5.1. Recessed loading docks for four vehicles or less; and
   5.2. Conditions where topography makes access from the fire department vehicle to the building impractical or impossible.

Given the available manpower on the fire department vehicle, standard fire-fighting operations and standard hose sizes, a 30-foot (9144 mm) vertical distance is generally considered the maximum height to which a typical fire department engine company can practically and readily extend its hose lines. Thus, the maximum vertical travel (height) threshold is based on the time it would take a typical fire department engine (pumper) company to manually suppress a fire. The standpipe connection reduces the time needed for the fire department to extend hose lines up or down stairways to advance and apply water to the fire. For this use, a minimum Class III standpipe system is required.

With respect to the height of the building, the threshold is measured from the level at which the fire department can gain access to the building directly from its vehicle and begin vertical movement. Floor levels above grade are measured from the lowest level of fire department vehicle access to the highest floor level above [see Figure 905.3.1(1)]. If a building contains floor levels below the level of fire department access.

---

![Diagram of Standpipe System](image)

**Figure 905.3.1(1)**

**HEIGHT THRESHOLD FOR STANDPIPES**

For SI: 1 foot = 304.8 mm.
vehicle access, the measurement is made from the highest level of fire department vehicle access to the lowest floor level. In cases where a building has more than one level of fire department vehicle access, the most restrictive measurement is used because it is not known at which level the fire department will access the building. In other words, the vertical distance is to be measured from the more restrictive level of fire department vehicle access to the level of the highest (or lowest, if below) floor [see Figure 905.3.1(2)].

The threshold based on the height of the building is independent of the occupancy of the building, the area of the building or the presence of an automatic sprinkler system. This is based on the universal need to be able to provide a water supply for fire suppression in any building and on the limitations of the physical effort necessary to extend hose lines vertically.

Before discussing the exceptions it is important to understand the differences between the different classes and operational characteristics of standpipes. More detailed information is included in Section 202 for the definitions of the different classes and types of standpipes.

Standpipes can be dry or wet, manual, automatic or semiautomatic. Automatic systems can be either wet or dry. Manual systems can be either wet or dry. A semiautomatic system is always in association with a dry system.

The code is written such that it could be assumed that the default is an automatic wet system. This is, however, not the case. The requirement is left to the design standard, NFPA 14. Section 5.4.1.1 of NFPA 14 indicates that Class I standpipes can be manual if the building is not high-rise. Section 5.4.1.4 of the standard indicates that a Class I standpipe must be wet except where the pipe is subject to freezing. Thus, where a Class I standpipe is installed, possibly as a part of Exception 1, the system can be manual wet if the building is not a high rise. This is consistent with IFC Committee Interpretation No. 33-03. As long as the building is not high rise, it can be provided with a Class I standpipe system that is manual wet.

Class II and III standpipes are required to be automatic-wet or semiautomatic wet except where the piping is subject to freezing according to Section 5.4.3 of NFPA 14. They cannot be manual. Only Class I standpipes can be manual and only be used under the conditions noted in this code. Note that other sections of the code may specify whether the system must be automatic or not. If the requirement is not noted elsewhere in the code, then the decision to use an automatic or manual system is left to the designer.

Exception 1 recognizes the fact that with a fully operational automatic sprinkler system, the time that the fire department has to extend hoses within the building is substantially increased and that the amount of effort required is greatly reduced. Consequently a single Class I connection can be provided. The second, 1 1/2-inch (38 mm) connection is allowed to be omitted. NFPA 14 also has a similar provision but is more restrictive as it only eliminates the hose station and additionally requires a 2 1/2-inch by 1 1/2-inch (65 mm by 40 mm) reducer and a cap attached with a chain (see Section 7.3.4.1). In accordance with
Section 102.7, the IFC would take precedence and the reducer and cap would not be required.

Exception 2 identifies one of the issues relative to open parking garages. This exception allows for the garage, when not more than 150 feet (45 720 mm) in height above the lowest level of fire department access, to have a wet standpipe but without additional operating pressure until the fire department connects and begins pumping into the system. This makes sense since normal operations typically do not begin until after the fire department is on the scene and has made its initial assessments. This is generally considered to be the maximum safe height for pumper to overcome the hydrostatic head presented by 150 feet (45 720 mm) of water. Careful considerations should be made since not all fire departments have equipment capable of this type of pumping capacity.

Exception 3 is similar to the prior exception but with the added provision that the standpipe can be dry if subject to freezing, regardless of height. Because the standpipe will be without water and dependant upon the fire department to provide both water and pressure, standpipe outlets must be spaced more frequently, as noted in Section 905.5 for Class II standpipes so that fire fighters can connect and begin operations quicker. The exception does not require Class II outlets; only that the spacing be consistent with the requirement for Class II.

Exception 4 is similar to Exception 1 but only addresses sprinklers in the basement. Thus it is possible to use this exception if only the basement is protected by automatic sprinklers. However, Class I connections can only be provided in the basements—not on the upper floors. The exception cannot be used for stories above grade unless the entire building is sprinklered and, therefore, compliant with Exception 1.

Exception 5 provides additional information about what must be considered when determining building height with respect to the level of fire department vehicle access. The first item is a practical one that excludes loading docks of a limited size. The second item notes that although it may be possible to have a fire department vehicle arrive adjacent to the building at a low level, it may not be possible for the fire department to access the building from that level. An example of this condition would be where a road surface is located below a building built on a bluff. Although the fire department vehicles can approach from the lower road, fire department personnel cannot access the building from that lower level. Thus, the standpipe requirement would not be based on the road below the bluff.

[F] 905.3.2 Group A, Class I automatic wet standpipes shall be provided in nonsprinklered Group A buildings having an occupant load exceeding 1,000 persons.

Exceptions:

1. Open-air-seating spaces without enclosed spaces.

2. Class I automatic dry and semiautomatic dry standpipes or manual wet standpipes are allowed in buildings that are not high-rise buildings.

The main concern in assembly occupancies with a high occupant load is evacuation. Many occupants may not be familiar with either their surroundings or the egress arrangement in the building. This section also assumes the building is not sprinklered; therefore, control and suppression of the fire is left to the fire department.

Exception 1 exempts open-air seating without enclosed spaces, such as grandstands and bleachers. In such occupancies, a buildup of smoke and hot gases is not possible because these structures are open to the atmosphere.

Exception 2 states that in lieu of a Class I automatic wet standpipe, automatic dry and semiautomatic dry Class I standpipes are permitted in buildings that are not considered to be a high rise.

[F] 905.3.3 Covered and open mall buildings. Covered mall and open mall buildings shall be equipped throughout with a standpipe system where required by Section 905.3.1. Mall buildings not required to be equipped with a standpipe system by Section 905.3.1 shall be equipped with Class I hose connections connected to the automatic sprinkler system sized to deliver water at 250 gallons per minute (946.4 L/min) at the most hydraulically remote hose connection while concurrently supplying the automatic sprinkler system demand. The standpipe system shall be designed to not exceed 50 pounds per square inch (psi) (345 kPa) residual pressure loss with a flow of 250 gallons per minute (946.4 L/min) from the fire department connection to the hydraulically most remote hose connection. Hose connections shall be provided at each of the following locations:

1. Within the mall at the entrance to each exit passageway or corridor.
2. At each floor-level landing within enclosed stairways opening directly on the mall.
3. At exterior public entrances to the mall of a covered mall building.
4. At public entrances at the perimeter line of an open mall building.
5. At other locations as necessary so that the distance to reach all portions of a tenant space does not exceed 200 feet (60 960 mm) from a hose connection.

Covered and open mall buildings are only required to have a standpipe system if Section 905.3.1 requires such features. If standpipes are not required due to building height, Class I hose connections that are connected to the automatic sprinkler system are still required. Also to ensure that both the sprinkler system and hose connections will function at an acceptable level, the system must be sized for both the sprinkler demand and the hose connection demand. This section specifies a minimum flow rate and a maximum pressure loss to the most remote hose connection so that the fire department can gain full
use of the hose connection during a fire. Hose connections are required when a standpipe system is not at key locations, such as entrances to exit passages and at entrances to the covered or open mall. Note that these locations are essentially the same locations required for Class I hose connections in Section 905.4, except that this section also requires that the distance of all portions of tenant spaces does not exceed 200 feet (60 960 mm) from a hose connection.

[F] 905.3.4 Stages. Stages greater than 1,000 square feet in area (93 m²) shall be equipped with a Class III wet standpipe system with 1½-inch and 2½-inch (38 mm and 64 mm) hose connections on each side of the stage.

Exception: Where the building or area is equipped throughout with an automatic sprinkler system, a 1½-inch (38 mm) hose connection shall be installed in accordance with NFPA 13 or in accordance with NFPA 14 for Class II or III standpipes.

Because of the potentially large fuel load and three-dimensional aspect of the fire hazard associated with stages greater than 1,000 square feet (93 m²) in area, Class III standpipes are required on each side of these large stages. The standpipes must be equipped with a 1½-inch (38 mm) hose connection and a 2½-inch (64 mm) hose connection. The 1½-inch (38 m²) connection is for the hose requirement in Section 905.3.4.1. The 2½-inch (64 mm) connection is to provide greater flexibility for the fire department in its fire-fighting operations.

Stages, as used in this section, are those stages defined in Section 410.2, which include overhead hanging curtains, drops, scenery or stage effects other than lighting and sound. These were traditionally referred to as "legitimate stages." It is not an appropriate application of this section to require standpipes for elevated areas in banquet rooms, or theatrical platforms where the higher fuel loads associated with a legitimate stage do not exist.

The exception recognizes the benefit of the building or area being sprinklered. If so, then only a single 1½-inch (38 mm) connection is required. This hose connection is intended to be used by the fire department and apply less water from the hose due to the suppression activity of the sprinkler system. Hose threads must be compatible with those of the fire department as required in Section 903.3.6.

In a fully sprinklered building it is acceptable to supply the hose connections through the same standpipe as the sprinklers. This is reflected in the reference to both NFPA 13, which acknowledges this concept, and NFPA 14, which contains similar provisions. If the provisions of NFPA 14 are used, although the standpipe must be wet and Class II in its installation, the design of the water supply and interconnection of systems can be in accordance with the requirements for Class II as well as for Class III standpipes.

[F] 905.3.4.1 Hose and cabinet. The 1½-inch (38 mm) hose connections shall be equipped with sufficient lengths of 1½-inch (38 mm) hose to provide fire protection for the stage area. Hose connections shall be equipped with an approved adjustable fog nozzle and be mounted in a cabinet or on a rack.

The 1½-inch (38 mm) standpipe hose installed for stages greater than 1,000 square feet (93 m²) in area is intended for use by stage personnel who have been trained to use it. The length of hose provided is a function of the size and configuration of the stage. This includes by definition the entire performance area and adjacent backstage and support areas not fire separated from the performance area. The effective reach of the fire stream from the fog nozzle is a function of the available water supply, and in particular, the pressure. Fog nozzles typically require 100 pounds per square inch (psi) (690 kPa) for optimum performance.

[F] 905.3.5 Underground buildings. Underground buildings shall be equipped throughout with a Class I automatic wet or manual wet standpipe system.

Underground buildings present unique hazards to life safety because of their isolation and inaccessibility. Additional fire protection and fire-fighting measures for the fire department are required to compensate for the lack of exterior access for fire suppression and rescue operations (see Section 405).

[F] 905.3.6 Helistops and heliports. Buildings with a rooftop helistop or heliport shall be equipped with a Class I or III standpipe system extended to the roof level on which the helistop or heliport is located in accordance with Section 2007.5 of the International Fire Code.

Buildings containing rooftop helistops or heliports are required to be equipped with a Class I or III standpipe. A heliport is a distinct hazard that will involve flammable fuels. In the event of an emergency, rapid deployment of hand hose lines will be necessary to attack a resulting fire, effectuate rescue and to protect exposures and the remainder of the building.

The requirement results in a standpipe system throughout the building, not just a connection at the roof level. This is critical in fire-fighting operations because many times the connection below the rooftop level may be needed just to gain access onto the roof. If the only connection is on the roof, it is of no use if the fire fighters cannot get to it.

Additionally, a heliport includes fueling operations. It is entirely possible for a spill to not only affect the rooftop, but also floors below as the liquid fuel spreads. The standpipe system will again be utilized in these situations.

Section 2007.5 of the IFC requires a 2½-inch (64 mm) standpipe outlet to be within 150 feet (45 675 mm) of all portions of the heliport or helistop area and be either Class I or III.
FIRE PROTECTION SYSTEMS

[F] 905.3.7 Marinas and boatyards. Standpipes in marinas and boatyards shall comply with Chapter 36 of the International Fire Code.

- Section 4504.2 of the IFC contains the specifics as to when standpipes are required at marinas. Marinas and boatyards have unique challenges for fire fighting. Although there is water readily available, it is not easily or effectively capable of being applied to a fire at such a facility. A fire in such facilities can spread from structure to structure and from vessel to vessel with no effective way to attack and control it. Section 4504.2 of the IFC references NFPA 303 for the standpipe requirements and additionally requires that no point on the marina pier or floating system exceed 150 feet (45 720 mm) from a standpipe hose connection (see commentary, Section 4504.2 of the IFC).

[F] 905.3.8 Rooftop gardens and landscaped roofs. Buildings or structures that have rooftop gardens or landscaped roofs and that are equipped with a standpipe system shall have the standpipe system extended to the roof level on which the rooftop garden or landscaped roof is located.

- This section requires that if the building is equipped with a standpipe system, whether or not such systems are required, it must be extended to a roof containing a garden or that which is landscaped. These requirements relate to the requirements in Section 317 of the IFC that address the increased fuel load being added to roofs.

[F] 905.4 Location of Class I standpipe hose connections. Class I standpipe hose connections shall be provided in all of the following locations:

1. In every required stairway, a hose connection shall be provided for each floor level above or below grade. Hose connections shall be located at an intermediate floor level landing between floors, unless otherwise approved by the fire code official.

2. On each side of the wall adjacent to the exit opening of a horizontal exit.

**Exception:** Where floor areas adjacent to a horizontal exit are reachable from exit stairway hose connections by a 30-foot (9144 mm) hose stream from a nozzle attached to 100 feet (30 480 mm) of hose, a hose connection shall not be required at the horizontal exit.

3. In every exit passageway, at the entrance from the exit passageway to other areas of a building.

**Exception:** Where floor areas adjacent to an exit passageway are reachable from exit stairway hose connections by a 30-foot (9144 mm) hose stream from a nozzle attached to 100 feet (30 480 mm) of hose, a hose connection shall not be required at the entrance from the exit passageway to other areas of the building.

4. In covered mall buildings, adjacent to each exterior public entrance to the mall and adjacent to each entrance from an exit passageway or exit corridor to the mall. In open mall buildings, adjacent to each public entrance to the mall at the perimeter line and adjacent to each entrance from an exit passageway or exit corridor to the mall.

5. Where the roof has a slope less than four units vertical in 12 units horizontal (33.3-percent slope), a hose connection shall be located to serve the roof or at the highest landing of a stairway with stair access to the roof provided in accordance with Section 1009.16.

6. Where the most remote portion of a nonsprinklered floor or story is more than 150 feet (45 720 mm) from a hose connection or the most remote portion of a sprinklered floor or story is more than 200 feet (60 960 mm) from a hose connection, the fire code official is authorized to require that additional hose connections be provided in approved locations.

- Hose connections are required for the fire department to make use of the standpipe system. Since the fire department will typically access the building using the stairways, and most fire departments do not permit entry to the fire floor without an operating hose line, a hose connection must be installed for each floor level of each required enclosed stairway.

Item 1 also specifies that the hose connections are to be located at intermediate landings between floors. This reduces congestion at the stairway door and may reduce the hose lay distance. The hose connections, however, are still permitted at each floor level of the exit stair instead of at the intermediate landing if this arrangement is approved by the fire code official.

Because horizontal exits are also primary entrances to the fire floor, Item 2 states that hose connections must also be provided at each horizontal exit. The construction of the fire separation assembly used as the horizontal exit will protect the fire fighters while they are connecting to the standpipe system. The hose connections are to be located on each side of the horizontal exit to enable fire fighters to be in a protected area, regardless of the location of the fire. The exception acknowledges that there may already be a hose connection in close proximity to the horizontal exit if there is a stairway adjacent to the horizontal exit. The intent is to allow fewer standpipe outlets if the area can be adequately covered by the standpipes in stairways since those are the standpipes typically used by the fire department.

Item 3 states that an exit passageway in a building required to have a standpipe system is typically used as an extension of a required exit stairway. This allows use of the exit passageway for fire-fighting staging operations in the same way as an exit stair. The exception acknowledges that there may already be a hose connection in close proximity to the exit passageway. If there is a stairway containing a hose connection in close proximity to the exit passageway that can meet the 30-foot (9144 mm) hose stream from a nozzle attached to 100 feet (30 480 mm) of hose, then an additional standpipe is not required. The intent is to allow fewer standpipe outlets if the
area can be adequately covered by the standpipes in stairways since those are the standpipes typically used by the fire department.

In covered and open mall buildings, Item 4 requires hose connections at each entrance to an exit pas-
sageway or exit corridor. In addition, covered mall buildings would be required to have connections at each exterior public entrance. Open malls would require connections at the public entrance perimeter line. These locations allow fire personnel to have a support line as soon as they enter the building.

Item 5 is consistent with NFPA 14 regarding the installation of Class I standpipe hose connections on the roofs of buildings. This requirement requires only one standpipe to extend to the roof level or highest landing of the stair serving the roof. This coordinate with Section 1009.16, which only requires one stair-
way to extend to the roof.

Hose connections in each exit stairway result in hose connections being located based on the travel distances permitted in Table 1016.1, which recognizes that most fire departments carry standpipe hose packs with 150 feet (45 720 mm) of hose or possibly with 100 feet (30 480 mm) of hose and an additional 50-foot (15 240 mm) section that could be easily connected.

With the typical travel distance permitted in non-
sprinklered buildings of 200 feet (60 960 mm), rea-
sonable coverage is provided when the effective reach of a fire stream is considered. Depending on the arrangement of the floor, however, all areas may not be effectively protected. Although this situation could easily be corrected by locating additional hose connections on the floor, such connections may rarely be used because of the difficulty in identifying their location during a fire and the fact that most fire departments require an operational hose line before they enter the fire floor. Because longer travel distances are allowed in sprinklered buildings, the prob-
lem is increased, but the need for prompt manual suppression is reduced by the presence of the sprink-
er system. Item 6 gives the fire code official the authority to require additional hose connections if needed.

[F] 905.4.1 Protection. Risers and laterals of Class I stand-
pipe systems not located within an enclosed stairway or pres-
surized enclosure shall be protected by a degree of fire resistance equal to that required for vertical enclosures in the building in which they are located.

Exception: In buildings equipped throughout with an approved automatic sprinkler system, laterals that are not located within an enclosed stairway or pressurized enclo-
sure are not required to be enclosed within fire-resistance-
rated construction.

To minimize the potential for damage to the stand-
pipe systems from a fire, the risers and laterals must be located in an enclosure having the same fire-resis-
tance rating as required for a vertical or shaft enclo-
sure within the building. The required fire-resistance rating for the enclosure can be determined as detailed in Section 713.4.

The enclosure is not required if the building is equipped throughout with an approved automatic sprinkler system. The potential for damage to the standpipe system is minimized by the protection provided by the sprinkler system. The automatic sprinkler system may be either an NFPA 13 or 13R system, depending on what was permitted for the building occupancy.

If the stair enclosure is not required to have a rated enclosure, such as in an open parking garage, the laterals are similarly not required to be in an enclo-
sure. The protection afforded the vertical riser in the stairway must be the same as that afforded the later-
als. If the stairway is not required by other sections of the code to be located in a rated enclosure then the laterals are not required to be in rated protection either.

[F] 905.4.2 Interconnection. In buildings where more than one standpipe is provided, the standpipes shall be intercon-
ected in accordance with NFPA 14.

• In cases where there are multiple Class I standpipe risers, the risers must be supplied from and interconnected to a common supply line. The required fire department connection must serve all of the sprinklers or standpipes in the building.

[F] 905.5 Location of Class II standpipe hose connections. Class II standpipe hose connections shall be accessible and located so that all portions of the building are within 30 feet (9144 mm) of a nozzle attached to 100 feet (30 480 mm) of hose.

• Sections 905.5.1 through 905.5.3 specify the require-
ments for Class II standpipe hose connections. Class II standpipe systems are primarily intended for use by the building occupants.

This section for Class II standpipes does not spe-
cifically require the hose station and uses the term "hose connection" with a location based upon 100 feet (30 480 mm) of hose. However, the definition of Class II and III standpipes and Section 7.3.3.1 of NFPA 14 specifically require hose stations. Section 905.2 specifically references NFPA 14.

Although NFPA 14 requires a hose station, the decision as to whether a hose station is required may be one that is affected by the policies and procedures of the local fire department. It should be remembered that Class II hose connections and hose stations are intended for occupant use and not necessarily for fire department use. The fire department typically uses the Class I connection that is compatible with 2" inch (64 mm) hose.

[F] 905.5.1 Groups A-1 and A-2. In Group A-1 and A-2 occupancies having occupant loads exceeding 1,000 persons, hose connections shall be located on each side of any stage,
on each side of the rear of the auditorium, on each side of the balcony and on each tier of dressing rooms.

- Because of the high occupant load density in Group A-1 and A-2 occupancies, providing additional means for controlling fires in their initial stage is important to enable prompt evacuation of the building. This section is independent of the Class I standpipe requirement for stages based on square footage as indicated in Section 905.3.4.

[F] 905.5.2 Protection. Fire-resistance-rated protection of risers and laterals of Class II standpipe systems is not required.

- Class II standpipe systems are normally not located in exit stairways; standpipe hose connections are located near the protected area to allow quick access. Therefore, it is likely that neither the risers nor the laterals would be located in any enclosure.

[F] 905.5.3 Class II system 1-inch hose. A minimum 1-inch (25 mm) hose shall be permitted to be used for hose stations in light-hazard occupancies where investigated and listed for this service and where approved by the code official.

- This section permits the use of 1-inch (25 mm) listed noncollapsible hose as an alternative to 11/2-inch (38 mm) hose, subject to the approval of the code official. This alternative is limited to light-hazard occupancies, such as office buildings and certain assembly occupancies that tend to have lower fuel loads, since a smaller hose can discharge less water.

[F] 905.6 Location of Class III standpipe hose connections. Class III standpipe systems shall have hose connections located as required for Class I standpipes in Section 905.4 and shall have Class II hose connections as required in Section 905.5.

- Class III standpipe systems that have both a 21/2-inch (64 mm) hose connection and a 11/2-inch (38 mm) hose connection must comply with the applicable requirements of Sections 905.4, 905.5 and 905.6. Thus, it is necessary to review and comply with all applicable provisions.

[F] 905.6.1 Protection. Risers and laterals of Class III standpipe systems shall be protected as required for Class I systems in accordance with Section 905.4.1.

- Because Class III standpipe systems are intended for use by fire-suppression personnel, they must be located in construction that has a fire-resistance rating equivalent to that of the vertical or shaft enclosure requirements of the building (see commentary, Section 905.4.1).

[F] 905.6.2 Interconnection. In buildings where more than one Class III standpipe is provided, the standpipes shall be interconnected in accordance with NFPA 14.

- As indicated in Section 905.4.2 for Class I standpipe systems, multiple standpipe risers must be interconnected with a common supply line. An indicating valve is typically installed at the base of each riser so that individual risers can be taken out of service without affecting the water supply or the operation of other standpipe risers.

[F] 905.7 Cabinets. Cabinets containing fire-fighting equipment such as standpipes, fire hoses, fire extinguishers or fire department valves shall not be blocked from use or obscured from view.

- This section does not require that cabinets be provided to contain fire protection equipment. However, if they are provided, cabinets must be readily visible and accessible at all times. Sections 905.7.1 and 905.7.2 contain additional criteria for the construction and identification of the cabinets. Where cabinets are located in fire-resistance-rated assemblies, the integrity of the assembly must be maintained. Cabinet design for hose connections, control valves or other devices that require manual operation should be such that there is sufficient clearance between the cabinet body and the device to allow grasping of the device (quite likely with a gloved hand) and prompt operation of it.

[F] 905.7.1 Cabinet equipment identification. Cabinets shall be identified in an approved manner by a permanently attached sign with letters not less than 2 inches (51 mm) high in a color that contrasts with the background color, indicating the equipment contained therein.

Exceptions:

1. Doors not large enough to accommodate a written sign shall be marked with a permanently attached pictogram of the equipment contained therein.

2. Doors that have either an approved visual identification clear glass panel or a complete glass door panel are not required to be marked.

- This section specifies the minimum criteria to make the signs readily visible. Different color combinations may be approved by the code official if the color contrast between the letters and the background is vivid enough to make the sign visible at an approved distance. The exceptions address alternatives to letter signage if the cabinet is still conspicuously identified or the contents are readily visible.

[F] 905.7.2 Locking cabinet doors. Cabinets shall be unlocked.

Exceptions:

1. Visual identification panels of glass or other approved transparent fragilible material that is easily broken and allows access.

2. Approved locking arrangements.

- Ready access to all fire-fighting equipment in the cabinet is essential. The exceptions, however, recognize the need to lock cabinets for security reasons and to
prevent theft or vandalism (see also commentary, Section 906.8).

[F] 905.8 Dry standpipes. Dry standpipes shall not be installed.

Exception: Where subject to freezing and in accordance with NFPA 14.

- Wet standpipe systems are preferred because they tend to be the most reliable type of standpipe system; therefore, dry standpipes are prohibited unless subject to freezing. For example, Class I manual standpipe systems, which do not have a permanent water supply, are permitted in open parking structures. This recognizes that open parking structures are not heated and that most fires are limited to the vehicle of origin. The use of any dry standpipe system instead of a wet standpipe should take into consideration the added response time and its effect on the occupancy characteristics of the building.

[F] 905.9 Valve supervision. Valves controlling water supplies shall be supervised in the open position so that a change in the normal position of the valve will generate a supervisory signal at the supervising station required by Section 903.4. Where a fire alarm system is provided, a signal shall also be transmitted to the control unit.

Exceptions:

1. Valves to underground key or hub valves in roadway boxes provided by the municipality or public utility do not require supervision.

2. Valves locked in the normal position and inspected as provided in this code in buildings not equipped with a fire alarm system.

- As with sprinkler systems, water control valves for standpipe systems must be electrically supervised as a means of determining that the system is operational (see commentary, Section 903.4).

Exception 1 recognizes that underground key or hub valves in roadway boxes are not normally supervised or need to be supervised whether the building contains a standpipe system or an automatic sprinkler system.

Exception 2 does not require the control valves for the standpipes to be electrically monitored if they are locked in the normal position and a fire alarm system is not installed in the building. When a fire alarm system is installed, the control valves for the standpipes must be electrically monitored and tied into the supervision required for the fire alarm system.

[F] 905.10 During construction. Standpipe systems required during construction and demolition operations shall be provided in accordance with Section 3311.

- As stated in Section 3311, at least one standpipe is required during construction of buildings four stories or more in height or during demolition of standpipe-equipped buildings. Standpipe systems must be accessible and operable during construction and demolition operations to assist in any potential fire (see commentary, Sections 3311.1 and 3311.2 of the code and Sections 3313.1 and 3313.2 of the IFC).

SECTION 906 PORTABLE FIRE EXTINGUISHERS

[F] 906.1 Where required. Portable fire extinguishers shall be installed in the following locations.

1. In Group A, B, E, F, H, I, M, R-1, R-2, R-4 and S occupancies.

   Exception: In Group R-2 occupancies, portable fire extinguishers shall be required only in locations specified in Items 2 through 6 where each dwelling unit is provided with a portable fire extinguisher having a minimum rating of 1-A:10-B:C.

2. Within 30 feet (9144 mm) of commercial cooking equipment.

3. In areas where flammable or combustible liquids are stored, used or dispensed.

4. On each floor of structures under construction, except Group R-3 occupancies, in accordance with Section 3315.1 of the International Fire Code.

5. Where required by the International Fire Code sections indicated in Table 906.1.

6. Special-hazard areas, including but not limited to laboratories, computer rooms and generator rooms, where required by the fire code official.

- Portable fire extinguishers are required in certain instances to give the occupants the means to suppress a fire in its incipient stage. The capability for manual fire suppression can contribute to the protection of the occupants, especially if there are evacuation difficulties associated with the occupancy or the specific hazard in the area. To be effective, personnel must be properly trained in the use of portable fire extinguishers.

Because of the high-hazard nature of building contents, portable fire extinguishers are required in occupancies in Group H.

Portable fire extinguishers are required in occupancies in Groups A, B, E, F, I, M, R-1, R-2, R-4 and S because of the need to control the fire in its early stages and because evacuation can be slowed by the density of the occupant load, the capability of the occupants to evacuate or the overall fuel load in the building. Because the code typically focuses upon new buildings, this section is applicable to new buildings.

Portable fire extinguishers are required in areas containing special hazards, such as commercial cooking equipment, and specific hazardous operations, as indicated in Table 906.1. Because of the potentially extreme fire hazard associated with such areas or occupancy conditions, prompt extinguishment of the fire is critical.

Portable fire extinguishers are required in all buildings under construction, except in occupancies in...
Group R-3. The extinguishers are intended for use by construction personnel to suppress a fire in its incipient stages.

Portable fire extinguishers are also required in laboratories, computer rooms and other work spaces in which fire hazards may exist based on the use of the space. Many of these will be addressed by the required occupancy group criteria or by the specific hazard provisions of Table 906.1. Laboratories, for example, may not be considered Group H, but still utilize limited amounts of hazardous materials that would make manual means of fire extinguishment desirable.

The old exception to Item 1 that exempts the installation of portable fire extinguishers (PFEs) in low-hazard areas of Group A, B and E occupancies when the fire areas are equipped with an automatic sprinkler system utilizing quick-response automatic sprinklers was deleted from the 2012 edition of the code and the IFC. The revision of this exception will result in additional PFEs being required in these occupancies and allow for a modification of the requirements in certain Group R-2 occupancies.

Several concerns arose over the years since the exception was first introduced in the 2000 edition of the IFC. The biggest issue was that many code officials believed it was inappropriate to place complete reliance on automatic sprinkler systems for the protection of assembly, business and educational occupancies. An analysis of fire loss data for Group A occupancies, performed by the National Institute of Science and Technology (NIST) during the investigation of a large life-loss fire, confirmed that this assumption was correct. While investigating the Station Fire, a nightclub fire where 100 people died in 2003, NIST also analyzed the performance of portable fire extinguishers in nightclubs. NIST also analyzed NFPA fire loss data for nightclubs from 1990 through 1994 and found that almost 36 percent of fires in public assembly structures were extinguished by PFEs or other means during the incipient phase. These data show that without PFEs, occupants commonly used other tools to try to extinguish incipient fires. The NIST analysis found that 28 percent of all incipient fires were extinguished using PFEs and the remaining 8 percent used makeshift means. The study concluded that it was important for fire code officials to reinforce and educate nightclub employees on the purpose and capability of PFEs for controlling incipient fires.

Another issue expressed by code officials was the retrofitting of an automatic sprinkler system into existing buildings. In several cases, these retrofits resulted in the removal of PFEs. The removal of PFEs is believed to reduce the level of protection in the building. Given that the old exception to Item 1 included Group A occupancies, based on the referenced NIST report, its deletion was warranted for Group A occupancies.

The exception to Item 1 as revised in the 2012 code, permits smaller PFEs in dwelling units of Group R-2 occupancies instead of larger PFEs in the common areas. Under the revised exception, the installation of 1-A:10-B.4 PFEs within individual dwelling units allows apartment owners to eliminate their installation in common areas such as corridors, laundry rooms and swimming pool areas. PFEs in these areas are susceptible to vandalism or theft. Another issue is that larger PFEs are more difficult for the infirm and elderly to safely deploy and operate.

For the period of 2003 through 2007, NFPA reports approximately 38,000 fires occur annually in apartment buildings. Sixty percent of these fires occur inside of dwelling units versus 14 percent that occur in common areas covered by Items 3 and 6 of Section 906.1. It is more logical to place PFEs inside of dwelling units versus common areas because it locates the extinguisher in an an area where statistically most fires occur. If the occupant cannot control the fire using the PFE, he or she can escape and allow the automatic sprinkler system to operate and control the fire. This particular code change improves the safety of Group R-2 residents because it does not require them to leave a dwelling involved in a fire, find a PFE and then return to the fire-involved dwelling unit to attempt incipient fire attack.

Including this requirement in the code alerts designers and building officials that the extinguishers are required. This will allow designers to plan for thicker walls where recessed cabinets may be used or to design locations where the extinguishers will not project into or obstruct the egress or circulation path.

**TABLE 906.1.** See page 9-47.

- Table 906.1 lists those sections of the IFC that represent specific occupancy conditions requiring portable fire extinguishers for incipient fire control. Wherever the code requires a fire extinguisher because of one of the listed occupancy conditions, it may identify the required rating of the extinguisher that is compatible with the hazard involved in addition to referencing Section 906.

**[F] 906.2 General requirements.** Portable fire extinguishers shall be selected and installed in accordance with this section and NFPA 10.

**Exceptions:**

1. The travel distance to reach an extinguisher shall not apply to the spectator seating portions of Group A-5 occupancies.

2. In Group 1-3, portable fire extinguishers shall be permitted to be located at staff locations.

- NFPA 10 contains minimum requirements for the selection, installation and maintenance of portable fire extinguishers. Portable fire extinguishers are investigated and rated in conformance to NFPA 10 and listed under a variety of standards. Portable fire extinguishers must be labeled and rated for use on fires of the type, severity and hazard class protected.
This section references NFPA 10 for the selection and installation of portable fire extinguishers and states that the code is focused on the initial construction versus long-term maintenance of a building. The maintenance of portable fire extinguishers is dealt with in the IFC.

Exception 1 recognizes the openness to the atmosphere associated with Group A-5 occupancies. A fire in open areas is more obvious to all spectators. Group A-5 occupancies also do not accumulate smoke and hot gases because they are not enclosed spaces. These reasons, plus the lengthy travel distances within seating areas, make it reasonable and practical not to apply the travel distance to a PFE criteria in Group A-5. Revised travel distance allowances would need to be approved by the code official. Group A-5 occupancies also tend to be more subject to the corrosive conditions of an outdoor environment, and may include freeze/thaw cycles that can be detrimental to fire extinguishers.

Exception 2 recognizes that portable fire extinguishers located throughout the facility are at times tampered with, removed or used for weapons by inmates in a detention or correctional setting. This exception would protect the extinguishers from damage or removal by inmates while still making them available to staff and employees for use in an emergency situation.

[F] 906.3 Size and distribution. The size and distribution of portable fire extinguishers shall be in accordance with Sections 906.3.1 through 906.3.4.

- Proper selection and distribution of portable fire extinguishers are essential to having adequate protection for the building structure and the occupancy conditions within. This section introduces the sections that provide those requirements. Determination of the desired type of portable fire extinguisher depends on the character of the fire anticipated, building occupancy, specific hazards and ambient temperature conditions [see commentary, Tables 906.3(1) and 906.3(2)].

[F] 906.3.1 Class A fire hazards. The minimum sizes and distribution of portable fire extinguishers for occupations that involve primarily Class A fire hazards shall comply with Table 906.3(1).

- Class A fires generally involve materials considered to be "ordinary combustibles," such as wood, cloth, paper, rubber and most plastics [see commentary, Table 906.3(1)].

[F] Table 906.3(1). See page 9-48.

- Table 906.3(1), which parallels Table 6.2.1.1 of NFPA 10, establishes the minimum number and rating of fire extinguishers for Class A fires in any particular occupancy. The occupancy classifications are further defined in NFPA 10. The maximum area that a single fire extinguisher can protect is determined based on the rating of the fire extinguisher. The travel distance limitation of 75 feet (22 860 mm) is intended

For SI: 1 inch = 25.4 mm. 1 foot = 304.8 mm.

Note: For requirements on water-soluble flammable liquids and alternative sizing criteria, see Section 5.5 of NFPA 10.

[F] 906.3.3 Class C fire hazards. Portable fire extinguishers for Class C fire hazards shall be selected and placed on the basis of the anticipated Class A or B hazard.

Class C fires involve energized electrical equipment where the electrical nonconductivity of the extinguishing agent is critical. The need for this class of extinguisher is simply based on the presence of the hazard in an occupancy and no numerical rating is required.

[F] 906.3.4 Class D fire hazards. Portable fire extinguishers for occupancies involving combustible metals shall be selected and placed in accordance with NFPA 10.

Class D fires involve flammable solids, the bulk of which are combustible metals including, but not limited to, magnesium, potassium, sodium and titanium. Most Class D extinguishers will have a special low-velocity nozzle or discharge wand to gently apply the agent in large volumes to avoid disrupting any finely divided burning materials. Extinguishing agents are also available in bulk and can be applied with a scoop or shovel. While Class D extinguishers are often referred to as "dry chemical" fire extinguishers, they are more properly called "dry powder" fire extinguishers because their mechanism of extinguishment is by a smothering action rather than by chemical reaction with the combustion process.

There are several Class D fire-extinguisher agents available—some will handle multiple types of metal fires, others will not. Sodium carbonate-based extinguishers are used to control sodium, potassium, and sodium-potassium alloy fires but have limited use on other metals. This material smotherers and forms a crust. Sodium chloride-based extinguishers contain sodium chloride salt and a thermoplastic additive. The plastic melts to form an oxygen-excluding crust over the metal, and the salt dissipates heat. This powder is useful on most alkali metals, including...
magnesium, titanium, aluminum, sodium, potassium and zirconium. Graphite-based extinguishers contain dry graphite powder that smothers burning metals. Unlike sodium chloride powder extinguishers, the graphite powder fire extinguishers can be used on very hot burning metal fires such as lithium, but the powder will not stick to and extinguish flowing or vertical lithium fires. The graphite powder acts as a heat sink as well as smothering the metal fire. See the commentary to Section 5906.5.7 of the IFC for a discussion of extinguishing flammable solid fires.

[F] 906.4 Cooking grease fires. Fire extinguishers provided for the protection of cooking grease fires shall be of an approved type compatible with the automatic fire-extinguishing system agent and in accordance with Section 904.11.5 of the International Fire Code.

- The combination of high-efficiency cooking appliances and hotter burning cooking media creates a potentially severe fire hazard. Although commercial cooking systems must have an approved exhaust hood and be protected by an approved automatic fire-extinguishing system, a manual means of extinguishment is desirable to attack a fire in its incipient stage.

As indicated in Section 904.11.5, a Class K-rated portable fire extinguisher must be located within 30 feet (9144 mm) of travel distance of commercial-type cooking equipment. Class K-rated extinguishers have been specifically tested on commercial cooking appliances using vegetable or animal oils or fats. These portable fire extinguishers are usually of sodium bicarbonate or potassium bicarbonate dry-chemical type.

[F] 906.5 Conspicuous location. Portable fire extinguishers shall be located in conspicuous locations where they will be readily accessible and immediately available for use. These locations shall be along normal paths of travel, unless the fire code official determines that the hazard posed indicates the need for placement away from normal paths of travel.

- Fire extinguishers must be located in readily accessible locations along normal egress paths. This increases the occupants, familiarity with the location of the fire extinguishers. When considering location, the most frequent occupants should be considered. These are the occupants who would become most familiar with the fire-extinguisher placement. For most buildings, it is the employees who are most familiar with their surroundings; therefore, a good understanding of employee operations is important for proper extinguisher placement.

[F] 906.6 Unobstructed and unobscured. Portable fire extinguishers shall not be obstructed or obscured from view. In rooms or areas in which visual obstruction cannot be completely avoided, means shall be provided to indicate the locations of extinguishers.

- Portable fire extinguishers must be located where they are readily visible at all times. If visual obstruction cannot be avoided, the location of the extinguisher must be marked by an approved means of identification. This could include additional signage, lights, arrows or other means approved by the fire code official. Unobstructed does not necessarily mean visible from all angles within the space. Often, columns or furnishings may obscure the extinguisher from one direction or another. These are not by themselves obstructions. The intent is that the extinguisher is not hidden but rather can be readily found. If the extinguisher is placed in the wall behind a door, it is clearly obstructed since it cannot be easily viewed. An extinguisher on a wall that is visible from most of the space would be considered unobstructed.

[F] 906.7 Hangers and brackets. Hand-held portable fire extinguishers, not housed in cabinets, shall be installed on the hangers or brackets supplied. Hangers or brackets shall be securely anchored to the mounting surface in accordance with the manufacturer's installation instructions.

- Portable fire extinguishers not housed in cabinets are usually mounted on walls or columns using securely fastened hangers. Brackets must be used where the fire extinguishers need to be protected from impact or other potential physical damage.

[F] 906.8 Cabinets. Cabinets used to house portable fire extinguishers shall not be locked.

Exceptions:

1. Where portable fire extinguishers subject to malicious use or damage are provided with a means of ready access.
2. In Group I-3 occupancies and in mental health areas in Group I-2 occupancies, access to portable fire extinguishers shall be permitted to be locked or to be located in staff locations provided the staff has keys.

- Cabinets housing fire extinguishers must not be locked in order to provide quick access in an emergency. Exception 1, however, allows the cabinets to be locked in occupancies where vandalism, theft or other malicious behavior is possible. Exception 2 also permits cabinets housing fire extinguishers to be locked or to be located in staff locations in Group I-3 occupancies and mental health areas in Group I-2 occupancies. Occupants in Group I-3 areas of jails, prisons or similar restrained occupancies should not have access to fire extinguishers because they could possibly be used as a weapon or be subject to vandalism. Staff adequately trained in the use of fire extinguishers are assumed to have ready access to the keys for the cabinets at all times.

[F] 906.9 Extinguisher installation. The installation of portable fire extinguishers shall be in accordance with Sections 906.9.1 through 906.9.3.

- This section introduces the installation criteria for portable fire extinguishers based on the weight of the unit.

[F] 906.9.1 Extinguishers weighing 40 pounds or less. Portable fire extinguishers having a gross weight not exceeding
40 pounds (18 kg) shall be installed so that their tops are not more than 5 feet (1524 mm) above the floor.

- Due to the varying height and physical strength levels of persons who might be called upon to operate a portable fire extinguisher, the mounting height of the extinguisher must be commensurate with its weight so that it may be easily retrieved by anyone from its mounting location and placed into use.

[F] 906.9.2 Extinguishers weighing more than 40 pounds. Hand-held portable fire extinguishers having a gross weight exceeding 40 pounds (18 kg) shall be installed so that their tops are not more than 3.5 feet (1067 mm) above the floor.

- See the commentary to Section 906.9.1.

[F] 906.9.3 Floor clearance. The clearance between the floor and the bottom of installed hand-held portable fire extinguishers shall not be less than 4 inches (102 mm).

- The clearance between the floor and the bottom of installed hand-held extinguishers must not be less than 4 inches (102 mm) to facilitate cleaning beneath the unit and reduce the likelihood of the extinguisher becoming dislodged during cleaning operations (floor mopping, sweeping, etc.).

[F] 906.10 Wheeled units. Wheeled fire extinguishers shall be conspicuously located in a designated location.

- Wheeled fire extinguishers consist of a large-capacity (up to several hundred pounds of agent) fire extinguisher assembly (either stored-pressure or pressure transfer type) equipped with a carriage and wheels and discharge hose. They are constructed so that one able-bodied person could move the unit to the fire area and begin extinguishment unassisted. Wheeled fire extinguishers are capable of delivering greater flow rates and stream range for various extinguishing agents than hand-held portable fire extinguishers. Wheeled fire extinguishers are generally more effective in high-hazard areas and, as with any extinguisher, must be readily available and stored in an approved location. The wheeled fire extinguisher should be located a safe distance from the hazardous area so that it will not become involved in the fire or access to it compromised by a fire. These units are typically found at airport fueling ramps, refineries, bulk plants and similar locations where high-challenge fires may be encountered. The extinguishing agents available in wheeled units include carbon dioxide, dry chemical, dry powder and foam.

SECTION 907
FIRE ALARM AND DETECTION SYSTEMS

[F] 907.1 General. This section covers the application, installation, performance and maintenance of fire alarm systems and their components.

- Fire alarm systems in new buildings, which typically include manual fire alarm systems and automatic smoke detection systems, must be installed in accordance with Section 907 and NFPA 72. Fire alarm systems in existing buildings are regulated by Chapter 11 of the IFC.

Manual fire alarm systems are installed in buildings to limit fire casualties and property losses. Fire alarm systems do this by promptly notifying the occupants of the building of an emergency, which increases the time available for evacuation. Similarly, when fire alarm systems are supervised, the fire department will be promptly notified and its response time relative to the onset of the fire will be reduced.

Automatic smoke detection systems are required under certain conditions to increase the likelihood that a fire is detected and occupants are given an early warning. The detection system is a system of devices and associated hardware that activates the alarm system. The automatic detecting devices are to be smoke detectors, unless a condition exists that calls for the use of a different type of detector.

[F] 907.1.1 Construction documents. Construction documents for fire alarm systems shall be of sufficient clarity to indicate the location, nature and extent of the work proposed and show in detail that it will conform to the provisions of this code, the International Fire Code, and relevant laws, ordinances, rules and regulations, as determined by the fire code official.

- Construction documents for fire alarm systems must be submitted for review to determine compliance with the code, the IFC and NFPA 72. All of the information required by this section may not be available during the design stage and initial permit process. Later submission of more detailed shop drawings may be required in accordance with Section 907.1.2. These provisions are intended to reflect the minimum scope of information needed to determine code compliance. When the work can be briefly described on the application form, the fire code official may utilize judgment in determining the need for more detailed documents.

[F] 907.1.2 Fire alarm shop drawings. Shop drawings for fire alarm systems shall be submitted for review and approval prior to system installation, and shall include, but not be limited to, all of the following:

1. A floor plan that indicates the use of all rooms.
2. Locations of alarm-initiating devices.
3. Locations of alarm notification appliances, including candela ratings for visible alarm notification appliances.
4. Location of fire alarm control unit, transponders and notification power supplies.
5. Annunciators.
6. Power connection.
7. Battery calculations.
8. Conductor type and sizes.
9. Voltage drop calculations.
10. Manufacturers' data sheets indicating model numbers and listing information for equipment, devices and materials.
11. Details of ceiling height and construction.
12. The interface of fire safety control functions.
13. Classification of the supervising station.

- Since the fire protection contractor(s) may not have been selected at the time a permit is issued for construction of a building, detailed shop drawings for fire alarm systems may not be available. Because they provide the information necessary to determine code compliance, as specified in this section, they must be submitted and approved by the fire code official before the contractor can begin installing the system.

[F] 907.1.3 Equipment. Systems and components shall be listed and approved for the purpose for which they are installed.

- The components of the fire alarm system must be approved for use in the planned system. NFPA 72 requires all devices, combinations of devices, appliances and equipment to be labeled for their proposed use. The testing agency will test the components for use in various types of systems and stipulate the use of the component on the label. Evidence of listing and labeling of the system components must be submitted with the shop drawings. In some instances, the entire system may be labeled.

At least one major testing agency, Underwriters Laboratories, Inc. (UL), has a program in which alarm installation and service companies are issued a certificate and become listed by the agency as being qualified to design, install and maintain local, auxiliary, remote station or proprietary fire alarm systems. The listed companies may then issue a certificate showing that the system is in compliance with Section 907. Terms of the company certification by UL include the company being responsible for keeping accurate system documentation, including as-built record drawings, acceptance test records and complete maintenance records on a given system. The company is also responsible for the required periodic inspection and testing of the system under contract with the owner. A similar program has been available for many years for central station alarm service, whereas the UL program is relatively new to the industry. Even though this company and system listing program is not required by the code or NFPA 72, it can be a valuable tool for the fire code official in determining compliance with the referenced standard.

Another issue that must be considered is the compatibility of the system components as required by NFPA 72. The labeling of system components discussed above should include any compatibility restrictions for components. Compatibility is primarily an issue of the ability of smoke detectors and fire alarm control panels (FACPs) to function properly when interconnected and affects the two-wire type of smoke detectors, which obtain their operating power over the same pair of wires used to transmit signals to the FACP (the control unit initiating device circuits).

Laboratories will test for component compatibility either by actual testing or by reviewing the circuit parameters of both the detector and the FACP. Generally, if both the two-wire detector and the FACP are of the same brand, there should not be a compatibility problem. Nevertheless, the fire code official must be satisfied that the components are listed as being compatible. Failure to comply with the compatibility requirements of NFPA 72 can lead to system malfunction or failure at a critical time.

[F] 907.2 Where required—new buildings and structures. An approved fire alarm system installed in accordance with the provisions of this code and NFPA 72 shall be provided in new buildings and structures in accordance with Sections 907.2.1 through 907.2.23 and provide occupant notification in accordance with Section 907.5, unless other requirements are provided by another section of this code.

A minimum of one manual fire alarm box shall be provided in an approved location to initiate a fire alarm signal for fire alarm systems employing automatic fire detectors or waterflow detection devices. Where other sections of this code allow elimination of fire alarm boxes due to sprinklers, a single fire alarm box shall be installed.

Exceptions:

1. The manual fire alarm box is not required for fire alarm systems dedicated to elevator recall control and supervisory service.

2. The manual fire alarm box is not required for Group R-2 occupancies unless required by the fire code official to provide a means for fire watch personnel to initiate an alarm during a sprinkler system impairment event. Where provided, the manual fire alarm box shall not be located in an area that is accessible to the public.

- This section specifies the occupancies or conditions in new buildings or structures that require some form of fire alarm system which is either a manual fire alarm system (manual fire alarm boxes) or an automatic smoke detection system. These systems must, upon activation, provide occupant notification throughout the area protected by the system unless other alternative provisions are allowed by this section.

Manual fire alarm systems must be installed in certain occupancies depending on the number of occupants, capabilities of the occupants and height of the building. An automatic smoke detection system must be installed in those occupancies and conditions where the need to detect the fire is essential to evacuation or protection of the occupants. The requirements for automatic smoke detection are generally based on the evacuation needs of the occupants and whether the occupancy includes sleeping accommodations.

Fire alarm systems must be installed in accordance with the code and NFPA 72. NFPA 72 identifies the minimum performance, location, mounting, testing and maintenance requirements for fire alarm sys-
tems. Smoke detectors must be used, except when ambient conditions would prohibit their use. In that case other detection methods may be used. The manufacturer's literature will identify the limitations on the use of smoke detectors, including environmental conditions such as humidity, temperature and airflow.

Only certain occupancies are required to have either a manual fire alarm or automatic fire detection system installed (see Figure 907.2). The need for either system is generally determined by the number of occupants, the height of the building or the ability of the occupants for self-preservation.

Note that generally the fire alarm requirements are based upon occupancy and not on fire area. Figure 907.2 contains the conditions that require when either system must be installed in a building. The extent that an alarm system must be installed in a building once it has been determined that such a system is required is based on a several factors. One, if it is the only occupancy in the building, then it would be required throughout the building. Two, if the building is a mixed occupancy, it can either be separated or non-

| College and university buildings (R-2 dormitories) | Common spaces; laundry, mechanical and storage rooms; interior corridors (exception for no interior corridors and each room has direct exit access or exit). |

Figure 907.2
SUMMARY OF MANUAL FIRE ALARM AND AUTOMATIC SMOKE DETECTION SYSTEM THRESHOLDS
separated. If the occupancy is separated in accordance with Section 508.4, then the alarm system is only required within that separated portion of the building. If the building is considered a nonseparated, mixed occupancy building, then Section 508.3.1 states that the code apply to each portion of the building based upon the occupancy classification of that space and that the most restrictive provisions of Chapter 9 shall apply to the building or portion thereof in which the nonseparated occupancies are located. Therefore, if you had a Group A occupancy in a nonseparated mixed occupancy (containing other occupancies such as Groups B and M) where the Group A occupancy exceeds an occupant load of 300, then the entire nonseparated mixed occupancy would require the alarm system. Note that Section 508.3.1 focuses on each space to determine occupancy and requirements. Once the occupant load is determined, any requirements, such as fire alarms, would be required throughout.

The code does not address whether or not a nonseparated mixed occupancy has a completely independent means of egress such as in a strip mall. Additionally, in a building containing primarily Group A occupancies, the code does not clearly address whether such occupancies within a building should be looked at as an aggregate or individual space. This issue has been clarified in the 2012 edition of the code through the use of the fire area concept for Group A occupancies, but only for the basic manual fire alarm requirements in Section 907.2.1. The emergency voice/alarm communication requirements in Section 907.2.1.1 still simply provide a criteria of 1,000 or more occupants in a Group A occupancy. A building with multiple Group A occupancies without using the concept of separation of egress paths would need to be reviewed in aggregate. Fire area separation could not be used to provide separation of occupancies in this case.

Figure 907.2 contains the threshold requirements for when a manual fire alarm system or an automatic fire detection system is required based on the occupancy group. It is important to remember that although the requirement for manual pull stations may not apply (e.g., sprinklered buildings), alarm and occupant notification may still be required. Sections 907.2.11 through 907.2.23 contain additional requirements for fire alarm systems depending on special occupancy conditions such as atriums, high-rise buildings or covered mall buildings.

The single manual fire alarm box required by this section is needed to provide a means of manually activating a fire alarm system that only contains automatic devices such as sprinkler waterflow switches or smoke detectors. Its primary use is for alarm system maintenance technicians to be able to manually activate the fire alarm system in the event of a fire during the time the system or portions of the system is down for maintenance. Note that this requirement is not subject to any of the exceptions in Sections 907.2.1 through 907.2.23 that might waive the need for manual fire alarm boxes in certain buildings.

Exception 1 recognizes the specialized nature of fire alarm systems installed only for emergency elevator control and supervision.

Exception 2 waives the single manual fire alarm box but gives the fire code official authority to require it in sprinklered buildings for use by fire watch personnel or sprinkler maintenance personnel to be able to manually activate the fire alarm system in the event of a fire during the time the sprinkler system is down for maintenance.

[F] 907.2.1 Group A. A manual fire alarm system that activates the occupant notification system in accordance with Section 907.5 shall be installed in Group A occupancies where the occupant load due to the assembly occupancy is 300 or more. Group A occupancies not separated from one another in accordance with Section 703.3.9 shall be considered as a single occupancy for the purposes of applying this section. Portions of Group E occupancies occupied for assembly purposes shall be provided with a fire alarm system as required for the Group E occupancy.

Exception: Manual fire alarm boxes are not required where the building is equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 and the occupant notification appliances will activate throughout the notification zones upon sprinkler waterflow.

- Group A occupancies are typically occupied by a significant number of people who are not completely familiar with their surroundings. The provisions of this section address three separate situations regarding the application of the alarm requirements for Group A occupancies. The three situations addressed by the provisions are: (1) where an assembly occupancy and another occupancy are involved; (2) where multiple assembly areas exist in a building; and (3) where the assembly use occurs in and is a part of a Group E occupancy.

In situations where an assembly area and another occupancy are involved, the code specifies that it is the occupant load "due to the assembly occupancy" that would need to be 300 or more before the manual alarm system is required. For example, if the building is constructed with an assembly occupancy, such as a restaurant, with an occupant load of 250 and an adjacent office area with an occupant load of 100, the assembly space would not require an alarm system because the occupant load "due to the assembly occupancy" is less than 300. This is really simply a clarification of the way the provisions were intended to be applied. This would be the intended way to apply the provision whether the building was constructed using the accessory-, separated- or nonseparated-occupancy requirements of Chapter 5.

In buildings that contain multiple assembly areas, the second portion of the code text requires that the aggregate occupant load of the assembly areas is used unless the spaces are separated as required for
fire areas in Section 707.3.9. Consider two examples to address this portion of the requirements. In a multi-
theater complex, the auditoriums are generally not separated from each other by the 2-hour fire-resis-
tance rating that Table 707.3.9 would require; therefore, the aggregate occupant load of all of the
assembly spaces would be combined to determine if the
capacity load was 300 or more. If it was, then the
manual alarm would be required in all of the assembly
spaces. As another example, consider a strip mall
shopping center with a restaurant at one end of the
building with an occupant load of 200 and a different
restaurant with an occupant load of 150 at the other
end of the building. Even though these are two com-
pletely separate establishments and have an amount
of retail occupancy between them, the occupant load
of the assembly areas does exceed 300. Therefore,
unless a 2-hour fire-resistance rated separation comply-
ing with Section 707.3.9 is provided somewhere
between the two restaurants to separate them into
different fire areas, a manual fire alarm would be
required in the Group A occupancies. If a complying
separation is provided at some point in the build-
ing, each assembly space can be reviewed indepen-
dently and would not require the installation of the
alarm system. Be aware that the separation between
assembly spaces or the need to aggregate the occup-
ant loads from them could occur not only on the
same floor within a building, but also to assembly
uses located on different stories.

The exception allows the omission of manual fire
alarm boxes in buildings equipped throughout with an
automatic sprinkler system if activation of the sprin-
kler system will activate the building evacuation
alarms associated with the manual fire alarm system.

This section also permits assembly type areas in
Group E occupancies to comply with Section 907.2.3
instead of the requirements of this section. A typical
high school, for example, contains many areas used
for assembly purposes such as a gymnasium, cafete-
ria, auditorium or library; however, they all exist to
serve as an educational facility as their main function.
The exception does not eliminate the fire alarm sys-
tem and occupant notification system, but rather per-
mits them to be initiated automatically by the sprinkler
waterflow switch(es) instead of by the manual fire
alarm boxes. It also reduces the possibility of mis-
chievous or malicious false alarms being turned on by
manual fire alarm boxes in venues where large num-
bers of people congregate.

[F] 907.2.1.1 System initiation in Group A occupancies
with an occupant load of 1,000 or more. Activation of the
fire alarm in Group A occupancies with an occupant load
of 1,000 or more shall initiate a signal using an emergency
voice/alarm communications system in accordance with Sec-
tion 907.5.2.2.

Exception: Where approved, the prerecorded announce-
ment is allowed to be manually deactivated for a period of
time, not to exceed 3 minutes, for the sole purpose of
allowing a live voice announcement from an approved,
constantly attended location.

In order to afford authorized personnel the ability to
selectively evacuate or manage occupant relocation
in large assembly venues, this section requires the
fire alarm system to operate through an emergency
voice/alarm communications system. The exception
allows the automatic alarm signals to be overridden
for live voice instructions if the live voice instructions
do not exceed 3 minutes. The location from which the
live voice announcement originates must be con-
stantly attended and approved by the fire code official
(see also commentary, Section 907.5.2.2). In terms of
the applicability of this section, it is not as specific as
Section 907.2.1. More specifically, the concept of
fire areas does not apply. Credit is not given to
reduce the occupant load through the use of the fire
area concept (see commentary, Section 907.2).

[F] 907.2.1.2 Emergency voice/alarm communication cap-
tions. Stadiums, arenas and grandstands required to caption
audible public announcements shall be in accordance with
Section 907.5.2.2.4.

A 2008 U.S. Federal Court case prompted a change
to the code and the IFC. The court ruled that persons
with hearing impairments who attend events at stadi-
ums, grandstands and arenas require a means of
equivalent communications in lieu of the public
address system. Providing occupant notification in
these structures is challenging because of the build-
ing area and the number and diversity of occupants.
Provisions were added in the code to require cap-
tioned messages in these buildings and grandstands
when public address (PA) systems are prescribed by
the accessibility requirements.

Section 1108.2.7.3 sets forth requirements for
audible PA systems in stadiums, arenas and grand-
stands. It requires that equivalent text information be
provided to the audience and that the delivery time
for these messages be the same as those broadcast
from the PA system. The requirements apply to pre-
recorded and real-time messages. Section 1108.2.7.3
also requires captioning of messages in
stadiums, arenas and grandstands that have more
than 15,000 fixed seats.

Because messages being broadcast can include
instructions to building or site occupants explaining
the actions they need to take in the event of an emer-
gency, the requirements of NFPA 72 are applicable
for captioning systems. Such a system falls within the
scope of Chapter 24, NFPA 72 "Emergency Commu-
nication Systems." NFPA 72 defines an emergency
communications system (ECS) as a system designed
for life safety that indicates the existence of an emer-
gency and communicates the appropriate response
and action. The ECS is required to be classified as
either a one- or two-way path system. It can be within
a building or over a wide area or can be targeted to a
particular group of recipients. The messages that will
be broadcast are based on an emergency response
plan developed during a risk analysis by the project stakeholders and is approved by the fire code official. The NFPA 72 ECS requirements are based on in-building or wide-area occupant notification. Wide-area systems could include the entire area of a jurisdiction. For a stadium, arena or grandstand captioning, NFPA 72 defines these as mass notification systems (MNS). In the context of the NFPA 72 requirements, this particular code change requires a one-way MNS where instructions are broadcasted by personnel authorized to distribute messages. This could include fire fighters during a fire event; also the system could be used by law enforcement officers during a domestic terrorism incident or a weather event like a tornado warning.

The design of the compliant MNS Chapter 24 of NFPA 72 is not prescriptive—an MNS is a performance-based design. Accordingly, fire code officials should require their design to be sealed by a registered professional engineer. Section 24.7 of the standard requires the preparation of a risk analysis based on the nature and anticipated risks of the facility. The risk analysis is part of the design brief, which will serve as the basis of the system design and is a required design document. NFPA 72 requires the following elements included in the risk analysis:

- The number of persons within the building, area, space, campus or region;
- The character of the occupancy, such as unique hazards and the rate at which the hazard can develop;
- The anticipated threats, including natural, technological and intentional events;
- The reliability and performance of the MNS;
- Security of the MNS and its components;
- How the building or staff implement the risk analysis, including the use of the MNS and
- How emergency services, such as the fire service and law enforcement agencies can employ the MNS.

In a stadium or arena, the captioning system is required to be a component of the emergency voice/communications alarm system (EV/ACS). Such a system is required by Section 907.2.1.1 in Group A occupancies with an occupant load of 1,000 or more.

The requirement in Section 907.5.2.2.4 specifies the captioning system would be connected to the EV/ACS. The fire alarm control unit will require a listed interface unit capable of displaying text messages. Textual visible appliances are allowed by NFPA 72 when used in conjunction with audible, visual or both types of notification appliances. In the public mode, textual visible appliances are located to ensure readability by the building occupants. Such a system can display messages using televisions or light emitting diode (LED) marquee signs.

The design concept of MNS is relatively new in the design community. Captioning systems might utilize components that are not listed for fire alarm service so the design will be required to comply with Section 24.2.21 of NFPA 72 for textual visible notification appliances. Emergency textual messages take precedence over any nonemergency text messages. Under NFPA 72 these devices require a primary and secondary power supply. If the devices are not monitored for integrity or loss of communications by an autonomous control or a fire alarm control unit, the appliance must clearly display its status. The size of characters displayed must comply with the requirements in NFPA 72. The NFPA 72 size, character and font requirements are based on the location of the display in relation to the height and distance from the persons viewing it.

[F] 907.2.2 Group B. A manual fire alarm system shall be installed in Group B occupancies where one of the following conditions exists:

1. The combined Group B occupant load of all floors is 500 or more.
2. The Group B occupant load is more than 100 persons above or below the lowest level of exit discharge.
3. The fire area contains an ambulatory care facility.

Exception: Manual fire alarm boxes are not required where the building is equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 and the occupant notification appliances will activate throughout the notification zones upon sprinkler water flow.

• Group B occupancies generally involve individuals or groups of people in separate office areas. As a result, the occupants are not necessarily aware of what is going on in other parts of the building. Group B buildings with large occupant loads, even in single-story buildings, or where a substantial number of occupants are above or below the level of exit discharge, increase the difficulty of alerting the occupants of a fire. This is especially true in nonsprinklered buildings with given occupant load thresholds. Group B occupancies include a specific use called ambulatory care facilities which present a higher level of life hazard than the typical Group B occupancy. The fact that the care recipients of such facilities may be rendered incapable of self-preservation for limited periods of time makes the need for a fire alarm system critical. Section 907.2.2 requires a manual alarm system any time a fire area contains a ambulatory care facility. See the commentary to Section 202, definition of "Ambulatory care facility" and Section 907.2.2.1.

The exception does not eliminate the fire alarm system, but rather permits it to be initiated automatically by the sprinkler water flow switch(es) instead of by the manual fire alarm boxes.

[F] 907.2.2.1 Ambulatory care facilities. Fire areas containing ambulatory care facilities shall be provided with an electronically supervised automatic smoke detection system.
installed within the ambulatory care facility and in public use areas outside of tenant spaces, including public corridors and elevator lobbies.

**Exception:** Buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1, provided the occupant notification appliances will activate throughout the notification zones upon sprinkler waterflow.

- Years ago, few surgical procedures were performed outside of a hospital. Today, complex outpatient surgeries conducted outside of a hospital are commonplace. They are performed in facilities often called "day surgery centers" or "ambulatory surgical centers" because patients are able to walk in and walk out the same day. Procedures render care recipients temporarily incapable of self-preservation by application of nerve blocks, sedation or anesthesia; however, they do typically recover quickly.

The code identifies health care Group I occupancies as including a 24-hour stay. Without a 24-hour stay, these surgery centers were classified as Group B which allowed the care providers to render an unlimited number of people incapable of self-preservation with no more protection than a business office. Since these types of facilities contain distinctly different hazards to life safety than other Group B occupancies, they are now required to have a higher level of life safety and fire protection as evidenced by the requirements of this section as well as Section 903.2.2 and the construction provisions of the code.

This section more specifically states that any time a fire area contains an ambulatory care facility, the fire area should be provided with a supervised smoke detection system in the ambulatory care facility and in public use areas outside of tenant spaces. Therefore, in a medical office building, for example, the ambulatory care facility contained within would have a full coverage system. The other offices in the building would not require smoke detection in the individual tenant spaces, but instead in the public areas, such as lobby or lounge areas.

The exception does not eliminate the fire alarm system, but rather permits it to be initiated automatically by the sprinkler waterflow switch(es) instead of by the smoke detection system.

[F] 907.2.3 **Group E.** A manual fire alarm system that initiates the occupant notification signal utilizing an emergency voice/alarm communication system meeting the requirements of Section 907.5.2.2 and installed in accordance with Section 907.6 shall be installed in Group E occupancies. When automatic sprinkler systems or smoke detectors are installed, such systems or detectors shall be connected to the building fire alarm system.

**Exception:** A manual fire alarm system is not required in Group E occupancies with an occupant load of 30 or less.

2. Manual fire alarm boxes are not required in Group E occupancies where all of the following apply:

   2.1. Interior corridors are protected by smoke detectors.

   2.2. Auditoriums, cafeterias, gymnasiums and similar areas are protected by heat detectors or other approved detection devices.

   2.3. Shops and laboratories involving dusts or vapors are protected by heat detectors or other approved detection devices.

3. Manual fire alarm boxes shall not be required in Group E occupancies where the building is equipped throughout with an approved automatic sprinkler system installed in accordance with Section 903.3.1.1, the emergency voice/alarm communication system will activate on sprinkler water flow and manual activation is provided from a normally occupied location.

- Section 404.3.3 of the IFC addresses the development and implementation of lockdown plans. These requirements were developed to ensure that the level of life safety inside of the building is not reduced or compromised during a lockdown. In order for a building to safely function in a lockdown condition, the code requires a means of communication between the established central location and each secured area. Section 404.3.3.1 of the IFC does not prescribe the means of communication, which could include the use of text messages to cell phones/mobile devices, e-mail messages or the use of preestablished audio or visual signals. The provisions in Section 404.3.3 of the IFC are not specific to Group E occupancies—they are applicable to all occupancies that develop and implement lockdown plans.

Because of concerns of school campus safety serving kindergarten through 12th grade students, specific requirements were put into the 2012 edition of the code and the IFC for enhanced communication between the school administrators, teachers and students when a lockdown plan is activated in Group E occupancies. As a result, emergency voice/alarm communication systems (EV/ACS) are prescribed in Group E occupancies. Previously, the code would have permitted the manual fire alarm system to use audible and visible alarm notification appliances and did not require the added capabilities that an EV/ACS provides.

Section 907.2.3 sets forth the requirements for automatic fire alarm and detection system requirements in Group E occupancies. Section 907.2.3 prescribes the installation of an EV/ACS as opposed to a traditional horn/strobe occupant notification system.

Exception 1 exempts Group E occupancies from requiring a fire alarm system when the occupant load is less than 30. This would exempt small day care centers that serve children older than 2 1/2 years of
age or a small Sunday school classroom at a place of religious worship.

Exception 2 exempts manual fire alarm boxes in interior corridors, laboratories, auditoriums, cafeterias, gymnasiums and similar spaces based on the installation of heat/smoke detectors. This is not an exception from the EV/ACS but simply an exemption of locations requiring manual fire alarm boxes. The applicability of Exception 2 is independent of whether an automatic sprinkler system is installed. If an automatic smoke detection system is installed, it must be connected to the building fire alarm system.

Exception 3 allows the omission of the manual fire alarm boxes in Group E occupancies equipped throughout with an automatic sprinkler system if the actuation of the sprinkler system will activate the EV/ACS. See Section 903.2.3 for sprinkler requirements in Group E buildings.

[F] 907.2.4 Group F. A manual fire alarm system that activates the occupant notification system in accordance with Section 907.5 shall be installed in Group F occupancies where both of the following conditions exist:

1. The Group F occupancy is two or more stories in height; and
2. The Group F occupancy has a combined occupant load of 500 or more above or below the lowest level of exit discharge.

Exception: Manual fire alarm boxes are not required where the building is equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 and the occupant notification appliances will activate throughout the notification zones upon sprinkler watering.

This section is intended to apply to large multistory manufacturing facilities. For this reason, a manual fire alarm system would be required only if the building were at least two stories in height and had 500 or more occupants above or below the level of exit discharge. An unlimited area, two-story Group F occupancy complying with Section 507.4 of the code would be indicative of an occupancy requiring a manual fire alarm system.

Buildings in compliance with Section 507.4 of the code, and large manufacturing facilities in general, however, must be fully sprinklered and would thus be eligible for the exception. The exception does not eliminate the fire alarm system but rather permits it to be initiated automatically by the sprinkler system's water flow switch(es) instead of by the manual fire alarm boxes.

[F] 907.2.5 Group H. A manual fire alarm system that activates the occupant notification system in accordance with Section 907.5 shall be installed in Group H-5 occupancies and in occupancies used for the manufacture of organic coatings. An automatic smoke detection system shall be installed for highly toxic gases, organic peroxides and oxidizers in accordance with Chapters 60, 62 and 63, respectively, of the International Fire Code.

Because of the nature and potential quantity of hazardous materials in Group H-5 occupancies, a manual means of activating an occupant notification system is essential for the safety of the occupants. In accordance with Section 415.10.8, the activation of the alarm system must initiate a local alarm and transmit a signal to the emergency control station. The manual fire alarm system requirement for the building is in addition to the emergency alarm requirements in Section 415.10.3.5 (see also Section 908.2).

Occupancies involved in the manufacture of organic coatings present special hazardous conditions because of the unstable character of the materials, such as nitrocellulose. Good housekeeping and control of ignition sources is critical. Chapter 418 of the code and Chapter 29 of the IFC contain additional requirements for organic coating manufacturing processes.

This section also requires an automatic smoke detection system in certain occupancy conditions involving either highly toxic gases or organic peroxides and oxidizers. The need for the automatic smoke detection system may depend on the class of materials and additional levels of fire protection provided. This requirement also assumes the quantity of materials is in excess of the maximum allowable quantities shown in Tables 307.1(1) and 307.1(2).

[F] 907.2.6 Group I. A manual fire alarm system that activates the occupant notification system in accordance with Section 907.5 shall be installed in Group I occupancies. An automatic smoke detection system that activates the occupant notification system in accordance with Section 907.5 shall be provided in accordance with Sections 907.2.6.1, 907.2.6.2 and 907.2.6.3.

Exceptions:

1. Manual fire alarm boxes in sleeping units of Group I-1 and I-2 occupancies shall not be required at exits if located at all care providers' control stations or other commonly attended staff locations, provided such stations are visible and continuously accessible and that travel distances required in Section 907.4.2.1 are not exceeded.

2. Occupant notification systems are not required to be activated where private mode signaling is installed in accordance with NFPA 72 is approved by the fire code official.

Because the protection and possible evacuation of the occupants in Group I occupancies are most often dependent on the response by care providers, occupancies in Group I must be protected with a manual fire alarm system and in certain instances, as described in Sections 907.2.6.1, 907.2.6.2 and 907.2.6.3, an automatic smoke detection system. In Group I-1, smoke alarms are also required in accor-
dance with Section 907.2.6.1.1.

It is not the intent of this Section to require a smoke detection system throughout all Group I occupancies. Smoke detectors are only generally required in the corridors and in waiting rooms that are open to corridors, unless noted otherwise. IFC Committee Interpretation No. 36-03 makes it clear that the Group I provisions only require a manual fire alarm system with smoke detectors in selected areas. To reduce the potential for unwanted alarms, manual fire alarm boxes may be located at the care providers' control stations or another constantly attended location.

Exception 1 reduces the likelihood of accidental or malicious false alarm system activations by manual means by allowing the pull stations to be located in a more controlled area. It assumes the approved location is always accessible by care providers and within 200 feet (60 960 mm) of travel distance. Exception 2 allows the common practice in Group I occupancies of only notifying the care providers instead of all building occupants in the event of a fire, subject to the approval of the fire code official.

[F] 907.2.6.1 Group I-1. In Group I-1 occupancies, an automatic smoke detection system shall be installed in corridors, waiting areas open to corridors and habitable spaces other than sleeping units and kitchens. The system shall be activated in accordance with Section 907.5.

Exceptions:

1. Smoke detection in habitable spaces is not required where the facility is equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1.

2. Smoke detection is not required for exterior balconies.

Occupancies in Group I-1 tend to be compartmentalized into small rooms so that a fire in one area of the building would not easily be noticed by occupants in another part of the building. Therefore, smoke detection is required in areas other than sleeping units and kitchens. Sleeping units are required by Section 907.2.6.1.1 to be equipped with single- and multiple-station smoke alarms in accordance with Section 907.2.11.

Since Group I-1 occupancies may not be supervised by care providers and to reduce the likelihood that a fire within a waiting area open to the corridor or the corridor itself could develop beyond the incipient stage, thereby jeopardizing the building egress, these areas must be equipped with automatic smoke detection.

Exception 1 allows smoke detectors to be eliminated from habitable spaces if the building is equipped throughout with an NFPA 13 automatic sprinkler system. The sprinkler system should control any fire and perform occupant notification through actuation of the workflow switch and subsequent activation of the building alarm notification appliances. A sprinkler system is required for all Group I occupancies in accordance with Section 903.2.6.

Exception 2 allows for omitting smoke detectors from exterior balconies for environmental reasons and does not require the installation of an alternative type of detector. The exterior balconies are assumed to be sufficiently open to the atmosphere to readily allow the dissipation of smoke and hot gases.

[F] 907.2.6.1.1 Smoke alarms. Single- and multiple-station smoke alarms shall be installed in accordance with Section 907.2.11.

As with dwelling units or sleeping units in any occupancy, this section requires that single- and multiple-station smoke alarms be installed in accordance with Section 907.2.11. Section 907.2.11.2 deals specifically with the requirements for Group I-1.

[F] 907.2.6.2 Group I-2. An automatic smoke detection system shall be installed in corridors in nursing homes, long-term care facilities, detoxification facilities and spaces permitted to be open to the corridors by Section 407.2. The system shall be activated in accordance with Section 907.5. Hospitals shall be equipped with smoke detection as required in Section 407.

Exceptions:

1. Corridor smoke detection is not required in smoke compartments that contain sleeping units where such units are provided with smoke detectors that comply with UL 268. Such detectors shall provide a visual display on the corridor side of each sleeping unit and shall provide an audible and visual alarm at the care provider station attending each unit.

2. Corridor smoke detection is not required in smoke compartments that contain sleeping units where sleeping unit doors are equipped with automatic door-closing devices with integral smoke detectors on the unit sides installed in accordance with their listing, provided that the integral detectors perform the required alerting function.

Automatic smoke detection is required in areas permitted to be open to corridors in occupancies classified as Group I-2 and corridors in nursing homes, long-term care facilities and detoxification facilities. In recognition of quick- response sprinkler technology and the fact that the sprinkler system is electronically supervised, and because the doors to care recipient's sleeping units are continuously supervised by care providers when in the open position, it is now believed that smoke detectors are not required for adequate fire safety in care recipient sleeping units.

In nursing homes, long-term care facilities and detoxification facilities, however, some redundancy is appropriate because such facilities typically have less control over furnishings and personal items, thereby resulting in a less predictable and usually higher fire hazard load than other Group I-2 occupancies. Also, there is generally less care provider's supervision in these facilities than in other health care facilities and thus less control over care recipient smoking and
other fire causes. Therefore, to provide additional protection against fires spreading from the room of origin, smoke detection is required in corridors of nursing homes, long-term care facilities and detoxification facilities.

Smoke detection is not required in corridors of other Group I-2 occupancies except where otherwise specifically required in the code. Similarly, because areas open to the corridor very often are the room of fire origin, and such areas are no longer required by the code to be under visual supervision by care providers, some redundancy to protection by the sprinkler system is requested. Accordingly, all areas open to corridors must be protected by an automatic smoke detection system. This requirement provides an additional level of protection against sprinkler system failures or lapses in care provider supervision.

These requirements are not applicable to hospitals. The scope of this section clearly indicates that its provisions are only applicable to detoxification facilities and nursing homes. Hospitals are noted as being subject to the provisions in Section 407.2. IFC Committee Interpretation No. 37-03 addresses this issue. Section 407.2 notes that smoke detection is only required for spaces open to corridors, such as waiting areas and mental health treatment areas where patients are not capable of self-preservation (see commentary, Section 407.2).

There are two exceptions to the requirement for an automatic fire detection system in corridors of nursing homes, long-term care facilities and detoxification facilities. Both exceptions provide an alternative method for redundant protection in care recipient sleeping units. For this reason, they provide either a backup to the notification of a fire or containment of fire in the room of origin.

Exception 1 requires smoke detectors in sleeping units that activate both a visual display on the corridor side of the care recipient sleeping unit and a visual and audible alarm at the care provider’s station serving or attending the room. Detectors complying with UL 268 are intended for open area protection and for connection to a normal power supply or as part of a fire alarm system. This exception, however, is specifically designed not to require the detectors to activate the building fire alarm system where approved care recipient sleeping unit smoke detectors are installed and where visual and audible alarms are provided. This is in response to the concern over unwanted alarms. The required alarm signals will not necessarily indicate to care providers that a fire emergency exists because the care provider call system may typically be used to identify numerous conditions within the room.

Exception 2 addresses the situation where smoke detectors are incorporated within automatic door-closing devices. The units are acceptable as long as the required alarm functions are still provided. Such units are usually listed as combination door closer and hold-open devices.

[F] 907.2.6.3 Group I-3 occupancies. Group I-3 occupancies shall be equipped with a manual fire alarm system and automatic smoke detection system installed for alerting staff.

❖ Because of the evacuation difficulties associated with Group I-3 occupancies and the dependence on adequate staff response, a manual fire alarm system and an automatic smoke detection system are required subject to the special occupancy conditions in Sections 907.2.6.3.1 through 907.2.6.3.3. This section recognizes that the evacuation of Group I-3 occupancies depends on an effective staff response. Section 408.7 of the IFC contains the requirements for an emergency plan, including employee training, staff availability, the need for occupants to notify staff and the need for the proper keys for unlocking doors for staff in Group I-3 occupancies.

[F] 907.2.6.3.1 System initiation. Actuation of an automatic fire-extinguishing system, automatic sprinkler system, a manual fire alarm box or a fire detector shall initiate an approved fire alarm signal which automatically notifies staff.

❖ This section specifies the systems that, upon activation, must initiate the required alarm signal immediately and automatically to the staff so that staff will respond in a timely manner.

[F] 907.2.6.3.2 Manual fire alarm boxes. Manual fire alarm boxes are not required to be located in accordance with Section 907.4.2 where the fire alarm boxes are provided at staff-attended locations having direct supervision over areas where manual fire alarm boxes have been omitted.

❖ Because of the potential for intentional false alarms and the resulting disruption to the facility, manual fire alarm boxes in Group I-3 occupancies may be either locked or made inaccessible to the occupants.

[F] 907.2.6.3.2.1 Manual fire alarm boxes in detainee areas. Manual fire alarm boxes are allowed to be locked in areas occupied by detainees, provided that staff members are present within the subject area and have keys readily available to operate the manual fire alarm boxes.

❖ The locking of manual fire alarm boxes is permitted only in areas where staff members are present and keys are readily available to them to unlock the boxes, or where the alarm boxes are located in a manned staff location that has direct supervision of the Group I-3 area.

[F] 907.2.6.3.3 Automatic smoke detection system. An automatic smoke detection system shall be installed throughout resident housing areas, including sleeping units and contiguous day rooms, group activity spaces and other common spaces normally accessible to residents.

Exceptions:

1. Other approved smoke detection arrangements providing equivalent protection, including, but not limited to, placing detectors in exhaust ducts from cells or behind protective guards listed for the purpose, are allowed when necessary to prevent damage or tampering.
FIRE PROTECTION SYSTEMS

2. Sleeping units in Use Conditions 2 and 3 as described in Section 308.

3. Smoke detectors are not required in sleeping units with four or fewer occupants in smoke compartments that are equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1.

Evacuation of Group I-3 facilities is impractical because of the need to maintain security. An automatic smoke detection system is therefore required to provide early warning of a fire.

As indicated in Exception 1, the installation of automatic smoke detectors must take into account the need to protect the detector from vandalism by residents. As a result, detectors may be located in return air ducts or be protected by a substantial physical barrier.

Since occupants in Use Condition 2 or 3 are not locked in their sleeping units, Exception 2 reduces the need for smoke detection.

Exception 3 allows smoke detectors to be omitted in sleeping units housing no more than four occupants on the basis that in a building that is protected throughout with an approved automatic sprinkler system, the system will provide both detection and suppression functions. Group I facilities are assumed to be fully sprinklered throughout in accordance with NFPA 13 as required by Section 903.2.6. The limitation of four occupants reduces the potential fuel load (mattresses, clothes, etc.) and the likelihood of involvement over an extended area.

[F] 907.2.7 Group M. A manual fire alarm system that activates the occupant notification system in accordance with Section 907.5 shall be installed in Group M occupancies where one of the following conditions exists:

1. The combined Group M occupant load of all floors is 500 or more persons.

2. The Group M occupant load is more than 100 persons above or below the lowest level of exit discharge.

Exceptions:

1. A manual fire alarm system is not required in covered or open mall buildings complying with Section 402.

2. Manual fire alarm boxes are not required where the building is equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 and the occupant notification appliances will automatically activate throughout the notification zones upon sprinkler flow.

Group M occupancies have the potential for large numbers of occupants who may not be familiar with their surroundings. The installation of a fire alarm system increases the ability to alert the occupants of a fire. Note that the occupant thresholds must be considered independently. If the total occupant load is 500 or more persons, a manual fire alarm system is required. If more than 100 persons are above or below the level of exit discharge, a manual fire alarm system is required.

This section also specifies that the manual fire alarm boxes must, upon activation, provide occupant notification throughout the Group M occupancy.

The extent of fire alarm application is based upon the area in which the Group M occupancy is located. If the building is considered as a separated mixed occupancy, then the fire alarm system is only required in the individual occupancy in which the occupant load exceeds the threshold quantity. The rest of the building would not require a fire alarm system. This approach is noted in Section 508.4.1, which states that each separated space must comply with the code based upon the occupancy classification of that portion of the building. If the Group M occupancy was part of a nonseparated mixed use building then the alarm system would be required in the entire building in accordance with Section 508.3.1. The determination as to when such a system is required would be based solely upon the Group M occupant load.

Exception 1 recognizes the increased level of fixed automatic protection inherently required in covered mall buildings including an automatic sprinkler system, and, possibly, a smoke control system. Covered mall buildings are also required to contain an emergency voice communication system (see Section 907.2.20).

Exception 2 does not eliminate the fire alarm system, but rather allows it to be initiated automatically by sprinkler system waterflow switch(es) instead of by manual fire alarm boxes. Buildings with a fire area containing a Group M occupancy in excess of 12,000 square feet (1115 m²) must be equipped with an automatic sprinkler system complying with Section 903.2.7.

[F] 907.2.7.1 Occupant notification. During times that the building is occupied, the initiation of a signal from a manual fire alarm box or from a waterflow switch shall not be required to activate the alarm notification appliances when an alarm signal is activated at a constantly attended location from which evacuation instructions shall be initiated over an emergency voice/alarms communication system installed in accordance with Section 907.5.2.2.

Occupants in a mercantile occupancy may assume the alarm is a false alarm or act inappropriately and thus delay evacuation of the building. To prevent such a dangerous situation, the manual fire alarm system may be part of an EV/ACS. The signal is to be sent to a constantly attended location on site from which evacuation instructions can be given.

It should be noted that, although the alarm notification alternative allows for the manual use of an EV/ACS, the alternative does not remove the requirement for audible and visual notification devices.
[F] **907.2.8 Group R-1.** Fire alarm systems and smoke alarms shall be installed in Group R-1 occupancies as required in Sections 907.2.8.1 through 907.2.8.3.

- Because residents of Group R-1 occupancies may be asleep and are usually transients who are unfamiliar with the building, and because such buildings contain numerous small rooms so that the occupants may not notice a fire in another part of the building, occupancies in Group R-1 must have a manual fire alarm system and an automatic smoke detection system installed throughout. Requirements for single- or multiple-station smoke alarms in sleeping units are contained in Section 907.2.11.1.

[F] **907.2.8.1 Manual fire alarm system.** A manual fire alarm system that activates the occupant notification system in accordance with Section 907.5 shall be installed in Group R-1 occupancies.

**Exceptions:**

1. A manual fire alarm system is not required in buildings not more than two stories in height where all individual sleeping units and contiguous attic and crawl spaces to those units are separated from each other and public or common areas by at least 1-hour fire partitions and each individual sleeping unit has an exit directly to a public way, egress court or yard.

2. Manual fire alarm boxes are not required throughout the building when all of the following conditions are met:

   2.1. The building is equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2;

   2.2. The notification appliances will activate upon sprinkler waterflow; and

   2.3. At least one manual fire alarm box is installed at an approved location.

- This section is specific to manual fire alarm systems and requires such systems in all Group R-1 occupancies, with two exceptions.

Exception 1 eliminates the requirement for a manual fire alarm system if the sleeping units have an exit discharging directly to a public way, exit court or yard. Even though the building may be two stories in height, the sleeping units on each floor must have access directly to an approved exit at grade level. The use of an exterior exit access balcony with exterior stairs serving the second floor does not constitute an exit directly at grade. The minimum 1-hour fire-resistance rating required for adequate separation of the sleeping units must be maintained.

Exception 2 does not omit the fire alarm system but rather permits it to be initiated automatically by sprinkler system waterflow switch(es) in lieu of manual fire alarm boxes. The sprinkler system must activate the occupant notification system and at least one manual fire alarm box shall be installed at an approved location. See the commentary to Section 907.2 for a discussion of the single manual fire alarm box.

The exceptions do not affect the independent provision in Section 907.2.11 for single- or multiple-station smoke alarms.

[F] **907.2.8.2 Automatic smoke detection system.** An automatic smoke detection system that activates the occupant notification system in accordance with Section 907.5 shall be installed throughout all interior corridors serving sleeping units.

**Exception:** An automatic smoke detection system is not required in buildings that do not have interior corridors serving sleeping units and where each sleeping unit has a means of egress door opening directly to an exit or to an exterior exit access that leads directly to an exit.

- This section requires an automatic smoke detection system within interior corridors. Such systems make use of smoke detectors for alarm initiation in accordance with Section 907.2, with one exception.

The exception provides that automatic fire detectors are not required in motels and hotels that do not have interior corridors and in which sleeping units have a door opening directly to an exterior exit access that leads directly to the exits. The intent of the exception is that the exit access from the sleeping unit door be exterior and not require reentering the building prior to entering the exit. Since the exit access is outside, the need for detectors other than the smoke alarms required by Section 907.2.8.3 in sleeping units is greatly reduced.

[F] **907.2.8.3 Smoke alarms.** Single- and multiple-station smoke alarms shall be installed in accordance with Section 907.2.11.

- The actual requirements for single- and multiple-station smoke alarms are located in Section 907.2.11. That section requires that the single- and multiple-station smoke alarms within sleeping units be connected to the emergency electrical system. Automatic activation of the fire alarm system is avoided to reduce unnecessary alarms within such buildings.

[F] **907.2.9 Group R-2.** Fire alarm systems and smoke alarms shall be installed in Group R-2 occupancies as required in Sections 907.2.9.1 through 907.2.9.3.

- This section introduces the fire alarm system and smoke alarm requirements for Group R-2 occupancies. This includes Group R-2 occupancies in general and also Group R-2 college and university buildings.

[F] **907.2.9.1 Manual fire alarm system.** A manual fire alarm system that activates the occupant notification system in accordance with Section 907.5 shall be installed in Group R-2 occupancies where:

1. Any dwelling unit or sleeping unit is located three or more stories above the lowest level of exit discharge;

2. Any dwelling unit or sleeping unit is located more than one story below the highest level of exit discharge of exits serving the dwelling unit or sleeping unit, or
3. The building contains more than 16 dwelling units or sleeping units.

Exceptions:

1. A fire alarm system is not required in buildings not more than two stories in height where all dwelling units or sleeping units and contiguous attic and crawl spaces are separated from each other and public or common areas by at least 1-hour fire partitions and each dwelling unit or sleeping unit has an exit directed to a public way, egress court or yard.

2. Manual fire alarm boxes are not required where the building is equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2 and the occupant notification appliances will automatically activate throughout the notification zones upon a sprinkler water flow.

3. A fire alarm system is not required in buildings that do not have interior corridors serving dwelling units and are protected by an approved automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2, provided that dwelling units either have a means of egress door opening directly to an exterior exit access that leads directly to the exits or are served by open-ended corridors designed in accordance with Section 1028.6, Exception 4.

- The occupants of Group R-2 occupancies are not considered to be as transient as those of Group R-1, which increases the probability that residents can more readily notify each other of a fire. Therefore, Group R-1 occupancies must have a manual fire alarm system with audible and visual notification appliances subject to the exceptions in Section 907.2.8.1, whereas Group R-2 occupancies are required to have only a manual fire alarm system as stipulated in one of the three listed conditions. The threshold conditions are meant to be applied independently of each other.

Exception 1 eliminates the requirement for a manual fire alarm system if the sleeping units have an exit discharging directly to a public way, exit court or yard. Even though the building may be two stories in height, the sleeping units on each floor must have access directly to an approved exit at grade level. The use of an exterior exit access balcony with exterior stairs serving the second floor does not constitute an exit directly at grade. The minimum 1-hour fire-resistance rating required for adequate separation of the sleeping units must be maintained.

Exception 2 does not omit the fire alarm system but rather permits it to be initiated automatically by sprinkler system water flow switch(es) in lieu of manual fire alarm boxes. The sprinkler system must activate the occupant notification system. This exception does not affect the independent provisions of Section 907.2.11.

Exception 3 allows the omission of a fire alarm system in fully sprinklered buildings (NFPA 13 or 13R) with no interior corridors and that exit directly to an exterior exit access or have open-ended corridors. The important thing to note is that the sprinkler system is not required to activate alarm notification appliances since a fire alarm system would not be required. Only the sprinkler alarms required by Section 903.4 would be required.

[F] 907.2.9.2 Smoke alarms. Single- and multiple-station smoke alarms shall be installed in accordance with Section 907.2.11.

- The actual requirements for single- and multiple-station smoke alarms are located in Section 907.2.11. That section requires that the single- and multiple-station smoke alarms within sleeping units be connected to the emergency electrical system. Automatic activation of the fire alarm system is avoided to reduce unnecessary alarms within such buildings.

[F] 907.2.9.3 Group R-2 college and university buildings. An automatic smoke detection system that activates the occupant notification system in accordance with Section 907.5 shall be installed in Group R-2 college and university buildings in the following locations:

1. Common spaces outside of dwelling units and sleeping units.

2. Laundry rooms, mechanical equipment rooms, and storage rooms.

3. All interior corridors serving sleeping units or dwelling units.

Required smoke alarms in dwelling units and sleeping units in Group R-2 college and university buildings shall be interconnected with the fire alarm system in accordance with NFPA 72.

Exception: An automatic smoke detection system is not required in buildings that do not have interior corridors serving sleeping units or dwelling units and where each sleeping unit or dwelling unit either has a means of egress door opening directly to an exterior exit access that leads directly to an exit or a means of egress door opening directly to an exit.

- This section is new to the 2012 code and requires an automatic smoke detection system in Group R-2 college and university buildings. It also requires the smoke alarms in individual units to be interconnected with the fire alarm system. This is more restrictive than a Group R-2 occupancy in general as typically all that is required is a manual fire alarm system and smoke alarms in the individual sleeping or dwelling units. The smoke detection system is focused on common areas, such as interior corridors, lounge areas, laundry, and areas such as mechanical rooms, which could be the source of a fire especially in these specific types of Group R-2 occupancies.

In a study completed by the New York State Governor’s Task Force on Campus Fire Safety it was cited that 43 percent of fires in college dormitories are located in dorm rooms or kitchens, leaving the other
57 percent to be located in areas that would not require smoke detection under the current code. The study also showed that there were approximately 300 fires on college campus over a three-year period while only 160 were reported to the fire department. The Center for Campus Fire Safety reports 99 deaths have been “reported” in fires in student housing since 2000.

An NFPA study on student housing showed 3,300 structural fires in dormitories, fraternities, sororities and barracks between 2002 and 2005. Since 1980, there has been an increase of 3 percent in reported fires in dormitory-type occupancies, while there has been a 52-percent decrease in overall reported structural fires.

The requirements in Section 907.2.9.3 are very similar to the recommendations of the study done in New York State. It is important to note that the recommendations for that study were specifically aimed at the properties of the colleges and universities so it was not the study’s intent to cover off-campus housing in this particular regard. There were recommendations for off-campus housing, such as sororities and fraternities to have annual inspections. This particular distinction was not addressed in detail during the code development process; however, since this is somewhat of a continuation of requirements that were added into Chapter 4 of the 2006 edition of the IFC for emergency preparedness and planning, and those requirements were intended to deal with buildings that were owned by a college or university, it seems reasonable to interpret that this new requirement is also limited to the buildings that are owned by the college or university and does not apply to Group R-2 occupancies not affiliated with a college or university. Although on-campus housing is clearly encompassed by the code, off-campus housing is less clearly addressed. It could be argued and would be consistent with the intent that off-campus fraternity and sorority housing is governed by this section. Privately owned apartments that rent space to college and university students, however, fall into a gray area. Such occupancies may have a few or many occupants who are not affiliated with a college or university. Thereby, these uses would be difficult to differentiate from any other Group R-2 occupancy. Because the code is somewhat vague with respect to these situations, enforcement becomes discretionary and it is recommended that jurisdictions adopt a policy on application of this section to off-campus housing. See Section 104.1 of the IFC for guidance on establishing local policies.

The exception allows for the elimination of the smoke detection system in a specific situation. The use of the wording “automatic smoke detection system” is important in the exception since it helps distinguish between the system that is required in the public and common areas by the first paragraph along with its three items and the smoke alarms that are required within the units. Within the units, Sections 907.2.9.2 and 907.2.11 require smoke alarms at specific locations. The second paragraph of Section 907.2.9.3 requires these smoke alarms to be interconnected with the fire alarm system. The exception does not eliminate the requirement for these smoke alarms within the units or the requirement that they be interconnected with the fire alarm system. The exception is intended to only apply to the “automatic smoke detection system” of the first paragraph and not to the “smoke alarm” requirement of the second paragraph.

Note that it is entirely possible that some areas that are required to have smoke detection may have ambient conditions that warrant a different type of alarm-initiating device. Section 907.4.3 addresses this concern.

[F] 907.2.10 Group R-4. Fire alarm systems and smoke alarms shall be installed in Group R-4 occupancies as required in Sections 907.2.10.1 through 907.2.10.3.

This section, based on the Group R-2 requirements for manual fire alarm systems and Group I-1 requirements for automatic smoke detection systems, contains manual fire alarm and automatic smoke detection system requirements for new Group R-4 occupancies. Reviewing the occupancy categories in Chapter 3 of the code, a Group R-4 could be considered either a small Group I-1 or a Group R-2 with occupants that have special needs or limitations. A further review found that both Group I-1 and R-2 occupancies had fire alarm requirements for new buildings, but Group R-4 did not, even though the IFC required a fire alarm system retroactively in existing Group R-4 occupancies (see Section 1103.8.7 of the IFC).

[F] 907.2.10.1 Manual fire alarm system. A manual fire alarm system that activates the occupant notification system in accordance with Section 907.5 shall be installed in Group R-4 occupancies.

Exceptions:
1. A manual fire alarm system is not required in buildings not more than two stories in height where all individual sleeping units and contiguous attic and crawl spaces to those units are separated from each other and public or common areas by at least 1-hour fire partitions and each individual sleeping unit has an exit directly to a public way, egress court or yard.
2. Manual fire alarm boxes are not required throughout the building when the following conditions are met:
   2.1. The building is equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2;
   2.2. The notification appliances will activate upon sprinkler waterflow; and
   2.3. At least one manual fire alarm box is installed at an approved location.
3. Manual fire alarm boxes in resident or patient sleeping areas shall not be required at exits where located at all nurses’ control stations or other constantly attended staff locations, provided such stations are visible and continuously accessible and that travel distances required in Section 907.4.2.1 are not exceeded.

- This section is specific to manual fire alarm systems and requires such systems in all Group R-4 occupancies, with three exceptions.

  Exception 1 eliminates the requirement for a manual fire alarm system if the sleeping units have an exit discharging directly to a public way, exit court or yard. Even though the building may be two stories in height, the sleeping units on each floor must have access directly to an approved exit at grade level. The use of an exterior exit access balcony with exterior stairs serving the second floor does not constitute an exit directly at grade. The minimum 1-hour fire-resistance rating required for adequate separation of the sleeping units must be maintained.

  Exception 2 does not omit the fire alarm system but rather permits it to be initiated automatically by sprinkler system water flow switch(es) in lieu of manual fire alarm boxes. The sprinkler system must activate the occupant notification system and at least one manual fire alarm box shall be installed at an approved location. See the commentary to Section 907.2 for a discussion of the single manual fire alarm box.

  Exception 3 reduces the likelihood of accidental or malicious false alarm system activations by manual means by allowing the pull stations to be located in a more controlled area. It assumes the approved location is always accessible by staff and within 200 feet (60 960 mm) of travel distance.

[F] 907.2.10.2 Automatic smoke detection system. An automatic smoke detection system that activates the occupant notification system in accordance with Section 907.5 shall be installed in corridors, waiting areas open to corridors and habitable spaces other than sleeping units and kitchens.

- Exceptions:

  1. Smoke detection in habitable spaces is not required where the facility is equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1.

  2. An automatic smoke detection system is not required in buildings that do not have interior corridors serving sleeping units and where each sleeping unit has a means of egress door opening directly to an exit or to an exterior exit access that leads directly to an exit.

- Occupancies in Group R-4 can be compartmentalized into small rooms so that a fire in one area of the building would not easily be noticed by occupants in another part of the building. Therefore, smoke detection is required in areas other than sleeping units and kitchens. Sleeping units are required by Section 907.2.10.3 to be equipped with single- and multiple-station smoke alarms in accordance with Section 907.2.11.

  Since Group R-4 occupancies may not be supervised by staff and to reduce the likelihood that a fire within a waiting area open to the corridor or the corridor itself could develop beyond the incipient stage, thereby jeopardizing the building egress, these areas must be equipped with automatic smoke detection.

  Exception 1 allows smoke detectors to be eliminated from habitable spaces if the building is equipped throughout with an NFPA 13 automatic sprinkler system. The sprinkler system should control any fire and perform occupant notification through actuation of the water flow switch and subsequent activation of the building alarm notification appliances. A sprinkler system is required for all Group R occupancies in accordance with Section 903.2.8.

  The exception provides that automatic fire detectors are not required in buildings that do not have interior corridors and in which sleeping units have a door opening to an exterior exit access that leads directly to the exits. The intent of the exception is that the exit access from the sleeping unit door be exterior and not require reentering the building prior to entering the exit. Since the exit access is outside, the need for detectors other than the smoke alarms required by Section 907.2.10.3 in sleeping units is greatly reduced.

[F] 907.2.10.3 Smoke alarms. Single- and multiple-station smoke alarms shall be installed in accordance with Section 907.2.11.

- The actual requirements for single- and multiple-station smoke alarms are located in Section 907.2.11. That section requires that the single- and multiple-station smoke alarms within sleeping units be connected to the emergency electrical system. Automatic activation of the fire alarm system is avoided to reduce unnecessary alarms within such buildings.

[F] 907.2.11 Single- and multiple-station smoke alarms. Listed single- and multiple-station smoke alarms complying with UL 217 shall be installed in accordance with Sections 907.2.11.1 through 907.2.11.4 and NFPA 72.

- Single- and multiple-station smoke alarms have evolved as one of the most important fire safety features in residential and similar occupancies having sleeping occupants. The value of early fire warning in these occupancies has been repeatedly demonstrated in fires involving both successful and unsuccessful smoke alarm performance.

  For successful smoke alarm operation and performance, single- and multiple-station smoke alarms must be listed in accordance with UL 217 and installed to comply with the code and Chapter 11 of NFPA 72, which contains the minimum requirements for the selection, installation, operation and maintenance of fire warning equipment for use in family living units. These devices are called “smoke alarms”
rather than "smoke detectors" because they are independent of a fire alarm system and include an integral alarm notification device.

[F] 907.2.11.1 Group R-1. Single- or multiple-station smoke alarms shall be installed in all of the following locations in Group R-1:

1. In sleeping areas.
2. In every room in the path of the means of egress from the sleeping area to the door leading from the sleeping unit.
3. In each story within the sleeping unit, including basements. For sleeping units with split levels and without an intervening door between the adjacent levels, a smoke alarm installed on the upper level shall suffice for the adjacent lower level provided that the lower level is less than one full story below the upper level.

Because the occupants of a sleeping unit or suite may be asleep and unaware of a fire developing in the room or in the egress path, single- or multiple-station smoke alarms must be provided in the sleeping unit and in any intervening room between the sleeping unit and the exit access door from the room. If the sleeping unit or suite involves more than one level, a smoke alarm must also be installed on every level. See the commentary to Section 202 definition of "Sleeping unit."

Smoke alarms are required in split-level arrangements, except those that meet the conditions described in Item 3. In accordance with Section 907.2.11.3, all smoke alarms within a sleeping unit or suite must be interconnected so that actuation of one alarm will actuate all smoke alarms within the sleeping unit or suite.

[F] 907.2.11.2 Groups R-2, R-3, R-4 and I-1. Single- or multiple-station smoke alarms shall be installed and maintained in Groups R-2, R-3, R-4 and I-1 regardless of occupant load at all of the following locations:

1. On the ceiling or wall outside of each separate sleeping area in the immediate vicinity of bedrooms.
2. In each room used for sleeping purposes.

Exception: Single- or multiple-station smoke alarms in Group I-1 shall not be required where smoke detectors are provided in the sleeping rooms as part of an automatic smoke detection system.

3. In each story within a dwelling unit, including basements but not including crawl spaces and uninhabitable attics. In dwellings or dwelling units with split levels and without an intervening door between the adjacent levels, a smoke alarm installed on the upper level shall suffice for the adjacent lower level provided that the lower level is less than one full story below the upper level.

Because the occupants of a dwelling unit may be asleep and unaware of a fire developing in the room or in an area within the dwelling unit that will affect their ability to escape, single- or multiple-station smoke alarms must be installed in every bedroom, in the vicinity of all bedrooms (e.g., hallways leading to the bedrooms) and on each story of the dwelling unit (see Figure 907.2.11.2 and the commentary to Section 202 definition of "Dwelling unit").

If a sprinkler system was installed throughout the building in accordance with NFPA 13, 13R or 13D, if applicable, smoke alarms would still be required in the bedrooms even if residential sprinklers were used.

Smoke alarms are required in split-level arrangements. As required by Section 907.2.11.3, all smoke alarms within a dwelling unit must be interconnected so that actuation of one alarm will actuate the alarms.
in all detectors within the dwelling unit.

These provisions do not apply to one- and two-family dwellings and multiple single-family dwellings (townhouses) not more than three stories in height with a separate means of egress that are regulated by the IRC. The IRC is intended to be a stand-alone document but if the residential units do not fall within the scope of the IRC or for other reasons are intended to be subject to this code, then the requirements of this section would apply. IFC Committee Interpretation No. 42-03 addresses this condition and contains additional explanatory information about the IRC and its relationship to the other International Codes.

Although the occupants of a sleeping unit in a Group I-I occupancy may be asleep, they are still considered capable of self-preservation. Regardless, smoke alarms are required in sleeping units. The exception allows single- or multiple-station smoke alarms to be eliminated in the room if an automatic fire detection system that includes in-room system smoke detectors is installed as required by Section 907.2.6.

[F] 907.2.11.3 Interconnection. Where more than one smoke alarm is required to be installed within an individual dwelling unit or sleeping unit in Group R or I-1 occupancies, the smoke alarms shall be interconnected in such a manner that the activation of one alarm will activate all of the alarms in the individual unit. Physical interconnection of smoke alarms shall not be required where listed wireless alarms are installed and all alarms sound upon activation of one alarm. The alarm shall be clearly audible in all bedrooms over background noise levels with all intervening doors closed.

醋 The installation of smoke alarms in areas remote from the sleeping area will be of minimal value if the alarm is not heard by the occupants. Interconnection of multiple smoke alarms within an individual dwelling unit or sleeping unit is required in order to alert a sleeping occupant of a remote fire within the unit before the combustion products reach the smoke alarm in the sleeping area and thus provide additional time for evacuation.

The term "interconnection" refers to either hard-wired systems or listed wireless systems. UL has listed smoke detectors that use this technology. It is presumed that on safely evacuating the unit or room of fire origin, an occupant will notify other occupants by actuating the manual fire alarm system or using other available means. Section 907.7.1 addresses the testing of the smoke alarms to demonstrate that interconnection of such smoke alarms is properly functioning.

Similar requirements can now be found in the IRC, IFC and International Existing Building Code® (IEBC®) for both new and existing buildings to allow interconnection with wireless technology of smoke alarms. All wirelessly interconnected smoke alarms are listed to UL 217 and are classified by NFPA 72 as low-power systems.

[F] 907.2.11.4 Power source. In new construction, required smoke alarms shall receive their primary power from the building wiring where such wiring is served from a commercial source and shall be equipped with a battery backup. Smoke alarms with integral strobes that are not equipped with battery backup shall be connected to an emergency electrical system. Smoke alarms shall emit a signal when the batteries are low. Wiring shall be permanent and without a disconnecting switch other than as required for overcurrent protection.

Exception: Smoke alarms are not required to be equipped with battery backup where they are connected to an emergency electrical system.

醋 Smoke alarms are required to use AC as a primary power source and battery power as a secondary source to improve their reliability. For example, during a power outage, the probability of fire is increased because of the use of candles or lanterns for temporary light. Required backup battery power is intended to provide continued functioning of the smoke alarms. Smoke alarms are commonly designed to emit a recurring signal when batteries are low and need to be replaced.

Certain occupancies may already have an emergency electrical system in the building to monitor other building system conditions. The emergency electrical system provides a level of reliability equivalent to battery backup.

[F] 907.2.12 Special amusement buildings. An automatic smoke detection system shall be provided in special amusement buildings in accordance with Sections 907.2.12.1 through 907.2.12.3.

醋 Special amusement buildings are buildings in which the means of egress is not readily apparent, is intentionally confounded or is not readily available. Special amusement buildings must also comply with the provisions of Section 411.

The approved automatic smoke detection system is required to provide early warning of a fire. The detection system is required regardless of the presence of staff in the building. The exception recognizes that the ambient conditions in some special amusement buildings may preclude the use of automatic smoke detectors. In those instances, an alternative detection device must be used for early detection of a fire.

[F] 907.2.12.1 Alarm. Activation of any single smoke detector, the automatic sprinkler system or any other automatic fire detection device shall immediately activate an audible and visible alarm at the building at a constantly attended location from which emergency action can be initiated, including the capability of manual initiation of requirements in Section 907.2.12.2.

醋 Upon activation of either a smoke detector or other automatic fire detection device or the automatic sprinkler system, an alarm must activate both an audible and visible alarm at a constantly attended location. The staff at the location is expected to be capable of
then providing the required egress illumination, stopping the conflicting or confusing sounds and distractions and activating the exit marking required by Section 907.2.12.2. The staff is also expected to be capable of preventing additional people from entering the building.

[F] 907.2.12.2 System response. The activation of two or more smoke detectors, a single smoke detector equipped with an alarm verification feature, the automatic sprinkler system or other approved fire detection device shall automatically:

1. Cause illumination of the means of egress with light of not less than 1 footcandle (11 lux) at the walking surface level;
2. Stop any conflicting or confusing sounds and visual distractions;
3. Activate an approved directional exit marking that will become apparent in an emergency; and
4. Activate a prerecorded message, audible throughout the special amusement building, instructing patrons to proceed to the nearest exit. Alarm signals used in conjunction with the prerecorded message shall produce a sound which is distinctive from other sounds used during normal operation.

- Once a fire has been detected, measures must be taken to stop the confusion or distractions. Additionally, the egress path must be illuminated and marked. These measures must occur automatically upon detection of the fire or sprinkler water supply. A prerecorded message that can be heard throughout the building instructing the occupants to proceed to the nearest exit must be automatically activated. The message and alarm signals should be designed to prevent panic. The prerecorded message capability is in addition to the EVCACS requirement of Section 907.2.12.3. The wiring of all devices must comply with NFPA 72.

[F] 907.2.12.3 Emergency voice/alarm communication system. An emergency voice/alarm communication system, which is also allowed to serve as a public address system, shall be installed in accordance with Section 907.5.2.2 and be audible throughout the entire special amusement building.

- Because of the problem associated with evacuating special amusement buildings, an emergency voice/alarm communication system is required (see also Section 907.5.2.2). This section allows the system to also serve as a public address (PA) system to have the capability to alert the occupants of a fire and give them evacuation instructions. The system must be designed so that once the voice alarm is activated, the typical public address function is superseded by the voice alarm. Because a manual override must be provided, it is possible that the same microphone used for the public address can be used for the override. However, a separate action would be necessary so that the override function can be used once the voice alarm is active.

[F] 907.2.13 High-rise buildings. High-rise buildings shall be provided with an automatic smoke detection system in accordance with Section 907.2.13.1, a fire department communication system in accordance with Section 907.2.13.2 and an emergency voice/alarm communication system in accordance with Section 907.5.2.2.

Exceptions:

1. Airport traffic control towers in accordance with Sections 907.2.22 and 412.
2. Open parking garages in accordance with Section 406.5.
4. Low-hazard special occupancies in accordance with Section 503.1.1.
5. Buildings with an occupancy in Group H-1, H-2 or H-3 in accordance with Section 415.
6. In Group I-1 and I-2 occupancies, the alarm shall sound at a constantly attended location and occupant notification shall be broadcast by the emergency voice/alarm communication system.

- High-rise buildings require additional fire protection systems because of the difficulties with smoke movement, egress time and fire department access. As a result, this section requires both an automatic fire alarm system and an emergency voice/alarm communication system (see commentary, Section 907.5.2.2). Exceptions 1 through 5 are the same as those in Section 403.1 regarding the applicability of the high-rise provisions.

Exception 1 addresses airport traffic control towers and is based on the limited fuel load and the limited number of persons occupying the tower.

Open parking garages and places of outdoor assembly (Group A-5) are exempted by Exceptions 2 and 3, respectively, because of the free ventilation to the outside that exists in such structures.

In Exception 4, low-hazard special industrial occupancies may be exempted when approved by the fire code official. Such buildings should be evaluated based on the occupant load and the hazards of the occupancy and its contents to determine whether the protection features required by Section 403 of the code are necessary.

Buildings with occupancies in Groups H-1, H-2 and H-3 are excluded from the requirements of this section by Exception 5 because the fire hazard characteristics of these occupancies have not yet been considered in high-rise buildings.

Exception 6 recognizes the supervised environment typical of institutional uses and the reliance placed on staff to act appropriately in an emergency. As is the case for most voice alarms, the key is in being able to deliver specific information to the people who can affect a safe egress—whether it be the public, employees, or both.
FIRE PROTECTION SYSTEMS

[F] 907.2.13.1 Automatic smoke detection. Automatic smoke detection in high-rise buildings shall be in accordance with Sections 907.2.13.1.1 and 907.2.13.1.2.

This section simply introduces the fire alarm and detection system requirements for high-rise buildings.

[F] 907.2.13.1.1 Area smoke detection. Area smoke detectors shall be provided in accordance with this section. Smoke detectors shall be connected to an automatic fire alarm system. The activation of any detector required by this section shall activate the emergency voice/alarm communication system in accordance with Section 907.5.2.2. In addition to smoke detectors required by Sections 907.2.1 through 907.2.10, smoke detectors shall be located as follows:

1. In each mechanical equipment, electrical, transformer, telephone equipment or similar room which is not provided with sprinkler protection.
2. In each elevator machine room and in elevator lobbies.

Automatic smoke detectors are required in all high-rise buildings in certain locations so that a fire will be detected in its early stages of development. The detectors must be connected to the automatic fire alarm system and be capable of initiating operation of the EV/ACS.

This section divides the automatic smoke detection requirement into two categories. Smoke detectors must be installed in rooms that are not typically occupied. This includes rooms used for: mechanical equipment, electrical equipment, transformer equipment, and telephone equipment where such rooms do not have automatic sprinkler protection. In most cases, these rooms will have sprinkler protection by virtue of being in a high-rise building and will therefore not require smoke detectors. However, in elevator machine rooms and elevator lobbies, smoke detectors are required regardless of sprinkler protection.

Note that smoke detection and smoke alarms may be required based upon occupancy related requirements elsewhere in Section 907.2.

[M] 907.2.13.1.2 Duct smoke detection. Duct smoke detectors complying with Section 907.3.1 shall be located as follows:

1. In the main return air and exhaust air plenum of each air-conditioning system having a capacity greater than 2,000 cubic feet per minute (cfm) (0.94 m³/s). Such detectors shall be located in a serviceable area downstream of the last duct inlet.

2. At each connection to a vertical duct or riser serving two or more stories from a return air duct or plenum of an air-conditioning system. In Group R-1 and R-2 occupancies, a smoke detector is allowed to be used in each return air riser carrying not more than 5,000 cfm (2.4 m³/s) and serving not more than 10 air-inlet openings.

Smoke detectors must be installed in the main return air and exhaust air plenum of each air-conditioning system having a design capacity exceeding 2,000 cubic feet per minute (cfm) (0.94 m³/s). Systems with design capacities equal to or less than 2,000 cfm (0.94 m³/s) are exempt from this requirement because their small size limits their capacity for spreading smoke to parts of the building not already involved with fire.

The area that could be served by a 2,000-cfm (0.94 m³) system (approximately 5 tons of cooling capacity) is comparatively small; therefore, the distribution of smoke in a system of that size would be minimal. Smoke detectors must be located so that they monitor the total airflow within the system. If a single detector is unable to sample the total airflow at all times, then multiple detectors are required. The smoke detectors must be made accessible for maintenance and inspection. Many failures and false alarms are caused by a lack of maintenance and cleaning of the smoke detectors.

Consistent with Section 606.2.3 of the IMC, return air risers serving two or more stories must have smoke detectors installed at each story. Item 2 allows the use of a single listed smoke detector in each return air riser in a Group R-1 or R-2 occupancy if the capacity of each riser does not exceed 5,000 cfm (2.4 m³/s) and does not serve more than 10 air-inlet openings. This alternative recognizes that it is not as necessary in buildings dedicated to residential occupancies only to monitor the return air from each story prior to intermixing the return air in the common riser.

[F] 907.2.13.2 Fire department communication system. Where a wired communication system is approved in lieu of an emergency responder radio coverage system in accordance with Section 510 of the International Fire Code, the wired fire department communication system shall be designed and installed in accordance with NFPA 72 and shall operate between a fire command center complying with Section 911, elevators, elevator lobbies, emergency and standby power rooms, fire pump rooms, areas of refuge and inside enclosed exit stairways. The fire department communication device shall be provided at each floor level within the enclosed exit stairway.

High-rise buildings have posed a challenge to the traditional communication systems used by the fire service for fire-to-ground communications to assist fire ground officers in communicating with the fire fighters working in various areas of the building. Where testing of the building's public safety communications system required by Section 403.4.4 of the code shows that the signal strengths are not satisfactory, Section 510.1, Exception 1, of the IFC allows for the alternative of installation of a wired communication system designed in accordance with this section. The system must be capable of operating between the fire command center and every elevator, elevator lobby, emergency/standby power room, fire pump room, area of refuge and exit stairway. Note that this sec-
tion does not offer specific criteria as to what constitutes an acceptable wired communication system or its components. It could be a component of an emergency voice/alarm communication system that complies with Section 907.5.2.2 or a building's telephone system. In any event, when applying Section 510.1, Exception 1, of the IFC and this section, the concurrent approval of the fire and building code officials is required.

[F] 907.2.14 Atriums connecting more than two stories. A fire alarm system shall be installed in occupancies with an atrium that connects more than two stories; with smoke detection installed throughout the atrium. The system shall be activated in accordance with Section 907.5. Such occupancies in Group A, E or M shall be provided with an emergency voice/alarm communication system complying with the requirements of Section 907.5.2.2.

- Buildings containing an atrium that connects more than two stories are to be equipped with a fire alarm system that can be used to notify building occupants to begin evacuating in case of a fire. The alarm system must be initiated in accordance with Section 907.4, which requires that in buildings containing an atrium, the alarm system is to be initiated by the sprinkler system and any automatic or manual fire alarm-initiating devices found in the atrium as well as elsewhere in the building. It does not intend to require certain features to be installed within the atrium but rather is simply requiring that any such features present initiate the occupant notification system. It would not necessarily be appropriate to also initiate the smoke control system upon activation of the alarm system within a building containing an atrium (see Section 909.12.2).

  - Groups A, E and M must have an emergency voice/alarm communication system that complies with Section 907.5.2.2 because of the number of persons to be evacuated and the lack of familiarity with the location of exits that is typical of occupants in Groups A and M. The alarm system is intended to warn occupants entering the atrium because smoke is being drawn to the atrium.

[F] 907.2.15 High-piled combustible storage areas. An automatic smoke detection system shall be installed throughout high-piled combustible storage areas where required by Section 3206.5 of the *International Fire Code*.

- Section 3206.5 of the IFC requires an automatic fire detection system in high-piled combustible storage areas depending on the commodity class, the size of the high-piled storage area and the presence of an automatic sprinkler system. High-piled storage is the storage of Class I through IV commodities in piles, bin boxes, on pallets or in racks more than 12 feet (3658 mm) high or for high-hazard commodities stored higher than 6 feet (1829 mm). Chapter 32 of the IFC and NFPA 13 contain additional requirements for all high-piled storage conditions.

[F] 907.2.16 Aerosol storage uses. Aerosol storage rooms and general-purpose warehouses containing aerosols shall be provided with an approved manual fire alarm system where required by the *International Fire Code*.

- Chapter 32 of the IFC and NFPA 30B contain additional guidance on the storage of and fire protection requirements for aerosol products. The requirements for storing the various levels of aerosol products are dependent on the level of sprinkler protection, the type of storage and the quantity of aerosol products. Although aerosol product fires generally involve property loss as opposed to loss of life, installation of a manual fire alarm system could aid in the prompt evacuation of the occupants. Fires involving aerosol products can spread rapidly through a building that is not properly protected and controlled.

[F] 907.2.17 Lumber, wood structural panel and veneer mills. Lumber, wood structural panel and veneer mills shall be provided with a manual fire alarm system.

- Any facility using mechanical methods to process wood into finished products produces debris and the potential for combustible dust. Such facilities include mills that produce solid wood lumber and wood veneers as well as those that manufacture structural wood panels such as waferboard, oriented strandboard, composite wood panels or plywood. Good housekeeping and control of ignition sources are therefore essential. To aid in the quick evacuation of occupants in an emergency, Section 2804.2.1 of the IFC requires a manual fire alarm system in lumber, wood structural panel and veneer mills that contain product dryers because of their potential as a source of ignition. A manual fire alarm system is not required, however, if the dryers and all other potential sources of ignition are protected by a supervised automatic sprinkler system.

[F] 907.2.18 Underground buildings with smoke control systems. Where a smoke control system is installed in an underground building in accordance with this code, automatic smoke detectors shall be provided in accordance with Section 907.2.18.1.

- As indicated in Section 405.5.2, each compartment of an underground building must have a smoke control/exhaust system that can be activated both automatically and manually. Floor levels more than 60 feet (18 288 mm) below the lowest level of exit discharge must be compartmented. Compartmentation is a key element in the egress and fire access plan for floor areas in an underground building. The smoke control system must not only facilitate egress during a fire, but also improve fire department access to the fire source by maintaining visibility that is otherwise impossible given the inability of the fire service to manually ventilate the underground portion of the building (see commentary, Section 405.4.1).

[F] 907.2.18.1 Smoke detectors. A minimum of one smoke detector listed for the intended purpose shall be installed in the following areas:

1. Mechanical equipment, electrical, transformer, telephone equipment, elevator machine or similar rooms.
2. Elevator lobbies.

3. The main return and exhaust air plenum of each air-conditioning system serving more than one story and located in a serviceable area downstream of the last duct inlet.

4. Each connection to a vertical duct or riser serving two or more floors from return air ducts or plenums of heating, ventilating and air-conditioning systems, except that in Group R occupancies, a listed smoke detector is allowed to be used in each return air riser carrying not more than 5,000 cfm (2.4 m³/s) and serving not more than 10 air-inlet openings.

- Automatic smoke detectors are required in certain locations in all underground buildings so that a fire will be detected in its early stages of development. Underground buildings are similar to high-rise buildings in that they present an unusual hazard by being virtually inaccessible to exterior fire department suppression and rescue operations with the increased potential to trap occupants inside the structure. For this reason, the smoke detector location requirements for underground buildings are similar to those in Section 907.2.13.1 for high-rise buildings (see commentary, Section 907.2.13.1). The requirement for a smoke detector in the main return and exhaust air plenum of an air-conditioning system in an underground building, however, differs from that of a high-rise building in that it is not a function of capacity [2,000 cfm (0.94 m³/s)] but rather a function of whether the system serves more than one floor level. There is more concern over the threat of smoke movement from floor to floor because the products of combustion cannot be vented directly to the atmosphere.

[F] 907.2.18.2 Alarm required. Activation of the smoke control system shall activate an audible alarm at a constantly attended location.

- The audible alarm is required to notify qualified personnel immediately that the smoke control system has been activated and to put emergency procedures into action quickly.

[F] 907.2.19 Deep underground buildings. Where the lowest level of a structure is more than 60 feet (18 288 mm) below the finished floor of the lowest level of exit discharge, the structure shall be equipped throughout with a manual fire alarm system, including an emergency voice/alarm communication system installed in accordance with Section 907.5.2.2.

- The ability to communicate and offer warning of a fire can increase the time available for egress from the building. Underground structures located more than 60 feet (18 288 mm) below the level of exit discharge must therefore have a manual fire alarm system. An emergency voice/alarm communication system is also required as part of this system (see commentary, Section 907.5.2.2).

[F] 907.2.20 Covered and open mall buildings. Where the total floor area exceeds 50,000 square feet (4645 m²) within either a covered mall building or within the perimeter line of an open mall building, an emergency voice/alarm communication system shall be provided. Emergency voice/alarm communication systems serving a mall, required or otherwise, shall be accessible to the fire department. The system shall be provided in accordance with Section 907.5.2.2.

- Because of the potentially large number of occupants and their unfamiliarity with their surroundings, an EV/ACS, accessible by the fire department, is required to aid in evacuation of covered mall buildings exceeding 50,000 square feet (4645 m²) measured within the perimeter lines of the open mall. Anchor stores are not included as part of the covered or open mall building (see commentary, Section 202 definition of "Covered mall building").

[F] 907.2.21 Residential aircraft hangars. A minimum of one single-station smoke alarm shall be installed within a residential aircraft hangar as defined in Chapter 2 and shall be interconnected into the residential smoke alarm or other sounding device to provide an alarm which will be audible in all sleeping areas of the dwelling.

- Residential aircraft hangars are assumed to be on the same property as a one- or two-family dwelling. Section 412.3 contains additional requirements for the construction of residential aircraft hangars. The hangar could be located immediately adjacent to the dwelling unit if it is separated by 1-hour fire-resistance-rated construction. Because of the potentially close proximity of the aircraft and its flammability and fuel source, at least one smoke alarm is required in the hangar that is interconnected to the residential smoke alarms. It should be noted, however, that the requirement for a smoke alarm is also applicable to residential aircraft hangars that are detached from the dwelling unit. Because a minimum separation distance is not specified, a fire in the hangar could still present a serious fire hazard to the dwelling unit.

[F] 907.2.22 Airport traffic control towers. An automatic smoke detection system that activates the occupant notification system in accordance with Section 907.5 shall be provided in airport control towers in all occupiable and equipment spaces.

Exception: Audible appliances shall not be installed within the control tower cab.

- Airport traffic control towers must be designed to comply with Section 412. These structures are unique in that they can be built to excessive heights, depending upon construction type, are permitted to have one exit stairway and are typically nonsprinklered. Section 903.2.11.3 specifically exempts airport control towers from the requirements of an automatic sprinkler system. An automatic fire detection system is required, however, for early warning notification of the occupants in an emergency. Equipment spaces are included because they may be areas within an airport traffic control tower where a fire may begin, but may not be occupied. Early warn-
ing of a fire in these areas is required so as to alert the occupants and emergency forces. The exception recognizes the sensitive nature of the operations that take place in the cab located at the top of the tower and prohibits the installation of audible alarm notification devices there. Notification of occupants within the cab is to be by visual notification appliances only.

[F] 907.2.23 Battery rooms. An automatic smoke detection system shall be installed in areas containing stationary storage battery systems with a liquid capacity of more than 50 gallons (189 L).

- Stationary lead-acid battery systems are commonly used for standby power, emergency power or uninterruptible power supplies. The release of hydrogen gas during battery system operation is usually minimal. Adequate ventilation will disperse the small amounts of liberated hydrogen. Because standby power and emergency power systems control many important building emergency systems and functions, a supervised automatic smoke detection system is required for early warning notification of a hazardous condition. Section 608 of the IFC contains additional requirements, including the need for safety venting; room enclosure requirements; spill control and neutralization provisions; ventilation criteria; signage and seismic protection. Section 508.2.5 also requires that such rooms in certain occupancies be separated by 1-hour construction.

[F] 907.3 Fire safety functions. Automatic fire detectors utilized for the purpose of performing fire safety functions shall be connected to the building's fire alarm control unit where a fire alarm system is required by Section 907.2. Detectors shall, upon actuation, perform the intended function and activate the alarm notification appliances or activate a visible and audible supervisory signal at a constantly attended location. In buildings not equipped with a fire alarm system, the automatic fire detector shall be powered by normal electrical service and, upon actuation, perform the intended function. The detectors shall be located in accordance with NFPA 72.

- When the code requires installation of automatic fire detectors to perform a specific function, such as elevator recall or smokeproof enclosure ventilation, or when detectors are installed to comply with a permitted alternative, such as door-closing devices, these detectors must be connected to the building's automatic fire alarm system if the building is required by the code to have such a system.

In addition to performing its intended function (for example, closing a door), if a detector is activated, it must also activate either the building alarm devices (if one is present) or a supervisory signal at a constantly attended location. This requirement recognizes that these detectors and the devices they control are part of the building fire protection system and are expected to perform as designed. If they are connected to a fire alarm system, they will have the supervision necessary for operational reliability. If they are not connected to and supervised by a fire alarm system, they still must be supervised through the constantly attended location.

An exception is provided for fire safety function detectors in buildings not required to have a fire alarm system. The fire safety function detectors must be powered by the building electrical system and be located as required by NFPA 72. Without this exception, these detectors could not be expected to perform as intended because there would be no power supply.

Note that in the IFC, this section is entitled "Where required in existing buildings and structures." but since the IBC does not apply retroactively, such requirements do not appear here. That is why all sections of Section 907 following Section 907.2.23 do not exactly correlate with the content of Section 907 of the IFC.

[F] 907.3.1 Duct smoke detectors. Smoke detectors installed in ducts shall be listed for the air velocity, temperature and humidity present in the duct. Duct smoke detectors shall be connected to the building's fire alarm control unit when a fire alarm system is required by Section 907.2. Activation of a duct smoke detector shall initiate a visible and audible supervisory signal at a constantly attended location and shall perform the intended fire safety function in accordance with this code and the International Mechanical Code. Duct smoke detectors shall not be used as a substitute for required open area detection.

Exceptions:

1. The supervisory signal at a constantly attended location is not required where duct smoke detectors activate the building's alarm notification appliances.

2. In occupancies not required to be equipped with a fire alarm system, actuation of a smoke detector shall activate a visible and an audible signal in an approved location. Smoke detector trouble conditions shall activate a visible or audible signal in an approved location and shall be identified as air duct detector trouble.

- It is not the intent of this section to send a signal to the fire department or to activate the alarm notification devices within a building. Instead, this section requires that a supervisory signal be sent to a constantly attended location. Smoke detectors must be connected to a fire alarm system where such systems are installed. Connection to the fire alarm system will activate a visible and audible supervisory signal at a constantly attended location, which will alert building supervisory personnel that a smoke alarm has activated and will also provide electronic supervision of the duct detectors, thereby indicating any problems that may develop in the detector system circuitry or power supply.

Exception 1 allows activation of the building alarm notification appliances in place of a supervisory signal. Causing the occupant notification system to sound would alert the occupants of the building that an alarm condition exists within the air distribution system, thereby performing the same function as a
supervisory signal sent to a constantly attended location.

Exception 2 recognizes the fact that not all buildings are required to have a fire alarm system. A visible and audible signal must be activated at an approved location that will alert building supervisory personnel to take action. Additionally, the duct smoke detectors must be electronically supervised to indicate trouble (system fault) in the detector system circuitry or power supply. A trouble condition must activate a distinct visible or audible signal at a location that will alert the responsible personnel.

[F] 907.3.2 Delayed egress locks. Where delayed egress locks are installed on means of egress doors in accordance with Section 1008.1.9.7, an automatic smoke or heat detection system shall be installed as required by that section.

- This section alerts the code user to additional requirements in Section 1008.1.9.7 that tie the operation of egress doors into the activation of an automatic fire detection system. A smoke or heat detection system is required to unlock delayed egress locks upon activation. The heat detection system can be the sprinkler system. For example, a similar requirement is found in Section 1008.1.4.3 that requires horizontal sliding doors used as a component of the means of egress, where required to be rated, to be self-closing or automatic-closing upon smoke detection. Also, access-controlled egress doors in occupancies as required by Section 1008.1.4.4 must be capable of being automatically unlocked by activation of an automatic fire detection system, if one is installed.

[F] 907.3.3 Elevator emergency operation. Automatic fire detectors installed for elevator emergency operation shall be installed in accordance with the provisions of ASME A17.1 and NFPA 72.

- This section provides correlation with Section 607.1 of the IFC by making it clear that automatic fire detection devices used to initiate Phase I emergency recall of elevators are to be installed in accordance with both ASME A17.1 and NFPA 72.

[F] 907.3.4 Wiring. The wiring to the auxiliary devices and equipment used to accomplish the above fire safety functions shall be monitored for integrity in accordance with NFPA 72.

- In order to provide a reasonable level of integrity and reliability to the installation of automatic fire detection devices and related equipment installed to perform various fire safety functions in accordance with Section 907.3, this section requires that all wiring interconnected such devices and equipment be monitored for integrity in accordance with NFPA 72.

[F] 907.4 Initiating devices. Where manual or automatic alarm initiation is required as part of a fire alarm system, the initiating devices shall be installed in accordance with Sections 907.4.1 through 907.4.3.1.

- This section introduces Sections 907.4.1 through 907.4.3, which contain requirements for the various types of manual or automatic fire alarm-initiating devices.

[F] 907.4.1 Protection of fire alarm control unit. In areas that are not continuously occupied, a single smoke detector shall be provided at the location of each fire alarm control unit, notification appliance circuit power extenders, and supervising station transmitting equipment.

- Exception: Where ambient conditions prohibit installation of a smoke detector, a heat detector shall be permitted.

- This section requires a smoke detector at the fire alarm control unit. This is consistent with Section 10.15 of NFPA 72. This smoke detector will activate the fire alarm control unit and allow it to either notify occupants or transmit a signal to a remote monitoring location before the fire impairs the fire alarm control unit. The exception parallels Section 907.4.3 by allowing a heat detector to be installed in lieu of a smoke detector in areas where the ambient environment is hostile to smoke detectors and could lead to unwanted alarm activations. This exception is also allowed by NFPA 72.

[F] 907.4.2 Manual fire alarm boxes. Where a manual fire alarm system is required by another section of this code, it shall be activated by fire alarm boxes installed in accordance with Sections 907.4.2.1 through 907.4.2.6.

- This section specifies the requirements for manual fire alarm boxes that are part of a required manual fire alarm system.

[F] 907.4.2.1 Location. Manual fire alarm boxes shall be located not more than 5 feet (1524 mm) from the entrance to each exit. Additional manual fire alarm boxes shall be located so that travel distance to the nearest box does not exceed 200 feet (60 960 mm).

- Manual fire alarm boxes must be located in the path of egress and be readily accessible to the occupants. They must be located within 5 feet (1524 mm) of the entrance to each exit on every story of the building. This would include the need to locate manual fire alarm boxes near each horizontal exit, as well as entrances to stairs and exit doors to the exterior.

- Manual fire alarm boxes are located near exits so that an adequate number of devices are available in the path of egress to transmit an alarm in a timely manner. These locations also encourage the activation of a manual fire alarm box on the fire floor prior to entering the stair, resulting in the alarm being received from the actual fire floor and not another floor along the path of egress.

- The location also presumes that individuals will be evacuating the area where the fire originated. When evacuation of the fire area is unlikely, consideration could be given to putting manual fire alarm boxes in more convenient places. Examples of such instances would be officer stations in Group I-3 occupancies and care providers stations in Group I-2 occupancies.

- The 200-foot (60 960 mm) travel distance limitation
is consistent with the exit access travel distance permitted for most nonsprinklered occupancies. If the 200-foot (60 960 mm) travel distance to a manual fire alarm box is exceeded, even in a fully sprinklered building, additional manual fire alarm boxes would be required.

[F] 907.4.2.2 Height. The height of the manual fire alarm boxes shall be a minimum of 42 inches (1067 mm) and a maximum of 48 inches (1372 mm) measured vertically, from the floor level to the activating handle or lever of the box.

- Manual fire alarm boxes must be reachable by the occupants of the building. They must also be mounted high enough to reduce the likelihood of damage or false alarms from something accidentally striking the device. Therefore, manual fire alarm boxes must be mounted a minimum of 42 inches (1067 mm) and a maximum of 48 inches (1372 mm) above the floor level. The 48-inch (1372 mm) measurement corresponds to the maximum unobstructed side-reach height by a person in a wheelchair.

[F] 907.4.2.3 Color. Manual fire alarm boxes shall be red in color.

- Manual fire alarm boxes are to be painted or manufactured in a distinctive and traditional red color to provide a visual cue to help building occupants identify the device.

[F] 907.4.2.4 Signs. Where fire alarm systems are not monitored by a supervising station, an approved permanent sign shall be installed adjacent to each manual fire alarm box that reads: WHEN ALARM SOUNDS CALL FIRE DEPARTMENT.

Exception: Where the manufacturer has permanently provided this information on the manual fire alarm box.

- This section has limited application because, as indicated in Section 907.6.5, fire alarm systems generally must be monitored by an approved supervising station. When a system is not monitored, such as possibly a fire alarm system that is not required by code, adequate signage must be displayed to tell occupants what response actions must be taken. Most building occupants assume that when an alarm device is activated, the fire department will automatically be notified as well. The sign must be conspicuously located next to the manual fire alarm box unless it is mounted on the manual fire alarm box itself by the manufacturer.

[F] 907.4.2.5 Protective covers. The fire code official is authorized to require the installation of listed manual fire alarm box protective covers to prevent malicious false alarms or to provide the manual fire alarm box with protection from physical damage. The protective cover shall be transparent or red in color with a transparent face to permit visibility of the manual fire alarm box. Each cover shall include proper operating instructions. A protective cover that emits a local alarm signal shall not be installed unless approved. Protective covers shall not project more than that permitted by Section 1003.3.3.

- Although manual fire alarm boxes must be readily available to all occupants in buildings required to have a manual fire alarm system, this section allows the use of protective covers if they are approved by the fire code official. Protective covers are commonly used to reduce either the potential for intentional false alarms or vandalism. They also provide protection in locations where the manual fire alarm boxes may be exposed to physical damage, such as in gymnasiums, indoor tennis courts and the like.

[F] 907.4.2.6 Unobstructed and unobscured. Manual fire alarm boxes shall be accessible, unobstructed, unobscured and visible at all times.

- This section addresses the concern that manual fire alarm boxes be kept clear and unobstructed. It is recommended that a minimum of 3 feet (914 mm) be kept clear but more may be needed. NFPA 72 does address the installation to be unobstructed in Section 17.14.5 and states that manual fire alarm boxes be conspicuous, unobstructed and accessible. This requirement will assist during the design, construction, inspection and future maintenance of manual fire alarm boxes when they are located where they will be provided with enough space to access and will not be obstructed.

[F] 907.4.3 Automatic smoke detection. Where an automatic smoke detection system is required it shall utilize smoke detectors unless ambient conditions prohibit such an installation. In spaces where smoke detectors cannot be utilized due to ambient conditions, approved automatic heat detectors shall be permitted.

- Smoke detectors must be used, except when ambient conditions would prohibit their use. This section would allow a heat detector to be installed in lieu of a smoke detector in areas where the ambient environment is hostile to smoke detectors and could lead to unwanted alarm activations. The smoke detector manufacturer's literature will identify the limitations on the use of smoke detectors, including environmental conditions such as humidity, temperature and airflow.

[F] 907.4.3.1 Automatic sprinkler system. For conditions other than specific fire safety functions noted in Section 907.3, in areas where ambient conditions prohibit the installation of smoke detectors, an automatic sprinkler system installed in such areas in accordance with Section 903.3.1.1 or 903.3.1.2 and that is connected to the fire alarm system shall be approved as automatic heat detection.

- This section states that automatic heat detection is not required when buildings are fully sprinklered in accordance with NFPA 13 or 13R. The presence of a sprinkler system exempts areas where a heat detector can be installed in place of a smoke detector, such as in storage or furnace rooms. The sprinkler head in
FIRE PROTECTION SYSTEMS

this case essentially acts as a heat detection device. Note that this provision does not apply to the fire safety functions indicated in Section 907.3.

[F] 907.5 Occupant notification systems. A fire alarm system shall annunciate at the fire alarm control unit and shall initiate occupant notification upon activation, in accordance with Sections 907.5.1 through 907.5.2.3.4. Where a fire alarm system is required by another section of this code, it shall be activated by:

1. Automatic fire detectors.
2. Automatic sprinkler system water flow devices.
4. Automatic fire-extinguishing systems.

Exception: Where notification systems are allowed elsewhere in Section 907 to annunciate at a constantly attended location.

This section makes it clear that fire alarm system activation begins first by activating the fire alarm control unit, then by notifying the occupants of an alarm condition and then goes on to introduce all of the components of an occupant notification system contained in Sections 907.5.1 through 907.5.2.3.4.

It also lists the system components that are to act as alarm initiation devices. The exception is a recognition that there are places in the code where an alternative to occupant notification is an alarm notification at a constantly attended location. The exception is intended to clarify the code so that there is no question as to whether this general provision for alarm activation is superseded by the other sections addressing the alarm notification at a constantly attended location.

[F] 907.5.1 Presignal feature. A presignal feature shall not be installed unless approved by the fire code official and the fire department. Where a presignal feature is provided, a signal shall be annunciated at a constantly attended location approved by the fire department, in order that occupant notification can be activated in the event of fire or other emergency.

A presignal feature on a fire alarm system allows the occupant notification devices to activate in selected, constantly attended locations only and from which human intervention is required to activate a general occupant notification signal. Alternatively, this feature can be programmed to delay the general alarm notification for more than 1 minute before it will automatically be activated by the control panel. In either presignal scenario, remote transmission of the alarm signal to the fire department is immediate. See NFPA 72 for additional information on the presignal feature.

Improper use of the presignal feature has been a contributing factor in several multiple-death fire incidents. In most instances, the staff failed to activate the general alarm quickly and the occupants of the building were unaware of the fire. Therefore, the use of a presignal feature is discouraged by the code. A presignal feature may be used only if it is approved by the fire code official and the fire department.

[F] 907.5.2 Alarm notification appliances. Alarm notification appliances shall be provided and shall be listed for their purpose.

The code requires that fire alarm systems be equipped with approved alarm notification appliances so that in an emergency, the fire alarm system will notify the occupants of the need for evacuation or implementation of the fire emergency plan. Alarm notification devices required by the code are of two general types: visible and audible. Except for voice/alarm signaling systems, once the system has been activated, all visible and audible alarms are required to activate. Voice/alarm signaling systems are special signaling systems that are activated selectively in response to specific emergency conditions.

[F] 907.5.2.1 Audible alarms. Audible alarm notification appliances shall be provided and emit a distinctive sound that is not to be used for any purpose other than that of a fire alarm.

Exceptions:

1. Visible alarm notification appliances shall be allowed in lieu of audible notification appliances in critical care areas of Group I-2 occupancies.

2. Where provided, audible notification appliances located in each occupant evacuation elevator lobby in accordance with Section 3008.5.1 shall be connected to a separate notification zone for manual paging only.

To attract the attention of building occupants, audible alarms must be distinctive, using a sound that is unique to the fire alarm system and used for no other purpose than alerting occupants to a fire emergency. Other emergencies, such as tornados, etc., must be signaled by another sound different from the fire signal.

Exception 1 recognizes that the occupants in critical care areas of Group I-2 occupancies are usually incapacitated. The audible alarms may have the effect of unnecessarily disrupting the care recipients who are most likely not capable of self-preservation. Likewise, audible alarms in operating theaters of hospitals could be hazardous because an alarm activation could startle a surgeon during a delicate procedure. Critical care areas are also assumed to be adequately staffed at all times and ready to respond upon activation of a visible alarm device.

Exception 2 is intended to address the concern that automatic emergency voice/alarm messages do not interfere with operation of the two-way communication associated with the occupant evacuation elevators. Live voice messages would be appropriate in the lobbies.

[F] 907.5.2.1.1 Average sound pressure. The audible alarm notification appliances shall provide a sound pressure level of 15 decibels (dBA) above the average ambient sound level or
5 dBA above the maximum sound level having a duration of at least 60 seconds, whichever is greater, in every occupiable space within the building.

- To attract the attention of building occupants, this section requires that the distinctive audible alarms must be capable of being heard above the ambient noise level in a space. The indicated levels are considered the minimum pressure differential that will be perceivable by most people. It prescribes that the sound pressure level (SPL) for notification appliances shall be a minimum of 15 decibels measured in the A-scale (dBA) above the ambient SPL or 5 dBA above the maximum SPL in every space that can be occupied in a building. These SPLs are based on a minimum 1-minute measurement period. SPLs for Group R and I-1 occupancies, mechanical rooms and other occupancies are no longer stipulated as they had been in previous editions of the code.

The values mandated in Section 907.5.2.1.1 in previous editions of the code were not consistent with the notification appliance SPL requirements in NFPA 72. NFPA 72 requirements for the audible notification appliances are based on if the devices emit alert or evacuation tones, voice messages or audible notifications for exit markings. The provisions in Section 907.5.2.1.1 would apply to all notification appliances designed to operate in either public- or private-mode. In sleeping areas, the minimum SPL is no longer specified in Section 907.5.2.1.1; however, for smoke alarms, Section 907.2.11 and NFPA 72 require a minimum 75 dBA SPL at the pillow.

Also note that the 2010 American with Disabilities Act Standard for Accessible Design has an exception for medical care facilities following industry practice that will allow a dependence upon staff. The activation of either audible or visible alarms could be detrimental to the care recipients in locations like operating rooms and intensive or critical care units.

[F] 907.5.2.1.2 Maximum sound pressure. The maximum sound pressure level for audible alarm notification appliances shall be 110 dBA at the minimum hearing distance from the audible appliance. Where the average ambient noise is greater than 95 dBA, visible alarm notification appliances shall be provided in accordance with NFPA 72 and audible alarm notification appliances shall not be required.

- In no case may the sound pressure level exceed 110 dBA at the minimum hearing distance from the audible appliance. This is consistent with Americans with Disabilities Act (ADA) requirements. Sound pressures above that level can cause pain or even permanent hearing loss. In such cases, audible alarms are not required to be installed but visual alarms would be necessary to compensate for the lack of audibility.

It should also be noted that in certain work areas, Occupational Safety and Health Administration (OSHA) requires employees to wear hearing protection, possibly preventing them from hearing an audible alarm. Additionally, the noise factor in these areas is high enough that an audible alarm may not be discernible. In these areas, as well as in others, the primary method of indicating a fire can be by a visible signal. Employees must be capable of identifying such a signal as indicating a fire.

[F] 907.5.2.2 Emergency voice/alarm communication systems. Emergency voice/alarm communication systems required by this code shall be designed and installed in accordance with NFPA 72. The operation of any automatic fire detector, sprinkler waterflow device or manual fire alarm box shall automatically sound an alert tone followed by voice instructions giving approved information and directions for a general or staged evacuation in accordance with the building's fire safety and evacuation plans required by Section 404 of the International Fire Code. In high-rise buildings, the system shall operate on a minimum of the alarming floor, the floor above and the floor below. Speakers shall be provided throughout the building by paging zones. At a minimum, paging zones shall be provided as follows:

1. Elevator groups.
2. Exit stairways.
3. Each floor.
4. Areas of refuge as defined in Section 1002.1.

Exception: In Group I-1 and I-2 occupancies, the alarm shall sound in a constantly attended area and a general occupant notification shall be broadcast over the overhead page.

- The primary purpose of an emergency voice/alarm communication system is to provide dedicated manual and automatic facilities for the origination, control and transmission of information and instructions pertaining to a fire alarm emergency to the occupants of a building. This section identifies that notification speakers are required throughout the building with a minimum of one speaker in each paging zone where an emergency voice/alarm communication system is required. The system may sound a general alarm or be a selective system in which only certain areas of the building receive the alarm indication for staged evacuation. See Chapter 4 of the IFC for evacuation plan requirements. The intent is to provide the capability to send out selective messages to individual areas; however, it does not prohibit the same message to be sent to all areas. In high-rise buildings, a minimum area of notification must include the alarming floor and one floor above and one floor below it.

This section also identifies the minimum paging zone arrangement. This does not preclude further zone divisions for logical staged evacuation in accordance with an approved evacuation plan.

This section also indicates that the emergency voice/alarm system is to be initiated as all other fire alarm systems are initiated. The functional operation of the system begins with an alert tone (usually 3 to 10 seconds in duration) followed by the evacuation signal (message). It is important to remember that the voice alarm system is not an "audible alarm." It has its own specific criteria for installation and approval according to NFPA 72. Consequently the sound pres-
sure requirements for audible alarms do not apply to voice alarm systems. For voice alarm systems, the intent is communication and an understanding of what is being said, not volume. The exception is similar to the one to Section 907.5.2.1 and recognizes the supervised environment typical of institutional uses and the reliance placed on staff to act appropriately in an emergency. As is the case for most voice alarms, the key is in being able to deliver specific information to the people who can affect a safe egress—whether this is the public, employees, or both.

[F] 907.5.2.2.1 Manual override. A manual override for emergency voice communication shall be provided on a selective and all-call basis for all paging zones.

- The intent of this section is to provide the ability to transmit live voice instructions over any previously initiated signals or prerecorded messages for all zones. This would include the ability to override the voice message at once throughout the building or to be able to select individual paging zones for the message override.

[F] 907.5.2.2.2 Live voice messages. The emergency voice/alarm communication system shall also have the capability to broadcast live voice messages by paging zones on a selective and all-call basis.

- This would include the ability to provide the live voice message at once throughout the building or to be able to select individual paging zones to receive the message. Speakers used for background music must not be used unless specifically listed for fire alarm system use. NFPA 72 has additional requirements for the placement, location and audibility of speakers used as part of an emergency voice/alarm communication system.

[F] 907.5.2.2.3 Alternate uses. The emergency voice/alarm communication system shall be allowed to be used for other announcements, provided the manual fire alarm use takes precedence over any other use.

- In certain circumstances which should be approved by the fire code officials, the emergency voice/alarm communications system could be used to convey information other than fire alarm-related items. This could include severe weather warnings that might require evacuation or relocation, lockdown instructions (see commentary, Section 404.3.3 of the IFC) and similar approved messages. In the event of such usage, the system must respond immediately to manual fire alarm box activations.

[F] 907.5.2.2.4 Emergency voice/alarm communication captions. Where stadiums, arenas and grandstands are required to caption audible public announcements in accordance with Section 1108.2.7.2, the emergency/voice alarm communication system shall also be captioned. Prerecorded or live emergency captions shall be from an approved location constantly attended by personnel trained to respond to an emergency.

- This provision links the EV/ACS with the requirements for captioning in Section 1108.2.7.3. Section 1108.2.7.3 requires that stadiums, arenas and grandstands have 15,000 fixed seats to provide captioning for audible announcements (see commentary, Section 907.2.1.2).

[F] 907.5.2.2.5 Emergency power. Emergency voice/alarm communications systems shall be provided with an approved emergency power source.

- Because the emergency voice/alarm communication system is a critical aid in evacuating the building, the system must be connected to an approved emergency power source complying with Section 2702.

[F] 907.5.2.3 Visible alarms. Visible alarm notification appliances shall be provided in accordance with Sections 907.5.2.3.1 through 907.5.2.3.4.

Exceptions:

1. Visible alarm notification appliances are not required in alterations, except where an existing fire alarm system is upgraded or replaced, or a new fire alarm system is installed.

2. Visible alarm notification appliances shall not be required in exits as defined in Chapter 2.

3. Visible alarm notification appliances shall not be required in elevator cars.

- This section contains alarm system requirements for occupants who are hearing impaired. Visible alarm notification appliances are to be installed in conjunction with the audible devices and located and oriented so that they will display alarm signals throughout a space. It is not the intent of the code to offer visible alarm signals as an option to audible alarm signals. Both are required. However, the code acknowledges conditions where audible alarms may be of little or no value, such as when the ambient sound level exceeds 105 dBA. In such cases, Section 907.5.2.1, similar to NFPA 72, allows for visible alarm notification appliances in the area.

Exception 1 states that visible alarm devices are not required in previously approved existing fire alarm systems or as part of minor alterations to existing fire alarm systems. Extensive modifications to an existing fire alarm system such as an upgrade or replacement would require the installation of visible alarm devices even if the previous existing system neither had them nor required them. The main reason is a combination of simple economics and practical application. Many existing systems that do not have visible signal devices do not have the wiring capability to include such devices. To make the necessary changes to the existing system, a total replacement of the existing system may need to take place. In many cases this is
cost prohibitive. Thus, if the alteration is small, the system can be left as is, without the visual devices. The second consideration is scope. If the alteration involves only a limited area, it could be confusing to have part of the area equipped with visual devices and part without. This is not good practice, as the alarm could be confusing. If an entire floor is being altered, then it becomes subject to consideration for an upgrade to an alarm system with visual devices. If only an office is being remodeled, then the implication is that the upgrade to visual devices may not be warranted. This determination will be subjective in many cases and should be applied based on the life safety benefit and financial expenses involved and whether adequate audible devices are present for full coverage.

In Exception 2, visible alarm devices are not required in exit elements because of the potential distraction during evacuation. Exits, as defined in Chapter 2, could include interior exit stairways or exit passageways but not exit access corridors. In tall buildings, exiting may be phased based on alarm zone. If the alarm floor and adjacent floors are notified of the emergency but the remainder of the building is not, then a visual device in the stairway would be confusing to those people who may not be coming from the alarm floor.

Previously, some jurisdictions were requiring visible alarm notification appliances to be installed in elevator cars since there was no exception in the code or NFPA 72 to allow omission of this type of notification appliance in elevator cars. Exception 3 will eliminate any confusion regarding the need to install visible notification appliances in elevator cars. The rationale for not installing visible notification appliances in elevator cars is the same as for interior exit stairways; high light intensity from these notification appliances may cause confusion and disorientation. Also, elevator passengers are “captive” in that they cannot respond to such devices until the elevator arrives at its destination or is recalled by the Phase 1 emergency recall feature, which could lead to passenger panic.

[F] 907.5.2.3.1 Public and common areas. Visible alarm notification appliances shall be provided in public areas and common areas.

- Visible alarm notification appliances must provide coverage in all areas open to the public as well as all shared or common areas (e.g., corridors, public restrooms, shared offices, classrooms, medical exam rooms, etc.). Areas where visible alarm notification appliances are not required include private offices, mechanical rooms or similar spaces. The intent with this section is to replicate the provisions included in the Americans with Disabilities Act Accessibility Guidelines for Buildings and Facilities (ADAG).

[F] 907.5.2.3.2 Employee work areas. Where employee work areas have audible alarm coverage, the notification appliance circuits serving the employee work areas shall be initially designed with a minimum of 20-percent spare capacity to account for the potential of adding visible notification appliances in the future to accommodate hearing impaired employee(s).

- This section provides for spare capacity on notification circuits to allow for those with hearing impairments to be accommodated as necessary. This spare capacity is intended to eliminate the potential for overloading notification circuits when a hearing impaired person is hired and needs to be accommodated, but reduces the initial construction cost as such alarms may not be necessary in every situation. This section is intended to apply to employee work areas that are not common areas.

[F] 907.5.2.3.3 Groups I-1 and R-1. Group I-1 and R-1 dwelling units or sleeping units in accordance with Table 907.5.2.3.3 shall be provided with a visible alarm notification appliance, activated by both the in-room smoke alarm and the building fire alarm system.

- Fire alarm systems in Group I-1 and R-1 sleeping accommodations must be equipped with visible alarms to the extent stated in Table 907.5.2.3.3. The visible alarm notification devices in these rooms are to be activated by both the required in-room smoke alarm and the building fire alarm system. All visible alarm notification appliances in a building, however, need not be activated by individual room smoke alarms. It is not a requirement that the accessible sleeping units be provided with visible alarm notification appliances even though some elderly patients or residents may be both mobility and hearing impaired.

- This table specifies the minimum number of sleeping units that are to be equipped with visible and audible alarms. The numbers are based on the total number of sleeping accommodations in the facility. The requirements in this table are intended to be consistent with the ADAAG.

[F] 907.5.2.3.4 Group R-2. In Group R-2 occupancies required by Section 907 to have a fire alarm system, all dwelling units and sleeping units shall be provided with the capability to support visible alarm notification appliances in
accordance with Chapter 10 of ICC A117.1. Such capability shall be permitted to include the potential for future interconnection of the building fire alarm system with the unit smoke alarms, replacement of audible appliances with combination audible/visible appliances, or future extension of the existing wiring from the unit smoke alarm locations to required locations for visible appliances.

- Group R-2 occupancies with a fire alarm system are required to have the capability to support visual alarm notification appliances in accordance with Chapter 10 of ICC A117.1. This requirement has been in the IBC and the language added in the 2012 edition is intended to provide more specific guidance as to what is meant by "capability." Note that this requirement includes all dwelling and sleeping units, not just those classified as either Type A or B. Sections 1006.2 through 1006.4.4 of ICC A117.1 address smoke and fire alarm requirements as they pertain to accessible communication features. More specifically, Section 1006.2 states that when unit smoke detection is provided, it shall provide audible notification in compliance with NFPA 72. Section 1006.3 is focused upon buildings where fire alarm systems are provided. If a fire alarm system is provided in the building, ICC A117.1 requires that the wiring be extended to a point within the unit in the vicinity of the smoke detection system. Based upon the type of unit and the strategy used by the designer, this location may vary. Section 1006.4 addresses the visible alarm requirements specifically and has various issues it addresses, as follows:

1. Complies with Section 702 of ICC A117.1, which focuses on the requirements of NFPA 72, and that such notification devices be hardwired.

2. Addresses the fact that all visible notification devices be activated within the unit either when the smoke alarms in the unit activate or when that portion of the building fire alarm system in that portion of the building activate.

3. Allows the same visible notification for the smoke alarms in the unit and the building fire alarm system.

4. Prohibits the use of the visible notification for anything other than the operation of the smoke alarms in the unit or the building fire alarm system.

In terms of the specific capability requirements, this section has been clarified to provide direction as to what may be meant by bringing the wiring to the unit. There has been confusion in the past and it has been interpreted that all units are required to be prewired for visible appliances, which was not the intent of ICC A117.1. More specifically, now the requirements provide essentially three options for future capability, as follows:

- Potential for future interconnection of the building fire alarm system with the unit smoke alarms.
- Replacement of audible appliance with combination audible/visible appliances.
- Extension of wiring from the unit smoke alarm locations to required locations of visible appliances.

It is important to remember that the location of visible notification devices, if installed, are driven by the requirements of NFPA 72 and may vary the approach taken, based upon the configuration of the space.

[F] 907.6 Installation. A fire alarm system shall be installed in accordance with this section and NFPA 72.

- This section specifies the requirements for fire alarm system installation and also references the installation requirements of NFPA 72.

[F] 907.6.1 Wiring. Wiring shall comply with the requirements of NFPA 70 and NFPA 72. Wireless protection systems utilizing radio-frequency transmitting devices shall comply with the special requirements for supervision of low-power wireless systems in NFPA 72.

- Wiring for fire alarm systems must be installed so that it is secure and will function reliably in an emergency. The code requires that the wiring for fire alarm systems meet the requirements of NFPA 70 and NFPA 72. This requirement is in addition to the general requirements for electrical installations set forth in Chapter 27 of the IBC. For reliability, systems that use radio-frequency transmitting devices for signal transmission are required to have supervised transmitting and receiving equipment that conforms to the special requirements contained in NFPA 72. This requirement is in addition to the general requirements for supervision in Section 907.6.5.

[F] 907.6.2 Power supply. The primary and secondary power supply for the fire alarm system shall be provided in accordance with NFPA 72.

Exception: Back-up power for single-station and multiple-station smoke alarms as required in Section 907.2.11.4.

- The operation of fire alarm systems is essential to life safety in buildings and must be reliable in the event the normal power supply fails. For proper operation of fire alarm systems, this section requires that the primary and secondary power supplies comply with NFPA 72. This is in addition to the general requirements for electrical installations in Chapter 27. NFPA 72 offers three alternatives for secondary supply: a 24-hour storage battery; storage batteries with a 4-hour capacity and a generator or multiple generators.

NFPA 72 requires that the primary and secondary power supplies for remotely located control equipment essential to the system operation must conform to the requirements for primary and secondary power supplies for the main system. Also, NFPA 72 contains requirements for monitoring the integrity of primary power supplies and requires a backup power supply.

[F] 907.6.3 Zones. Each floor shall be zoned separately and a zone shall not exceed 22,500 square feet (2090 m²). The

9-78

2012 INTERNATIONAL BUILDING CODE® COMMENTARY
length of any zone shall not exceed 300 feet (91 440 mm) in any direction.

**Exception:** Automatic sprinkler system zones shall not exceed the area permitted by NFPA 13.

- Since the fire alarm system also aids emergency personnel in locating the fire, the system must be zoned to shorten response time to the fire location. Zoning is also critical if the fire alarm system initiates certain other fire protection systems or control features, such as smoke control systems.

  At a minimum, each floor of a building must constitute one zone of the system. If the floor area exceeds 22,500 square feet (2090 m²), additional zones per floor are required. The maximum length of a zone is 300 feet (91 440 mm).

  The exception states that NFPA 13 defines the maximum areas to be protected by one sprinkler system and that the sprinkler system need not be designed to meet the 22,500-square-foot (2090 m²) area limitations for a fire alarm system zone. For example, NFPA 13 permits a sprinkler system riser in a light-hazard occupancy to protect an area of 52,000 square feet (4831 m²) per floor. In accordance with the exception, a single workflow switch is installed on a single fire alarm system zone, which is acceptable. If other alarm-initiating devices are present, the floor area can be divided into separate zones to meet the 22,500-square-foot (2098 m²) limitation.

  It is not intended that this section apply to sprinkler systems. This section only applies where a fire alarm system is required in accordance with Section 907. Unless the building is categorized as a high rise and must comply with Section 907.6.3.2, the code does not mandate the zoning of sprinkler systems per floor. With today's fully addressable fire alarm systems, each detector effectively becomes its own zone. The intent with zoning is to identify and limit the search area for fire alarm systems. Addressable devices will indicate the precise location of the alarm condition, thereby eliminating the need for the zoning contemplated by this section when approved by the fire code official in accordance with Section 104.11.

[F] 907.6.3.1 Zoning indicator panel. A zoning indicator panel and the associated controls shall be provided in an approved location. The visual zone indication shall lock in until the system is reset and shall not be canceled by the operation of an audible-alarm silencing switch.

- The zoning indicator panel, which can be the fire alarm control unit or a separate fire alarm annunciator panel (FAAP), must be installed in a location approved by the fire code official. One of the key considerations in determining panel placement is whether or not the panel is located to permit ready access by emergency responders. Once an alarm-initiating device within a zone has been activated, the annunciation of the zone must lock in until the system is reset.

[F] 907.6.3.2 High-rise buildings. In high-rise buildings, a separate zone by floor shall be provided for each of the following types of alarm-initiating devices where provided:

1. Smoke detectors.
2. Sprinkler workflow devices.
4. Other approved types of automatic fire detection devices or suppression systems.

- High-rise buildings must have a separate zone by floor for each indicated type of alarm-initiating device. Although this feature may be desirable in all buildings, the incremental cost difference is substantially higher in low-rise buildings in which basic fire alarm systems are installed. State-of-the-art fire alarm systems installed in high-rise buildings are addressable and by their nature automatically provide this minimum zoning.

[F] 907.6.4 Access. Access shall be provided to each fire alarm device and notification appliance for periodic inspection, maintenance and testing.

- Automatic fire detectors, especially smoke detectors, require periodic cleaning to reduce the likelihood of malfunctions. Section 907.8 and NFPA 72 require inspection and testing at regular intervals. Access to perform the required inspections, necessary maintenance and testing is a particularly important consideration for those detectors that are installed within a concealed space, such as an air duct.

[F] 907.6.5 Monitoring. Fire alarm systems required by this chapter or by the International Fire Code shall be monitored by an approved supervising station in accordance with NFPA 72.

**Exception:** Monitoring by a supervising station is not required for:

1. Single- and multiple-station smoke alarms required by Section 907.2.11.
2. Smoke detectors in Group I-3 occupancies.
3. Automatic sprinkler systems in one- and two-family dwellings.

- Fire alarm systems required by Section 907 are required to be electrically supervised by one of the methods prescribed in NFPA 72.

  Exception 1 exempts single- and multiple-station smoke alarms from being supervised due to the potential for unwanted false alarms.

  Exception 2 recognizes a similar problem in Group I-3 occupancies. Accordingly, due to the concern over unwanted alarms, smoke detectors in Group I-3 occupancies need only sound an approved alarm signal that automatically notifies staff (see Section 907.2.6.3.1). Smoke detectors in such occupancies are typically subject to misuse and abuse, and frequent unwanted alarms would negate the effectiveness of the system.
Exception 3 clarifies that sprinkler systems in one- and two-family dwellings are not part of a dedicated fire alarm system and are typically designed in accordance with NFPA 13D, which does not require electrical supervision.

[F] 907.6.5.1 Automatic telephone-dialing devices. Automatic telephone-dialing devices used to transmit an emergency alarm shall not be connected to any fire department telephone number unless approved by the fire chief.

- Upon initiation of an alarm, supervisory or trouble signal, an automatic telephone-dialing device takes control of the telephone line for the reliability of transmission of all signals. The device, however, must not be connected to the fire department telephone number unless specifically approved by the fire department because that could disrupt any potential emergency (911) calls. NFPA 72 contains additional guidance on such devices, including digital alarm-communicator systems.

[F] 907.6.5.2 Termination of monitoring service. Termination of fire alarm monitoring services shall be in accordance with Section 901.9 of the International Fire Code.

- This is simply a cross link to a requirement in the IFC related to the termination of monitoring service. Section 901.9 requires the monitoring service itself to notify the fire code official of the service being terminated. Although the ultimate responsibility rests with the building owner, he or she is not cited in this section since if they discontinued the service, they would likely not understand the implications, and if they did, would have no incentive to contact the fire code official.

[F] 907.7 Acceptance tests and completion. Upon completion of the installation, the fire alarm system and all fire alarm components shall be tested in accordance with NFPA 72.

- A complete performance test of the fire alarm system must be conducted to determine that the system is operating as required by the code. The acceptance test must include a test of each circuit, alarm-initiating device, alarm notification appliance and any supplementary functions, such as activation of closers and dampers. The operation of the primary and secondary (emergency) power supplies must also be tested, as well as the supervisory function of the control panel. Section 901.5 assigns responsibility for conducting the acceptance tests to the owner or the owner’s representative.

NFPA 72 contains specific acceptance test procedures. Additional guidance on periodic testing and inspection can also be obtained from Section 907.8 and NFPA 72.

[F] 907.7.1 Single- and multiple-station alarm devices. When the installation of the alarm devices is complete, each device and interconnecting wiring for multiple-station alarm devices shall be tested in accordance with the smoke alarm provisions of NFPA 72.

- To determine that smoke alarms have been properly installed and are ready to function as intended, they must be actuated during an acceptance test. The test also confirms that interconnected detectors will operate simultaneously as required. The responsibility for conducting the acceptance tests rests with the owner or the owner representative as stated in Section 901.5.

[F] 907.7.2 Record of completion. A record of completion in accordance with NFPA 72 verifying that the system has been installed and tested in accordance with the approved plans and specifications shall be provided.

- In accordance with NFPA 72, this section requires a written statement from the installing contractor that the fire alarm system has been tested and installed in compliance with the approved plans and the manufacturer's specifications. Any deviations from the approved plans or the applicable provisions of NFPA 72 are to be noted in the record of completion.

[F] 907.7.3 Instructions. Operating, testing and maintenance instructions and record drawings ("as-builts") and equipment specifications shall be provided at an approved location.

- To permit adequate testing, maintenance and troubleshooting of the installed fire alarm system, an owner’s manual with complete installation instructions must be kept on site or in another approved location. The instructions include a description of the system, operating procedures and testing and maintenance requirements.

[F] 907.8 Inspection, testing and maintenance. The maintenance and testing schedules and procedures for fire alarm and fire detection systems shall be in accordance with Section 907.8 of the International Fire Code.

- Fire alarms and smoke detection systems are to be inspected, tested and maintained in accordance with Sections 907.9.1 through 907.9.5 of the IFC and the applicable requirements of NFPA 72. It is the building owner’s responsibility to keep these systems operable at all times.

SECTION 908
EMERGENCY ALARM SYSTEMS

[F] 908.1 Group H occupancies. Emergency alarms for the detection and notification of an emergency condition in Group H occupancies shall be provided in accordance with Section 414.7.

- Emergency alarm systems provide indication and warning of emergency situations involving hazardous materials. An emergency alarm system is required in all Group H occupancies, as indicated in Sections 5004.9 and 5005.4.4 of the IFC, as well as Group H-5 HPM facilities as indicated in Section 908.2. The Group H occupancy classification assumes the storage or use of hazardous materials exceeds the maximum allowable quantities specified in Tables 307.1(1) and 307.1(2).

An emergency alarm system should include an emergency alarm-initiating device outside each inte-
rior door of hazardous material storage areas, a local alarm device and adequate supervision.

Even though ozone gas-generator rooms (see Section 908.4), repair garages (see Section 908.5) and refrigeration systems (see Section 908.6) are not typically classified as Group H occupancies, the potential hazards associated with these occupancy conditions are great enough to require additional means of early warning detection.

[F] 908.2 Group H-5 occupancy. Emergency alarms for notification of an emergency condition in an HPM facility shall be provided as required in Section 415.10.3.5. A continuous gas detection system shall be provided for HPM gases in accordance with Section 415.10.7.

- In addition to hazardous material storage areas as regulated by Section 2704.9 of the IFC, Section 2703.12.1 of the IFC also requires emergency alarms for service corridors, exit access corridors and exit stairways because of the potential transport of hazardous materials through these areas. Section 2703.13 of the IFC requires a continuous gas detection system for early detection of leaks in areas where HPM gas is used. Gas detection systems are required to initiate a local alarm and transmit a signal to the emergency control station upon detection (see commentary, Sections 2703.12 and 2703.13 of the IFC).

[F] 908.3 Highly toxic and toxic materials. A gas detection system shall be provided to detect the presence of highly toxic or toxic gas at or below the permissible exposure limit (PEL) or ceiling limit of the gas for which detection is provided. The system shall be capable of monitoring the discharge from the treatment system at or below one-half the immediately dangerous to life and health (IDLH) limit.

Exception: A gas-detection system is not required for toxic gases when the physiological warning threshold level for the gas is at a level below the accepted PEL for the gas.

- A gas detection system in the room or area utilized for indoor storage or the use of highly toxic or toxic gases provides early notification of a leak that is occurring before the escaping gas reaches hazardous exposure concentration levels. The exception recognizes that certain toxic compressed gases do not pose a severe exposure hazard. Those toxic gases whose properties under standard conditions are still below the 8-hour weighted average concentration for the permitted exposure limit (PEL) are exempt from the requirement for a gas detection system.

This section also specifies the discharge requirements for treatment system performance to establish a maximum allowable concentration of highly toxic or toxic gases at the point of discharge to the atmosphere. The concentration level of one-half the immediately dangerous to life and health (IDLH) limit represents a minimum acceptable level of dilution at the point of discharge where the location of discharge is away from the general public. Where the treatment system processes more than one type of compressed gas, the maximum allowable concentration must be based on the release rate, quantity and IDLH for the gas that poses the worst-case release scenario.

[F] 908.3.1 Alarms. The gas detection system shall initiate a local alarm and transmit a signal to a constantly attended control station when a short-term hazard condition is detected. The alarm shall be both visible and audible and shall provide warning both inside and outside the area where gas is detected. The audible alarm shall be distinct from all other alarms.

Exception: Signal transmission to a constantly attended control station is not required when not more than one cylinder of highly toxic or toxic gas is stored.

- The required local alarm is intended to alert occupants to a hazardous condition in the vicinity of the inside storage room or area. The alarm is not intended to be an evacuation alarm; however, it is required to be monitored to hasten emergency personnel response. The exception allows the omission of supervision for the gas detection system where a single cylinder of highly toxic or toxic gas is stored. It should be noted that this section is only intended to apply when the maximum allowable quantity of a specific gas per control area is exceeded. A single cylinder would not require a gas detection system if it contained less than the maximum allowable quantities indicated in Tables 307.1(1) and 307.1(2).

[F] 908.3.2 Shutoff of gas supply. The gas detection system shall automatically close the shutoff valve at the source on gas supply piping and tubing related to the system being monitored for whichever gas is detected.

Exception: Automatic shutdown is not required for reactors utilized for the production of highly toxic or toxic compressed gases where such reactors are:

1. Operated at pressures less than 15 pounds per square inch gauge (psig) (103.4 kPa).
2. Constantly attended.
3. Provided with readily accessible emergency shutoff valves.

- Actuation of the gas detection system is required to close automatically all valves controlling highly toxic or toxic gases. This degree of protection is deemed necessary to provide a life safety measure in areas where highly toxic and toxic gases are being utilized for filling, dispensing or other operations.

In most situations, dispensing and use operations are assumed to be constantly attended because of the potential hazard and need to monitor operations involving highly toxic and toxic compressed gases.

The exception recognizes the decreased level of hazard for constantly attended operations involving reactors in manufacturing processes with low operating pressures. With low operating pressures, the rate at which the volume of the affected space would be
FIRE PROTECTION SYSTEMS

filled by the released gas is minimized. Readily accessible manual shutoff valves would thus be permitted in lieu of an automatic-closing shutoff valve.

[F] 908.3.3 Valve closure. The automatic closure of shutoff valves shall be in accordance with the following:

1. When the gas-detection sampling point initiating the gas detection system alarm is within a gas cabinet or exhausted enclosure, the shutoff valve in the gas cabinet or exhausted enclosure for the specific gas detected shall automatically close.

2. Where the gas-detection sampling point initiating the gas detection system alarm is within a gas room and compressed gas containers are not in gas cabinets or exhausted enclosures, the shutoff valves on all gas lines for the specific gas detected shall automatically close.

3. Where the gas-detection sampling point initiating the gas detection system alarm is within a piping distribution manifold enclosure, the shutoff valve for the compressed container of specific gas detected supplying the manifold shall automatically close.

Exception: When the gas-detection sampling point initiating the gas detection system alarm is at a use location or within a gas valve enclosure of a branch line downstream of a piping distribution manifold, the shutoff valve in the gas valve enclosure for the branch line located in the piping distribution manifold enclosure shall automatically close.

This section specifies the conditions where the shutoff valve for the gas supply is required to automatically close. The requirement depends on the location of the gas detection sampling point, which would initiate the actuation of the gas detection system, and the use of gas cabinets, exhaust enclosures or a piping distribution manifold enclosure.

[F] 908.4 Ozone gas-generator rooms. Ozone gas-generator rooms shall be equipped with a continuous gas-detection system that will shut off the generator and sound a local alarm when concentrations above the PEL occur.

To monitor the potential buildup of dangerous levels of ozone, a gas detection system is required to, upon actuation, shut off the generator and sound a local alarm. Ozone gas generators are commonly used in water treatment applications. The ozone gas-generator room should not be a normally occupied area or be used for the storage of combustibles or other hazardous materials. Section 6005 of the IFC contains additional requirements for ozone gas generators.

[F] 908.5 Repair garages. A flammable-gas detection system shall be provided in repair garages for vehicles fueled by nonodorized gases in accordance with Section 406.8.5.

As indicated in Section 406.8.5, an approved flammable-gas detection system is required for garages used for repair of vehicles fueled by nonodorized gases, such as hydrogen and nonodorized LNG. To prevent a hazardous potential buildup of flammable gas caused by normal leakage and use conditions, the flammable-gas detection system is required to activate when the level of flammable gas exceeds 25 percent of the lower explosive limit (LEL) (see commentary, Section 406.8.5).

[F] 908.6 Refrigerant detector. Machinery rooms shall contain a refrigerant detector with an audible and visual alarm. The detector, or a sampling tube that draws air to the detector, shall be located in an area where refrigerant from a leak will concentrate. The alarm shall be actuated at a value not greater than the corresponding TLV-TWA values for the refrigerant classification indicated in the International Mechanical Code. Detectors and alarms shall be placed in approved locations.

A refrigerant-specific detector is required for the purpose of leak detection, early warning and actuation of emergency exhaust systems. Depending on the density of the refrigerants, leakage may collect near the floor, near the ceiling or disperse equally throughout. Refrigerant detector locations must be carefully considered. Most refrigerants are heavier than air; thus, floor depressions and pits are natural areas for accumulation. The code is silent on the location of sensors due to the endless variety of equipment room designs. The key to properly locating a detector in the machinery room is to remember that occupant safety is the primary objective, and the danger is in breathing refrigerant. Placing the sensor below the common breathing height of 5 feet (1525 mm) provides an additional safety margin because all commonly used halocarbon refrigerants are three to five times heavier than air. When undistributed by airflow, such escaping refrigerant will fall to the floor, seeking the lowest levels, and fill the room from the bottom up. Since pits, stairwells or trenches are likely to fill with refrigerant first, detectors should be also be placed in any of these areas that may be occupied. The alarm actuation threshold is dictated by the TLV-TWA values for the refrigerant classification in accordance with Table 1103.1 of the IMC.

Manufacturer’s instructions for detectors provide installation guidance for the location and required number of detectors for any given room size.

The exception recognizes that ammonia refrigerant is “self-alarming” because of its strong odor and that ammonia machinery rooms are required to be continuously ventilated in accordance with the IMC.

Most general machinery rooms are unoccupied for long periods of time. Because of this, a refrigeration leak may go undetected, allowing a buildup of refrigerant that can pose a threat to the building occupants and the maintenance personnel who will be required to enter the machinery room. Also, the refrigerants may or may not be detectable by the sense of smell, depending upon the chemical nature and concentration in air of the refrigerant. This can be especially critical when a toxic refrigerant is used in the refrigeration system.

There are three levels of refrigerant exposure that are defined by the American Conference of Govern-
ment Industrial Hygienists (ACGIH). Level 1 is the allowable exposure limit (AEL), which is the level at which a person can be exposed for 8 hours per day for 40 hours per week without having an adverse effect on health. At this level, a person exposed to the refrigerant should not suffer any adverse health effects. Level 2 is the short-term exposure limit (STEL), which is defined as three times the AEL. At this level, a person should not be exposed for more than 30 minutes at a time. Persons working in a machinery room having this concentration of refrigerant should be equipped with respiratory protection. Level 3 is the emergency exposure limit (EEL). At this level, persons should not be in the room without a self-contained breathing apparatus.

Early detection of leaking refrigerant is dependent upon the location of the refrigerant detectors. If improperly located, a refrigerant leak could go undetected for an undesirable period of time, thus allowing a significant amount of refrigerant to escape. It is therefore advantageous to locate the detectors in positions that will provide early detection and minimize the amount of refrigerant leakage.

Factors to be considered when choosing locations for detectors are the airflow patterns of the room, the particular refrigerant density and the fact that the primary hazard to the occupants is through inhalation. Specifically, halocarbon refrigerants are oxygen displacers; that is, they are heavier than air and will occupy the lowest areas of the room first. This suggests that the location of detectors should be below the breathing zone height. Additionally, detectors should be located so as to prevent the normal ventilation system from interfering with detection. Placing detectors between the refrigeration system and exhaust fan inlets should help to ensure that the presence of refrigerant will be detected. Depending on the size of the machinery room and the number and type of refrigeration systems, more than one detector may be necessary. Manufacturer’s installation instructions for the refrigeration detection system should be followed when choosing the location and number of sensors for a particular machinery room application.

[F] 908.7 Carbon monoxide alarms. Group I or R occupancies located in a building containing a fuel-burning appliance or in a building which has an attached garage shall be equipped with single-station carbon monoxide alarms. The carbon monoxide alarms shall be listed as complying with UL 2034 and be installed and maintained in accordance with NFPA 720 and the manufacturer’s instructions. An open parking garage, as defined in Chapter 2, or an enclosed parking garage ventilated in accordance with Section 404 of the International Mechanical Code shall not be considered an attached garage.

Exception: Sleeping units or dwelling units which do not themselves contain a fuel-burning appliance or have an attached garage, but which are located in a building with a fuel-burning appliance or an attached garage, need not be equipped with single-station carbon monoxide alarms provided that:

1. The sleeping unit or dwelling unit is located more than one story above or below any story which contains a fuel-burning appliance or an attached garage;
2. The sleeping unit or dwelling unit is not connected by duct work or ventilation shafts to any room containing a fuel-burning appliance or to an attached garage; and
3. The building is equipped with a common area carbon monoxide alarm system.

Section 908.7 of both the 2012 code and IFC contains requirements for carbon monoxide (CO) detectors in all residential (Group R) and institutional (Group I) occupancies. These provisions apply to new construction and a similar requirement was added into the IFC to deal with existing buildings. The retroactive provisions in Section 1106.1 of the IFC apply to existing buildings classified as Group R or I in jurisdictions adopting the 2012 IFC.

These provisions were added to the code and the IFC to be consistent with the requirements for carbon monoxide (CO) detectors in all new construction of one- and two-family dwellings that had been added to the IRC in the 2009 edition. Another reason for its approval was technical data in a 1998 article published by the Journal of the American Medical Association. The particular paper stated that approximately 2,100 deaths occur annually as a result of CO poisoning. That annual number is based on the findings of a paper prepared by the U.S. Department of Health Centers for Disease Control (CDC). The referenced paper documented epidemiological research by two CDC physicians who examined 56,133 death certificates over a 10-year period. Excluding suicides, homicides, structure fires and deaths resulting from CO poisoning in motor vehicles, the death rate steadily decreased for the sample period, from a value of 1513 people in 1979 to 878 in 1988. The highest death rates occurred in winter and among males, African Americans, the elderly and residents in northern states.

CO is a colorless, tasteless, odorless gas that interrupts the attachment of oxygen molecules to hemoglobin in blood cells and can cause headaches, confusion and dizziness. At higher concentrations CO can cause loss of consciousness and eventual death. Exposures above 100 parts/million are dangerous to human health. It is not a Toxic or Highly Toxic gas as defined in Chapter 2 but is classified as a Flammable gas.

Section 908.7 requires the installation of a CO alarm in any new Group I or R occupancy when it contains a fuel-burning appliance or it has an attached garage. As mentioned previously, Section 1103.9 of the IFC retroactively prescribes the installation of CO alarms in existing Group I and R occupan-
smokes. CO alarms are not required in open or enclosed parking garages ventilated in accordance with Section 404. The wording of Sections 908.7 and 1106.1 of the IFC do not require the installation of single-station CO alarms when the building does not contain fuel-burning appliances or have an attached garage. The exception indicates that a single-station CO alarm is not required in each sleeping or dwelling unit when they are located one or more stories above or below the floor or level housing the fuel-burning appliance or an attached garage and there are no ducts or ventilation shafts that connect between the unit and the fuel-burning appliance or attached garage. However, in such a building, a common area CO detection system is required. Such a system would be required to comply with the requirements of NFPA 72 and NFPA 720, Standard for the Installation of Carbon Monoxide (CO) Warning Equipment in Dwelling Units, including the installation of listed detectors and occupant notification devices.

CO alarms installed in accordance with the code are listed in accordance with UL 2034, Standard for Single and Multiple Station Carbon Monoxide Alarms. They are designed to initiate an audible alarm when the level of CO is below that which can cause a loss of the ability to react to the dangers of CO exposure. UL specifies that CO alarms activate at a level where the CO concentration over a given period of time can achieve 10 percent carboxyhemoglobin (COHb) in the body. 10 percent COHb will not cause physiological injury, but is a level at which increases in the CO concentration will begin to affect the human body.

Unless listed as low-power wireless, CO alarms require a primary and secondary power supply. The primary power supply is utility power and secondary power supply is typically a battery. NFPA 720 requires a CO alarm outside of each sleeping unit in the immediate vicinity of the bedroom and on every occupiable level of a dwelling, including basements. CO alarms are not required in attics or crawl spaces. When a combination CO/smoke alarm is provided, the fire alarm signal takes precedence over any other alarm signals. NFPA 720 requires the CO alarm be capable of transmitting a distinct audible signal that is different than the smoke alarm signal.

[F] 908.7.1 Carbon monoxide detection systems. Carbon monoxide detection systems, which include carbon monoxide detectors and audible notification appliances, installed and maintained in accordance with this section for carbon monoxide alarms and NFPA 720 shall be permitted. The carbon monoxide detectors shall be listed as complying with UL 2075.

The purpose of this section is simply to recognize that a carbon monoxide detection system can be used in lieu of carbon monoxide alarms. This is allowed when in compliance with NFPA 720 and the listing of the detectors is in compliance with UL2075. Note that CO detectors have a different listing requirement than CO alarms.

SECTION 909
SMOKE CONTROL SYSTEMS

[F] 909.1 Scope and purpose. This section applies to mechanical or passive smoke control systems when they are required by other provisions of this code. The purpose of this section is to establish minimum requirements for the design, installation and acceptance testing of smoke control systems that are intended to provide a tenable environment for the evacuation or relocation of occupants. These provisions are not intended for the preservation of contents, the timely restoration of operations or for assistance in fire suppression or overhaul activities. Smoke control systems regulated by this section serve a different purpose than the smoke- and heat-venting provisions found in Section 910. Mechanical smoke control systems shall not be considered exhaust systems under Chapter 5 of the International Mechanical Code.

This section is clarifying the intent of smoke control provisions, which is to provide a tenable environment to occupants during evacuation and relocation and not to protect the contents, enable timely restoration of operations or facilitate fire suppression and overhaul activities. There are provisions for high-rise buildings in Section 403.4.6 that are focused upon the removal of smoke for post fire and overhaul operations, which is very different than the smoke control provisions in Section 909. Another element addressed in this section is that smoke control systems serve a different purpose than smoke and heat vents (see Section 910). This eliminates any confusion that smoke and heat vents can be used as a substitution for smoke control. Additionally, a clarification is provided to note that smoke control systems are not considered an exhaust system in accordance with Chapter 5 of the IMC. This is due to the fact that such systems are unique in their operation and are not necessarily designed to exhaust smoke but are focused upon tenability for occupants during egress. It should be noted that the smoke control provisions are duplicated in Chapter 5 of the IMC.

It is important to note that these provisions only apply when smoke control is required by other sections of the code. The code requires smoke management within atrium spaces (see Section 404.5) and underground buildings (see Section 405.5). High-rise facilities require smokeproof exit enclosures in accordance with Sections 909.20 and 1019.1.8 (see Section 403.5.4). Also, covered mall buildings that contain atriums that connect more than two stories require smoke control (see Section 402.10).

Section 909 focuses primarily on mechanical smoke control systems, but there are many instances within the code where smoke is required to be managed in a passive way through the use of concepts such as smoke compartments. Smoke compartments are formed through the use of smoke barriers in accordance with Section 709. Smoke barriers can be used simply as a passive smoke management system or can be a design component of a mechanical smoke control system in accordance with Section
909. Some examples of occupancies requiring passive systems include hospitals, nursing homes and similar facilities (Group I-2 occupancies) and detention facilities (Group I-3 occupancies) (see Sections 407.4 and 408.6).

In some cases, mechanical smoke control in accordance with Section 909 is allowed as an option for compliance. More specifically if a Group I-3 contains windowless areas of the facility, natural or mechanical smoke management is required (see Section 408.9).

In the last several years, smoke control provisions have become more complex. The reason is related to the fact that smoke is a complex problem, while a generic solution of six air changes has repeatedly and scientifically been shown to be inadequate. Six air changes per hour does not take into account factors such as buoyancy; expansion of gases; wind; the geometry of the space and of communicating spaces; the dynamics of the fire, including heat release rate; the production and distribution of smoke and the interaction of the building systems.

Smoke control systems can be either passive or active. Active systems are sometimes referred to as mechanical. Passive smoke control systems take advantage of smoke barriers surrounding the zone in which the fire event occurs or high bay areas that act as reservoirs to control the movement of smoke to other areas of the building. Active systems utilize pressure differences to contain smoke within the event zone or exhaust flow rates sufficient to slow the descent of the upper-level smoke accumulation to some predetermined position above necessary exit paths through the event zone. On rare occasions, there is also a possibility of controlling the movement of smoke horizontally by opposed airflow, but this method requires a specific architectural geometry to function properly that does not create an even greater hazard.

Essentially, there are three methods of mechanical or active smoke control that can be used separately or in combination within a design: pressurization, exhaust and, in rare and very special circumstances, opposed airflow.

Of course, all of these active approaches can be used in combination with the passive method.

Typically, the mechanical pressurization method is used in high-rise buildings when pressurizing stairways and for zoned smoke control. Pressurization is not practical in large open spaces such as atriums or malls, since it is difficult to develop the required pressure differences due to the large volume of the space.

The exhaust method is typically used in large open spaces such as atriums and malls. As noted, the pressurization method would not be practical within large spaces. The opposed airflow method, which basically uses a velocity of air horizontally to slow the movement of smoke, is typically applied in combination with either a pressurization method or exhaust method within hallways or openings into atriums and malls.

The application of each of these methods will be dependent on the specifics of the building design. Smoke control within a building is fundamentally an architecturally driven problem. Different architectural geometries first dictate the need or lack thereof for smoke control, and then define the bounds of available solutions to the problem.

[F] 909.2 General design requirements. Buildings, structures or parts thereof required by this code to have a smoke control system or systems shall have such systems designed in accordance with the applicable requirements of Section 909 and the generally accepted and well-established principles of engineering relevant to the design. The construction documents shall include sufficient information and detail to adequately describe the elements of the design necessary for the proper implementation of the smoke control systems. These documents shall be accompanied by sufficient information and analysis to demonstrate compliance with these provisions.

This section simply states that when smoke control systems are required by the code, the design is required to be in accordance with the provisions of this section. As noted in the commentary to Section 909.1, there are instances within the code that have smoke management systems that are purely passive in nature and do not reference Section 909.

This section stresses that designs in accordance with this section need to follow "generally accepted and well-established principles of engineering relevant to the design," essentially requiring a certain level of qualifications in the applicable areas of engineering to prepare such designs. The primary engineering disciplines tend to be fire engineering and mechanical engineering. It should be noted that each state in the U.S. typically requires minimum qualifications to undertake engineering design. Two important resources when designing smoke control systems are the International Code Council's (ICC) A Guide to Smoke Control in the 2006 IBC and American Society of Heating, Refrigerating and Air-Conditioning Engineers' (ASHRAE) Design of Smoke Management Systems. Additionally, Section 909.8 requires the use of NFPA 92B for the design of smoke control systems using the exhaust method. This standard has many relevant aspects beyond the design that are beneficial. In particular, Annex B provides resources in terms of determination of fire size for design. ICC'S A Guide to Smoke Control in the 2006 IBC also provides guidance on design fires.

A key element covered in this section is the need for detailed and clear construction documents so that the system is installed correctly. In most complex designs, the key to success is appropriate communication to the contractors as to what needs to be installed. The more complex a design becomes, the more likely there is to be construction errors. Most smoke control systems are complex, which is why
special inspections in accordance with Section 909.3 and Chapter 17 are critical for smoke control systems. Additionally, in order for the design to be accepted, analyses and justifications need to be provided in enough detail to evaluate for compliance. Adequate documentation is critical to the commissioning, inspection, testing and maintenance of smoke control systems and significantly contributes to the overall reliability and effectiveness of such systems.

[F] **909.3 Special inspection and test requirements.** In addition to the ordinary inspection and test requirements which buildings, structures and parts thereof are required to undergo, smoke control systems subject to the provisions of Section 909 shall undergo special inspections and tests sufficient to verify the proper commissioning of the smoke control design in its final installed condition. The design submission accompanying the construction documents shall clearly detail procedures and methods to be used and the items subject to such inspections and tests. Such commissioning shall be in accordance with generally accepted engineering practice and, where possible, based on published standards for the particular testing involved. The special inspections and tests required by this section shall be conducted under the same terms in Section 1704.

- Due to the complexity and uniqueness of each design, special inspection and testing must be conducted. The designer needs to provide specific recommendations for special inspection and testing within his or her documentation. In fact, the code specifies in Chapter 17 that special inspection agencies for smoke control have expertise in fire protection engineering, mechanical engineering and certification as air balancers. Since the designs are unique to each building, there probably will not be a generic approach available to inspect and test such systems. The designer can and should, however, use any available published standards or guides when developing the special inspection and testing requirements for that particular design. ICC's A Guide to Smoke Control in the 2006 IBC provides some background on such inspections. Also, ASHRAE Guideline 5 is a good starting place, but only as a general outline. In addition, NFPA 92A and NFPA 92B also have extensive testing, documentation and maintenance requirements that may be a good resource. NFPA 92B is referenced in Section 909.8 for the design of smoke control systems using the exhaust method. Each system will require a unique commissioning plan that can be developed only after careful and thoughtful examination of the final design and all of its components and interrelationships. Generally, these provisions may be included in design standards or engineering guides.

[F] **909.4 Analysis.** A rational analysis supporting the types of smoke control systems to be employed, their methods of operation, the systems supporting them and the methods of construction to be utilized shall accompany the submitted construction documents and shall include, but not be limited to, the items indicated in Sections 909.4.1 through 909.4.6.

- This section indicates that simply determining airflow, exhaust rates and pressures to maintain tenable conditions is not adequate. There are many factors that could alter the effectiveness of a smoke control system, including stack effect, temperature effect of fire, wind effect, heating, ventilating and air-conditioning (HVAC) system interaction and climate, as well as the placement, quantity of inlets/outlets and velocity of supply and exhaust air. These factors are addressed in the sections that follow. Additionally, the duration of operation of any smoke control system is mandated at a minimum of 20 minutes or 1.5 times the egress time, whichever is less. The code cannot reasonably anticipate every conceivable building arrangement and condition the building may be subject to over its life and must depend on such factors being addressed through a rational analysis.

[F] **909.4.1 Stack effect.** The system shall be designed such that the maximum probable normal or reverse stack effect will not adversely interfere with the system's capabilities. In determining the maximum probable stack effect, altitude, elevation, weather history and interior temperatures shall be used.

- Stack effect is the tendency for air to rise within a heated building when the temperature is colder on the exterior of the building. Reverse stack effect is the tendency for air to flow downward within a building when the interior is cooler than the exterior of the building. This air movement can affect the intended operation of a smoke control system. If stack effect is great enough, it may overcome the pressures determined during the design analyses and allow smoke to enter areas outside the zone of origin (see Figure 909.4.1).

[F] **909.4.2 Temperature effect of fire.** Buoyancy and expansion caused by the design fire in accordance with Section 909.9 shall be analyzed. The system shall be designed such that these effects do not adversely interfere with the system's capabilities.

- This section requires that the design account for the effect temperature may have on the success of the system. When air or any gases are heated they will expand. This expansion makes the gases lighter and therefore more buoyant. The buoyancy of hot gases is important when the design is to exhaust such gases from a location in or close to the ceiling; therefore, if sprinklers are part of the design, as required by Section 909, the gases may be significantly cooler than an unsprinklered fire, making it more difficult to remove the smoke and alter the plume dynamics. The fact that air expands when heated needs to be accounted for in the design.

When using the pressurization method, the expansion of hot gases needs to be accounted for, since it will take a larger volume of air to create the neces-
sary pressure differences to maintain the area of fire origin in negative pressure. The expansion of the gases has the effect of pushing the hot gases out of the area of fire origin. Since sprinklers will tend to cool the gases, the effect of expansion is lower. The pressure differences required in Section 909.6.1 are specifically based on a sprinklered building. If the building is nonsprinklered, higher pressure differences may be required. The minimum pressure difference for certain unsprinklered ceiling height buildings is as follows:

<table>
<thead>
<tr>
<th>Ceiling height (feet)</th>
<th>Minimum pressure difference (inch water gage)</th>
</tr>
</thead>
<tbody>
<tr>
<td>9</td>
<td>.10</td>
</tr>
<tr>
<td>15</td>
<td>.14</td>
</tr>
<tr>
<td>21</td>
<td>.18</td>
</tr>
</tbody>
</table>

This is a very complex issue that needs to be part of the design analysis. It needs to address the type and reaction of the fire protection systems, ceiling heights and the size of the design fire.

[F] 909.4.3 Wind effect. The design shall consider the adverse effects of wind. Such consideration shall be consistent with the wind-loading provisions of Chapter 16.

- The effect of wind on a smoke control system within a building is very complex. It is generally known that wind exerts a load upon a building. The loads are looked at as windward (positive pressure) and leeward (negative pressure). The velocity of winds will vary based on the terrain and the height above grade; therefore, the height of the building and surrounding obstructions will have an effect on these velocities. These pressures alter the operation of fans, especially propeller fans, thus altering the pressure differences and airflow direction in the building. There is not an easy solution to dealing with these effects. In fact, little research has been done in this area.

- It should be noted that in larger buildings a wind study is normally undertaken for the structural design. The data from those studies can be used in the analysis of the effects on the pressures and airflow within the building with regard to the performance of the smoke control system.

[F] 909.4.4 HVAC systems. The design shall consider the effects of the heating, ventilating and air-conditioning (HVAC) systems on both smoke and fire transport. The analysis shall include all permutations of systems status. The design shall consider the effects of the fire on the HVAC systems.

- If not properly configured to shut down or included as part of the design, the HVAC system can alter the smoke control design. More specifically, if dampers are not provided between smoke zones within the HVAC system ducts, smoke could be transported from one zone to another. Additionally, if the HVAC system places more supply air than assumed for the smoke control system design, the velocity of the air may adversely affect the fire plume or a positive pressure may be created. Generally, an analysis of the smoke control design and the HVAC system in all potential modes should occur and be noted within the design documentation as well as incorporated into inspection, testing and maintenance procedures. This is critical as these systems need to be maintained and tested to help ensure that they operate and shut down systems as required.

[F] 909.4.5 Climate. The design shall consider the effects of low temperatures on systems, property and occupants. Air inlets and exhausts shall be located so as to prevent snow or ice blockage.

- This section is focused on properly protecting equipment from weather conditions that may affect the reliability of the design. For instance, extremely cold or hot air may damage critical equipment within the sys-
FIRE PROTECTION SYSTEMS

tem when pulled directly from the outside. Some list-
ings of duct smoke detectors are for specific tem-
erature ranges; therefore, placing such detec-
tors within areas exposed to extreme temperatures
may void the listing. Also, the equipment and air
inlets and outlets should be designed and located so
as to not collect snow and ice that could block air
from entering or exiting the building.

[F] 909.4.6 Duration of operation. All portions of active or
passive smoke control systems shall be capable of continued
operation after detection of the fire event for a period of not
less than either 20 minutes or 1.5 times the calculated egress
time, whichever is less.

• The intent of the smoke control provisions is to pro-
provide a tenable environment for occupants to either evacu-
ate or relocate to a safe place. Evacuation and relocation
activities include notifying occupants, possible investigation
for occupants, decision time and the actual travel time. In order to achieve
this goal, the code has established 20 minutes or 1.5
times the calculated egress time, whichever is less,
as a minimum time for evacuation or relocation. Basi-
cally this allows a designer to undertake an analysis to
more closely determine the necessary time
required. The code provides a safety factor of 1.5
times the egress time to account for uncertainty
related to human behavior. It is stressed that the 20-
minute duration as well as the calculated egress time,
whichever approach is chosen, begins after the
detection of the fire event and notification to the build-
ing occupants to evacuate has occurred, since occu-
pants need to be alerted before evacuation can
occur. The calculation of evacuation time needs to
include delays with notification and the start of evacu-
ation (i.e., premovement time, etc.). It is stressed that the
code states 20 minutes or 1.5 times the egress
time, whichever is less (i.e., 20 minutes is a maxi-
mum). Egress of occupants can be addressed
through hand calculations or through the use of com-
puterized egress models. Some of the more
advanced models can address a variety of factors,
including the building layout, different sizes of people,
different movement speeds and different egress
paths available. With these types of programs, the
actual time can be more precisely calculated. Of
course it is cautioned that in many cases these mod-
els provide the optimal time for egress. The safety
factor of 1.5 within the code is intended to address
many of these uncertainties.

Note that this section applies to all types of smoke
control designed in accordance with Section 909.
Also, most smoke control systems will typically have
the ability to run for longer than the 20 minute max-
imum as they are on standby power and may be able
to continue to achieve the tenability goals. In some
cases even if the system runs longer than 20 min-
utes, the tenability may not be able to continue. It
simply depends on the system design and the fire
hazards within the building.

System response as required in Section 909.17
needs to be accounted for when determining the abil-
ity of the smoke control system to keep the smoke
layer interface at the appropriate level (see com-
mentary, Section 909.17).

[F] 909.5 Smoke barrier construction. Smoke barriers shall
comply with Section 710, and shall be constructed and sealed to
limit leakage areas exclusive of protected openings. The
maximum allowable leakage area shall be the aggregate area
calculated using the following leakage area ratios:

1. Walls: $A/A_w = 0.00100$
2. Interior exit stairways and ramps and exit passageways:
   $A/A_w = 0.00035$
3. Enclosed exit access stairways and ramps and all other
   shafts: $A/A_w = 0.00150$
4. Floors and roofs: $A/A_w = 0.00050$

where:

- $A$ = Total leakage area, square feet ($m^2$).
- $A_w$ = Unit floor or roof area of barrier, square feet ($m^2$).
- $A_w$ = Unit wall area of barrier, square feet ($m^2$).

The leakage area ratios shown do not include openings due
to doors, operable windows or similar gaps. These shall be
included in calculating the total leakage area.

• Part of the strategy of smoke control systems, partic-
ularly smoke control systems using the pressurization
method (often termed zoned smoke control) is the
use of smoke barriers to divide a building into sepa-
rate smoke zones (or compartments). This strategy is
used in both passive and mechanical systems. It
should be noted that not all walls, ceilings or floors
would be considered smoke barriers. Only walls that
designate separate smoke zones within a building
need to be constructed as smoke barriers. This sec-
ton is simply providing requirements for walls, floors
and ceilings that are used as smoke barriers. It
should be noted that it is possible that a smoke con-
tral system utilizing the exhaust method may not
need to utilize a smoke barrier to divide the building
into separate smoke zones; therefore, the evalua-
tion of barrier construction and leakage area may not be
necessary and, as noted, is primarily focused upon
designs using the pressurization method.

In order for smoke to not travel from one smoke
zone to another, specific construction requirements
are necessary in accordance with the code. It should
be noted that openings such as doors and windows
are dealt with separately within Section 909.5.2 from
openings such as cracks or penetrations.

[F] 909.5.1 Leakage area. The total leakage area of the bar-
tier is the product of the smoke barrier gross area multipli-
ed by the allowable leakage area ratio, plus the area of other
openings such as gaps and operable windows. Compliance
shall be determined by achieving the minimum air pressure
difference across the barrier with the system in the smoke
control mode for mechanical smoke control systems. Passive
smoke control systems tested using other approved means such as door fan testing shall be as approved by the fire code official.

- It is impossible for walls and floors to be constructed that are completely free from openings that may allow the migration of smoke; therefore, leakage needs to be compensated for within the design by calculating the leakage area of walls, ceilings and floors. The factors provided in Section 909.5, which originate from ASHRAE’s provisions on leaky buildings, are used to calculate the total leakage area. The total leakage area is then used in the design process to determine the proper amount of air to create the required pressure differences across these surfaces that form smoke zones. These pressure differences then need to be verified when the system is in smoke control mode.

Additionally, Section 909.5 provides ratios to determine the maximum allowable leakage in walls, interior exit stairways, shafts, floors and roofs. These leakage areas are critical in determining whether the proper pressure differences are provided when utilizing the pressurization method of smoke control. Pressure differences will decrease as the openings get larger.

**FIRE PROTECTION SYSTEMS**

**[F] 909.5.2 Opening protection.** Openings in smoke barriers shall be protected by automatic-closing devices actuated by the required controls for the mechanical smoke control system. Door openings shall be protected by fire door assemblies complying with Section 716.5.3.

**Exceptions:**

1. Passive smoke control systems with automatic-closing devices actuated by spot-type smoke detectors listed for releasing service installed in accordance with Section 907.3.

2. Fixed openings between smoke zones that are protected utilizing the airflow method.

3. In Group I-2, where such doors are installed across corridors, a pair of opposite-swinging doors without a center mullion shall be installed having vision panels with fire protection-rated glazing materials in fire protection-rated frames, the area of which shall not exceed that tested. The doors shall be close-fitting within operational tolerances and shall not have undercuts, louvers or grilles. The doors shall have head and jamb stops, astragals or rabbets at meeting edges and shall be automatic-closing by smoke detection in accordance with Section 716.5.9.3. Positive-latching devices are not required.

5. Openings between smoke zones with clear ceiling heights of 14 feet (4267 mm) or greater and bank-down capacity of greater than 20 minutes as determined by the design fire size.

- Similar to concerns of smoke leakage between smoke zones, openings may compromise the necessary pressure differences between smoke zones.

Openings in smoke barriers, such as doors and windows, must be either constantly or automatically closed when the smoke control system is operating. This section requires that doors be automatically closed through the activation of an automatic closing device linked to the smoke control system. Essentially, when the smoke control system is activated, all openings are automatically closed. This most likely would mean that the mechanism that activates the smoke control system would also automatically close all openings. The smoke control system will be activated by a specifically zoned smoke detection or sprinkler system as required by Sections 909.12.2 and 909.12.3.

In terms of actual opening protection, Section 909.5.2 is simply referring the user to Section 715.4.3 for specific construction requirements for doors located in smoke barriers. Note that smoke barriers are different from fire barriers, since the intended measure of performance is different. One is focused on fire spread from the perspective of heat, the other from the perspective of smoke passage. Smoke barriers do require a 1-hour fire-resistance rating.

There are several exceptions to this particular section. Exception 1 is specifically for passive systems. Passive systems, as noted, are systems in which there is no use of mechanical systems. Instead, the system operates primarily upon the configuration of barriers and layout of the building to provide smoke control. Passive systems can use spot-type detectors to close doors that constitute portions of a smoke barrier. Essentially, this means a full fire alarm system would not be required. Instead, single station detectors would be allowed to close the doors. Such doors would need to fail in the closed position if power is lost. The specifics as to approved devices would be found in NFPA 72.

Exception 2 is based on the fact that some systems take advantage of the opposed airflow method such that smoke is prevented from migrating past the doors. Therefore, since the design already accounts for potential smoke migration at these openings through the use of air movement, it is unnecessary to require the barrier to be closed.

Exception 3 is specifically related to the unique requirements for Group I-2 occupancies. Essentially, a very specific alternative, which meets the functional needs of Group I-2 occupancies, is provided. One aspect of the alternative approach is that doors have vision panels with approved fire protection-rated glazing in fire protection-rated frames of a size that does not exceed the type tested.

Exception 4 allows an exemption from the automatic-closing requirements for all Group I-3 occupancies. This is related to the fact that facilities that have occupants under restraint or specific security restrictions have unique requirements in accordance with Section 408 of the code. These requirements accomplish the intent of providing reliable barriers between each smoke zone since, for the most part,
such facilities will have a majority of doors closed and in a locked position due to the nature of the facility. The staff very closely controls these types of facilities.

Exception 5 relates to the behavior of smoke. The assumption is that smoke rises due to the buoyancy of hot gases, and if the ceiling is sufficiently high, the smoke layer will be contained for a longer period of time before it begins to move into the next smoke zone. Therefore, it is not as critical that the doors automatically close. This allowance is dependent on the specific design fire for a building. See Section 909.9 for more information on design fire determination. Different size design fires create different amounts of smoke that, depending on the layout of the building, may migrate in different ways throughout the building. This section mandates that smoke cannot begin to migrate into the next smoke zone for at least 20 minutes. This is consistent with the 20-minute maximum duration of operation of smoke control systems required in Section 909.4.6. It should be noted that a minimum of 14-foot (4267 mm) ceilings are required to take advantage of this exception. This exception would require an engineering analysis.

[F] 909.5.2.1 Ducts and air transfer openings. Ducts and air transfer openings are required to be protected with a minimum Class II, 250°F (121°C) smoke damper complying with Section 717.

Another factor that adds to the reliability of smoke barriers is the protection of ducts and air transfer openings within smoke barriers. Left open, these openings may allow the transfer of smoke between smoke zones. These ducts and air transfer openings most often are part of the HVAC system. Damper operation and the reaction with the smoke control system will be evaluated during acceptance testing. It should be noted that there are duct systems used within a smoke control design that are controlled by the smoke control system and should not automatically close upon detection of smoke via a smoke damper.

It should be noted that a smoke damper works differently than a fire damper. Fire dampers react to heat via a fusible link, while smoke dampers activate upon the detection of smoke. The smoke dampers used should be rated as Class II, 250°F (121°C). The class of the smoke damper refers to its level of performance relative to leakage. The temperature rating is related to its ability to withstand the heat of smoke resulting from a fire. It should be noted that although smoke barriers are only required to utilize smoke dampers, there may be many instances where a fire damper is also required. For instance, the smoke barrier may also be used as a fire barrier. Also, Section 717.5.3 would require penetration of shafts to contain both a smoke and fire damper. Therefore, in some cases both a smoke damper and fire damper would be required. There are listings specific to combination smoke and fire dampers. Note that the exceptions to Section 717.5.3 recognize that smoke and fire dampers may interfere with a smoke control design.

More specific requirements about dampers can be found in Chapter 7 of this code and Chapter 6 of the IMC.

[F] 909.6 Pressurization method. The primary mechanical means of controlling smoke shall be by pressure differences across smoke barriers. Maintenance of a tenable environment is not required in the smoke control zone of fire origin.

There are several methods or strategies that may be used to control smoke movement. One of these methods is pressurization, wherein the system primarily utilizes pressure differences across smoke barriers to control the movement of smoke. Basically, if the area of fire origin maintains a negative pressure, then the smoke will be contained to that smoke zone. A typical approach used to obtain a negative pressure is to exhaust the fire floor. This is a fairly common practice in high-rise buildings. Interior exit stairways also utilize the concept of pressurization by keeping the interior exit stairways under positive pressure. The pressurization method in large open spaces, such as malls and atria, is impractical since it would take a large quantity of supply air to create the necessary pressure differences. It should be noted that pressurization is mandated as the primary method for mechanical smoke control design—but this is related to the primary methods historically used for smoke control in high-rise buildings. Currently high-rise buildings do not require smoke control. Airflow and exhaust methods are only allowed when appropriate. The exhaust method is the most commonly applied method due to the use of the atrium provisions in Section 404.5.

The pressurization method does not require that tenable conditions be maintained in the smoke zone where the fire originates. Maintaining this area tenable would be impossible, based on the fact that pressures from the surrounding smoke zones would be placing a negative pressure within the zone of origin to keep the smoke from migrating.

Pressurization is used often with interior exit stairways. This method provides a positive pressure within the interior exit stairways to resist the passage of smoke. Stair pressurization is one method of compliance for stairways in high-rise or underground buildings where the floor surface is located more than 75 feet (22 860 mm) above the lowest level of fire department vehicle access or more than 30 feet (9144 mm) below the floor surface of the lowest level of exit discharge. It should be noted that there are two methods found in the code that address smoke movement—smokeproof enclosures or pressurized stairs. A smokeproof enclosure requires a certain fire-resistance rating along with access through a ventilated vestibule or an exterior balcony. The vestibule can be ventilated in two ways: using natural ventilation or mechanical ventilation as outlined in Sections 909.20.3 and 909.20.4. The pressurization method requires a sprinklered building and a minimum pressure difference of 0.15 inch (37 Pa) of water and a maximum of 0.35 inch (87 Pa) of water. These pres-
pressure differences are to be available with all doors closed under maximum stack pressures (see Sections 909.20 and 1022.9 for more details). As noted, the pressurization method utilizes pressure differences across smoke barriers to achieve control of smoke. Sections 909.6.1 and 909.6.2 provide the criteria for smoke control design in terms of minimum and maximum pressure differences.

In summary, the pressurization method is used in two ways. The first is through the use of smoke zones where the zone of origin is exhausted, creating a negative pressure. The second is stair pressurization that creates a positive pressure within the stair to avoid the penetration of smoke. Note that the code allows the use of a smokeproof enclosure instead of pressurization.

[F] 909.6.1 Minimum pressure difference. The minimum pressure difference across a smoke barrier shall be 0.05-inch water gage (0.0124 kPa) in fully sprinklered buildings.

In buildings permitted to be other than fully sprinklered, the smoke control system shall be designed to achieve pressure differences at least two times the maximum calculated pressure difference produced by the design fire.

- The minimum pressure difference is established as 0.05-inch water gage (12 Pa) in fully sprinklered buildings. This particular criterion is related to the pressures needed to overcome buoyancy and the pressures generated by the fire, which include expansion. This particular criterion is based upon a sprinklered building. The pressure difference would need to be higher in a building that is not sprinklered. Additionally, the pressure difference needs to be provided based upon the possible stack and wind effects present.

[F] 909.6.2 Maximum pressure difference. The maximum air pressure difference across a smoke barrier shall be determined by required door-opening or closing forces. The actual force required to open exit doors when the system is in the smoke control mode shall be in accordance with Section 1008.1.3. Opening and closing forces for other doors shall be determined by standard engineering methods for the resolution of forces and reactions. The calculated force to set a side-hinged, swinging door in motion shall be determined by:

\[ F = F_{oc} + K(WA\Delta P)/2(W-d) \]  

(Equation 9-1)

where:

- \( A \) = Door area, square feet (m²).
- \( d \) = Distance from door handle to latch edge of door, feet (m).
- \( F \) = Total door opening force, pounds (N).
- \( F_{oc} \) = Force required to overcome closing device, pounds (N)
- \( K \) = Coefficient 5.2 (1.0).
- \( W \) = Door width, feet (m).
- \( \Delta P \) = Design pressure difference, inches of water (Pa).

- The maximum pressure difference is based primarily upon the force needed to open and close doors. The code establishes maximum opening forces for doors. This maximum opening force cannot be exceeded, taking into account the pressure differences across a doorway in a pressurized environment. Essentially, based on the opening force requirements of Section 1008.1.3, the maximum pressure difference can be calculated in accordance with Equation 9-1. In accordance with Chapter 10, the maximum opening force of a door has three components, including:

  - Door latch release: Maximum of 15 pounds (67 N)
  - Set door in motion: Maximum of 30 pounds (134 N)
  - Swing to full open position: Maximum of 15 pounds (67 N)

Equation 9-1 is used to calculate the total force to set the door into motion when in the smoke control mode; therefore, the limiting criteria would be 30 pounds (134 N). It should be noted that although the accessibility requirements related to door opening force are more restrictive in Section 404.2.8 of ICC A117.1, fire doors do not require compliance with these requirements.

[F] 909.7 Airflow design method. When approved by the fire code official, smoke migration through openings fixed in a permanently open position, which are located between smoke control zones by the use of the airflow method, shall be permitted. The design airflow shall be in accordance with this section. Airflow shall be directed to limit smoke migration from the fire zone. The geometry of openings shall be considered to prevent flow reversal from turbulent effects.

- This method is only allowed when approved by the building official. As the title states, this method utilizes airflow to avoid the migration of smoke across smoke barriers. This has been referred to as opposed airflow. Specifically, this method is suited for the protection of smoke migration through doors and related openings fixed in a permanently open position. This method consists of providing a particular velocity of air based upon the temperature of the smoke and the height of the opening. The temperature of the smoke will depend on the design fire that is established for the particular building. The higher the temperature of the smoke and the larger the opening, the higher the velocity necessary to maintain the smoke from migrating into the smoke zone. It should be noted that the airflow method seldom works for large openings, since the velocity to oppose the smoke becomes too high. This method tends to work better for smaller openings, such as pass-through windows. Equation 9-2 provides the method to calculate the necessary velocity.

[F] 909.7.1 Velocity. The minimum average velocity through a fixed opening shall not be less than:

\[ v = 217.2[h(T_r - T_d)/(T_r + 460) ]^{1/2} \]  

(Equation 9-2)

For SI: \[ v = 119.9[h(T_r - T_d)/T_r ]^{1/2} \]
where:

\( h = \) Height of opening, feet (m).
\( T_r = \) Temperature of smoke, °F (K).
\( T_o = \) Temperature of ambient air, °F (K).
\( v = \) Air velocity, feet per minute (m/minute).

- This section provides the formula for the minimum average velocity through a fixed opening. The minimum velocity is based on the velocity needed to prevent the smoke from migrating into the smoke zone. Consideration needs to be given to the eventual exhaust of the air introduced for this approach. See the commentary to Section 909.7 for further discussion.

[F] 909.7.2 Prohibited conditions. This method shall not be employed where either the quantity of air or the velocity of the airflow will adversely affect other portions of the smoke control system, unduly intensify the fire, disrupt plume dynamics or interfere with exiting. In no case shall airflow toward the fire exceed 200 feet per minute (1.02 m/s). Where the formula in Section 909.7.1 requires airflow to exceed this limit, the airflow method shall not be used.

- The airflow method has a limitation on maximum velocity. This limitation is based upon the fact that air may distort the flame and cause additional entrainment and turbulence; therefore, having a high velocity of air entering the zone of fire origin has the potential of increasing the amount of smoke produced. The velocity may also interact with other portions of the smoke control design. For instance, the pressure differences in other areas of the building may be altered, which may exceed the limitations of Sections 909.6.1 and 909.6.2. This section requires that when a velocity of over 200 feet per minute (1.02 m/sec) is calculated, the airflow method is not allowed. The solution may result in requiring a barrier such as a wall or door.

If the airflow design method is chosen to protect areas communicating with an atrium, the air added to the smoke layer needs to be accounted for in the exhaust rate.

[F] 909.8 Exhaust method. When approved by the fire code official, mechanical smoke control for large enclosed volumes, such as in atriums or malls, shall be permitted to utilize the exhaust method. Smoke control systems using the exhaust method shall be designed in accordance with NFPA 92B.

- This method is only allowed when approved by the building official. The primary application of the exhaust method is in large spaces, such as atriums and malls and is the most widely used method in the IBC. The strategy of this method is to keep the smoke layer at a certain level within the space. This is primarily accomplished through exhausting smoke. The amount of exhaust depends upon the design fire [see Figure 909.8(1)]. Essentially, fires produce different amounts and properties of smoke based on the material being burned, and size and placement of the fire; therefore, NFPA 92B is referenced for the design of such systems. NFPA 92B presents several ways to address the control of smoke, which includes the use of the following tools:
  - Scale Modeling (Small scale testing)—Utilizes the concept of scaling to allow small scale tests
to be conducted to understand the smoke movement within a space.

- Benefits—More realistic understanding of smoke movement in spaces with unusual configurations or projections than algebraic calculations.
- Disadvantages—Expensive and the application of results is limited to the uniqueness of the space being analyzed.
- Algebraic (Calculations—similar to 2003 IBC)—Empirically derived (based upon testing) modeling in its simplest form.
  - Benefits—Simple, cost-effective analysis.
  - Disadvantages—Limited applicability due to the range of values they were derived from, only appropriate with certain types of design fires, typically over conservative outputs that increase equipment needs, equipment costs and can impact aesthetics and architectural design.
- Computer Modeling [Computational fluid dynamics (CFD) or zone models]—Combination of theory and empirical values to determine the smoke movement and fire induced conditions within a space and effectiveness of the smoke control system.
  - Benefits—More realistic understanding of smoke movement in spaces with unusual configurations or projections and less expensive than scale modeling. Helps significantly in designing smoke control systems tailored to spaces and achieving cost-effective designs, and can help limit the impact to architectural design.
  - Disadvantages—Computing time and cost can be longer than algebraic calculations but benefits typically outweigh this disadvantage. Early planning is important and can limit these adverse impacts.

In terms of computer modeling, as noted, there are essentially two methods that include zone models and CFD models. Zone models are based upon the unifying assumption that in any room or space where the effects of the fire are present there are distinct layers (not upper layer, cool lower layer). In real life such distinct layers do not exist. Some examples of zone models used in such applications include Consolidated Model of Fire Growth and Smoke Transport (C-FAST) and Available Safe Egress Time (ASET). See Section 3-7 of the SFPE Handbook of Fire Protection Engineering for further information. CFD models take this much further and actually divide the space into thousands or millions of interconnected "cells" or "fields." The model then evaluates the fire dynamics and heat and mass in each individual cell and how it interacts with those adjacent to it. The use of such models becomes more accurate with more numerous and smaller cells but the computing power and expertise required is much higher than for zone models. As noted the use of either types of models can be advantageous but such use must be undertaken by someone qualified. Proper review and verification of the input and output is critical. The most popular model in the area of CFD with regard to fire is the Fire Dynamics Simulator (FDS) developed by NIST. Other models such as Fluent are sometimes used (Fluent Inc.).

Depending upon the space being evaluated, some design strategies may provide a better approach than others. Past editions of the code smoke control provisions for the exhaust method mandated the use of the algebraic methods with a steady fire. This of course also mandated a mechanical system be used, whereas NFPA 92B allows an overall review of smoke layer movement and whether the design goals, which in this case are mandated by the code, can be met. Therefore, if it can be shown that the smoke layer interface can be held at 6 feet (1829 mm) as mandated in Section 909.8.1 for the design operation time required by Section 909.4.6 without mechanical ventilation, then the space would comply with Section 909. NFPA 92B presents several design approaches. This allows more flexibility in design than that found in previous editions of the code.

NFPA 92B as a standard does not set the minimum smoke layer interface height or duration for system operation. Such criteria is found within Sections 909.8.1 and 909.4.6, respectively. See the commentary for those sections.

If the algebraic approach is used, consideration of three types of fire plumes may be required to determine which one is the most demanding in terms of smoke removal needs based upon the space being assessed. They include:

- Axisymmetric plumes—Smoke rises unimpeded by walls, balconies or similar projections [see Figure 909.8(2)].
- Balcony spill plumes—Smoke flows under and around edges of a horizontal projection [see Figure 909.8(3)].
- Window plumes—Smoke flows through an opening into a large-volume space [see Figure 909.8(4)].

It should be noted that prior to the reference to NFPA 92B in the code, the balcony spill and window plume calculations had been eliminated from the smoke control requirements of the code due to concerns with the applicability of those calculations. The major difference is that NFPA 92B does not mandate the use of such equations as did previous editions of the IBC. The use of such equations will depend upon the design fires agreed upon for the particular design and whether an algebraic approach is chosen. These equations are used to determine a mass flow rate of smoke to ultimately determine the required exhaust
volume for that space. If the potential for a balcony or window spill plumes is known to exist within the space, then appropriate measures need to be taken to address these, as they typically result in more onerous exhaust and supply requirements. Part of the reason for the initial deletion of these equations was the fact that such scenarios are not as likely or their impact is significantly reduced in sprinklered buildings. There is also some concern with the applicability of the balcony spill plume equation in a variety of applications. These potential fire scenarios and resulting plumes may further the need to undertake a CFD analysis to address such hazards more appropriately and effectively.

Another key aspect that NFPA 92B included within the algebraic methods is equations to determine that a minimum number of exhaust inlets are available to prevent plugholing. Plugholing occurs when air from below the smoke layer is pulled through the smoke layer into the smoke exhaust inlets. As such, if plugholing occurs, some of the fan capacity is used to exhaust air rather than smoke and thus can affect the ability to maintain the smoke layer at or above the design height. Scale modeling and computer fire modeling would demonstrate these potential problems during the testing and analysis, respectively (see Figure 909.8(5)).

It should be noted that this section specifically references NFPA 92B for the design of smoke control using the exhaust method. Therefore the requirements in NFPA 92B related to testing, documentation and maintenance would not be applicable though they may be a good resource. Equipment and controls would be part of the design; therefore, related
provisions of NFPA 92B would apply. Generally, the code addresses equipment and controls in a similar fashion.

[F] 909.8.1 Smoke layer. The height of the lowest horizontal surface of the smoke layer interface shall be maintained at least 6 feet (1829 mm) above any walking surface that forms a portion of a required egress system within the smoke zone.

- The design criteria to be used when applying NFPA 92B is to maintain the smoke layer interface at least 6 feet (1829 mm) above any walking surface that is considered part of the required egress within the particular smoke zone, such as an atrium, for 20 minutes or 1.5 times the calculated egress time (see Section 909.4.6). Chapter 10 considers the majority of occupiable space as part of the means of egress system. Also keep in mind that the criteria of 6 feet (1829 mm) does not apply just to the main floor surface of the mall or atrium but to any level where occupants may be exposed (for example, balconies) [see Figure 909.8.1(1)].

The code uses the terminology "lowest horizontal
surface of the accumulating smoke layer interface." NFPA 92B has several definitions related to smoke layer, which include the following:

Smoke layer. The accumulated thickness of smoke below a physical barrier.

Smoke layer interface. The theoretical boundary between a smoke layer and the smoke-free air. (Note: This boundary is at the beginning of the transition zone.)

First indication of smoke. The boundary between the transition zone and the smoke-free air.

Transition zone. The layer between the smoke layer interface and the first indication of smoke in which the smoke layer temperature decreases to ambient. The transition zone may be several feet thick (large open space) or may barely exist (small area with intense fire).

See also Figure 909.8.1(2).

NFPA 92B provides algebraic equations to determine the first indication of smoke but is limited to very specific conditions such as a uniform cross section, specific aspect ratios, steady or unsteady fires and no smoke exhaust operating. When using algebraic equations for smoke layer interface looking at different types of plumes, the smoke layer interface terminology is used and the user enters the desired smoke layer interface height. Zone models use simplifying assumptions so the layers are distinct from one another. In contrast, when CFD or scale modeling is used, the data must be analyzed to verify that the smoke layer interface is located at or above the 6 feet (1829 mm) during the event. This is not a simple analysis, as CFD and scale modeling provide more detail on actual smoke behavior; therefore, the location of the smoke layer interface may not be initially clear without some level of analysis. Again it depends on the depth of the transition layer. This may require reviewing tenability within the transition zone. Tenability limits need to be agreed upon by the stakeholders involved. Using CFD or scale modeling would likely need to occur through the alternative methods and materials section (see Section 104.11) due to the need to review tenability limits. It should be noted that NFPA 92B Annex A suggests that there are methods to determine where the smoke layer interface and first indication of smoke are located when undertaking CFD and scale modeling using a limited number of point measurements.

Also, Section 909.8.1 specifies a minimum distance for the smoke layer interface from any walking surface whereas Section 4.5.3 of NFPA 92B has provisions that simply allow the analysis to demonstrate tenability regardless of where the layer height is located above the floor. Defining tenability can be more difficult as there is not a standard definition. Any design using that approach would need to be addressed through Section 104.11.

Note that the response time of the system components (detection, activation, ramp up time, shutting down HVAC, opening/closing doors and dampers, etc.) needs to be accounted for when analyzing the location of the smoke layer interface in relation to the duration of operations stated in Section 909.4.6 (see commentary, Section 909.17).

**Figure 909.8.1(1)**
EXAMPLE, CRITICAL LEVEL OF SMOKE
[F] 909.9 Design fire. The design fire shall be based on a rational analysis performed by the registered design professional and approved by the fire code official. The design fire shall be based on the analysis in accordance with Section 909.4 and this section.

- The design fire is the most critical element in the smoke control system design. The fire is what produces the smoke to be controlled by the system; thus, the size of the fire directly impacts the quantity of smoke being produced. This section ensures that the design fire be determined through a rational analysis by a registered design professional with knowledge in this area. Such professionals should have experience in the area of fire dynamics, fire engineering and general building design, including mechanical systems. When determining the design fire the designer should work with various stakeholders to determine the types of hazards and combustible materials (fire scenarios) on a permanent as well as temporary basis (i.e., Christmas/holiday decorative materials or scenery, temporary art exhibits) that may be present throughout the use of the building once occupied. Those hazards then need to be translated to potential design fires to be used when determining the smoke layer interface height for the duration as determined by Section 909.4.6. See the commentary for Section 909.9.3 for potential sources when determining design fires.

This section also does not mandate the type of fire (i.e., steady versus unsteady). A steady fire assumes a constant heat release rate over a period of time, where unsteady fires do not. An unsteady fire includes the growth and decay phases of the fire, as well as the peak heat release rate. An unsteady fire will hit a peak heat release rate when burning in the open, like an axisymmetric fire. An unsteady fire is a more realistic view of how fires actually burn. It should be noted that fires can be a combination of unsteady and steady fires when the sufficient fuel is available. In other words, the fire initially grows (unsteady) then reaches a steady state and burns for sometime at a particular heat release rate before decay occurs.

Design fire information should therefore typically include growth rate, peak heat release rate, duration and decay as well as information related to fire locations and products of combustion yield (CO, smoke, etc.) that are produced by the various design fires that are deemed credible for the space.

To provide an order of magnitude of fire sizes obtained from various combustibles, the following data from fire tests is provided. The following heat release rates, found in Section 3, Chapter 3-1 of the 2nd edition of the SFPE Handbook of Fire Protection Engineering, are peak heat release rates:

- Plastic trash bags/paper trash: 114-332 Btu/sec (120-350 kw)
- Latex foam pillow: 114 Btu/sec approximately (120 kw)
- Dry Christmas tree: 475-618 Btu/sec (500-650 kw)
- Sofa: 2,852 Btu/sec approximately (3,000 kw)
- Plywood wardrobe: 2,947-6,084 Btu/sec (3,100-6,400 kw)

[F] 909.9.1 Factors considered. The engineering analysis shall include the characteristics of the fuel, fuel load, effects included by the fire and whether the fire is likely to be steady or unsteady.

- This section simply provides more detail on the factors that should be taken under consideration when determining the design fire size. To determine the appropriate fire size, an engineering analysis is nec-

![Figure 909.B.1(2) Smoke Layer Interface](image-url)
FIRE PROTECTION SYSTEMS

tassy that takes into account the following elements: fuel (potential burning rates), fuel load (how much), effects included by the fire (smoke particulate size and density), steady or unsteady (burn steadily or simply peak and dissipate) and likelihood of sprinkler activation (based on height and distance from the fire).

[F] 909.9.2 Design fire fuel. Determination of the design fire shall include consideration of the type of fuel, fuel spacing and configuration.

- The design fire size may also be affected by surrounding combustibles, which may have the effect of increasing the fire size. More specifically, there is concern that if sufficient separation is not maintained between combustibles, then a larger design fire is likely. The code does not provide extensive detail on this as such determination is left to the rational analysis undertaken by the design professional. NFPA 92B provides one method in which you determine the critical separation distance, R. This is based upon fire size and the critical radiant heat flux for nonpiloted ignition. Nonpiloted ignition means the radiated heat from the fire without direct flame contact will ignite adjacent combustibles.

[F] 909.9.3 Heat-release assumptions. The analysis shall make use of best available data from approved sources and shall not be based on excessively stringent limitations of combustible material.

- This section is merely stressing the fact that data obtained for use in a rational analysis needs to come from relevant and appropriate sources. Data can be obtained from groups such as NIST or from Annex B of NFPA 92B. Data from fire tests is available and is a good resource for such analysis. As noted earlier, such data is not prevalent (see also Chapter 8, Analysis of Design Fires of A Guide to Smoke Control in the 2006 IBC® and Section 3, Chapter 3-1, of the SFPE Handbook of Fire Protection Engineering).

[F] 909.9.4 Sprinkler effectiveness assumptions. A documented engineering analysis shall be provided for conditions that assume fire growth is halted at the time of sprinkler activation.

- This section raises a few questions regarding activation of sprinklers and their impact on the fire both in terms of their ability to "control" as well as "extinguish" a fire. The first is concerning an assumption that sprinklers will immediately control the fire as soon as they are activated (i.e., control results in limiting further growth and maintaining the heat release rate at approximately the same fire size as when the sprinklers activated). This assumption may be true in some cases, but for high ceilings the sprinkler may not activate or may be ineffective. Sprinklers may be ineffective in high spaces, since by the time they are activated the fire is too large to control. Essentially, the fire plume may push away and evaporate the water before it actually reaches the seat of the fire. In addition the fire may be shielded from sprinkler spray so that insufficient quantities of water reach the fuel. These are common problems with high-piled storage as well as other fires including retail and has been shown in actual tests. Also, if the fire becomes too large before the sprinklers are activated, the available water supply and pressure for the system may be compromised. Additionally, based on the layout of the room and the movement of the fire effluents, the wrong sprinklers could be activated, which leads to a larger fire size and depletion of the available water supply and pressure.

Another issue is whether the sprinklers "control" or "extinguish" the fire. Typical sprinklers are assumed only to control fires as opposed to extinguishing them. Sprinklers may be able to extinguish the fire but it should not automatically be assumed. A fire that is controlled will achieve steady state and maintain a certain fire size, which is very different from a fire that is actually extinguished.

Based upon these concerns, each scenario needs to be looked at individually to determine whether sprinklers would be effective in halting the growth or extinguishing the fire. More specifically, the evaluation should include droplet size, density and area of coverage and should also be based on actual test results.

[F] 909.10 Equipment. Equipment including, but not limited to, fans, ducts, automatic dampers and balance dampers, shall be suitable for its intended use, suitable for the probable exposure temperatures that the rational analysis indicates and as approved by the fire code official.

- Section 909.10 and subsequent sections are primarily related to the reliability of the system components to provide a smoke control system that works according to the design. One of the largest concerns when using smoke control provisions is the overall reliability of the system. Such systems have many different components, such as smoke and fire dampers; fans; ducts and controls associated with such components. The more components a system has, the less reliable it becomes. In fact, one approach in providing a higher level of reliability is utilizing the normal building systems such as the HVAC to provide the smoke control system. Basically, systems used every day are more likely to be working appropriately, since they are essentially being tested daily; however, there are many components that are specific to the smoke control system, such as exhaust fans in an atrium or the smoke control panel.

Also, there is not a generic prescriptive set of requirements as to how all smoke control system elements should operate, since each design may be fairly unique. The specifics on operation of such a system need to be included within the design and construction documents. Most components used in smoke control systems are elements used in many other applications such as HVAC systems; therefore, the basic mechanisms of a fan used in a smoke control system may not be different, although they may be applied differently.
[F] 909.10.1 Exhaust fans. Components of exhaust fans shall be rated and certified by the manufacturer for the probable temperature rise to which the components will be exposed. This temperature rise shall be computed by:

\[ T_e = \frac{Q_v}{mc} + T_a \]  

(Equation 9-3)  

where:\n
- \( c \) = Specific heat of smoke at smoke layer temperature, Btu/lb°F (kJ/kg °K).  
- \( m \) = Exhaust rate, pounds per second (kg/s).  
- \( Q_v \) = Convective heat output of fire, Btu/s (kW).  
- \( T_a \) = Ambient temperature, °F (K).  
- \( T_e \) = Smoke temperature, °F (K).  

Exception: Reduced \( T_e \) as calculated based on the assurance of adequate dilution air.

- Fans used for smoke control systems must be able to tolerate the possible elevated temperatures to which they will be exposed. Again, like many other factors this depends upon the specifics of the design fire. Essentially, Equation 9-3 requires the calculation of the potential temperature rise. The exhaust fans must be specifically rated and certified by the manufacturer to be able to handle these rises in temperature. There is an exception that allows reduction of the temperature if it can be shown that adequate temperature reduction will occur. In many cases if the exhaust fans are near the ceiling, the smoke will be much cooler than the value resulting from Equation 9-3 since the smoke may cool considerably by the time it reaches the ceiling. Also, sprinkler activation will assist in cooling the smoke further.

[F] 909.10.2 Ducts. Duct materials and joints shall be capable of withstanding the probable temperatures and pressures to which they are exposed as determined in accordance with Section 909.10.1. Ducts shall be constructed and supported in accordance with the International Mechanical Code. Ducts shall be leak tested to 1.5 times the maximum design pressure in accordance with nationally accepted practices. Measured leakage shall not exceed 5 percent of design flow. Results of such testing shall be a part of the documentation procedure. Ducts shall be supported directly from fire-resistance-rated structural elements of the building by substantial, noncombustible supports.

Exception: Flexible connections (for the purpose of vibration isolation) complying with the International Mechanical Code, that are constructed of approved fire-resistance-rated materials.

- The next essential component of a smoke control system is the integrity of the ducts to transport supply and exhaust air. The integrity of ducts is also important for an HVAC system, but is more critical in this case since it is not simply a comfort issue but one of life safety. The key concern with ducts in smoke control systems is that they can withstand elevated temperatures and that there will be minimal leakage. The concern with leakage is the potential of leaking smoke into another smoke zone or not providing the proper amount of supply air to support the system.

More specifically, all ducts need to be leak tested to 1.5 times the maximum static design pressure. The leakage resulting should be no more than 5 percent of the design flow. For example, a duct that has a design flow of 300 cubic feet per minute (cfm) (0.141 m³/s) would be allowed 15 cfm (0.007 m³/s) of leakage when exposed to a pressure equal to 1.5 times the design pressure for that duct. The tests should be in accordance with nationally accepted practices. This criterion will often limit ductwork for smoke control systems to lined systems, since the amount of leakage in such systems is much less.

As part of the concern for possible exposure to fire and fire products, the ducts are required to be supported by way of substantial noncombustible supports connected to the fire-resistance-rated structural elements of the building. As noted, the system needs to be able to run for 20 minutes starting from the detection of the fire. The exception to this section is really more of an acknowledgement that flexible connections for vibration isolation are acceptable when constructed of approved fire-resistance-rated materials. More specifically, it is often necessary to use such connections for connecting the duct to the fan. These connections cannot necessarily meet the requirements of the main section, but are a minimal part of the ductwork and as long as they perform adequately with regard to fire resistance they are permitted. Note that the term “approved” is used to determine the required fire resistance, therefore, flexibility is provided. The code does not specifically address this determination but perhaps a relationship to the duration or operation and these flexible connections could be made to determine the necessary performance.

[F] 909.10.3 Equipment, inlets and outlets. Equipment shall be located so as to not expose uninvolved portions of the building to an additional fire hazard. Outside air inlets shall be located so as to minimize the potential for introducing smoke or flame into the building. Exhaust outlets shall be so located as to minimize reintroduction of smoke into the building and to limit exposure of the building or adjacent buildings to an additional fire hazard.

- The intent of this section is to minimize the likelihood of smoke being reintroduced into the building due to poorly placed outdoor air inlets and exhaust air outlets; therefore, placing one right next to another on the exterior of the building would be inappropriate. In addition, wind and other adverse conditions should be considered when choosing locations for these inlets and outlets. Particular attention should be paid to introducing exhausted smoke into another smoke zone. Also, smoke should be exhausted in a direction that will not introduce it into surrounding buildings or facilities. Within the building itself, the supply air and exhaust outlets should also be strategically located. The exhaust inlets and supply air should be evenly distributed to reduce the likelihood of a high velocity
FIRE PROTECTION SYSTEMS

of air that may disrupt the fire plume and also push smoke back into occupied areas. See the commentary to Section 909.8 for discussion on avoiding plugholing.

[F] 909.10.4 Automatic dampers. Automatic dampers, regardless of the purpose for which they are installed within the smoke control system, shall be listed and conform to the requirements of approved, recognized standards.

- This section addresses the reliability of any dampers used within a smoke control system. This particular provision requires that the dampers be listed and conform to the appropriate recognized standards. More specifically, Section 717 contains more detailed information on the specific requirements for smoke and fire dampers. Smoke and fire dampers should be listed in accordance with UL 555S and 55S, respectively. Also, remember that each smoke control design is unique and the sequence and methods used to activate the dampers may vary from design to design. This information needs to be addressed in the construction documents.

Another factor to take into account, with regard to timing of the system, is the fact that some dampers react more quickly than others, simply due to the particular smoke damper characteristics. Additionally, during the commissioning of the system, the damper is going to be exposed to many repetitions. These repetitions need to be accounted for in the overall reliability of the system.

[F] 909.10.5 Fans. In addition to other requirements, belt-driven fans shall have 1.5 times the number of belts required for the design duty, with the minimum number of belts being two. Fans shall be selected for stable performance based on normal temperature and, where applicable, elevated temperature. Calculations and manufacturer’s fan curves shall be part of the documentation procedures. Fans shall be supported and restrained by noncombustible devices in accordance with the requirements of Chapter 16. Motors driving fans shall not be operated beyond their nameplate horsepower (kilowatts), as determined from measurement of actual current draw, and shall have a minimum service factor of 1.15.

- Part of the overall reliability requires that fans used to provide supply air and exhaust capacity will be functioning when necessary; therefore, a safety factor of 1.5 is placed upon the required belts for fans. All fans used as part of a smoke control system must provide 1.5 times the number of required belts with a minimum of two belts for all fans.

This section also points out that the fan chosen should fit the specific application. It should be able to withstand the temperature rise as calculated in Section 909.10.1 and generally be able to handle typical exposure conditions, such as location and wind. For instance, propeller fans are highly sensitive to the effects of wind. When located on the windward side of a building, wall-mounted, nonhooded propeller fans are not able to compensate for wind effects. Additionally, even hooded propeller fans located on the leeward side of the building may not adequately compensate for the decrease in pressure caused by wind effects. In general, when designing a system, it should be remembered that field conditions might vary from the calculations; therefore, flexibility should be built into the design that would account for things such as variations in wind conditions.

Finally, this section stresses that fan motors not be operated beyond their rated horsepower.

[F] 909.11 Power systems. The smoke control system shall be supplied with two sources of power. Primary power shall be from the normal building power systems. Secondary power shall be from an approved standby source complying with Chapter 27 of this code. The standby power source and its transfer switches shall be in a room separate from the normal power transformers and switch gears and ventilated directly to and from the exterior. The room shall be enclosed with not less than 1-hour fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both. The transfer to full standby power shall be automatic and within 60 seconds of failure of the primary power.

- As with any life safety system, a level of redundancy with regard to power supply is required to enable the functioning of the system during a fire. The primary source is the building’s normal power system. The secondary power system is by means of standby power. One of the key elements is that standby power systems are intended to operate within 60 seconds of loss of primary power. It should be noted that the primary difference between standby power and emergency power is that emergency power must operate within 10 seconds of loss of primary power versus 60 seconds. This section also requires isolation from normal building power systems via a 1-hour fire barrier, 1-hour horizontal assembly, or both, depending upon the location within the building. This increases the reliability and reduces the likelihood that a single event could remove both power supplies.

[F] 909.11.1 Power sources and power surges. Elements of the smoke control system relying on volatile memories or the like shall be supplied with uninterruptable power sources of sufficient duration to span 15-minute primary power interruption. Elements of the smoke control system susceptible to power surges shall be suitably protected by conditioners, suppressors or other approved means.

- Smoke control systems have many components, sometimes highly sensitive electronics, that are adversely affected by any interruption in or sudden surges of power. Therefore, Section 909.11.1 requires that any components of a smoke control system, such as volatile memories, be supplied with an uninterruptable power system for the first 15 minutes of loss of primary power. Volatile memory components will lose memory upon any loss of power no matter how short the time period. Once the 15 minutes elapses, these elements can be transitioned to the already operating standby power supply.

With regard to components sensitive to power...
surges, they need to be provided with surge protection in the form of conditioners, suppressors or other approved means.

[F] 909.12 Detection and control systems. Fire detection systems providing control input or output signals to mechanical smoke control systems or elements thereof shall comply with the requirements of Section 907. Such systems shall be equipped with a control unit complying with UL 864 and listed as smoke control equipment.

Control systems for mechanical smoke control systems shall include provisions for verification. Verification shall include positive confirmation of actuation, testing, manual override, the presence of power downstream of all disconnects and, through a preprogrammed weekly test sequence, report abnormal conditions audibly, visually and by printed report.

This section is focused upon two main elements. The first is the proper operation and monitoring of the fire detection system that activates the smoke control system through compliance with Section 907 and UL 864. This requires a specific listing as smoke control equipment. UL 864 has a subcategory (UUKL) specific to fire alarm control panels for smoke control system applications.

The second aspect is related to the mechanical elements of the smoke control system once the system is activated. In particular, there is a focus upon verification of activities. Verification would include the following two aspects according to the second paragraph of this section:

1. The system is able to verify actuations, testing, manual overrides and the presence of power downstream. This would require information reported back to the smoke control panel, which can be accomplished via the weekly test sequence or through full electronic monitoring of the system.

2. Conduct a preprogrammed weekly test that simulates an actual (smoke) event to test the components of the system. These components would include elements such as smoke dampers, fans and doors. Abnormal conditions need to be reported in three ways:
   a. Audibly;
   b. Visually; and
   c. Printed report.

It should be noted that electrical monitoring of the control components is not required (supervision). Such supervision verifies integrity of the conductors from a fire alarm control unit to the control system input. The weekly test is considered sufficient verification of system performance and is often termed end-to-end verification. In other words, the control system input provides the expected results. Verification can be accomplished through any sensor that is calibrated to distinguish between the difference in proper operation and a fault condition. For fans, proper operation means that the fan is moving air with the intent of its design. Fault conditions include power failure, broken fan belts, adverse wind effects, a locked rotor condition and/or filters or large ducts that are blocked causing significantly reduced airflow. In addition to differential pressure transmitters and sail switches, this can be accomplished by the present state of the art current sensors. More discussion on verification for elements such as ducts and fire doors is discussed in Chapter 9 of A Guide to Smoke Control in the 2006 IBC.

Also, the fact that a smoke control system is non-dedicated (integrated with an HVAC system) does not mean that it is automatically being tested on a daily basis. It is cautioned that simply depending upon occupant discomfort, for example, is sometimes an insufficient indicator of a fully functioning smoke control system. There may be various modes in which the HVAC system could operate that may not exercise the smoke control features and the sequence in which the system should operate. An example is an air-conditioning system operating only in full recirculating mode versus exhaust mode. This failure will likely not affect occupants and will not exercise the exhaust function. Plus, doors, which may be part of the smoke barrier, may not need to be closed in normal building operations but would need to be closed during smoke control system operation. This is why this section does not necessarily differentiate between dedicated and nondedicated smoke control systems and requires the system components to be tested.

It is important to note that this weekly test sequence is not an actual smoke event and is only intended to activate the system to ensure that the components are working correctly.

Although NFPA 92B is only referenced for design Sections 7.3.1 and 7.3.8 of that standard coordinate with this section. More specifically, Section 7.3.8 also requires the weekly test but as provided for by the UL 864-UUKL-listed smoke control panel. NFPA 92B Section 7.3.6.2 requires off-normal indication at the smoke control panel within 200 seconds when a positive confirmation is failed to be achieved. Section 909.12 only requires that abnormal conditions be reported weekly.

[F] 909.12.1 Wiring. In addition to meeting requirements of NFPA 70, all wiring, regardless of voltage, shall be fully enclosed within continuous raceways.

Wiring is required to be placed within continuous raceways, which provides an additional level of reliability for the system. The definition of the term "raceway" in NFPA 70 lists several acceptable types of complying raceway that can be used; however, manufactured cable assemblies such as metal-clad cable (Type MC) or armored cable (Type AC) are not included.
[F] 909.12.2 Activation. Smoke control systems shall be activated in accordance with this section.

- The activation of a smoke control system is dependent on when such a system is required. Mechanical smoke control systems, which could include pressurization, airflow or exhaust methods, require an automatic activation mechanism. When using a passive system, which depends upon compartmentation, spot-type detectors are acceptable for the release of door closers and similar openings. Whereas with more complex mechanical systems, such activation needs to go beyond single station detectors and be part of an automatic coordinated system.

[F] 909.12.2.1 Pressurization, airflow or exhaust method. Mechanical smoke control systems using the pressurization, airflow or exhaust method shall have completely automatic control.

- Automatic activation of such systems is especially critical as tenability is much more difficult to achieve if a delay occurred waiting for manual activation of the system. See Sections 909.6 for the pressurization method, 909.7 for the airflow design method and 909.8 for the exhaust method.

[F] 909.12.2.2 Passive method. Passive smoke control systems actuated by approved spot-type detectors listed for releasing service shall be permitted.

- This section recognizes that a passive system does not address smoke containment through mechanical means; therefore, it does not need to be “automatically activated” except in cases where smoke barriers have openings. These openings would be required to have smoke detectors to close openings where required by the design. Although spot-type detectors are technically automatic, they are not part of a more coordinated system of activation as needed for mechanical smoke control systems. Such detectors are simply standalone devices that fail in the fail safe position. In other words, if the power were lost a door on a magnetic hold would simply close.

[F] 909.12.3 Automatic control. Where completely automatic control is required or used, the automatic-control sequences shall be initiated from an appropriately zoned automatic sprinkler system complying with Section 903.3.1.1. Manual controls that are readily accessible to the fire department and any smoke detectors required by engineering analysis.

- When automatic activation is required, it must be accomplished by a properly zoned automatic sprinkler system and, if the engineering analysis requires them, smoke detectors. Manual control for the fire department needs to be provided. An important point with this particular requirement is that smoke control systems are engineered systems and a prescribed smoke detection system may not fit the needs of the specific design. Other types of detectors, such as beam detectors (within an atrium), may be used and could be more useful and more practical from a maintenance standpoint. Also, it may not be practical or appropriate for the building’s fire alarm system to activate such systems, as it may alter the effectiveness of the system by pulling smoke through the building versus removing or containing the smoke. For example, a building with an atrium may have several floors below the space. If a fire occurs in one of the floors not associated with the atrium, the atrium smoke control system could possibly pull smoke throughout the building if the detection is zoned incorrectly.

[F] 909.13 Control air tubing. Control air tubing shall be of sufficient size to meet the required response times. Tubing shall be flushed clean and dry prior to final connections and shall be adequately supported and protected from damage. Tubing passing through concrete or masonry shall be sleeved and protected from abrasion and electrolytic action.

- Control tubing is a method that uses pneumatics to operate components such as the opening and closing of dampers. Due to the sophistication of electronic systems today, control tubing is becoming less common.

These particular requirements provide the criteria for properly designing and installing control tubing. Essentially, it is up to the design professional to determine the size requirements and to properly design appropriate supports. This information needs to be detailed within the construction documents. Additionally, due to the effect of moisture and other contaminants on control tubing, it must be flushed clean then dried before installation.

[F] 909.13.1 Materials. Control-air tubing shall be hard-drawn copper, Type L, ACR in accordance with ASTM B 42, ASTM B 43, ASTM B 68, ASTM B 88, ASTM B 251 and ASTM B 280. Fittings shall be wrought copper or brass, solder type in accordance with ASME B 16.18 or ASME B16.22. Changes in direction shall be made with appropriate tool bends. Brass compression-type fittings shall be used at final connection to devices; other joints shall be brazed using a BCuP-5 brazing alloy with soldus above 1,100°F (593°C) and liquids below 1,500°F (816°C). Brazing flux shall be used on copper-to-brass joints only.

Exception: Nonmetallic tubing used within control panels and at the final connection to devices provided all of the following conditions are met:

1. Tubing shall comply with the requirements of Section 602.2.1.3 of the International Mechanical Code.

2. Tubing and connected devices shall be completely enclosed within a galvanized or paint-grade steel enclosure having a minimum thickness of 0.0296 inch (0.7534 mm) (No.22 gage). Entry to the enclosure shall be by copper tubing with protective grommet of neoprene or teflon or by suitable brass compression to male barbed adapter.

3. Tubing shall be identified by appropriately documented coding.

4. Tubing shall be neatly tied and supported within the enclosure. Tubing bridging cabinets and doors or
moveable devices shall be of sufficient length to avoid tension and excessive stress. Tubing shall be protected against abrasion. Tubing serving devices on doors shall be fastened along hinges.

- This section addresses the materials allowed for control air tubing along with approved methods of connection. All of this information needs to be documented, as it will be subject to review by the special inspector.

[F] 909.13.2 Isolation from other functions. Control tubing serving other than smoke control functions shall be isolated by automatic isolation valves or shall be an independent system.

- This section requires separation of control tubing used for other functions through the use of isolation valves or a completely separate system. This is due to the difference in requirements for control tubing used in a smoke control system versus other building systems. The isolation of the control air tubing for a smoke control system needs to be specifically noted on the construction documents.

[F] 909.13.3 Testing. Control air tubing shall be tested at three times the operating pressure for not less than 30 minutes without any noticeable loss in gauge pressure prior to final connection to devices.

- As part of the acceptance testing of the smoke control system, the control air tubing will be pressure tested three times the operating pressure for 30 minutes or more. The performance criteria as to whether the control tubing is considered a failure is when there is any noticeable loss in gauge pressure prior to final connection of devices during the 30-minute duration test.

[F] 909.14 Marking and identification. The detection and control systems shall be clearly marked at all junctions, accesses and terminations.

- This section requires that all portions of the fire detection system that activate the smoke control system be marked and identified appropriately. This includes all applicable fire alarm-initiating devices, the respective junction boxes, all data-gathering panels and fire alarm control panels. Additionally, all components of the smoke control system, which are not considered a fire detection system, are required to be properly identified and marked. This would include all applicable junction boxes, control tubing, temperature control modules, relays, damper sensors, automatic door sensors and air movement sensors.

[F] 909.15 Control diagrams. Identical control diagrams showing all devices in the system and identifying their location and function shall be maintained current and kept on file with the fire code official, the fire department and in the fire command center in a format and manner approved by the fire chief.

- The purpose of control diagrams is to provide consistent information on the system in several key locations, including the building department, the fire department and the fire command center. If a fire command center is not required or provided, the diagrams need to be located such that they can be readily accessed during an emergency. Some possible locations may be the security office, the building manager’s office or, if possible, within the smoke control panel. This information is intended to assist in the use and operation of the smoke control system. The format of the control diagram is as approved by the fire chief. This is necessary since the fire department is the agency that will be using such a system during a fire and when the system is tested in the future. The more clearly the information is communicated, the more effective the smoke control system will be.

- It should be noted that the fire department may want all smoke control systems within a jurisdiction to follow a particular protocol for control diagrams. Generally, the control diagrams should indicate the required reaction of the system in all scenarios. The status or position of every fan and damper in every scenario must be clearly identified.

[F] 909.16 Fire-fighter’s smoke control panel. A fire-fighter’s smoke control panel for fire department emergency response purposes only shall be provided and shall include manual control or override of automatic control for mechanical smoke control systems. The panel shall be located in a fire command center complying with Section 911 in high-rise buildings or buildings with smoke-protected assembly seating. In all other buildings, the fire-fighter’s smoke control panel shall be installed in an approved location adjacent to the fire alarm control panel. The fire-fighter’s smoke control panel shall comply with Sections 909.16.1 through 909.16.3.

- One of the elements that makes a smoke control system effective is that its activity is successfully communicated to the fire department and the fire department is able to manually operate the system. The following sections provide requirements for a control panel specifically for smoke control systems. This panel is required to be located within a fire command center when it is located in a high-rise building or there is smoke-protected seating. Section 403.4.5 would require a fire command center for high-rise buildings. Smoke-protected seating does not require a fire command center in Chapter 10 but this provision would ensure that one exists and contains the smoke control panel. Facilities with smoke-protected seating tend to be larger facilities that, at the very least, would already have a central security center if not a fire command center as required by the jurisdiction. All other locations would only need to provide the panel in an approved location as long as it is located with the fire alarm panel. The specific location will depend on the needs of the fire department in that jurisdiction. The reason not all fire-fighter smoke control panels need to be located in a fire command center is that many smoke control systems are located in a building containing an atrium that may only be three stories in height. A 200-square-foot (19 m²) fire command center would be excessive for such buildings. There are two components that include the require-
components for the display and for the controls. This control panel will provide an ability to override any other controls whether manual or automatic within the building as they relate to the smoke control system.

Note that the publication Guide to Smoke Control in the 2006 IBC goes into more detail about the fire fighter smoke control panel requirements.

[F] 909.16.1 Smoke control systems. Fans within the building shall be shown on the fire-fighter's control panel. A clear indication of the direction of airflow and the relationship of components shall be displayed. Status indicators shall be provided for all smoke control equipment, annunciated by fan and zone, and by pilot-lamp-type indicators as follows:

1. Fans, dampers and other operating equipment in their normal status—WHITE.
2. Fans, dampers and other operating equipment in their off or closed status—RED.
3. Fans, dampers and other operating equipment in their on or open status—GREEN.
4. Fans, dampers and other operating equipment in a fault status—YELLOW/AMBER.

This section denotes what should be displayed on the control panel. The display is required to include all fans, an indication of the direction of airflow and the relationship of the components. Also, status lights are required, and this section sets out specific standardized colors to indicate normal status, closed status, open status and fault status. A standardized approach increases the likelihood that the fire department will be able to quickly become familiar with a system. Since the fire department has the ability to override the automatic functions of the system, this information is critical.

[F] 909.16.2 Smoke control panel. The fire-fighter's control panel shall provide control capability over the complete smoke-control system equipment within the building as follows:

1. ON-AUTO-OFF control over each individual piece of operating smoke control equipment that can also be controlled from other sources within the building. This includes stairway pressurization fans; smoke exhaust fans; supply, return and exhaust fans; elevator shaft fans and other operating equipment used or intended for smoke control purposes.
2. OPEN-AUTO-CLOSE control over individual dampers relating to smoke control and that are also controlled from other sources within the building.
3. ON-OFF or OPEN-CLOSE control over smoke control and other critical equipment associated with a fire or smoke emergency and that can only be controlled from the fire-fighter's control panel.

Exceptions:

1. Complex systems, where approved, where the controls and indicators are combined to control and indicate all elements of a single smoke zone as a unit.

2. Complex systems, where approved, where the control is accomplished by computer interface using approved, plain English commands.

This section sets the requirements as to which controls need to be provided for the fire department on the control panel.

There are two aspects to the controls. The controls will include on-auto-off and open-auto-close settings or will be strictly on-off or open-close. If the system or component can be set on automatic (auto), it can be controlled from other locations beyond the fire command center. This would include an automatic smoke detection system or by manual activation. If a control only contains on-off or open-close settings, the only way the system component can be controlled is in the fire command center.

It should be noted that components such as fans are usually associated with on-off-type controls, whereas components such as dampers are associated with open-close-type controls.

[F] 909.16.3 Control action and priorities. The fire-fighter's control panel actions shall be as follows:

1. ON-OFF and OPEN-CLOSE control actions shall have the highest priority of any control point within the building. Once issued from the fire-fighter's control panel, no automatic or manual control from any other control point within the building shall contradict the control action. Where automatic means are provided to interrupt normal, nonemergency equipment operation or produce a specific result to safeguard the building or equipment (i.e., duct freezestats, duct smoke detectors, high-temperature cutouts, temperature-actuated linkage and similar devices), such means shall be capable of being overridden by the fire-fighter's control panel. The last control action as indicated by each fire-fighter's control panel switch position shall prevail. In no case shall control actions require the smoke control system to assume more than one configuration at any one time.

Exception: Power disconnects required by NFPA 70.

2. Only the AUTO position of each three-position fire-fighter's control panel switch shall allow automatic or manual control action from other control points within the building. The AUTO position shall be the NORMAL, nonemergency, building control position. Where a fire-fighter's control panel is in the AUTO position, the actual status of the device (on, off, open, closed) shall continue to be indicated by the status indicator described above. When directed by an automatic signal to assume an emergency condition, the NORMAL position shall become the emergency condition for that device or group of devices within the zone. In no case shall control actions require the smoke control system to assume more than one configuration at any one time.

This section clarifies that when a component of the system is placed in an on-off or open-close configuration, no other control point in the building, whether automatic or manual, can override the action estab-
lished in the fire command center. If a system component is configured in auto mode, it can be controlled from locations within the building beyond the fire command center. Some controls are specifically designed to only allow an action from the fire command center.

[F] 909.17 System response time. Smoke-control system activation shall be initiated immediately after receipt of an appropriate automatic or manual activation command. Smoke control systems shall activate individual components (such as dampers and fans) in the sequence necessary to prevent physical damage to the fans, dampers, ducts and other equipment. For purposes of smoke control, the fire-fighter's control panel response time shall be the same for automatic or manual smoke control action initiated from any other building control point. The total response time, including that necessary for detection, shutdown of operating equipment and smoke control system startup, shall allow for full operational mode to be achieved before the conditions in the space exceed the design smoke condition. The system response time for each component and their sequential relationships shall be detailed in the required rational analysis and verification of their installed condition reported in the required final report.

- This particular section provides the criteria as to when the smoke control system is required to begin operation. Whether or not the activation is manual or automatic, this criteria clarifies that the system be initiated immediately. Also, it requires that components activate in a sequence that will not potentially damage the fans, dampers, ducts and other equipment. Unrealistic timing of the system has the potential of creating an unsuccessful system. Delays in the system can be seen in slow dampers, fans that ramp up or down, systems that poll slowly and intentional built-in delays. These factors can add significantly to the reaction time of the system and may hamper achieving the design goals.

The key element is that the system be fully operational before the smoke conditions exceed the design parameters. The design should include these possible delays when analyzing the smoke layer interface location. The sequence of events need to be justified within the design analysis and described clearly in the construction documents.

[F] 909.18 Acceptance testing. Devices, equipment, components and sequences shall be individually tested. These tests, in addition to those required by other provisions of this code, shall consist of determination of function, sequence and, where applicable, capacity of their installed condition.

- In order to achieve a certain level of performance, the smoke control system needs to be thoroughly tested. Section 909.18 requires that all devices, equipment components and sequences be individually tested.

[F] 909.18.1 Detection devices. Smoke or fire detectors that are part of a smoke control system shall be tested in accordance with Chapter 9 in their installed condition. When appli-

cable, this testing shall include verification of airflow in both minimum and maximum conditions.

- Detection devices are required to be tested in accordance with the fire protection requirements found in Chapter 9. Also, since such detectors may be subject to higher air velocities than typical detectors, their operation needs to be verified in the minimum and maximum anticipated airflow conditions.

[F] 909.18.2 Ducts. Ducts that are part of a smoke control system shall be traversed using generally accepted practices to determine actual air quantities.

- This section requires ducts that are part of the smoke control system to be tested to show that the proper amount of air is flowing. It should be noted that Section 909.10.2 requires that the ducts be leak tested to 1.5 times the maximum design pressure. Such leakage is not allowed to exceed 5 percent of the design flow.

[F] 909.18.3 Dampers. Dampers shall be tested for function in their installed condition.

- This section notes that all dampers need to be inspected to meet the function for which they are installed. For instance, a damper that is to be open when the system is in smoke control mode should be verified to be open when testing the system. Also, a damper may have a specific timing associated with its operation that would need to be verified though testing.

[F] 909.18.4 Inlets and outlets. Inlets and outlets shall be read using generally accepted practices to determine air quantities.

- Similar to ducts, the appropriate amount of air that is entering or exiting the inlets and outlets, respectively, must be checked.

[F] 909.18.5 Fans. Fans shall be examined for correct rotation. Measurements of voltage, amperage, revolutions per minute (rpm) and belt tension shall be made.

- This section requires the testing of fans for the following: correct rotation, voltage, amperage, revolutions per minute and belt tension. These features are key in having the system run as designed.

A common problem with fans is that they are often installed in the reverse direction. Also, to verify the reliability of the fans, elements such as the appropriate voltage and belt tension need to be tested.

[F] 909.18.6 Smoke barriers. Measurements using inclined manometers or other approved calibrated measuring devices shall be made of the pressure differences across smoke barriers. Such measurements shall be conducted for each possible smoke control condition.

- As discussed in Section 909.5.1, the testing of pressure differences across smoke barriers needs to be measured in the smoke control mode. As noted in Section 909.18.6, such testing is to be performed for
every possible smoke control condition, and the measurements will be taken using an inclined manometer or other approved methods. Electronic devices are also available. Qualified individuals must calibrate these types of devices. Additionally, before using an alternative method of testing, the building official needs to approve such a method.

[F] 909.18.7 Controls. Each smoke zone equipped with an automatic-initiation device shall be put into operation by the actuation of one such device. Each additional device within the zone shall be verified to cause the same sequence without requiring the operation of fan motors in order to prevent damage. Control sequences shall be verified throughout the system, including verification of override from the fire-fighter’s control panel and simulation of standby power conditions.

- This section requires the overall testing of the system. More specifically, each zone needs to individually initiate the smoke control system by the activation of an automatic initiation device. Once that has occurred, all other devices within each zone need to be verified that they will activate the system, but to avoid damage, the fans do not need to be activated.

In addition to determining that all the appropriate devices initiate the system, it must also be verified that all of the controls on the fire-fighter control panel initiate the appropriate aspects of the smoke control system, including the override capability.

Finally, the initiation and availability of the standby power system need to be verified.

[F] 909.18.8 Special inspections for smoke control. Smoke control systems shall be tested by a special inspector.

- Smoke control systems require special inspection since they are unique and complex life safety systems. Section 1704.16 provides the same requirements for special inspection as presented in Sections 909.18.8.1 and 909.18.8.2.

[F] 909.18.8.1 Scope of testing. Special inspections shall be conducted in accordance with the following:

1. During erection of ductwork and prior to concealment for the purposes of leakage testing and recording of device location.

2. Prior to occupancy and after sufficient completion for the purposes of pressure-difference testing, flow measurements, and detection and control verification.

- Special inspections need to occur at two different stages during construction to facilitate the necessary inspections. The first round of special inspections occurs before concealment of the ductwork or fire protection elements. The special inspector needs to verify the leakage as noted in Section 909.10.2. Additionally, the location of all fire protection devices needs to be verified and documented at this time.

The second round of special inspections occurs just prior to occupancy. The inspections include the verification of pressure differences across smoke barriers, as required in Sections 909.5.1 and 909.18.6, the verification of appropriate volumes of airflow as noted in the design and finally the verification of the appropriate operation of the detection and control mechanisms as required in Sections 909.18.1 and 909.18.7. These tests need to occur just prior to occupancy, since the test result will more clearly represent actual conditions. This also makes a strong design and quality assurance during construction critical, as it is very costly and difficult in most cases to make changes at this stage. Note that the test does not actually place smoke into the space and demonstrate the smoke layer interface location. Instead, the testing is focused on all the elements of the design such as airflow and duct closure as prescribed by the specific design.

[F] 909.18.8.2 Qualifications. Special inspection agencies for smoke control shall have expertise in fire protection engineering, mechanical engineering and certification as air balancers.

- As noted in Section 909.3, special inspections are required for smoke control systems. This means a certain level of qualification that would include the need for expertise in fire protection engineering, mechanical engineering and certification as air balancers.

[F] 909.18.8.3 Reports. A complete report of testing shall be prepared by the special inspector or special inspection agency. The report shall include identification of all devices by manufacturer, nameplate data, design values, measured values and identification tag or mark. The report shall be reviewed by the responsible registered design professional and, when satisfied that the design intent has been achieved, the responsible registered design professional shall seal, sign and date the report.

- Once the special inspections are complete, documentation of the activity is required. This documentation is to be prepared in the form of a report that identifies all devices by manufacturer, nameplate data, design values, measured values and identification or mark.

[F] 909.18.8.3.1 Report filing. A copy of the final report shall be filed with the fire code official and an identical copy shall be maintained in an approved location at the building.

- The report needs to be reviewed, approved and then signed, sealed and dated. This report is to be provided to the building official and a copy is also to remain in the building in an approved location. When a fire command center is required this is the best location for such documents. Otherwise, a location such as the security office or building manager's office might be appropriate.

[F] 909.18.9 Identification and documentation. Charts, drawings and other documents identifying and locating each component of the smoke control system, and describing its proper function and maintenance requirements, shall be maintained on file at the building as an attachment to the report required by Section 909.18.8.3. Devices shall have an approved identifying tag or mark on them consistent with the
other required documentation and shall be dated indicating the last time they were successfully tested and by whom.

- Additional documentation that needs to be maintained includes charts, drawings and other related documentation that assists in the identification of each aspect of the smoke control system. This documentation is where information, such as the last time a device or component was successfully tested and by whom, is recorded. This will serve as the main documentation for the system. Again, the fire command center, if required, is the most appropriate location for such information (see commentary, Section 909.18.3.1).

[F] 909.19 System acceptance. Buildings, or portions thereof, required by this code to comply with this section shall not be issued a certificate of occupancy until such time that the fire code official determines that the provisions of this section have been fully complied with and that the fire department has received satisfactory instruction on the operation, both automatic and manual, of the system and a written maintenance program complying with the requirements of Section 909.20.1 of the International Fire Code has been submitted and approved by the fire code official.

Exception: In buildings of phased construction, a temporary certificate of occupancy, as approved by the fire code official, shall be allowed provided that those portions of the building to be occupied meet the requirements of this section and that the remainder does not pose a significant hazard to the safety of the proposed occupants or adjacent buildings.

- This section stipulates that the certificate of occupancy cannot be issued unless the smoke control system has been accepted. It is essential that the system be inspected and approved since it is a life safety system. There is an exception for buildings that are constructed in phases where a temporary certificate of occupancy is allowed. For example, a building where the portion requiring smoke control is not yet occupied so egress concerns through that space are not relevant. This space needs to be separated by smoke barriers (different smoke zone). The IFC also requires a maintenance program for smoke control systems since the long-term success of such systems depends heavily on proper maintenance in addition to rigorous acceptance testing. The IBC simply provides a reference to that section of the IFC.

909.20 Smokeproof enclosures. Where required by Section 1022.10, a smokeproof enclosure shall be constructed in accordance with this section. A smokeproof enclosure shall consist of an enclosed interior exit stairway that conforms to Section 1022.2 and an open exterior balcony or ventilated vestibule meeting the requirements of this section. Where access to the roof is required by the International Fire Code, such access shall be from the smokeproof enclosure where a smokeproof enclosure is required.

- In a building that serves stories where the floor surface is located more than 75 feet (22860 mm) above the level of fire department access or more than 30 feet (9144 mm) below the level of exit discharge stairways, either a smokeproof enclosure or a pressurized stairway is required.

A smokeproof enclosure essentially takes advantage of fire-resistance-rated construction surrounding the stair shaft and a buffer zone created by an outside balcony or ventilated vestibule to avoid the accumulation of smoke within the exit stairway. The premise is that if access to the smokeproof enclosure provides a sufficient buffer to the effects of smoke via ventilation or simply being located outside, the smoke will not migrate into the enclosure.

The vestibule as noted is required to be ventilated. There are two alternatives provided in Section 909.20. They include natural ventilation, covered in Section 909.20.3, and mechanical ventilation, covered in Section 909.20.4. It should be noted that a smokeproof enclosure is not considered a pressurized stairway. The method of pressurizing stairways is recognized as an alternative to the smokeproof enclosures in Section 909.20.5, but is not required.

909.20.1 Access. Access to the stair shall be by way of a vestibule or an open exterior balcony. The minimum dimension of the vestibule shall not be less than the required width of the corridor leading to the vestibule but shall not have a width of less than 44 inches (1118 mm) and shall not have a length of less than 72 inches (1829 mm) in the direction of egress travel.

- As noted, access to the stair in a smokeproof enclosure is via an exterior balcony or a ventilated vestibule. This section provides the minimum dimensions for access to the smokeproof enclosure through a vestibule and then travel space to the entrance into the stairway. If a vestibule is chosen, the minimum width is established as the larger of 44 inches (1118 mm) or the width of the corridor. Additionally, when entering a vestibule there needs to be at least 72 inches (1829 mm) in the direction of travel (see Figure 909.20.1). It should be noted that the pressurized stairway alternative would not require a vestibule.

909.20.2 Construction. The smokeproof enclosure shall be separated from the remainder of the building by not less than 2-hour fire barriers constructed in accordance with Section 701 or horizontal assemblies constructed in accordance with Section 711, or both. Openings are not permitted other than the required means of egress doors. The vestibule shall be separated from the stairway by not less than 2-hour fire barriers constructed in accordance with Section 701 or horizontal assemblies constructed in accordance with Section 711, or both. The open exterior balcony shall be constructed in accordance with the fire-resistance rating requirements for floor assemblies.

- This section sets the basic construction requirements for the stairway and the associated vestibule or exterior balcony. Essentially, a 2-hour fire-resistance-rated fire barrier or horizontal assembly is required between the enclosure and the rest of the building. Additionally, vestibules need to be separated from the stairway by a 2-hour fire barrier or horizontal
assembly. The exterior balcony, if used, would only be required to comply with the fire-rating requirements for floor construction. The opening protection for doors into the stairway from the vestibule are only required to be fire protection-rated for 20 minutes (see Sections 909.20.3.2 and 909.20.4.1).

909.20.2.1 Door closers. Doors in a smokeproof enclosure shall be self- or automatic closing by actuation of a smoke detector in accordance with Section 716.5.9.3 and shall be installed at the floor-side entrance to the smokeproof enclosure. The actuation of the smoke detector on any door shall activate the closing devices on all doors in the smokeproof enclosure at all levels. Smoke detectors shall be installed in accordance with Section 907.3.

- In order to maintain the separation between the smokeproof enclosure and the rest of the building, the doors need to be self-closing or automatic closing through the actuation of a smoke detector. Also, when a smoke detector is activated on any floor, doors at all levels are required to close for that particular smokeproof enclosure.

909.20.3 Natural ventilation alternative. The provisions of Sections 909.20.3.1 through 909.20.3.3 shall apply to ventilation of smokeproof enclosures by natural means.

- Smoke and hot gases generated by fire may enter smokeproof enclosures through the doorways. This section provides for the diffusion of smoke and gases to the outside of the building by means of unenclosed openings to the outside.

909.20.3.1 Balcony doors. Where access to the stairway is by way of an open exterior balcony, the door assembly into the enclosure shall be a fire door assembly in accordance with Section 716.5.

- Where an open exterior balcony is used for entry into the stairway, the doorways to the stairway are required to have a $1^{1/2}$-hour fire protection rating as required for 2-hour fire-resistance-rated wall assemblies in accordance with the requirements of Section 715.4. If a vestibule is used the rating of the door from the vestibule into the stairway would only be required to be fire protection rated for 20 minutes. The door into the vestibule would require a fire protection rating of $1^{1/2}$ hours.

909.20.3.2 Vestibule doors. Where access to the stairway is by way of a vestibule, the door assembly into the vestibule shall be a fire door assembly complying with Section 715.4. The door assembly from the vestibule to the stairway shall have not less than a 20-minute fire protection rating complying with Section 716.5.

- When a smokeproof enclosure is of the type that employs a vestibule as the means of access to an enclosed exit stairway, the entry into the vestibule from the exit access must consist of a fire door assembly having a $1^{1/2}$-hour fire protection rating. This requirement is commensurate with the 2-hour fire-resistance- rated smokeproof enclosure construction requirement and the associated fire protection ratings specified in Table 715.4. Essentially, the fire door assemblies and the enclosure walls serve as the primary exit enclosure protection from fires occurring in adjacent spaces.

The entry from a vestibule into the stairway requires a 20-minute fire-protection-rated door assembly. These doorways are not normally subject to direct fire exposure and, therefore, only a nominal fire protection rating is required as a standard of construction that would minimize air leakage and thus reduce the possibilities of smoke and hot gases penetrating the stairway in amounts that could become a threat to life safety.

Door assemblies must comply with the requirements of Section 715.4 (see Figure 909.20.3.2).

![Figure 909.20.1](image)

DIMENSIONAL REQUIREMENTS FOR SMOKEPROOF ENCLOSURE VESTIBULE

For SI: 1 inch = 25.4 mm.
909.20.3.3 Vestibule ventilation. Each vestibule shall have a minimum net area of 16 square feet (1.5 m²) of opening in a wall facing an outer court, yard or public way that is at least 20 feet (6096 mm) in width.

- Natural ventilation is allowed for vestibules that have a minimum net opening of 16 square feet (1.49 m²) and open into an outer court, yard or public way that is at least 20 feet (6096 mm) in width. Basically, this option is intended to take advantage of the fact that smoke may disperse into an open area before entering the stair enclosure.

909.20.4 Mechanical ventilation alternative. The provisions of Sections 909.20.4.1 through 909.20.4.4 shall apply to ventilation of smokeproof enclosures by mechanical means.

- When an exterior balcony is not possible or when the clear open area cannot be achieved, then the mechanical ventilation alternative is necessary.

909.20.4.1 Vestibule doors. The door assembly from the building into the vestibule shall be a fire door assembly complying with Section 716.5.3. The door assembly from the vestibule to the stairway shall not have less than a 20-minute fire protection rating and meet the requirements for a smoke door assembly in accordance with Section 716.5.3. The door shall be installed in accordance with NFPA 105.

- The entry into the vestibule from the exit access must consist of a fire assembly having a 1 1/2-hour fire protection rating. This requirement is commensurate with the 2-hour fire-resistance-rated smokeproof enclosure construction requirement and the associated fire protection ratings specified in Table 715.4. Essentially, the fire door assemblies and the enclosure walls serve as the primary interior exit stairway protection from fires occurring in adjacent spaces.

The entry from a vestibule into the stairway requires a 20-minute fire protection-rated door assembly that also meets the requirements for a smoke door assembly. Vestibule doors into stairways for the natural ventilation option (see Section 909.20.3.2) would not require the smoke door assembly rating in accordance with Section 715.4.3. The natural ventilation option requires an opening to the outside that is intended to compensate for this difference (see Figure 909.20.4.1).

909.20.4.2 Vestibule ventilation. The vestibule shall be supplied with not less than one air change per minute and the exhaust shall not be less than 150 percent of supply. Supply air shall enter and exhaust air shall discharge from the vestibule through separate, tightly constructed ducts used only for that purpose. Supply air shall enter the vestibule within 6 inches (152 mm) of the floor level. The top of the exhaust register shall be located at the top of the smoke trap but not more than 6 inches (152 mm) down from the top of the trap, and shall be entirely within the smoke trap area. Doors in the open position shall not obstruct duct openings. Duct openings with controlling dampers are permitted where necessary to meet the design requirements, but dampers are not otherwise required.

- This section provides the basic criteria for the mechanical ventilation of the vestibule during a fire situation. Such ventilation is required to be activated via a smoke detector in accordance with Section 909.20.6. The basic requirements are for one air change per minute within the vestibule. Also the exhaust is required to be 150 percent of the supply. The exhaust is required to exceed the supply so that air will not be pushed into the stairway due to a positive pressure being created within the vestibule.

![Figure 909.20.3.2](image)
should be noted that there is not a minimum pressure difference requirement. Instead, the code simply prescribes a particular air change rate (exhaust).

This section also prescribes criteria as to where supply air and exhaust air are to enter and exit, respectively, and requires that those paths are clear (see Figure 909.20.4.2).

It should be noted that this section does not specify when and how such systems should activate. Activation is addressed by Section 909.20.6.

909.20.4.2.1 Engineered ventilation system. Where a specially engineered system is used, the system shall exhaust a quantity of air equal to not less than 90 air changes per hour from any vestibule in the emergency operation mode and shall be sized to handle three vestibules simultaneously. Smoke detectors shall be located at the floor-side entrance to each vestibule and shall activate the system for the affected vestibule. Smoke detectors shall be installed in accordance with Section 907.3.

- If the method prescribed in Section 909.20.4.2 for mechanical ventilation of vestibules is not chosen, then minimum criteria is provided for engineered systems. Essentially, the designer can create a design that meets the flexibility needs of the building and at the same time meets basic criteria. Once designed and installed, the vestibules must be ventilated at 90 air changes per hour, which is 30 more air changes per hour than the prescriptive solution would require. The exhaust rate is not mandated. It is simply left to the designer to achieve the 90 air changes per hour within the space (vestibule). Additionally, this system needs to be sized to handle at least three vestibules simultaneously. Finally, the engineered systems are required to operate in accordance with the initiation of a smoke detector located on the floor-side entrance of the affected vestibule; therefore, a smoke detector would be required on each floor at the entrance to each vestibule. The system would only need to be activated on the floors where smoke is detected.

909.20.4.3 Smoke trap. The vestibule ceiling shall be at least 20 inches (508 mm) higher than the door opening into the vestibule to serve as a smoke and heat trap and to provide an upward-moving air column. The height shall not be decreased unless approved and justified by design and test.

- This section requires a 20-inch (508 mm) difference in height between the door openings into the vestibule and the ceiling. This is intended to allow an additional safeguard to assist in the containment of smoke inside the vestibule and outside the stair shaft. Essentially, as the title states, it provides a smoke trap. This arrangement also has the effect of keeping the air movement upward.

909.20.4.4 Stair shaft air movement system. The stair shaft shall be provided with a dampered relief opening and supplied with sufficient air to maintain a minimum positive pressure of 0.10 inch of water (25 Pa) in the shaft relative to the vestibule with all doors closed.

- In order to prevent smoke from migrating into the stairway from the vestibule, a positive pressure of 0.10 inch (25 Pa) of water in the stair shaft relative to the vestibule is required. This pressure difference is

---

For SI: 1 inch = 25.4 mm.

Figure 909.20.4.1

SMOKEPROOF ENCLOSURE WITH CORRIDOR ARRANGEMENT

9-110  2012 INTERNATIONAL BUILDING CODE® COMMENTARY
to be available when all doors are closed. This pressure difference is lower than that required by the stair pressurization alternative. This would not be considered a pressurized stair. This pressure difference would need to be tested to obtain approval once constructed.

909.20.5 Stair pressurization alternative. Where the building is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1, the vestibule is not required, provided that interior exit stairways are pressurized to a minimum of 0.10 inches of water (25 Pa) and a maximum of 0.35 inches of water (87 Pa) in the shaft relative to the building measured with all stairway doors closed under maximum anticipated conditions of stack effect and wind effect.

- This method is allowed only when the building is fully sprinklered. This is partially related to the fact that these pressure differences were developed based upon a sprinklered fire. It should be noted that smokeproof enclosures are not required to be in fully sprinklered buildings, but areas where smokeproof enclosures are required are often sprinklered buildings (i.e., high-rise buildings). This alternative would not require vestibules or an exterior exit balcony. The criteria for smoke control design is provided in terms of minimum and maximum pressure differences of 0.10 inch (37 Pa) of water and 0.35 inch (87 Pa) of water, respectively, between the shaft and the building. This pressure difference is to be achieved when all doors are closed and maximum conditions of wind and stack effect have been taken into account. It should be noted that additional limitations may be placed on the maximum pressure differences for pressurized stairs due to the lower opening forces required in order to comply with Section 1008.1.3. If the maximum pressure difference of .35 would exceed the requirements of Section 1008.1.3, the maximum pressure difference would need to be lowered. Also note that Section 404.2.8 of ICC A117.1 would not require opening forces to be lowered for accessibility purposes if the door is a fire door. Finally, as with all other smoke control systems addressed in Section 909, such systems need to be designed through a rational analysis, tested and documented as such.

909.20.6 Ventilating equipment. The activation of ventilating equipment required by the alternatives in Sections 909.20.4 and 909.20.5 shall be by smoke detectors installed at each floor level at an approved location at the entrance to the smokeproof enclosure. When the closing device for the stair shaft and vestibule doors is activated by smoke detection or power failure, the mechanical equipment shall activate and operate at the required performance levels. Smoke detectors shall be installed in accordance with Section 907.3.

- This section clarifies that the activation mechanism for both mechanical means of smoke management for interior exit stairways in Sections 909.20.4 and 909.20.5 should be via a smoke detector located at each level outside the door leading into the vestibule and stairway, respectively. For systems that use automatic-closing devices on the doors, whether for vestibules in smokeproof enclosures or for pressur-
IZED STAIRWAYS, IF THE DOOR CLOSES, THE SYSTEM MUST ACTIVATE. THIS INCLUDES NORMAL ACTIVATION OF THE SMOKE DETECTOR OR IN THE EVENT OF A POWER FAILURE. ESSENTIALLY, IF THERE IS A POWER FAILURE IT WILL OPERATE IN A FAIL-SAFE MANNER EVEN IF THERE IS NOT A FIRE.

909.20.6.1 VENTILATION SYSTEMS. SMOKEPROOF ENCLOSURE VENTILATION SYSTEMS SHALL BE INDEPENDENT OF OTHER BUILDING VENTILATION SYSTEMS. THE EQUIPMENT, CONTROL WIRING, POWER WIRING AND DUCTWORK SHALL COMPLY WITH ONE OF THE FOLLOWING:

1. EQUIPMENT, CONTROL WIRING, POWER WIRING AND DUCTWORK SHALL BE LOCATED EXTERIOR TO THE BUILDING AND DIRECTLY CONNECTED TO THE SMOKEPROOF ENCLOSURE OR CONNECTED TO THE SMOKEPROOF ENCLOSURE BY DUCTWORK ENCLOSED BY NOT LESS THAN 2-HOUR FIRE BARRIERS CONSTRUCTED IN ACCORDANCE WITH SECTION 707 OR HORIZONTAL ASSEMBLIES CONSTRUCTED IN ACCORDANCE WITH SECTION 711, OR BOTH.

2. EQUIPMENT, CONTROL WIRING, POWER WIRING AND DUCTWORK SHALL BE LOCATED WITHIN THE SMOKEPROOF ENCLOSURE WITH INTAKE OR EXHAUST DIRECTLY FROM AND TO THE OUTSIDE OR THROUGH DUCTWORK ENCLOSED BY NOT LESS THAN 2-HOUR FIRE BARRIERS CONSTRUCTED IN ACCORDANCE WITH SECTION 707 OR HORIZONTAL ASSEMBLIES CONSTRUCTED IN ACCORDANCE WITH SECTION 711, OR BOTH.

3. EQUIPMENT, CONTROL WIRING, POWER WIRING AND DUCTWORK SHALL BE LOCATED WITHIN THE BUILDING IF SEPARATED FROM THE REMAINDER OF THE BUILDING, INCLUDING OTHER MECHANICAL EQUIPMENT, BY NOT LESS THAN 2-HOUR FIRE BARRIERS CONSTRUCTED IN ACCORDANCE WITH SECTION 707 OR HORIZONTAL ASSEMBLIES CONSTRUCTED IN ACCORDANCE WITH SECTION 711, OR BOTH.

EXCEPTIONS:

1. CONTROL WIRING AND POWER WIRING UTILIZING A 2-HOUR RATED CABLE OR CABLE SYSTEM.

2. WHERE ENCASED WITH NOT LESS THAN 2 INCHES (51 MM) OF CONCRETE.

△ SMOKEPROOF ENCLOSURES AND PRESSURIZED STAIR SHAFT VENTILATION SYSTEMS MUST BE INDEPENDENT OF OTHER BUILDING VENTILATING SYSTEMS. THIS SECTION PROVIDES THREE OPTIONS FOR THE LOCATION OF THE DUCTWORK ASSOCIATED WITH SMOKEPROOF ENCLOSURES AND STAIR PRESSURIZATION MECHANICAL EQUIPMENT. THE THREE OPTIONS INCLUDE THE FOLLOWING:

• LOCATED ON THE EXTERIOR OF THE BUILDING AND DIRECTLY CONNECTED TO THE SMOKEPROOF ENCLOSURE;

• WITHIN THE SMOKEPROOF ENCLOSURE; OR

• WITHIN THE BUILDING BUT SEPARATED FROM THE REMAINDER OF THE BUILDING BY 2-HOUR FIRE-BARRIERS OR HORIZONTAL BARRIERS, OR BOTH.

909.20.6.2 STANDBY POWER. MECHANICAL VESTIBULE AND STAIR SHAFT VENTILATION SYSTEMS AND AUTOMATIC FIRE DETECTION SYSTEMS SHALL BE POWERED BY AN APPROVED STANDBY POWER SYSTEM CONFORMING TO SECTION 403.4.8 AND CHAPTER 27.

△ THIS SECTION REQUIRES STANDBY POWER FOR MECHANICAL SYSTEMS FOR PRESSURIZED STAIR SHAFTS, MECHANICALLY VENTILATED VESTIBULES, STAIR SHAFTS FOR SMOKEPROOF ENCLOSURES AND ANY AUTOMATIC FIRE DETECTION SYSTEMS RELATED TO THE ACTIVATION OF SUCH SYSTEMS.

909.20.6.3 ACCEPTANCE AND TESTING. BEFORE THE MECHANICAL EQUIPMENT IS APPROVED, THE SYSTEM SHALL BE TESTED IN THE PRESENCE OF THE BUILDING OFFICIAL TO CONFIRM THAT THE SYSTEM IS OPERATING IN COMPLIANCE WITH THESE REQUIREMENTS.

• THIS SECTION REQUIRES VERIFICATION OF SUCCESSFUL TESTING OF THE SYSTEM TO THE BUILDING OFFICIAL. THE REQUIREMENTS OF SECTIONS 909.18 AND 909.19 SHOULD BE ADDRESSED WHEN TESTING SMOKEPROOF ENCLOSURES OR PRESSURIZED STAIRS. IT SHOULD BE NOTED THAT THE IFC DOES NOT CONTAIN THE PROVISIONS FOR SMOKEPROOF ENCLOSURES AND PRESSURIZED STAIRWAYS, BUT IT MAY BE IN THE BEST INTEREST TO ALSO NOTIFY THE FIRE DEPARTMENT OF SUCH TESTING AND ACCEPTANCE.

909.21 ELEVATOR HOISTWAY PRESSURIZATION ALTERNATIVE. WHERE ELEVATOR HOISTWAY PRESSURIZATION IS PROVIDED IN LIEU OF REQUIRED ENCLOSED ELEVATOR LOBBIES, THE PRESSURIZATION SYSTEM SHALL COMPLY WITH SECTIONS 909.21.1 THROUGH 909.21.11.

• THIS SECTION SETS OUT THE REQUIREMENTS FOR HOISTWAY PRESSURIZATION WHEN USED AS AN EXCEPTION TO THE ELEVATOR LOBBY REQUIREMENTS IN SECTION 713.14.1. THE MINIMUM AND MAXIMUM PRESSURES ARE SIMILAR TO THOSE FOR PRESSURIZED STAIRS IN SECTION 909.20.5. THE PROVISIONS ARE LOCATED IN SECTION 909 TO GROUP ALL THE SMOKE CONTROL TECHNIQUES AND REQUIREMENTS INTO THE SAME SECTION. THIS WILL PROMOTE MORE CONSISTENCY IN CODE APPLICATION WHEN ADDRESSING SMOKE CONTROL.

909.21.1 PRESSURIZATION REQUIREMENTS. ELEVATOR HOISTWAYS SHALL BE PRESSURIZED TO MAINTAIN A MINIMUM POSITIVE PRESSURE OF 0.10 INCHES OF WATER (25 PA) AND A MAXIMUM POSITIVE PRESSURE OF 0.25 INCHES OF WATER (67 PA) WITH RESPECT TO ADJACENT OCCUPIED SPACE ON ALL FLOORS. THIS PRESSURE SHALL BE MEASURED AT THE MIDPOINT OF EACH HOISTWAY DOOR, WITH ALL ELEVATOR CARS AT THE FLOOR OF RECALL AND ALL HOISTWAY DOORS ON THE FLOOR OF RECALL OPEN AND ALL OTHER HOISTWAY DOORS CLOSED. THE OPENING AND CLOSING OF HOISTWAY DOORS AT EACH LEVEL MUST BE DEMONSTRATED DURING THIS TEST. THE SUPPLY AIR INTAKE SHALL BE FROM AN OUTSIDE, UNCONTAMINATED SOURCE LOCATED A MINIMUM DISTANCE OF 20 FEET (6096 MM) FROM ANY EXHAUST SYSTEM OR OUTLET.

• THIS SECTION STATES THE MINIMUM AND THE MAXIMUM POSITIVE PRESSURE THAT MUST BE ACHIEVED BY THE SMOKE CONTROL MECHANICAL PRESSURIZATION SYSTEM. THE MINIMUM POSITIVE PRESSURE IS 0.10 INCH OF WATER COLUMN (0.02 KPA), THE SAME AS REQUIRED FOR STAIRWAY PRESSURIZATION IN SECTION 909.20.5. THE MAXIMUM PRESSURE IS 0.25 INCH OF WATER COLUMN (0.06 KPA) WHICH IS A LITTLE LESS THAN THE MAXIMUM ALLOWED FOR STAIRWAY PRESSURIZATION. THE MINIMUM PRESSURE IS TO ENSURE THAT THE STACK EFFECT IS OVERCOME AND THE MAXIMUM PRESSURE IS AN UPPER LIMIT TO ENSURE THAT THE DOORS WILL OPERATE PROPERLY. THIS SECTION REQUIRES A TEST WHEN THE SYSTEM IS COMPLETE. THE PRESSURES ARE MEASURED AT THE MIDPOINT OF EACH HOISTWAY DOOR WITH ALL ELEVATOR CARS AT THE RECALL FLOOR AND ALL THE HOISTWAY DOORS OPEN ON THAT LEVEL. THIS SIMULATES THE PHASE 1 RECALL REQUIREMENTS IN SECTION 3003.2. HOISTWAY
doors are then tested on each level to ensure proper operation. The supply air intake for the pressurization system must be located at least 20 feet (6096 mm) away from any source of contamination to ensure that the hoistway remains tenable through the fire event or well into it before the elevators can no longer be used. Also, if smoke is drawn into the supply air, the system will only spread smoke and not prevent its spread.

909.21.2 Rational analysis. A rational analysis complying with Section 909.4 shall be submitted with the construction documents.

- Section 909.4 recognizes that there are many factors involved in a smoke control system, including stack effect due to height, temperature effect of fire, wind effect, interaction of the HVAC system, the weather and the egress time, all of which must be evaluated. The report must be submitted with the permit documents. Most importantly, the duration of operation of the smoke control system is a function of 1.5 times the egress time or 20 minutes, whichever is less. More discussion on the duration of operation is found in the commentary for Section 909.4.6.

909.21.3 Ducts for system. Any duct system that is part of the pressurization system shall be protected with the same fire-resistance rating as required for the elevator shaft enclosure.

- All ductwork necessary for hoistway pressurization must be protected from the effects of fire by enclosure in fire-resistance-rated construction equivalent to that required for the elevator hoistway shaft enclosure.

909.21.4 Fan system. The fan system provided for the pressurization system shall be as required by Sections 909.21.4.1 through 909.21.4.4.

- This section details the requirements for the mechanical system used for pressurization of the hoistway enclosure.

909.21.4.1 Fire resistance. When located within the building, the fan system that provides the pressurization shall be protected with the same fire-resistance rating required for the elevator shaft enclosure.

- The only way to ensure that the mechanical pressurization system can operate during a fire is to locate it in a safe place. If located within the building it must be in an enclosed room protected with the same fire-resistance-rated construction required for the hoistway enclosure.

909.21.4.2 Smoke detection. The fan system shall be equipped with a smoke detector that will automatically shut down the fan system when smoke is detected within the system.

- The airflow must be free of smoke or it will only increase the likelihood of smoke spreading throughout the building. The smoke detector required by this section should be located on the intake side of the blower fan.

909.21.4.3 Separate systems. A separate fan system shall be used for each elevator hoistway.

- This section requires that each hoistway enclosure have its own mechanical system. This provides a more redundant system and helps to increase the likelihood that fans will be operational during a fire.

909.21.4.4 Fan capacity. The supply fan shall either be adjustable with a capacity of at least 1,000 cfm (0.4719 m³/s) per door, or that specified by a registered design professional to meet the requirements of a designed pressurization system.

- The fan capacity should be as specified by the registered design professional to meet the operational ranges of pressure at each door or be adjustable with a capacity of at least 1,000 cfm (0.4719 m³/s) per hoistway door. In either case, it is subject to field testing and adjustments to meet the pressure ranges.

909.21.5 Standby power. The pressurization system shall be provided with standby power from the same source as other required emergency systems for the building.

- The elevator hoistway pressurization system is an emergency system and must have provisions for standby power like other emergency systems. Section 2702 states the requirements that standby power systems must meet. It is consistent with other smoke control systems required by Section 909 in that such systems have standby power as they are life-safety systems.

909.21.6 Activation of pressurization system. The elevator pressurization system shall be activated upon activation of the building fire alarm system or upon activation of the elevator lobby smoke detectors. Where both a building fire alarm system and elevator lobby smoke detectors are present, each shall be independently capable of activating the pressurization system.

- This section requires that the pressurization system will be activated when the general building fire alarm system or an elevator lobby smoke detector is activated. All buildings using this pressurization option will more than likely be required to have both. High-rise buildings require elevator lobby smoke detectors, but other buildings may not. Section 909.12 requires smoke detectors to activate the pressurization system if the design requires it to operate to remove the smoke.

909.21.7 Special inspection. Special inspection for performance shall be required in accordance with Section 909.18.8. System acceptance shall be in accordance with Section 909.19.

- A field inspection will be required to evaluate the performance of the completed system (see commentary, Sections 909.18 and 909.19).

909.21.8 Marking and identification. Detection and control systems shall be marked in accordance with Section 909.14.

- See the commentary to Section 909.14.
909.21.9 Control diagrams. Control diagrams shall be provided in accordance with Section 909.15.

- See the commentary to Section 909.15.

909.21.10 Control panel. A control panel complying with Section 909.16 shall be provided.

- See the commentary to Section 909.16.

909.21.11 System response time. Hoistway pressurization systems shall comply with the requirements for smoke control system response time in Section 909.17.

- See the commentary to Section 909.17.

SECTION 910
SMOKE AND HEAT REMOVAL

[F] 910.1 General. Where required by this code or otherwise installed, smoke and heat vents, or mechanical smoke exhaust systems, and draft curtains shall conform to the requirements of this section.

Exceptions:

1. Frozen food warehouses used solely for storage of Class I and II commodities where protected by an approved automatic sprinkler system.

2. Where areas of buildings are equipped with early suppression fast-response (ESFR) sprinklers, automatic smoke and heat vents shall not be required within these areas.

- Smoke and heat vents must be provided in buildings, structures or portions thereof where required by Section 910.2. It should be noted that Chapter 32 of the IFC would also be applicable (see commentary, Section 910.2.2). The systems must be designed, installed, maintained and operated in accordance with the provisions of this section.

The purpose of smoke and heat vents has historically been related to the needs of fire fighters. More specifically, smoke and heat vents, when activated, have the potential effect of lifting the height of the smoke layer and providing more tenable conditions to undertake fire-fighting activities. Other potential benefits include a decrease in property damage and the creation of more tenable conditions for occupants. The purpose of draft curtains, as addressed in Section 910.3.5, is both to contain the smoke in certain areas and potentially increase the speed in the activation of the smoke and heat vents.

Exception 1 recognizes the "building-within-a-building" nature of typical frozen food warehouses. As such, smoke from a fire within a freezer would be contained within the freezer, thus negating the usefulness of smoke and heat vents at the roof level.

Exception 2 recognizes the negative effect that smoke and heat vents can have on the operation of early suppression fast response (ESFR) sprinklers. Those negative effects include diverting heat away from the sprinklers, which could delay their activation or result in the activation of more sprinklers in areas away from the source of the fire, which may overwhelm the system. This section coordinates with the ESFR exception for draft curtains in Section 910.3.5. Both smoke and heat vents and draft curtains have a negative effect on ESFR sprinkler systems.

The intent of the code change that added this exception was to not require smoke and heat vents when ESFR sprinklers were used. The term "required" was used versus "prohibited" in an attempt to allow the installation of manual smoke and heat venting in some cases. Note j in Table 3206.2 of the IFC correlates with this exception but has a slightly different applicability. First, Note j only applies to high-piled storage. Second, the footnote does not differentiate between automatic or manual smoke and heat vents; it simply does not require them when an ESFR system is used.

[F] 910.2 Where required. Smoke and heat vents shall be installed in the roofs of buildings or portions thereof occupied for the uses set forth in Sections 910.2.1 and 910.2.2.

Exception: In occupied portions of a building where the upper surface of the story is not a roof assembly, mechanical smoke exhaust in accordance with Section 910.4 shall be an acceptable alternative.

- Smoke and heat vents are required in buildings but only by the provisions of Sections 910.2.1 and 910.2.2. It should be noted that smoke and heat vents are typically only of use in a single story or the top story of a building; therefore, the exception recognizes that stories of buildings that do not have a roof should be able to use mechanical smoke exhaust. Note that in previous editions of the code the requirements were simply limited to one-story buildings. The current requirements are more restrictive since multi-story buildings need to address smoke and heat venting as well. The fire-safety concerns that this section provides for should not be limited to one-story buildings. The need for smoke and heat venting is more critical in multi-story buildings due to increased travel distances to an exit discharge and the additional time it takes firefighting crews to reach an area of high-piled combustible storage located above or below grade plane level within a building.

[F] 910.2.1 Group F-1 or S-1. Buildings and portions thereof used as a Group F-1 or S-1 occupancy having more than 50,000 square feet (4646 m²) in undivided area.

Exception: Group S-1 aircraft repair hangars.

- Large-area buildings with moderate to heavy fire loads present special challenges to the fire department in disposing of the smoke generated in a fire. In order to provide the fire department with the ability to rapidly and efficiently dispose of smoke in large-area Groups F-1 and S-1 buildings exceeding 50,000 square feet (4645 m²) in undivided area without the exposure of personnel to the dangers associated with cutting ventilation holes in the roof, smoke and heat vents (or, alternatively, mechanical smoke removal facilities) must be provided.

In order to subdivide a more than 50,000-square-
foot (4645 m²) undivided area as one method of avoiding the use of smoke and heat vents, the dividing element would only need to be a partition constructed of materials equivalent to the construction of a draft curtain but that would extend from floor to ceiling in the space being separated. A fire barrier, smoke barrier, fire partition or smoke partition would be more than what is required and would therefore be an acceptable method of dividing the area.

This requirement is independent of the requirements related to high-piled storage in Section 910.2.2. Smoke and heat vent area requirements in Table 910.3 tend to be more restrictive for high-piled storage. High-piled storage is not occupancy specific.

[F] 910.2.2 High-piled combustible storage. Buildings and portions thereof containing high-piled combustible stock or rack storage in any occupancy group in accordance with Section 413 and the International Fire Code.

This section alerts the code user to the specific high-piled combustible storage requirements contained in Chapter 32 of the IFC. High-piled storage, whether solid piled, palletized or in racks, in excess of 12 feet (3658 mm) in height [6 feet (1829 mm) for high-hazard commodities] requires specific consideration, including fire protection design features and smoke and heat vents in order to be adequately protected. Not all high-piled storage will require the use of smoke and heat vents and draft curtains. In fact, if the high-piled storage is properly sprinklered (in accordance with Chapter 32 of the IFC and NFPA 13), draft curtains are not required (see commentary, Chapter 32 and Table 3206.2 of the IFC). In addition, where ESFR sprinklers are used, smoke and heat venting is not required. See Section 910.1, Exception 2 and Note j to Table 3206.2 of the IFC.

[F] 910.3 Design and installation. The design and installation of smoke and heat vents and draft curtains shall be as specified in Sections 910.3.1 through 910.3.5.2 and Table 910.3.

- Careful design and installation of smoke and heat vents is vital to their efficient operation in case of fire. The design criteria for these fire protection tools are organized for convenience and ready reference in Table 910.3, which is referenced by this section.

**TABLE 910.3.** See below.

- When smoke and heat vents and draft curtains are required, Table 910.3 identifies the required vent area in terms of ratio of vent area to floor area and draft curtain area and depth requirements. The table is essentially divided into two parts. The first part is for Group F-1 and S-2 occupancies, while the second portion is for high-piled combustible storage (organized by commodity type).

In applying the provisions of the table, note that the term "high hazard" is only referring to the high-piled storage commodity type, not the occupancy group classification (see Section 3203.6 of the IFC). Smoke and heat venting requirements for high-piled storage are not occupancy specific and originate from Chapter 32 of the IFC. The focus is upon the commodity classification, configuration and the size of the high-piled storage area. Chapter 32 of the IFC only requires smoke and heat venting and draft curtains

</table>

For SI: 1 foot = 304.8 mm, 1 square foot = 0.0929 m².

a. Additional requirements for rack storage heights in excess of those indicated shall be in accordance with Chapter 32 of the International Fire Code. For solid-piled storage heights in excess of those indicated, an approved engineering design shall be used.

b. Vents adjacent to walls or draft curtains shall be located within a horizontal distance not greater than the maximum distance specified in this column as measured perpendicular to the wall or draft curtain that forms the perimeter of the draft curtained area.

c. Where draft curtains are not required, the vent area to floor area ratio shall be calculated based on a minimum draft curtain depth of 6 feet (Option 1).

d. "H" is the height of the vent, in feet, above the floor.
for larger storage areas and areas that do not utilize ESFR sprinklers. The required vent areas vary based upon the commodity classification (I through IV or high hazard) and height of storage. The higher the storage, the higher the potential for a larger fire. Two options ("Option 1" and "Option 2") are given for commodity classifications I through IV and high hazard. The only significance to these options is that one option allows a lower vent-to-floor area ratio if a deeper draft curtain is chosen, simply providing some credit for the fact that the deeper draft curtains are more likely to contain more smoke than a shorter draft curtain; thus, the area contained by the draft curtains also varies. If draft curtains are not required, then these options are not necessary and the lower vent/area ratio can be used. Note c specifically allows the use of the lower vent-to-floor ratio (Option 1) where smoke and heat vents are required and draft curtains are not. Note d simply explains what "H" stands for as used in Column 3, Row 1. The last column of the table provides the maximum distance from walls or draft curtains that a smoke and heat vent can be located when the vent is adjacent to a wall or draft curtain. This would not apply to vents located in the middle of a cumbered area. Note b addresses how this is to be measured.

[F] 910.3.1 Design. Smoke and heat vents shall be listed and labeled to indicate compliance with UL 793.

This section specifically requires that all smoke and heat vents be both listed and labeled in accordance with UL 793. This provides consistency and a level of quality when smoke and heat vents are required. The standard addresses smoke and heat vents that automatically operate during fires via nonelectrical means. Automatic vents listed and labeled to this standard can be operated both automatically and manually. There are main mechanisms for activation that include a heat responsive device or on the action of a plastic cover shrinking and falling from place due to fire exposure.

[F] 910.3.2 Vent operation. Smoke and heat vents shall be capable of being operated by approved automatic and manual means. Automatic operation of smoke and heat vents shall conform to the provisions of Sections 910.3.2.1 through 910.3.2.3.

Since vents are used as a component of an active venting system, the releasing device is required to be automatic, such as a fusible link. The next several subsections of this section provide requirements for automatic activation of smoke and heat vents. The fusible link ratings are prescribed for nonsprinklered buildings but the strategy will vary in sprinklered buildings.

In addition to automatic operation of the vents, a manual means of operating them by the fire department during fire suppression operations must also be provided. It should be remembered that one of the main reasons smoke and heat vents were initially introduced was to reduce the need for fire fighters to have to ventilate the fire by getting on the roof of the burning building, often having to traverse large expanses of roof in order to get to the area over the fire and breaching the roof manually. Accordingly, the mechanisms for release and the needs of the fire department should be carefully considered.

[F] 910.3.2.1 Gravity-operated drop-out vents. Automatic smoke and heat vents containing heat-sensitive glazing designed to shrink and drop out of the vent opening when exposed to fire shall fully open within 5 minutes after the vent cavity is exposed to a simulated fire, represented by a time-temperature gradient that reaches an air temperature of 500°F (260°C) within 5 minutes.

This section establishes minimum performance criteria for drop-out vents, which include a nonmetallic, clear or opaque glazing element designed to shrink from its frame and fall away when exposed to heat from a fire. Such vent design must be capable of completely opening the roof vent within 5 minutes of exposure to a simulated fire represented by a time-temperature gradient that reaches an air temperature of 500°F (260°C) within 5 minutes. Drop-out vents tested in accordance with UL 793 must begin to operate at a maximum temperature of 286°F (141°C) in order to be labeled.

[F] 910.3.2.2 Sprinklered buildings. Where installed in buildings provided with an approved automatic sprinkler system, smoke and heat vents shall be designed to operate automatically.

Where smoke and heat vents are installed in sprinklered buildings, their operation must be automatic and coordinated with the operation of the sprinkler system. Caution should be exercised in the design of smoke and heat vents and the required draft curtains so that the draft curtains do not interfere with the operation of the automatic sprinklers, since locating a draft curtain too close to a sprinkler head could prevent proper water distribution over the fire. In addition, draft curtains will contain smoke and hot gases and can direct them away from the area where the fire is actually burning, thus activating sprinklers in the wrong area. This has the potential of overwhelming the sprinkler system.

More specifically, the fusible link operating temperatures should be coordinated with sprinkler head operating temperatures. The premature operation of a vent-opening mechanism could retard the operation of higher temperature-rated sprinkler heads by dissipating the level of heat needed to make the fusible link of the sprinkler(s) operate.

Delaying the operation of sprinklers can have the negative effect of causing an excessive number of sprinklers to operate, including some located outside the immediate area of fire danger. Concern over this issue has increased with the introduction of new sprinkler technology, such as the use of ESFR sprinklers, which are designed to act quickly to apply larger volumes of water to extinguish rather than simply control the fire. For that reason, ESFR sprinklers
are specifically exempted in Sections 910.1 from the smoke and heat vent requirements.

[F] 910.3.3 Nonsprinklered buildings. Where installed in buildings not provided with an approved automatic sprinkler system, smoke and heat vents shall operate automatically by actuation of a heat-responsive device rated at between 100°F (38°C) and 220°F (104°C) above ambient.

Exception: Gravity-operated drop-out vents complying with Section 910.3.2.1.

- Where smoke and heat vents are installed in buildings that are not equipped with an automatic sprinkler system, their operation must be automatic, with their operating elements set at between 100 and 220°F (38 and 104°C) above the ambient temperature of the area in which they are installed. Smoke and heat vents in nonsprinklered buildings do not have concerns with sprinkler interaction; therefore, the operation is specifically prescribed. The exception indicates that gravity-operated drop-out vents are not subject to this requirement because of their higher required operating temperatures and unique design.

[F] 910.3.3 Vent dimensions. The effective venting area shall not be less than 16 square feet (1.5 m²) with no dimension less than 4 feet (1219 mm), excluding ribs or gutters having a total width not exceeding 6 inches (152 mm).

- This section prescribes the minimum clear area required for each individual smoke and heat vent, exclusive of any obstructions (see Figure 910.3.4). The design of the aggregate vent area actually needed is based, in part, on the area defined by the draft curtains and the depth of the curtained area, the objective of the design being to prevent either smoke from spilling out of the curtained area or the smoke interface from interfering with egress visibility. It has also been argued that draft curtains are intended to speed the operation of the smoke and heat vents by keeping the smoke in a smaller area.

[F] 910.3.4 Vent locations. Smoke and heat vents shall be located 20 feet (6096 mm) or more from adjacent lot lines and fire walls and 10 feet (3048 mm) or more from fire barriers. Vents shall be uniformly located within the roof in the areas of the building where the vents are required to be installed by Section 910.2 with consideration given to roof pitch, draft curtain location, sprinkler location and structural members.

- This section has two functions, the first being a focus on hazards to adjacent buildings and the second being proper function of smoke and heat vents through proper placement.

In terms of adjacent properties, this section requires a minimum distance to lot lines and fire walls and then a minimum distance to fire barriers. The first set of distances focuses upon separate buildings and exposures, whereas the distance to fire barriers is less restrictive since it focuses upon different uses and occupancies within the same building (see Figure 910.3.4).

To enhance vent performance within the area containing the smoke and heat vents, such vents need to

For St: 1 foot = 304.8 mm, 1 square foot = 0.0929 m².

Figure 910.3.4
SMOKE AND HEAT VENT SPACING
be uniformly spaced. Consideration of issues such as sprinkler location and roof pitch are also essential to proper vent location.

[F] 910.3.5 Draft curtains. Where required by Table 910.3, draft curtains shall be installed on the underside of the roof in accordance with this section.

Exception: Where areas of buildings are equipped with ESFR sprinklers, draft curtains shall not be provided within these areas. Draft curtains shall only be provided at the separation between the ESFR sprinklers and the non-ESFR sprinklers.

- Draft curtains (sometimes termed "curtain boards") are required to be installed in conjunction with smoke and heat vents in accordance with Table 910.3 and as required by Section 413 of the code and Chapter 32 of the IFC. They are installed within and at the perimeter of a protected area to restrict smoke and heat movement beyond the area of fire origin or the protected area and enhance smoke and heat removal through the roof vents. Table 3206.2 of the IFC does not require draft curtains in sprinklered buildings. Instead, only smoke and heat vents are required in certain cases (larger areas of high-piled storage). The extent of the protection is addressed in Chapter 32 of the IFC. If draft curtains are required by Chapter 32 of the IFC, they need only extend 15 feet (4572 mm) beyond the high-piled storage area. This section also contains an exception for draft curtains when ESFR sprinklers are used. This exception would only apply to Group S-1 and F-1 occupancies as required in Section 910.2.1 because as noted, Chapter 23 of the IFC only requires draft curtains in unsprinklered buildings (see commentary, Table 3206.2 of the IFC). It should be noted that draft curtains are required between areas containing ESFR sprinklers and areas containing standard response sprinklers.

[F] 910.3.5.1 Construction. Draft curtains shall be constructed of sheet metal, lath and plaster, gypsum board or other approved materials which provide equivalent performance to resist the passage of smoke. Joints and connections shall be smoke tight.

- In order not to contribute to the fire load of a building and to increase the likelihood that draft curtains will remain intact under fire conditions, they must be constructed of noncombustible materials or an approved equivalent (see the commentary to Section 703.4 for further information on noncombustibility), but are not required to possess a fire-resistance rating. Draft curtains need only be capable of resisting the passage of smoke.

[F] 910.3.5.2 Location and depth. The location and minimum depth of draft curtains shall be in accordance with Table 910.3.

- The requirements for depth and location of draft curtains are provided in Table 910.3 based on the occupancy being Group S-1 or F-1 or, in the case of high-piled storage, the commodity classification of the stored materials and the height of the storage. High-piled storage areas would only be subject to these requirements when a building exceeds a certain minimum high-piled storage area threshold and not sprinklered. See the commentary to Table 910.3 for an explanation of how the options presented in the table should be applied.

[F] 910.4 Mechanical smoke exhaust. Where approved by the fire code official, engineered mechanical smoke exhaust shall be an acceptable alternate to smoke and heat vents.

- This section recognizes that providing a mechanical smoke exhaust system may, under certain circumstances, be more desirable, practical or efficient than installing automatic smoke and heat roof vents. The intent of Sections 910.4.1 through 910.4.6 is to create a mechanical system that performs at least as efficiently as smoke and heat vents designed in accordance with Section 910.3. Installation of an alternative mechanical smoke exhaust system is subject to the specific approval of the building official and fire code official so that the design can be reviewed and the operational sequence and control information can be shared with the fire department. Note that this smoke exhaust system is not considered a smoke control system. As discussed earlier, Section 910 is focused upon the needs of fire fighters in fighting a fire and the overhaul after the fire is extinguished. Section 909 addresses smoke control systems that focus upon tenable conditions for evacuation. Smoke control more specifically looks at the fire hazard and provides a system focused upon achieving certain life safety goals. The smoke exhaust system in this section is simply exhausting smoke at a rate that is not linked to a particular fire size.

[F] 910.4.1 Location. Exhaust fans shall be uniformly spaced within each draft-curtained area and the maximum distance between fans shall not be greater than 100 feet (30 480 mm).

- One or more smoke exhaust fans must be provided in each area defined by draft curtains, and when more than one fan is provided in a curtained area the fans must be spaced uniformly within that area, no more than 100 feet (30 480 mm) apart. Locating fans in this manner will enhance the uniform removal of smoke from curtained areas and reduce the likelihood of smoke spillage under the draft curtains. If draft curtains are not required, the fans simply need to meet the maximum separation distances and be uniformly distributed.

[F] 910.4.2 Size. Fans shall have a maximum individual capacity of 30,000 cfm (14.2 m³/s). The aggregate capacity of smoke exhaust fans shall be determined by the equation:

\[ C = A \times 300 \]  
(Equation 9-4)

where:

- \( C \) = Capacity of mechanical ventilation required, in cubic feet per minute (m³/s).
The intent of the sizing requirements of this section is to provide a smoke exhaust rate at least equivalent to the venting capacity provided by roof vents. The exhaust rate required by this section, based on Equation 9-10, is equivalent to 300 cubic feet per minute per square foot (153 m³/s · m²) of the roof vent area required by Table 910.3, with no single fan exceeding 30,000 cfm (14.2 m³/s) rate.

For example, a Group F-1 factory with maximum-sized draft-curtained areas of 50,000 square feet (4545 m²) would be required to have a total vent area of 500 square feet (46 m²) in each curtained area in accordance with Table 910.3. The mechanical exhaust rate required based on Equation 9-4 would then be 500 x 300 = 150,000 cfm (70.8 m³/s), which could be supplied by five 30,000 cfm (14.2 m³/s) fans spaced in accordance with Section 910.4.1 in each curtained area.

[F] 910.4.3 Operation. Mechanical smoke exhaust fans shall be automatically activated by the automatic sprinkler system or by heat detectors having operating characteristics equivalent to those described in Section 910.3.2. Individual manual controls of each fan unit shall also be provided.

The activation of the mechanical smoke exhaust system must be capable of being accomplished by activation of the automatic sprinkler system or, in nonsprinklered buildings, by heat detectors with a temperature rating of between 100 and 220°F (38 and 104°C) as required for smoke vents in Section 910.3.2.3 and manual controls. The manual control is for fire department use to increase the reliability of the system and to allow the fire department to activate the exhaust system to assist in the removal of smoke during or after a fire. Since manual control of the system is primarily for fire department use, the location of the controls should be subject to approval by the fire department. While not specifically stated in this section, a manual fire alarm system, if provided, can be more prone to intentional false activations; therefore, activation of the smoke exhaust system should not be allowed by this means. In addition, such systems should not be operated by the activation of smoke detection because the system may be activated before the sprinklers operate, which could be detrimental to the success of the sprinklers in suppressing the fire.

[F] 910.4.4 Wiring and control. Wiring for operation and control of smoke exhaust fans shall be connected ahead of the main disconnect and protected against exposure to temperatures in excess of 1,000°F (538°C) for a period of not less than 15 minutes. Controls shall be located so as to be immediately accessible to the fire service from the exterior of the building and protected against interior fire exposure by not less than 1-hour fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both.

Unless the mechanical smoke exhaust system also functions as a component of a smoke control system, standby power is not specifically required (see commentary, Sections 909.11 and 2702). In order to provide an enhanced level of operational reliability, this section requires that the power supply to smoke exhaust fans must be provided from a circuit connected on the supply side (i.e., ahead of) the building's main electrical service disconnecting means. Note that this is one of the sources of standby power recognized by NFPA 70, Section 701.11(E). Such a circuit connected "ahead of the main" must still have its own approved overcurrent protection.

This section also requires that the wiring for smoke exhaust fans be thermally protected in a manner approved by the building official that will protect the wiring from heat damage in the event of an interior fire. This protection could be provided by an approved wiring material listed for the temperature application, by physical protection with approved materials or assemblies or by installation outside of the building.

Since smoke exhaust systems are a vital fire-fighting tool, their operating controls are also required to be protected from interior fire exposure by 1-hour fire barriers constructed in accordance with Section 707, horizontal assemblies constructed in accordance with Section 711, or both. Exterior access to the controls allows fire department personnel to promptly operate the system from a protected area without entering the building. Controls should also be clearly identified in an approved, permanent manner.

[F] 910.4.5 Supply air. Supply air for exhaust fans shall be provided at or near the floor level and shall be sized to provide a minimum of 50 percent of required exhaust. Openings for supply air shall be uniformly distributed around the periphery of the area served.

The introduction of makeup air is critical to the proper operation of all exhaust systems. Too little makeup air will cause a negative pressure to develop in the area being exhausted, thereby reducing the exhaust flow.

This section requires that makeup air be introduced to the area equipped with a mechanical smoke exhaust system in order to maintain the required exhaust flow. Since the system can only exhaust as much air as is introduced into the area, and this section allows mechanical or gravity makeup air openings to provide only 50 percent of the required makeup air, this section allows the designer to rely upon infiltration air to provide up to the remaining 50 percent of the design makeup air required to allow the system to perform. Although not specifically stated in this section, where a mechanical makeup air
source is utilized, it should be electrically interlocked and controlled by a single start switch, such that makeup air is always being supplied when the smoke exhaust system is in operation.

The even distribution of makeup air is important because if too much air is coming from one particular direction, it has the potential to vary the dynamics of the fire and the ability of the system to capture the smoke.

[F] 910.4.6 Interlocks. In combination comfort air-handling/ smoke removal systems or independent comfort air-handling systems, fans shall be controlled to shut down in accordance with the approved smoke control sequence.

- This section was created to reduce the likelihood that the HVAC system will interfere with the proper function of the smoke exhaust system. It is important to emphasize that the system described in Section 910.4 is a smoke exhaust system and not a smoke control system; therefore, the actual fire performance is not as clearly understood. The concern is that HVAC systems should not work against the intended operation of the smoke exhaust system. In some case, the system may be a combination system where shutdown is not necessary or appropriate. It really depends on how the smoke exhaust system has been designed.

SECTION 911
FIRE COMMAND CENTER

[F] 911.1 General. Where required by other sections of this code and in all buildings classified as high-rise buildings by this code, a fire command center for fire department operations shall be provided and shall comply with Sections 911.1.1 through 911.1.5.

- Fireground operations usually involve establishing an incident command post where the incident command officer can observe what is happening; control arriving personnel and equipment and direct the resources and fire-fighting operations effectively. Because of the difficulties in controlling a fire in a high-rise building, a protected, readily accessible, separate room for this purpose within the building must be established to assist the incident command officer (see commentary, Section 202 for the definition of "Fire command center").

- A fire command center is also required in buildings containing smoke-protected assembly seating to house the fire-fighter’s smoke control panel. Facilities with smoke-protected seating tend to be larger facilities that, at the very least, would already have a central security center which could also function as a fire command center where approved by the jurisdiction (see commentary, Section 909.16).

[F] 911.1.1 Location and access. The location and accessibility of the fire command center shall be approved by the fire chief.

- Due to its importance to fire suppression and rescue operations, the fire command center must be provided at a location that is acceptable to the fire department, usually near the front of the building near the main entrance, so that the first arriving command officer can access it quickly and undertake operations. Since fireground operations are based on local operational procedures, it is only reasonable that the fire chief of the jurisdiction have approval authority over the location of and access to the fire command center.

[F] 911.1.2 Separation. The fire command center shall be separated from the remainder of the building by not less than a 1-hour fire barrier constructed in accordance with Section 707 or horizontal assembly constructed in accordance with Section 711, or both.

- Again, due to its importance to fire suppression and rescue operations, the fire command center must be separated from the remainder of the building by 1-hour fire barriers and horizontal assemblies, including opening protective, to protect the room, its contents and the occupants from an incident in adjacent areas of the building and to limit noise and distractions during command operations within the room.

[F] 911.1.3 Size. The room shall be a minimum of 200 square feet (19 m²) with a minimum dimension of 10 feet (3048 mm).

- This section is intended to provide a minimum size and configuration of the fire command center that allows sufficient space for the necessary command personnel to effectively perform the required tasks associated with a fire command center without interfering with each other. Fire command centers need to be designed to accommodate several emergency response commanders wearing full protective equipment and also provide space to review building emergency plans during incidents, colocate decision makers within the Incident Command System (ICS) and interpret fire protection system and building system information generated by the features required by Section 911.1.5. Given the multiple uses of the fire command center, a room any smaller would compromise the effectiveness of incident management.

[F] 911.1.4 Layout approval. A layout of the fire command center and all features required by this section to be contained therein shall be submitted for approval prior to installation.

- The flow of critical tactical information into, within and out of a fire command center is, by its very nature, both high in volume and intense in nature and has a direct bearing on the safety of building occupants and
the emergency response forces at work at an incident. For that reason, the layout and arrangement of the fire command center must comport with the operational procedures of the local fire department to optimize the receipt, processing and dissemination of operational information and orders. Accordingly, the fire code official must review and approve the arrangement of the fire command center prior to the installation of any of the controls and features required by Section 911.1.5. Consistent with Section 911.1.1, given the operational importance of the fire command center, the fire code official should work closely with the jurisdiction's fire chief to make sure that all operational needs are identified and met during the design stages.

[F] 911.1.5 Required features. The fire command center shall comply with NFPA 72 and shall contain the following features:

1. The emergency voice/alarm communication system control unit.
2. The fire department communications system.
3. Fire detection and alarm system annunciator.
4. Annunciator unit visually indicating the location of the elevators and whether they are operational.
5. Status indicators and controls for air distribution systems.
6. The fire-fighter's control panel required by Section 909.16 for smoke control systems installed in the building.
7. Controls for unlocking stairway doors simultaneously.
8. Sprinkler valve and water flow detector display panels.
9. Emergency and standby power status indicators.
10. A telephone for fire department use with controlled access to the public telephone system.
11. Fire pump status indicators.
12. Schematic building plans indicating the typical floor plan and detailing the building core, means of egress, fire protection systems, fire-fighting equipment and fire department access and the location of fire walls, fire barriers, fire partitions, smoke barriers and smoke partitions.
13. An approved Building Information Card that contains, but is not limited to, the following information:
   13.1. General building information that includes: property name, address, the number of floors in the building (above and below grade), use and occupancy classification (for mixed uses, identify the different types of occupancies on each floor), estimated building population (i.e., day, night, weekend);
   13.2. Building emergency contact information that includes: a list of the building’s emergency contacts (e.g., building manager, building engineer, etc.) and their respective work phone number, cell phone number, e-mail address;
13.3. Building construction information that includes: the type of building construction (e.g., floors, walls, columns, and roof assembly);
13.4. Exit stair information that includes: number of exit stairs in building, each exit stair designation and floors served, location where each exit stair discharges, exit stairs that are pressurized, exit stairs provided with emergency lighting, each exit stair that allows reentry, exit stairs providing roof access; elevator information that includes: number of elevator banks, elevator bank designation, elevator car numbers and respective floors that they serve, location of elevator machine rooms, location of sky lobby, location of freight elevator banks;
13.5. Building services and system information that includes: location of mechanical rooms, location of building management system, location and capacity of all fuel oil tanks, location of emergency generator, location of natural gas service;
13.6. Fire protection system information that includes: locations of standpipes, location of fire pump room, location of fire department connections, floors protected by automatic sprinklers, location of different types of sprinkler systems installed (e.g., dry, wet, pre-action, etc.); and
13.7 Hazardous material information that includes: location of hazardous material, quantity of hazardous material.

15. Generator supervision devices, manual start and transfer features.
16. Public address system, where specifically required by other sections of this code.
17. Elevator fire recall switch in accordance with ASME A17.1.
18. Elevator emergency or standby power selector switch(es), where emergency or standby power is provided.

\[\text{\textbullet} \text{The fire command center must contain all equipment and information necessary to enable the incident commander to monitor or control fire protection and other building service systems as listed in this section (see also commentary, Section 909.16). The number and types of features required by this section can create a large volume of data, thus reinforcing the need for an approved layout as required by Section 911.1.4.}\]
SECTION 912
FIRE DEPARTMENT CONNECTIONS

[F] 912.1 Installation. Fire department connections shall be installed in accordance with the NFPA standard applicable to the system design and shall comply with Sections 912.2 through 912.5.

- An FDC is required as part of a water-based suppression system as the auxiliary water supply. These connections give the fire department the capability of supplying the necessary water to the automatic sprinkler or standpipe system at a sufficient pressure. The FDC also serves as an alternative source of water should a valve in the primary water supply be closed. A fire department connection does not, however, constitute an automatic water source. See Figure 903.3.1.1 for a typical FDC arrangement on a wet pipe sprinkler system.

The requirements for the FDC depend on the type of sprinkler system installed and whether a standpipe system is installed. NFPA 13 and 13R, for example, include design considerations for FDCs that are an auxiliary water supply source for automatic sprinkler systems; NFPA 14 is the design standard to use for FDCs serving standpipe systems. Threads for FDCs to sprinkler systems, standpipes, yard hydrants or any other fire hose connection must be approved (NFPA 1963 may be utilized as part of the approval or as otherwise approved) and be compatible with the connections used by the local fire department (see commentary, Sections 903.3.6 and 905.1).

[F] 912.2 Location. With respect to hydrants, driveways, buildings and landscaping, fire department connections shall be so located that fire apparatus and hose connected to supply the system will not obstruct access to the buildings for other fire apparatus. The location of fire department connections shall be approved by the fire chief.

- This section specifies that the FDC must be located so that vehicles and hose lines will not interfere with access to the building for the use of other fire department apparatus. The location of potential connected hose lines to the FDC and hydrants must be pre-planned with the fire department. Many fire departments have a policy restricting the distance that a FDC may be from a fire hydrant. Some also have policies that indicate the maximum distance from the nearest point of fire department vehicle access (often, the curb). Since fireground operations are based on local operational procedures, it is only reasonable that the fire chief of the jurisdiction have approval authority over the location of and access to the FDC.

Landscaping can also be a hindrance to fire department operations. Even where the FDC is visible, the extensive use of landscaping may make access difficult. Landscaping also changes over time. What may not have been an obstruction when it was planted can sometimes grow into an obstruction over time.

[F] 912.2.1 Visible location. Fire department connections shall be located on the street side of buildings, fully visible and recognizable from the street or nearest point of fire department vehicle access or as otherwise approved by the fire chief.

- FDCs must be readily visible and easily accessed. A local policy constituting what is readily visible and accessible needs to be established. While the intent is clearly understandable, its application can vary widely. A precise policy is the best way to avoid ambiguous directives that result in inconsistent and arbitrary enforcement. Usually, the policy will address issues such as location on the outside of the building and proximity to fire hydrants.

Landscaping is often used to hide the FDCs from the public. This can greatly hamper the efforts of the fire department in staging operations and supplying water to the fire protection systems. Landscaping must be designed so that it does not obstruct the visibility of the FDC. Since fireground operations are based on local operational procedures, it is only reasonable that the fire chief of the jurisdiction have final approval authority over the visibility of and access to the FDC.

[F] 912.2.2 Existing buildings. On existing buildings, wherever the fire department connection is not visible to approaching fire apparatus, the fire department connection shall be indicated by an approved sign mounted on the street front or on the side of the building. Such sign shall have the letters "FDC" at least 6 inches (152 mm) high and words in letters at least 2 inches (51 mm) high or an arrow to indicate the location. All such signs shall be subject to the approval of the fire code official.

- The section acknowledges that FDCs on existing buildings may not always be readily visible from the street or nearest point of fire department vehicle access. In those instances, the location of the connection must be clearly marked with signage. The FDC may be located on the side of the building or in an alley, not visible to arriving fire-fighting forces. A sign is necessary so that those driving the arriving apparatus know where to maneuver the vehicle to get close to the FDC.

[F] 912.3 Access. Immediate access to fire department connections shall be maintained at all times and without obstruction by fences, bushes, trees, walls or any other fixed or moveable object. Access to fire department connections shall be approved by the fire chief.

Exception: Fences, where provided with an access gate equipped with a sign complying with the legend requirements of Section 912.4 and a means of emergency operation. The gate and the means of emergency operation shall be approved by the fire chief and maintained operational at all times.

- The FDC must be readily accessible to fire fighters and allow fire-fighting personnel an adequate area to
maneuver a hose for the connection. Landscaping design must not block a clear view of the FDC from arriving fire department vehicles. Depending on the type of landscaping materials, an active maintenance program may be necessary to maintain ready access over time. This section also recognizes that the obstructing objects regulated here can be either fixed or moveable (such as outdoor furnishings, shopping cart queue areas, etc.). Note that no specific dimension is given as was the case in previous editions of the code. This performance language avoids previous misinterpretations that the code intended to allow obstructions to FDC access as long as they were kept 3 feet (914 mm) away. Since firefighting operations are based on local operational procedures, it is only reasonable that the fire chief of the jurisdiction have final approval authority over the access to the FDC.

The exception recognizes the practical fact that sometimes, security or other considerations make installation of a fence around a building necessary as long as the fence meets the stated criteria. The sign requirement intends to provide a visual location cue to approaching fire apparatus where the height of the fence may obscure the visibility of the FDC.

[F] 912.3.1 Locking fire department connection caps. The fire code official is authorized to require locking caps on fire department connections for water-based fire protection systems where the responding fire department carries appropriate key wrenches for removal.

- This section allows for the FDC caps to be equipped with locks as long as the fire departments that respond to that building or facility have the appropriate key wrenches. This avoids vandalism and affords a more functional FDC when needed. Locking caps, even more so than regular FDC caps, need proper maintenance so that they can be removed when required. Any time that an additional mechanical function is added to something that is exposed to the elements, it must be done with the understanding that the corrosive nature of the elements can place the FDC out of commission if the cap cannot be removed (see Figure 912.3.1).

[F] 912.3.2 Clear space around connections. A working space of not less than 36 inches (762 mm) in width, 36 inches (914 mm) in depth and 78 inches (1981 mm) in height shall be provided and maintained in front of and to the sides of wall-mounted fire department connections and around the circumference of free-standing fire department connections, except as otherwise required or approved by the fire chief.

- Care must be taken so that fences, utility poles, barricades and other obstructions do not prevent access to and use of FDCs. A clear space of 3 feet (914 mm) must be maintained in front of and to either side of wall-mounted FDCs and around free-standing FDCs to allow easy hose connections to the fitting and efficient use of spanner wrenches and other tools needed by the apparatus engineer.

Though not specifically mentioned in this section, it is also important that FDCs be installed with the hose connections well above adjoining grade to accommodate the free turning of a spanner wrench when connecting hoses to the FDC.

[F] 912.3.3 Physical protection. Where fire department connections are subject to impact by a motor vehicle, vehicle impact protection shall be provided in accordance with Section 312 of the International Fire Code.

- Section 312 of the IFC requires vehicle impact protection by placing steel posts filled with concrete around the FDC. Section 312 of the IFC gives the specifications for the posts.

[F] 912.4 Signs. A metal sign with raised letters at least 1 inch (25 mm) in size shall be mounted on all fire department connections serving automatic sprinklers, standpipes or fire pump connections. Such signs shall read: AUTOMATIC SPRINKLERS or STANDPIPES or TEST CONNECTION or a combination thereof as applicable. Where the fire department connection does not serve the entire building, a sign shall be provided indicating the portions of the building served.

- The purpose of the sign is to provide the responding fire fighters with the correct information on which portions of a building are served by the fire department connection. They identify the type of system or zone served by a given FDC. Many buildings include multiple sets of fire department connections which are not interconnected, such as separate connections for the building sprinkler system and the dry standpipe system in open parking structures. Some buildings may have only a partial sprinkler system, such as rehabilitated buildings where a sprinkler system is only installed on certain floors or a building that only has
basement sprinklers in accordance with Section 903.2.11.

Signs may also distinguish FDCs from fire pump test headers. Usually, FDCs may be distinguished from fire pump test headers by the types of couplings provided. FDCs are customarily equipped with female couplings, while fire pump test headers usually have separately valved male couplings. Furthermore, fire pump test headers are equipped with one 2 1/2-inch (64 mm) outlet for each 250 gallon per minute (gpm) (16 L/s) of rated capacity.

Raised letters are required so that any repainting or fading of the colors on the sign will not affect its ability to be read. Each letter must be at least 1 inch (25 mm) in height so that the wording is clear. Often the wording may be abbreviated such that "AUTOMATIC SPRINKLERS" reads as "AUTO. SPKR." Existing signs may use language slightly different than that noted in the code. As long as the information is adequately communicated, there should be no reason to require new signage to replace existing ones (see Figure 912.4).

Figure 912.4
FIRE DEPARTMENT CONNECTION WITH SIGN

[F] 912.5 Backflow protection. The potable water supply to automatic sprinkler and standpipe systems shall be protected against backflow as required by the International Plumbing Code.

Section 608.16.4 of the IPC requires all connections to automatic sprinkler systems and standpipe systems to be equipped with a means to protect the potable water supply. The means of backflow protection can be either a double check-valve assembly or a reduced-pressure-principle backflow preventer. This, in general, assumes a FDC is required. For example, a limited-area sprinkler system off the domestic supply does not necessarily require a FDC and would not require backflow protection.

SECTION 913
FIRE PUMPS

[F] 913.1 General. Where provided, fire pumps shall be installed in accordance with this section and NFPA 20.

- This section contains specific installation requirements for fire pumps supplying water to fire protection systems. Inspection, testing and maintenance requirements comply with NFPA 20 unless noted otherwise. Applicable maintenance standards are also identified.

Fire pumps are installed in sprinkler and standpipe systems to pressurize the water supply for the minimum required sprinkler and standpipe operation. They are considered a design feature or component of the system. Fire pumps can improve only the pressure of the incoming water supply, not the volume of water available.

When the volume from a water supply is not adequate to supply sprinkler or standpipe demand, water tanks for private fire protection, improvements in the size and capacity of fire mains or water distribution systems or all of these for the installation of a fire pump are needed.

When fire pumps are required to meet the pressure requirements of sprinkler and standpipe systems, they must be installed and tested in accordance with NFPA 20.

[F] 913.2 Protection against interruption of service. The fire pump, driver and controller shall be protected in accordance with NFPA 20 against possible interruption of service through damage caused by explosion, fire, flood, earthquake, rodents, insects, windstorm, freezing, vandalism and other adverse conditions.

- This section lists hazards that must be taken into account when determining the extent of protection required for the fire pump and its auxiliary equipment. A pump room in a building that is protected against the listed hazards in compliance with the code would be considered in compliance. Because fire pumps are also typically located in separate detached structures, geographical and security issues must also be considered.

913.2.1 Protection of fire pump rooms. Fire pumps shall be located in rooms that are separated from all other areas of the building by 2-hour fire barriers constructed in accordance with Section 707 or 2-hour horizontal assemblies constructed in accordance with Section 711, or both.

Exceptions:

1. In other than high-rise buildings, separation by 1-hour fire barriers constructed in accordance with Section 707 or 1-hour horizontal assemblies constructed in accordance with Section 711, or both,
shall be permitted in buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2.

2. Separation is not required for fire pumps physically separated in accordance with NFPA 20.

- This section correlates the NFPA 20 requirements for separation of fire pumps with the IFC and specifies the required degree of fire-resistance as a requirement in the code so that designers and building officials are made aware of it. It requires fire pumps to be separated using either fire-resistive barriers or horizontal assemblies when the pump is located inside of a building or by using spatial separation (physical distance) when the fire pump is located outside of the building it serves.

The requirements are based on the criteria found in NFPA 20, Table 508.2.5, when used as a means for dealing with mixed uses in a building, and this section require fire pump units located inside of high-rise buildings to have a minimum 2-hour separation from the remainder of the building. The 2-hour separation requirement is consistent with the requirements in NFPA 20. Separation must be in the form of fire barriers used in conjunction with a horizontal assembly, as applicable, with both being of 2-hour fire-resistance-rated construction.

In all other buildings, consistent with similar exceptions elsewhere in the code, Exception 1 and Table 508.2.5, if applicable, recognize the protection afforded by complete automatic sprinkler protection in accordance with NFPA 13 or 13R as being equivalent to 1 hour of fire resistance.

A fire pump unit also may be located outside of a building. This is a common practice because it limits the exposure of a fire pump unit from a fire inside of the building it is serving. When a fire pump unit is located outdoors, Exception 2 recognizes spatial separation of at least 50 feet (15 240 mm) in accordance with Section 5.12 of NFPA 20 as an acceptable alternative to fire-resistance-rated protection.

[F] 913.3 Temperature of pump room. Suitable means shall be provided for maintaining the temperature of a pump room or pump house, where required, above 40°F (5°C).

- As previously noted for sprinkler systems, standpipe systems and other water-based fire protection systems, pump rooms or pump houses must be maintained at a temperature of 40°F (4°C) or above to prevent the system from freezing. This is consistent with Section 5.12.2.1 of NFPA 20.

[F] 913.3.1 Engine manufacturer’s recommendation. Temperature of the pump room, pump house or area where engines are installed shall never be less than the minimum recommended by the engine manufacturer. The engine manufacturer’s recommendations for oil heaters shall be followed.

- If the engine manufacturer’s recommended minimum temperature is higher than the minimum established in Section 913.3, that recommendation must be complied with. Maintaining the desired engine temperature enhances the startability of the engine. Maintaining water heaters and oil heaters as required for diesel engines, for example, will improve the starting capabilities of the fire pump and reduce engine wear and the drain on batteries.

[F] 913.4 Valve supervision. Where provided, the fire pump suction, discharge and bypass valves, and isolation valves on the backflow prevention device or assembly shall be supervised open by one of the following methods:

1. Central-station, proprietary or remote-station signaling service.
2. Local signaling service that will cause the sounding of an audible signal at a constantly attended location.
3. Locking valves open.
4. Sealing of valves and approved weekly recorded inspection where valves are located within fenced enclosures under the control of the owner.

- As was the case with sprinkler systems, water control valves that are a part of the fire pump installation must be supervised in the open position so that the system is operational when needed and also to reduce the chance of a system failure (see commentary, Section 903.4). In most cases the required water-based extinguishing system, which the fire pump is an integral component of, will be electrically supervised. Locking or sealing valves open as the only means of supervision may not be permitted, depending on the type of valve. Section 903.4, for example, specifically exempts jockey pump control valves from being electrically supervised if they are sealed or locked in the open position.

[F] 913.4.1 Test outlet valve supervision. Fire pump test outlet valves shall be supervised in the closed position.

- Fire pump test outlet valves are for performance testing of the fire pump and do not control the available water supply to either a sprinkler system or a standpipe system. These valves are normally in a closed position and are supervised accordingly.

[F] 913.5 Acceptance test. Acceptance testing shall be done in accordance with the requirements of NFPA 20.

- Chapter 14 of NFPA 20 details the procedure for conducting a fire pump acceptance test. This test is run to determine that the installation matches the sprinkler or standpipe system design criteria, the approved shop drawings and the pump manufacturer's performance specifications. The test is to be conducted in the presence of the building official in accordance with Section 901.5 by the installing contractor and representatives of the pump manufacturer and the controller manufacturer. Where the pump engine and/or transfer switch are separately supplied components, their manufacturer representative must also be present.
SECTION 914
EMERGENCY RESPONDER SAFETY FEATURES

[F] 914.1 Shaftway markings. Vertical shafts shall be identified as required by Sections 914.1.1 and 914.1.2.

- This section was developed to prevent fire fighters from falling through shafts when entering buildings off ladders placed on the exterior of the building or from passing through an interior opening that leads to a shaft.

[F] 914.1.1 Exterior access to shaftways. Outside openings accessible to the fire department and that open directly on a hoistway or shaftway communicating between two or more floors in a building shall be plainly marked with the word “SHAFTWAY” in red letters at least 6 inches (152 mm) high on a white background. Such warning signs shall be placed so as to be readily discernible from the outside of the building.

- All exterior wall openings that are accessible to fire fighters by way of ladders and aerial equipment and open directly into shafts or hoistways communicating between two or more floors must be clearly marked (see Figure 914.1.1). The markings serve to warn emergency responders that the opening is unsafe for laddering to gain access to upper floors and could result in a fall to the bottom of the shaft if such a mistake were made.

![SHAFTWAY Signage](image)

**Figure 914.1.1**

SHAFTWAY SIGNAGE

[F] 914.1.2 Interior access to shaftways. Door or window openings to a hoistway or shaftway from the interior of the building shall be plainly marked with the word “SHAFTWAY” in red letters at least 6 inches (152 mm) high on a white background. Such warning signs shall be placed so as to be readily discernible.

- Exception: Markings shall not be required on shaftway openings that are readily discernible as openings onto a shaftway by the construction or arrangement.

- Openings into shaftways from the interior of the building pose a threat to fire fighters when visibility is poor.

Interior shaft openings must be marked so that they are plainly visible from the interior of the building. If fire fighters can readily identify an opening into a shaft by the way the opening is constructed, the shaft opening need not be marked, keeping in mind that the fire fighter may be feeling his or her way in heavy smoke or darkness.

[F] 914.2 Equipment room identification. Fire protection equipment shall be identified in an approved manner. Rooms containing controls for air-conditioning systems, sprinkler risers and valves or other fire detection, suppression or control elements shall be identified for the use of the fire department. Approved signs required to identify fire protection equipment and equipment location shall be constructed of durable materials, permanently installed and readily visible.

- In an emergency, it is vitally important that the fire department and other emergency responders be able to quickly locate and access critical controls for fire protection systems. Obstructed or poorly marked equipment can cause delays in fire-fighting operations while fire fighters locate other hose stations and stretch additional hose, for example. Valves and other controls are often located in rooms or other enclosures and their location must be clearly identified with written or pictographic signs, which must be clearly visible and legible. Signs using the NFPA 170 symbols for fire protection equipment can provide standardized markings throughout a jurisdiction. White reflective symbols on a red reflective background are effective. For exterior signs, heavy-gage, sign-grade aluminum is recommended. Interior signs may be constructed of plastic, light-gage aluminum or other approved, durable, water-resistant material. As a general rule, fire protection piping, cabinets, enclosures, wiring, equipment and accessories are red or are identified by red or red/white markings. The manner of identification is subject to the approval of the building official.

SECTION 915
EMERGENCY RESPONDER RADIO COVERAGE

[F] 915.1 General. Emergency responder radio coverage shall be provided in all new buildings in accordance with Section 510 of the International Fire Code.

- The provisions of Section 915 are new to the 2009 edition and are concerned with the reliability of portable radios used by emergency responders inside of buildings. This is in keeping with the philosophy inherent in the International Codes that, when a facility grows too large or complex for effective fire response, fire protection features must be provided within the building. See the commentary to Section 510 of the IFC (and its companion Appendix J) for complete information on this topic.
Bibliography

The following resource materials were used in the preparation of the commentary for this chapter of the code.

Chapter 10: Means of Egress

General Comments
The general criteria set forth in Chapter 10 regulating the design of the means of egress are established as the primary method for protection of people in buildings. Chapter 10 provides the minimum requirements for means of egress in all buildings and structures. Both prescriptive and performance language is utilized in this chapter to provide for a basic approach in the determination of a safe exiting system for all occupancies. It addresses all portions of the egress system and includes design requirements as well as provisions regulating individual components. The requirements detail the size, arrangement, number and protection of means of egress components. Functional and operational characteristics also are specified for the components that will permit their safe use without special knowledge or effort.

A zonal approach to egress provides a general basis for the chapter's format through regulation of the exit access, exit and exit discharge portions of the means of egress. Section 1001 includes the administrative provisions. Section 1002 shows a list of defined terms that are primarily associated with Chapter 10. For commentary on these definitions, see Chapter 2.

A means of egress system has three parts: exit access, exit and exit discharge. Sections 1003 through 1013 include general provisions that apply to all three components. The exit access requirements are in Sections 1014 through 1019, the exit requirements are in Sections 1020 through 1026 and the exit discharge requirements are in Section 1027. Section 1028 includes those means of egress requirements that are unique to spaces used for assembly purposes. Emergency e-cape and rescue opening requirements are in Section 1029. Chapter 10 requirements are repeated in Chapter 10 of the International Fire Code® (IFC®). The IFC has one additional section at the end of the chapter dealing with maintenance of the means of egress (see commentary, Section 1001.3). For means of egress requirements in existing buildings, refer to Chapter 34 of the code or Chapter 46 of the IFC. See the commentary to Sections 1003, 1014, 1020 and 1028.

The evolution of means of egress requirements has been influenced by lessons learned from real fire incidents. While contemporary fires may reinforce some of these lessons, one must view each incident as an opportunity to assess critically the safety and reasonability of current regulations.

Cooperation among the developers of model codes and standards has resulted in agreement on many basic terms and concepts. The text of the code, including this chapter, is consistent with these national uniformity efforts.

National uniformity in an area such as means of egress has many benefits for the building official and other code users. At the top of the list are the lessons to be learned from experiences throughout the nation and the world, which can be reported in commonly used terminology and conditions that we can all relate to and clearly understand.

Purpose
A primary purpose of codes in general and building codes in particular is to safeguard life in the presence of a fire. Integral to this purpose is the path of egress travel for occupants to escape and avoid a fire. Means of egress can be considered the lifeline of a building. The principles on which means of egress are based and that form the fundamental criteria for requirements are to provide a system:

1. That will give occupants alternative paths of travel to a place of safety to avoid fire.
2. That will shelter occupants from fire and the products of combustion.
3. That will accommodate all occupants of a structure.
4. That is clear, unobstructed, well marked and illuminated and in which all components are under control of the user without requiring any tools, keys or special knowledge or effort.

History is marked with the severe loss of life from fire. Early as well as contemporary multiple fire fatalities can be traced to a compromise of one or more of the above principles.

Life safety from fire is a matter of successfully evacuating or relocating the occupants of a building to a place of safety. As a result, life safety is a function of time: time for detection, time for notification and time for safe egress. The fire growth rate over a period of time is also a critical factor in addressing life safety. Other sections of the code, such as protection of vertical openings (see Chapter 7), interior finish (see Chapter 8), fire suppression and detection systems (see Chapter 9) and numerous others, also have an impact on life safety. This chapter addresses the issues related to the means available to relocate or evacuate building occupants.
MEANS OF EGRESS

SECTION 1001
ADMINISTRATION

1001.1 General. Buildings or portions thereof shall be provided with a means of egress system as required by this chapter. The provisions of this chapter shall control the design, construction and arrangement of means of egress components required to provide an approved means of egress from structures and portions thereof.

- The minimum requirements for emergency evacuation, or means of egress, are to be incorporated in all new structures as specified in this chapter. The system shall include exit access, exit and exit discharge and address the needs for all occupants of the facility. Such application would be effective on the date the code is adopted and placed into effect.

1001.2 Minimum requirements. It shall be unlawful to alter a building or structure in a manner that will reduce the number of exits or the capacity of the means of egress to less than required by this code.

- A fundamental concept in life safety design is that the means of egress system is to be constantly available throughout the life of a building. Any change in the building or its contents, either by physical reconstruction, alteration or by a change of occupancy, is cause to review the resulting egress system. At a minimum, a building’s means of egress is to be continued as initially approved. If a building or portion thereof has a change of occupancy, the complete egress system is to be evaluated and approved for compliance with the current code requirements for new occupancies (see Chapter 34).

The means of egress in an existing building that experiences a change of occupancy, such as from Group S-2 (storage) to A-3 (assembly), would require reevaluation for code compliance based on the new occupancy. Similarly, the means of egress in an existing Group A-3 occupancy in which additional seating is to be provided, thereby increasing the occupant load, would require reevaluation for code compliance based on the increased occupant load.

The temptation is to temporarily remove egress components or other fire protection features from service during an alteration, repair to or temporary occupancy of a building. During such times, a building is frequently more vulnerable to fire and the spread of products of combustion. Either the occupants should not occupy those spaces where the means of egress has been compromised by the construction or compensating fire safety features should be considered that will provide equivalent safety for the occupants. Occupants in adjacent areas may also require access to the egress facilities in the area under construction.

[F] 1001.3 Maintenance. Means of egress shall be maintained in accordance with the International Fire Code.

- This section provides a cross reference to the code requirements that address the maintenance of the means of egress in an existing building. The means of egress must be maintained so that occupants are not prevented from exiting the building quickly in case of an emergency.

Sections 1003 through 1029 in the code are repeated in the IFC. These sections are maintained by the building code committees so that there will be consistency between the two documents. Note the [B] in front of the main section headings in the IFC. Note the [F] in front of this section. This means that this section is maintained by the International Fire Code Development Committee. Additionally, the IFC includes Section 1030, which applies to maintenance of the means of egress. For means of egress in existing buildings, refer to Chapter 46 of the IFC and Chapter 34 of the code.

[F] 1001.4 Fire safety and evacuation plans. Fire safety and evacuation plans shall be provided for all occupancies and buildings where required by the International Fire Code. Such fire safety and evacuation plans shall comply with the applicable provisions of Sections 401.2 and 404 of the International Fire Code.

Preplanning on how to handle emergencies and practice of that plan is an important part of managing emergencies in order to minimize the hazard for occupants. This reference to Section 401.2 of the IFC clarifies that fire and safety evacuation plans must be approved by the fire official. Section 404 of the IFC states for which facilities fire and safety evacuation plans are required. Fire evacuation plans include information on: emergency egress routes; phased evacuation options; operation of critical equipment; assisted rescue; verification of evacuation; notification to occupants and responders and responsible personnel. Fire safety plans include information on: reporting a fire; life-safety strategy; notifying, relocating or evacuating occupants; assisted rescue; site plans indicating occupancy assembly point, fire hydrants and fire department vehicle access; floor plans indicating exits, evacuation routes (general and accessible), fire alarm boxes, portable fire extinguishers, fire hose stations, fire alarms and controls; major fire hazards in the building; sprinkler systems; alarm and detection equipment and responsible personnel.

Some facilities, such as schools and courthouses, have developed lockdown plans for other emergencies. Rather than evacuating, the appropriate response may be to defend in place. Typically, there are different levels, depending on the emergency. For example a school may have: (1) police emergency action in town; (2) police emergency action in the immediate area and (3) police emergency in the building. Lockdown plans include information on: initiation of the plan; persons accountable; recall; communication and practice drills.

These plans must be reevaluated on an annual basis or when needed. Copies must be provided to building tenants and the fire department.
SECTION 1002
DEFINITIONS

1002.1 Definitions. The following terms are defined in Chapter 2:

ACCESSIBLE MEANS OF EGRESS.
AISLE.
AISLE ACCESSWAY.
ALTERNATING TREAD DEVICE.
AREA OF REFUGE.
BLEACHERS.
COMMON PATH OF EGRESS TRAVEL.
CORRIDOR.
DOOR, BALANCED.
EGRESS COURT.
EMERGENCY ESCAPE AND RESCUE OPENING.
EXIT.
EXIT ACCESS.
EXIT ACCESS DOORWAY.
EXIT ACCESS RAMP.
EXIT ACCESS STAIRWAY.
EXIT DISCHARGE.
EXIT DISCHARGE, LEVEL OF.
EXIT, HORIZONTAL.
EXIT PASSAGEWAY.
FIRE EXIT HARDWARE.
FIXED SEATING.
FLIGHT.
FLOOR AREA, GROSS.
FLOOR AREA, NET.
FOLDING AND TELESCOPIC SEATING.
GRANDSTAND.
GUARD.
HANDRAIL.
INTERIOR EXIT RAMP.
INTERIOR EXIT STAIRWAY.
MEANS OF EGRESS.
MERCHANDISE PAD.
NOSING.
OCCUPANT LOAD.
PANIC HARDWARE.
PHOTOLUMINESCENT.
PUBLIC WAY.
RAMP.
SCISSOR STAIR.
SELF-LUMINOUS.

SMOKE-PROTECTED ASSEMBLY SEATING.
STAIR.
STAIRWAY.
STAIRWAY, EXTERIOR.
STAIRWAY, INTERIOR.
STAIRWAY, SPIRAL.
WINDER.

This section lists terms that are specifically associated with the subject matter of this chapter. It is important to emphasize that these terms are not exclusively related to this chapter, but may or may not also be applicable where the term is used elsewhere in the code.

Definitions of terms can help in the understanding and application of the code requirements. The purpose for including a list within this chapter is to provide more convenient access to terms that may have a specific or limited application within this chapter. For the complete definition and associated commentary, refer back to Chapter 2. Terms that are italicized provide a visual identification throughout the code that a definition exists for that term. The use and application of all defined terms are set forth in Section 201.

SECTION 1003
GENERAL MEANS OF EGRESS

1003.1 Applicability. The general requirements specified in Sections 1003 through 1013 shall apply to all three elements of the means of egress system, in addition to those specific requirements for the exit access, the exit and the exit discharge detailed elsewhere in this chapter.

The requirements in the chapter address the three parts of a means of egress system: the exit access, the exit and the exit discharge. This section specifies that the requirements of Sections 1003 through 1013 apply to the components of all three parts of the system. For example, the stair tread and riser dimensions in Section 1009 apply to interior exit access stairways, such as those leading from a mezzanine and also apply to enclosed exit stairways per Section 1022, exterior exit stairways per Section 1026 and steps in the exit discharge per Section 1027.

The following sections are applicable for all parts of the means of egress:

- Section 1003 deals with the path for means of egress to remain free of obstructions and tripping hazards.
- Section 1004 provides criteria for determining occupant loads for a space. These numbers are used for determining means of egress, as a threshold for some suppression requirements and to determine the required plumbing fixture count.
MEANS OF EGRESS

- Section 1005 deals with the required size (i.e., width) of the path of travel for emergency evacuation. It is important not to create a "bottleneck" that could increase the amount of time necessary for occupants to exit the buildings.
- Section 1006 deals with illumination for the path of travel for the means of egress. Both general lighting and emergency backup lighting are addressed.
- Section 1007 – Chapter 11 indicated how to get people with mobility impairments into a building. Section 1007 explains the options to allow people with mobility impairments to self-evacuate or how to arrange for assisted rescue. The accessible means of egress is an important part of the fire and safety evacuation plans (see Section 1001.4).
- Section 1008 includes requirements for doors, gates, and stairwells that are part of the path of travel from any occupied spaces. For example, doors that lead to a walk-in closet must comply with this section, but doors for reach-in closets are exempted.
- Section 1009 provides information on all types of stairways: both interior and exterior; and from one riser to stairways with multiple flights and landings. Aisle steps for areas within assembly seating are specifically addressed in Section 1028.
- Section 1010 deals with ramps. Aisle ramps serving assembly seating areas are specifically addressed in Section 1028. The ramp provisions are coordinated with ICC A117.1 and the 2010 Standard for Accessible Design [formerly the Americans with Disabilities Act Accessibility Guidelines (ADAAG), now referred to as the 2010 Standard].
- Section 1011 described where exit signs are required and what criteria they need to meet to be readily visible.
- Section 1012 describes handrail requirements for stairways and ramps. Handrails are important for guidance and to arrest a possible fall.
- Section 1013 provides criteria for the vertical portions of barriers that serve to protect people from possible falls at dropoffs greater than 30 inches (762 mm).

1003.2 Ceiling height. The means of egress shall have a ceiling height of not less than 7 feet 6 inches (2286 mm).

Exceptions:
1. Sloped ceilings in accordance with Section 1208.2.
2. Ceilings of dwelling units and sleeping units within residential occupancies in accordance with Section 1208.2.
3. Allowable projections in accordance with Section 1003.3.

4. Stairheadroom in accordance with Section 1009.5.
5. Door height in accordance with Section 1008.1.1.
6. Ramp headroom in accordance with Section 1010.6.2.
7. The clear height of floor levels in vehicular and pedestrian traffic areas in parking garages in accordance with Section 406.4.1.
8. Areas above and below mezzanine floors in accordance with Section 505.2.

✓ Generally, the specified ceiling height is the minimum allowed in any part of the egress path. The exceptions are intended to address conditions where the code allows the ceiling height to be lower than specified in this section.

This section is consistent with the minimum ceiling height for other areas as specified in Section 1208. The exceptions are pointers to the lower headroom areas permitted in the code. For example, the headroom above and below a mezzanine is 7 feet (2134 mm) minimum.

1003.3 Protruding objects. Protruding objects shall comply with the requirements of Sections 1003.3.1 through 1003.3.4.

✓ This section begins the provisions that apply to protruding objects and helps to improve awareness of these safety and accessibility-related provisions.

1003.3.1 Headroom. Protruding objects are permitted to extend below the minimum ceiling height required by Section 1003.2 provided a minimum headroom of 80 inches (2032 mm) shall be provided for any walking surface, including walls, corridors, aisles and passageways. Not more than 50 percent of the ceiling area of a means of egress shall be reduced in height by protruding objects.

Exception: Door closers and stops shall not reduce headroom to less than 78 inches (1981 mm).

A barrier shall be provided where the vertical clearance is less than 80 inches (2032 mm) high. The leading edge of such a barrier shall be located 27 inches (686 mm) maximum above the floor.

✓ This provision is applicable to all components of the means of egress. Specifically, the limitations in this section and those in Sections 1003.3.2 and 1003.3.3 provide a reasonable level of safety for people with vision impairments as well as during emergency events when vision may be obscured by smoke or low lighting.

Minimum dimensions for headroom clearance are specified in this section. The minimum headroom clearance over all walking surfaces is required to be maintained at 80 inches (2032 mm). This minimum headroom clearance is consistent with the requirements in Section 1009.5 for stairs and Section 1010.6.2 for ramps. Allowance must be made for door closers and stops, since their design and function necessitates placement within the door opening. The minimum headroom clearance for door closers and stops is allowed to be 78 inches (1981 mm) [see
Figure 1003.3.1(1). The 2-inch (51 mm) projection into the doorway height is reasonable since these devices are normally mounted away from the center of the door opening, thus minimizing the potential for contact with a person moving through the opening. This is consistent with the exception in Section 1008.1.1.1.

The limitation on overhangs is of primary importance to those individuals with visual impairments. When vertical clearance along a walking surface is less than 80 inches (2032 mm), such as underneath the stairway on the ground floor, some sort of barrier that is detectable by a person using a cane must be provided. This can be a full-height wall, a rail at or below 27 inches (686 mm), a planter, fixed seating, etc. A low curb is not effective as a barrier. A person with visual impairments might mistake it for a stair tread, step up onto it and strike their head. A rail at handrail height would not be detectable by a person using a cane, and he or she could possibly walk into the rail before detecting it. Also, when making decisions on the choice of type of barrier, keep in mind that persons of shorter stature and children have a detectable range that may be below 27 inches (686 mm) [see Figure 1003.3.1(2)].

1003.3.2 Post-mounted objects. A free-standing object mounted on a post or pylon shall not overhang that post or pylon more than 4 inches (102 mm) where the lowest point of the leading edge is more than 27 inches (686 mm) and less than 80 inches (2032 mm) above the walking surface. Where a sign or other obstruction is mounted between posts or pylons and the clear distance between the posts or pylons is greater than 12 inches (305 mm), the lowest edge of such sign or obstruction shall be 27 inches (686 mm) maximum or 80 inches (2032 mm) minimum above the finished floor or ground.

Exception: These requirements shall not apply to sloping portions of handrails between the top and bottom riser of stairs and above the ramp run.

Post-mounted objects, such as signs or some types of drinking fountains or phone boxes, are not permitted to overhang more than 4 inches (102 mm) past the post where the bottom edge is located higher than 27 inches (686 mm) above the walking surface [see Figure 1003.3.2(1)]. Since the minimum required height of doorways, stairways and ramps in the means of egress is 80 inches (2032 mm), protruding objects located higher than 80 inches (2032 mm) above the walking surface are not regulated. Protrusions that are located lower than 27 inches (686 mm) above the walking surface are also permitted since they are more readily detected by a person using a long cane, provided that the minimum required width of the egress element is maintained. This is consistent with the post-mounted objects requirements in Section 307.3 of ICC A117.1, Accessible and Usable Buildings and Facilities. The intent is to reduce the potential for accidental impact for a person who is visually impaired.

When signs are provided on multiple posts, the posts must be located closer than 12 inches (305 mm) apart, or the bottom edge of the sign must be
MEANS OF EGRESS

lower than 27 inches (686 mm) so it is within detectable cane range or above 80 inches (2032 mm) so that it is above headroom clearances [see Figure 1003.3.2(2)].

The exception is intended for handrails that are located along the run of a stairway flight or ramp run. The extensions at the top and bottom of stairways and ramps must meet the requirements for protruding objects where people walk perpendicular to the stair or ramp.

For SI: 1 inch = 25.4 mm.

Figure 1003.3.2(1)
POST-MOUNTED OBJECTS

Figure 1003.3.2(2)
POST-MOUNTED PROTRUDING OBJECTS
1003.3.3 Horizontal projections. Structural elements, fixtures or furnishings shall not project horizontally from either side more than 4 inches (102 mm) over any walking surface between the heights of 27 inches (686 mm) and 80 inches (2032 mm) above the walking surface.

Exception: Handrails are permitted to protrude 4\(\frac{1}{2}\) inches (114 mm) from the wall.

- Protruding objects could slow down the egress flow through a corridor or passageway and injure someone hurriedly passing by or someone with a visual impairment. Persons with a visual impairment, who use a long cane for guidance, must have sufficient warning of a protruding object. Where protrusions are located higher than 27 inches (686 mm) above the walking surface, the cane will most likely not encounter the protrusion before the person collides with the object.

Additionally, people with poor visual acuity or poor depth perception may have difficulty identifying protruding objects higher than 27 inches (686 mm). Therefore, objects such as lights, signs and door hardware, located between 27 inches (686 mm) and 80 inches (2032 mm) above the walking surface, are not permitted to extend more than 4 inches (102 mm) from each wall (see Figure 1003.3.3). The requirement for protrusions into the door clear width in Section 1008.1.1.1 is different because it deals with allowances for panic hardware on a door. It is not the intent of this section to prohibit column, pilasters or wing walls to project into a corridor as long as adequate egress width is maintained. These types of structural elements are detectable by persons using a long cane.

The exception is an allowance for handrails when they are provided along a wall, such as in some hospitals or nursing homes. The 4\(\frac{1}{2}\) inches (114 mm) is intended to be consistent with protrusions by handrails into the required width of stairways and ramps in Section 1012.8. There are additional requirements when talking about the required width (see Section 1005.2).

1003.3.4 Clear width. Protruding objects shall not reduce the minimum clear width of accessible routes.

- The intent of this section is to limit the projections into an accessible route so that a minimum clear width of 36 inches (914 mm) is maintained along the route. ICC A117.1 is referenced by Chapter 11 for technical requirements for accessibility. ICC A117.1, Section 403.5, allows the accessible route to be reduced in width to 32 inches (914 mm) for segments not to exceed 24 inches (635 mm) in length and spaced a minimum of 48 inches (1219 mm) apart. This allows for movement through a doorway or through a gap in planters or counters.

1003.4 Floor surface. Walking surfaces of the means of egress shall have a slip-resistant surface and be securely attached.

- As the pace of exit travel becomes hurried during emergency situations, the probability of slipping on smooth or slick floor surfaces increases. To minimize the hazard, all floor surfaces in the means of egress are required to be slip resistant. The use of hard floor materials with highly polished, glazed, glossy or finely finished surfaces should be avoided.

Field testing and uniform enforcement of the concept of slip resistance are not practical. One method used to establish slip resistance is that the static coefficient of friction between leather [Type 1 (Vegetable Tanned) of Federal Specification K-K-165C] and the floor surface is greater than 0.5. Laboratory test procedures, such as ASTM D 2047, can determine the static coefficient of resistance. Bulletin No. 4 titled "Surfaces" issued by the U.S. Architectural and Transportation Barriers Compliance Board (ATBCB or Access Board) contains further information regarding slip resistance.

1003.5 Elevation change. Where changes in elevation of less than 12 inches (305 mm) exist in the means of egress, sloped surfaces shall be used. Where the slope is greater than one unit vertical in 20 units horizontal (5-percent slope), ramps complying with Section 1010 shall be used. Where the difference in elevation is 6 inches (152 mm) or less, the ramp shall be equipped with either handrails or floor finish materials that contrast with adjacent floor finish materials.

Exceptions:

1. A single step with a maximum riser height of 7 inches (178 mm) is permitted for buildings with occupancies in Groups F, H, R-2, R-3, S and U at
exterior doors not required to be accessible by Chapter 11.

2. A stair with a single riser or with two risers and a tread is permitted at locations not required to be accessible by Chapter 11, provided that the risers and treads comply with Section 1009.7, the minimum depth of the tread is 13 inches (330 mm) and at least one handrail complying with Section 1012 is provided within 30 inches (762 mm) of the centerline of the normal path of egress travel on the stair.

3. A step is permitted in aisles serving seating that has a difference in elevation less than 12 inches (305 mm) at locations not required to be accessible by Chapter 11, provided that the risers and treads comply with Section 1028.11 and the aisle is provided with a handrail complying with Section 1028.13.

Throughout a story in a Group I-2 occupancy, any change in elevation in portions of the means of egress that serve nonambulatory persons shall be by means of a ramp or sloped walkway.

- Minor changes in elevation, such as a single step that is located in any portion of the means of egress (i.e., exit access, exit or exit discharge) may not be readily apparent during normal use or emergency egress and are considered to present a potential tripping hazard. Where the elevation change is less than 12 inches (305 mm), a ramp or sloped surface is specified to make the transition from higher to lower levels. This is intended to reduce accidental falls associated with the tripping hazard of an unseen step. Ramps must be constructed in accordance with Section 1010.1. The presence of the ramp must be readily apparent from the directions from which it is approached. Handrails are one method of identifying the change in elevation. In lieu of handrails, the surface of the ramp must be finished with materials that visually contrast with the surrounding floor surfaces. The walking surface of the ramp should contrast both visually and physically.

None of the exceptions are permitted along an accessible route required for either entry or egress from a space or building.

Exception 1 allows up to a 7-inch (178 mm) step at exterior doors to avoid blocking the outward swing of the door by a buildup of snow or ice in locations that are not used by the public on a regular basis (see Figure 1003.5). This exception is coordinated with Exception 2 of Section 1008.1.5, and is only applicable in occupancies that have relatively low occupant densities, such as factory and industrial structures. This exception is not applicable to exterior doors that are required to serve as an accessible entrance or that are part of a required accessible route. If this exception is utilized at a Group R-2 or R-3 occupancy, the designer may want to consider the issues of potential tripping hazards if this is a common entrance for a large number of occupants.

Exception 2 allows the transition from higher to lower elevations to be accomplished through the construction of stairs with one or two risers. The pitch of the stairway, however, must be shallower than that required for typical stairways (see Section 1009.7.2). Since the total elevation change is limited to 12 inches (305 mm), each riser must be approximately 6 inches (152 mm) in height. The elevation change must be readily apparent from the directions from which it is approached. At least one handrail is required. It must be constructed in accordance with Section 1012 and located so as to provide a graspable surface from the normal walking path.

Exception 3 is basically a cross reference to the assembly provisions for stepped aisles in Section 1025.

None of the exceptions are permitted in a Group I-2 occupancy (e.g., nursing home, hospital) in areas where nonambulatory persons may need access. The mobility impairments of these individuals require additional consideration.

![Figure 1003.5](image-url)

**Figure 1003.5**

**ELEVATION CHANGE**

1003.6 Means of egress continuity. The path of egress travel along a means of egress shall not be interrupted by any building element other than a means of egress component as specified in this chapter. Obstructions shall not be placed in the required width of a means of egress except projections permitted by this chapter. The required capacity of a means of egress system shall not be diminished along the path of egress travel.

- The purpose of this section requires that the entire means of egress path is clear of obstructions that
could reduce the egress capacity at any point. The
egress path is also not allowed to be reduced in width
such that the design occupant load would not be
served. Note, however, that the egress path could be
reduced in width in situations where it is wider than
required by the code based on the occupant load. For
example, if the required width of a corridor was 52
inches (1321 mm) based on the number of occupants
using the corridor and the corridor provided was 96
inches (2438 mm) in width, the corridor would be
allowed to be reduced to the minimum required width
of 52 inches (1321 mm) since that width would still
serve the number of occupants required by the code.
In the context of this section, a "means of egress
component" would most likely be a door or doorway.

1003.7 Elevators, escalators and moving walks. Elevators,
escalators and moving walks shall not be used as a compo-
nent of a required means of egress from any other part of
the building.

Exception: Elevators used as an accessible means of
egress in accordance with Section 1007.4.

The code does not allow elevators, escalators
and moving sidewalks to be used as a required
means of egress. The concern is that due to possible
power outages, escalators and moving sidewalks
may not provide a safe and reliable means of egress
that is available for use at all times.

Elevators are not typically used for unassisted evacuation
during fire emergencies. However, in
taller buildings fire fighters use the elevators for both
staging to fight the fire and assisted evacuation.
They can verify that the shaft is not full of smoke, that the
elevators will remain operational and, since they
know the fire location, what floors the elevator is safe
to access. In accordance with the exception, eleva-
tors are allowed to be part of an accessible means of
egress (i.e., assisted evacuation), provided they com-
ply with the requirements of Section 1007.4. Where
elevators are required to serve as part of the accessi-
ble means of egress is addressed in Section
1007.2.1. There are new provisions for fire service
elevators and occupant evacuation elevators for high
rises in Sections 403, 3007 and 3008. These specific
provisions will provide a level of safety that would
meet the intent of the means of egress provisions in
Chapter 10.

SECTION 1004
OCCUPANT LOAD

1004.1 Design occupant load. In determining means of
egress requirements, the number of occupants for whom
means of egress facilities shall be provided shall be deter-
mined in accordance with this section.

The design occupant load is the number of people
that are intended to occupy a building or portion
thereof at any one time; essentially the number for
which the means of egress is to be designed. It is the
largest number derived by the application of Sections
1004.1 through 1004.9. There is a limit to the density
of occupants permitted in an area to enable a reason-
able amount of freedom of movement (see Section
1004.2). The design occupant load is also utilized to
determine the required plumbing fixture count (see
commentary, Chapter 29) and other building require-
ments, such as automatic sprinkler systems and fire
alarm and detection systems (see Chapter 9).

The intent of this section is to indicate the proce-
dure by which design occupant loads are determined.
This is particularly important because accurate deter-
mination of design occupant load is fundamental to
the proper design of any means of egress system.

1004.1.1 Cumulative occupant loads. Where the path of
egress travel includes intervening rooms, areas or spaces,
cumulative occupant loads shall be determined in accordance
with this section.

When occupants from an accessory area move
through another area to exit, the combined number of
occupants must be utilized to determine means of
egress capacity. It is not the intent of this section to
"double count" occupants. For example, the means of
egress from a lobby must be sized for the cumulative
occupant load of the adjacent office spaces if the
occupants must travel through the lobby to reach an
exit. Likewise, if an adjacent room has an egress
route independent of the lobby, the occupant load of
that room would not be combined with the occupant
loads of the other rooms that pass through that lobby.
If a portion of the adjacent room’s occupant load is to
travel through the lobby, only that portion would be
combined with the lobby occupant load for determin-
ing lobby egress (see Figure 1004.1.1). This is particu-
larly important in determining the capacity and the
number of means of egress.

1004.1.1.1 Intervening spaces. Where occupants egress
from one room, area or space through another, the design
occupant load shall be based on the cumulative occupant
loads of all rooms, areas or spaces to that point along the path
of egress travel.

An example of intervening spaces could be small ten-
ant spaces within a large mercantile. It is common for
banks or coffee shops to be located within large gro-
cery stores. Another example would be a dentist’s
office where people in the staff and exam room areas
would egress through the reception area.

1004.1.2 Adjacent levels. The occupant load of a mezza-
nine or storey with egress through a room, area or space on an
adjacent level shall be added to the occupant load of that
room, area or space.

The egress requirements for mezzanines or second
floors that use exit access stairways to move to the
ground level are handled similar to those spaces with
accessory areas addressed in Section 1004.1.1.1,
versus the requirements for exiting from multiple lev-
els in Section 1021. That is, that portion of the mez-
zanine/second floor occupant load that travel through
the floor below to the exit is to be added to the occu-
MEANS OF EGRESS

pant load of the space on the floor below. The sizing and number of the egress components must reflect this combined occupant load. This does not apply to the means of egress from a mezzanine/second floor that does not require travel through another level (i.e., an interior exit stairway serving the mezzanine/second floor). Section 505 contains additional criteria for the means of egress from mezzanines.

1004.1.2 Areas without fixed seating. The number of occupants shall be computed at the rate of one occupant per unit of area as prescribed in Table 1004.1.2. For areas without fixed seating, the occupant load shall not be less than that number determined by dividing the floor area under consideration by the occupant load factor assigned to the function of the space as set forth in Table 1004.1.2. Where an intended function is not listed in Table 1004.1.2, the building official shall establish a function based on a listed function that most nearly resembles the intended function.

Exception: Where approved by the building official, the actual number of occupants for whom each occupied space, floor or building is designed, although less than those determined by calculation, shall be permitted to be used in the determination of the design occupant load.

The numbers for floor area per occupant load factor in the table reflect common and traditional occupant density based on empirical data for the density of similar spaces. The number determined using the occupant load factors in Table 1004.1.2 generally establishes the minimum occupant load for which the egress facilities of the rooms, spaces and building must be designed. The design occupant load is also utilized for other code requirements, such as determining the required plumbing fixture count (see commentary, Chapter 29) and other building requirements, including automatic sprinkler systems and alarm and detection systems (see Chapter 9).

It is difficult to predict the many conditions by which a space within a building will be occupied over time. An assembly banquet room in a hotel, for example, could be arranged with rows of chairs to host a business seminar one day and with mixed tables and chairs to host a dinner reception the next day. In some instances, the room will be arranged with no tables and very few chairs to accommodate primarily standing occupants. In such a situation, the egress facilities must safely accommodate the maximum number of persons permitted to occupy the space. When determining the occupant load of this type of occupancy, the various arrangements (e.g., tables and chairs, chairs only, standing space) should be recognized. The worst-case scenario should be utilized to determine the requirements for the means of egress elements. This is consistent with the requirements for multiple use spaces addressed in Section 302.1.

While some of the values in the table utilize the net floor area, most utilize the gross floor area. See the commentary to Table 1004.1.2 and the definitions for "Floor area, gross" and "Floor area, net" in Chapter 2 for additional discussion and examples.

The occupant load determined in accordance with this section is typically the minimum occupant load upon which means of egress requirements are to be based. Some occupancies may not typically contain an occupant load totally consistent with the occupant load density factors of Table 1004.1.2. The exception is intended to address the limited circumstances where the actual occupant load is less than the calculated occupant load. Previously, designing for a

![Figure 1004.1.1](image)

**Figure 1004.1.1**
COMBINED OCCUPANT LOAD FOR EGRESS DESIGN
reduced occupant load was permitted only through the variance process. With this exception, the building official can make a determination if a design that would use the actual occupant load was permissible. The building official may want to create specific conditions for approval. For example, the building official could choose to permit the actual occupant load to be utilized to determine the plumbing fixture count, but not the means of egress or sprinkler design; the determination could be that the reduced occupant load may be utilized in a specific area, such as in the storage warehouse, but not in the factory or office areas. Another point to consider would be the potential of the space being utilized for different purposes at different times, or the potential of a future change of tenancy without knowledge of the building department. Any special considerations for such unique uses must be documented and justified. Additionally, the owner must be aware that such special considerations will impact the future use of the building with respect to the means of egress and other protection features.

**TABLE 1004.1.1.** See next column.

- Table 1004.1.2 establishes minimum occupant densities based on the function or actual use of the space (not group classification). The table presents the maximum floor area allowance per occupant (i.e., occupant load factor) based on studies and counts of the number of occupants in typical buildings. The use of this table, then, results in the minimum occupant load for which rooms, spaces and the building must be designed. While an assumed normal occupancy may be viewed as somewhat less than that determined by the use of the table factors, such a normal occupant load is not necessarily an appropriate design criterion. The greatest hazard to the occupants occurs when an unusually large crowd is present. The code does not limit the occupant load density of an area, except as provided for in Section 1004.2, but once the occupant load is established, the means of egress must be designed for at least that capacity. If it is intended that the occupant load will exceed that calculated in accordance with the table, then the occupant load is to be based on the estimated actual number of people, but not to exceed the maximum allowance in accordance with Section 1004.2. Therefore, the occupant load of the office or business areas in a storage warehouse or nightclub is to be determined using the occupant load factor most appropriate to that space—one person for each 100 square feet (9 m²) of gross floor area.

The use of net and gross floor areas as defined in Chapter 2 is intended to provide a refinement in the occupant load determination. The gross floor area technique applied to a building only allows the deduction of the plan area of the exterior walls, vent shafts and interior courts from the plan area of the building.

The net floor area permits the exclusion of certain spaces that would be included in the gross floor area. The net floor area is intended to apply to the actual

For SI: 1 square foot = 0.0929 m².

a. Floor area in square feet per occupant.
MEANS OF EGRESS

occupied floor areas. The area used for permanent building components, such as shafts, fixed equipment, thicknesses of walls, corridors, stairways, toilet rooms, mechanical rooms and closets, is not included in net floor area. For example, consider a restaurant dining area with dimensions measured from the inside of the enclosing walls of 80 feet by 60 feet (24.384 mm by 18.288 mm) (see Figure 1004.1.2). Within the restaurant area is a 6-inch (152 mm) privacy wall running the length of the room [80 feet by 0.5 feet = 40 square feet (3.7 m²)], a fireplace [40 square feet (3.7 m²)] and a cloak room [60 square feet (5.6 m²)]. Each of these areas is deducted from the restaurant area, resulting in a net floor area of 4,660 square feet (433 m²). Since the restaurant intends to have uncentrated seating that involves loose tables and chairs, the resulting occupant load is 311 persons (4,660 divided by 15). As the definition of "Floor area, net" indicates, certain spaces are to be excluded from the gross floor area to derive the net floor area. The key point in this definition is that the net floor area is to include the actual occupied area and does not include spaces uncharacteristic of that occupancy.

In determining the occupant load of a building with mixed groups, each floor area of a single occupancy must be separately analyzed, such as required by Section 1004.6. The occupant load of the business portion of an office/warehouse building is determined at a rate of one person for each 100 square feet (9 m²) of office space, whereas the occupant load of the warehouse portion is determined at the rate of one person for each 300 square feet (28 m²). There may even be different uses within the same room. For example, a restaurant dining room would have seating but may also have a waiting area with standing room, a take-out window with a queue line or employee areas behind a bar or reception desk.

If a specific type of facility is not found in the table, the occupancy it most closely resembles should be utilized. For example, a training room in a business office may utilize the 20-square-feet (1.86 m²) net established for educational classroom areas, or a dance or karate studio may use the occupant load for rinks and pools for the studio areas.

Table 1004.1.2 presents a method of determining the absolute base minimum occupant load of a space that the means of egress is to accommodate.

The table occupant loads are based on the stereotypical configuration of spaces. For example, the dorm requirements were written based on dormitories with sleeping rooms with two to four students, a gang bathroom and a meeting/study lounge on each floor.

---

**Figure 1004.1.2**

TYPICAL NET FLOOR AREA OCCUPANT LOAD CALCULATION

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm,
1 square foot = 0.0929 m².
Dormitory buildings that operate like army barracks may have a heavier occupant load, while facilities with groups of rooms with private bathrooms, living and even kitchenette areas may have a lower occupant load. Industrial facilities are based on typical fabricating plants. Warehouses are based on consistent movement in and out of product by employees. Factories with largely mechanized operations or warehouses that contain long-term storage are other examples where discussion with the building official and the application of the exception in Section 1004.1.2 might be considered.

In addition to the table, Section 402 contains the basis for calculating the occupant load of a covered mall building; however, Table 1004.1.2 should be used for determining the occupant load of each anchor store.

1004.2 Increased occupant load. The occupant load permitted in any building, or portion thereof, is permitted to be increased from that number established for the occupancies in Table 1004.1.2, provided that all other requirements of the code are also met based on such modified number and the occupant load does not exceed one occupant per 7 square feet (0.65 m²) of occupiable floor space. Where required by the building official, an approved aisle, seating or fixed equipment diagram substantiating any increase in occupant load shall be submitted. Where required by the building official, such diagram shall be posted.

- An increased occupant load is permitted above that developed by using Table 1004.1.2; for example, utilizing the actual occupant load. However, if the occupant load exceeds that which is determined in accordance with Section 1004.1.2, the building official has the authority to require aisle, seating and equipment diagrams to confirm that all occupants have access to an exit, the exits provide sufficient capacity for all occupants and compliance with this section is attained.

The maximum area of 7 square feet (0.65 m²) per occupant should allow for sufficient occupant movement in actual fire situations. This is not a conflict with the standing space provisions of 5 square feet (0.46 m²) net in accordance with Table 1004.1.2. Standing space is typically limited to a portion of a larger area, such as the area immediately in front of the bar or the waiting area in a restaurant, while the rest of the dining area would use 15 square feet (1.4 m²) net per occupant.

1004.3 Posting of occupant load. Every room or space that is an assembly occupancy shall have the occupant load of the room or space posted in a conspicuous place, near the main exit or exit access doorway from the room or space. Posted signs shall be of an approved legible permanent design and shall be maintained by the owner or authorized agent.

- Each room or space used for an assembly occupancy is required to display the approved occupant load. The placard must be posted in a visible location (near the main entrance) (see Figure 1004.3 for an example of an occupant load limit sign).

The posting is required to provide a means by which to determine that the maximum approved occupant load is not exceeded. This permanent and readily visible sign provides a constant reminder to building personnel and is a reference for building officials during periodic inspections.

While the composition and organization of information in the sign are not specified, information must be recorded in a permanent manner. This means that a sign with changeable numbers would not be acceptable.

**Keep Posted Under Penalty Of Law**

**Figure 1004.3**

**EXAMPLE OF OCCUPANT LOAD LIMIT SIGN**

1004.4 Fixed seating. For areas having fixed seats and aisles, the occupant load shall be determined by the number of fixed seats installed therein. The occupant load for areas in which fixed seating is not installed, such as waiting spaces, shall be determined in accordance with Section 1004.1.2 and added to the number of fixed seats.

The occupant load of wheelchair spaces and the associated companion seat shall be based on one occupant for each wheelchair space and one occupant for the associated companion seat provided in accordance with Section 1108.2.3.

For areas having fixed seating without dividing arms, the occupant load shall not be less than the number of seats based on one person for each 18 inches (457 mm) of seating length.

The occupant load of seating booths shall be based on one person for each 24 inches (610 mm) of booth seat length measured at the backrest of the seating booth.

- The occupant load in an area with fixed seats is readily determined. In spaces with a combination of fixed and loose seating, the occupant load is determined by a combination of the occupant density number from Table 1004.1.2 and a count of the fixed seats.

For bleachers, booths and other seating facilities without dividing arms, the occupant load is simply based on the number of people that can be accom-
modated in the length of the seat. Measured at the hips, an average person occupies about 18 inches (457 mm) on a bench. In a booth, additional space is necessary for "elbow room" while eating. In a circular or curved booth or bench, the measurement should be taken just a few inches from the back of the seat, which is where a person's hips would be located (see Figure 1004.4).

Some assembly spaces may have areas for standing or waiting. For example, some large sports stadiums have "standing room only" areas that they use for sell-out games. The Globe Theater in England has standing room in an area at the front of the theater. This section is not intended to assign an occupant load to the typical circulation aisles in an assembly space. Occupant load for wheelchair spaces should be based on the number of wheelchairs and companion seats that the space was designed for. As specified in Section 1004.6, if the wheelchair spaces may also be utilized for standing space or removable seating, the occupant load must be determined by the worst-case scenario.

**1004.5 Outdoor areas.** Yards, patios, courts and similar outdoor areas accessible to and usable by the building occupants shall be provided with means of egress as required by this chapter. The occupant load of such outdoor areas shall be assigned by the building official in accordance with the anticipated use. Where outdoor areas are to be used by persons in addition to the occupants of the building, and the path of egress travel from the outdoor areas passes through the building, means of egress requirements for the building shall be based on the sum of the occupant loads of the building plus the outdoor areas.

**Exceptions:**

1. Outdoor areas used exclusively for service of the building need only have one means of egress.
2. Both outdoor areas associated with Group R-3 and individual dwelling units of Group R-2.

This section addresses the means of egress of outdoor areas such as yards, patios and courts. The primary concern is for those outdoor areas used for functions that may include occupants other than the building occupants or solely by the building occupants where egress from the outdoor area is back through the building to reach the exit discharge. An example is an interior court of an office building where assembly functions are held during normal business hours for persons other than the building occupants. When court occupants must egress from the interior court back through the building, the building's egress system is to be designed for the building occupants, plus the assembly occupants from the interior court. Another example would be an outdoor dining area that exited back through the restaurant.

The occupant load is to be assigned by the building official based on use. It is suggested that the design occupant load be determined in accordance with

![Figure 1004.4](image)

**Typical Fixed Seating**

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.
Section 1004.1.2.
Exception 1 describes conditions where the occupant load is very limited, such as areas where an interior courtyard had strictly plants or mechanical equipment. If the courtyard was open for building occupants, other than maintenance personnel, to use the space, the space must be designed with the occupant loads in Table 1004.1.2. balconies or patios associated with individual dwelling units, in Exception 2, would typically be used by the occupants of the unit. Means of egress can be back through the building in accordance with Section 1014.2.

1004.6 Multiple occupancies. Where a building contains two or more occupancies, the means of egress requirements shall apply to each portion of the building based on the occupancy of that space. Where two or more occupancies utilize portions of the same means of egress system, those egress components shall meet the more stringent requirements of all occupancies that are served.

Since the means of egress systems are designed for the specific occupancy of a space, the provisions of this chapter are to be applied based on the actual occupancy conditions of the space served.

For example, a hospital is classified as Group I-2 and normally includes the associated administrative or business functions found in the same building. Chapter 3 would permit the entire building to be constructed to the more restrictive provisions for Group I-2; however, each area of the building need only have the means of egress designed in accordance with the actual occupancy conditions, such as Groups I-2 and B. If the corridor serves only the occupants in the business use (i.e., administrative staff), and is not intended to serve as a required means of egress for patients, the corridor need only be 36 or 44 inches (914 or 1118 mm) in width, depending on the occupant load.

Where the corridor is used by both Group I-2 and B occupancies, it must meet the most stringent requirement. For example, if a corridor in the business area is also used for the movement of beds (i.e., exit access from a patient care area), it would need to be a minimum of 96 inches (2438 mm) in clear width.

SECTION 1005
MEANS OF EGRESS SIZING

1005.1 General. All portions of the means of egress system shall be sized in accordance with this section.

Exception: Means of egress complying with Section 1028.

This section is a charging paragraph for sizing for the means of egress system in a tenant space, floor or building. The exception is based on the understanding that the criteria for spaces that serve as assembly areas have unique criteria based on the high occupant load and possibility of stepped or sloped aisles.

1005.2 Minimum width based on component. The minimum width, in inches (mm), of any means of egress components shall not be less than that specified for such component, elsewhere in this code.

The code requires the utilization of two methods to determine the minimum width of egress components. While this section provides a methodology for determining required widths based on the design occupant load, calculated in accordance with Section 1004.1, other sections provide minimum widths of various components. The actual width that is provided is to be the larger of the two widths.

1005.3 Required capacity based on occupant load. The required capacity, in inches (mm), of the means of egress for any room, area, space or story shall not be less than that determined in accordance with Sections 1005.3.1 and 1005.3.2.

For this section, the sum of the capacities of the means of egress components that serve each space must equal or exceed the occupant load of that space. For example, the combined width of all the exit stairways from a floor needs to be considered to determine if the stairways have adequate capacity for everyone to evacuate the building. All elements must meet the minimum width requirements specified in other sections (e.g., Section 1008.1.1 for doors; Sections 1007.3 and 1009.1 for stairs). This section establishes the necessary width of each egress component on a "per-occupant" basis. Means of egress components are separated between "stairs" and "other," "other" being doors, doorways, corridors, ramps, aisles, etc.

The traditional unit of measurement of egress capacity was based on a "unit exit width" that was to simulate the body ellipse with a basic dimensional width of 22 inches (559 mm)—approximately the shoulder width of an average adult male. This unit exit width was combined with assumed egress movement (such as single file or staggered file) to result in an egress capacity per unit exit width for various occupancies. This assumption simplifies the dynamic egress process since contemporary studies have indicated that people do not egress in such precise and predictable movements. As traditionally used in the codes, the method of determining capacity per unit of clear width implies a higher level of accuracy than can realistically be achieved. The resulting factors preserve the features of the past practices that can be documented, while providing a more straightforward method of determining egress capacity.

1005.3.1 Stairways. The capacity, in inches (mm), of means of egress stairways shall be calculated by multiplying the occupant load served by such stairway by a means of egress
MEANS OF EGRESS

capacity factor of 0.3 inch (7.6 mm) per occupant. Where stairways serve more than one story, only the occupant load of each story considered individually shall be used in calculating the required capacity of the stairways serving that story.

**Exception:** For other than Group H and I-2 occupancies, the capacity, in inches (mm), of means of egress stairways shall be calculated by multiplying the occupant load served by such stairway by a means of egress capacity factor of 0.2 inch (5.1 mm) per occupant in buildings equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2 and an emergency voice/alarm communication system in accordance with Section 907.5.2.2.

- The capacity factor for stairways is larger than "other egress components" due to the slowdown of travel to negotiate the steps. When the required occupant capacity of an egress component is determined, multiplication by the appropriate factor results in the required clear width of the component in inches, based on capacity. Similarly, if the clear width of a component is known, division by the appropriate factor results in the permitted capacity of that component.

Per the exception, other than in Group H or I-2, if the building is sprinklered and has an emergency voice/alarm communication system, the capacity factor for stairways is permitted to be reduced to 0.2 inches (5.1 mm) per occupant. The 2009 edition of the code did not include the exception for sprinklered buildings; however, editions previous to 2009 included similar allowances in a table.

The following illustrate typical calculations for stairways from a nonsprinklered, two-story, two-exit office building:

1. Determine the minimum required stairway width with a second-floor occupant load of 350:
   - 350 occupants divided by 0.3 inches = 105 inches (2667 mm) minimum;
   - 105 inches divided by two stairways is 52 1/2 inches (1334 mm) minimum per stairway; or
   - Section 1009.1 prescribes that the width of an interior stairway cannot be less than 44 inches (1118 mm).

   The capacity criteria are more restrictive and, therefore, the minimum required width for each stairway is 52 1/2 inches (1334 mm).

2. Determine the minimum required stairways width with a second-floor occupant load of 90:
   - 90 occupants divided by 0.3 inches (7.62 mm) = 27 inches (686 mm) minimum;
   - 27 inches (686 mm) divided by two stairways is 13 1/2 inches (343 mm); or
   - Section 1009.1 prescribes that the width of an interior stairway cannot be less than 44 inches (1118 mm). Note that the stair width reduction in Section 1009.1, Exception 1, is applicable only when the entire occupant load of a story is less than 50.

The minimum clear width requirements are more restrictive and, therefore, the minimum required width for each stairway is 44 inches (1118 mm).

The maximum capacity of a 44-inch (1118 mm) stairway is 44 inches divided by 0.3 inches (7.62 mm) per occupant = 146 occupants. Therefore, a floor level with two exit stairways could have 292 occupants before the capacity would control the stairway egress width.

Using the exception for sprinklered buildings, a 44-inch (1118 mm) stairway divided by 0.2 inches (5.08 mm) per occupant = 220 occupants. Therefore, a floor level with two exit stairways could have 440 occupants before the capacity would control the stairway egress width.

Keep in mind that accessible means of egress stairways in nonsprinklered buildings require a minimum clear width of 48 inches (1219 mm) between handrails.

**1005.3.2 Other egress components.** The capacity, in inches (mm), of means of egress components other than stairways shall be calculated by multiplying the occupant load served by such component by a means of egress capacity factor of 0.2 inch (5.1 mm) per occupant.

**Exception:** For other than Group H and I-2 occupancies, the capacity, in inches (mm), of means of egress components other than stairways shall be calculated by multiplying the occupant load served by such component by a means of egress capacity factor of 0.15 inch (3.8 mm) per occupant in buildings equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2 and an emergency voice/alarm communication system in accordance with Section 907.5.2.2.

- The capacity factor for "other egress components" (i.e., doors, gates, corridors, aisles, ramps) is less than stairways due to the slowdown of travel to negotiate the steps. When the required occupant capacity of an egress component is determined, multiplication by the appropriate factor results in the required clear width of the component in inches, based on capacity. Similarly, if the clear width of a component is known, division by the appropriate factor results in the permitted capacity of that component.

Per the exception, other than in Group H or I-2, if the building is sprinklered and has an emergency voice/alarm communication system, the capacity factor for doors, corridors, aisles, etc., is permitted to be...
MEANS OF EGRESS

reduced to 0.15 inches (3.8 mm) per occupant. The 2009 edition of the code did not include the exception for sprinklered buildings; however, previous editions included similar allowances in a table.

For example, two exit access doorways from a room with an occupant load of 300 would each have a required capacity of not less than 150. Based on the minimum required clear door width [32 inch (813 mm) clear width per door divided by 0.2 inch (5.08 mm) per occupant = 160 occupants], two 32-inch (813 mm) clear width doors would meet both the minimum clear width (Section 1008.1.1) and the capacity requirements. Two exits from a space with an occupant load of 450 would each have a required capacity of not less than 225, necessitating more doors or larger door leaves.

Using the exception, the door capacity would increase [32-inch (813 mm) clear width per door divided by 0.15 inch (3.08 mm) per occupant = 213 occupants].

1005.4 Continuity. The capacity of the means of egress required from any story of a building shall not be reduced along the path of egress travel until the public way.

- The requirement that the maximum capacity from any floor is to be provided all the way along the exit to the termination, typically down the stairway to the exterior exit door at the level of exit discharge, results in an egress width that is adequate for the exit discharge.

The sum total capacity of the exits that serve a floor is not to be less than the occupant load of the floor as determined by Section 1004.1. If an exit, such as a stairway, also serves a second floor and the required capacity of the exit serving the occupants of the second floor is greater than the first floor, the greater capacity would govern the egress components that the occupants of the floors share. For example, if an exit stairway serves two floors, with occupant loads of 300 on the lower floor and 500 on the upper floor, assuming that two stairways serve each floor, the two stairways would be designed for a capacity of 250 people each, using the upper-floor occupant load of 500 as the basis of determination. Note that the doors to the stairways on the lower floor would be designed for a capacity of 150 and the doors to the stairways on the upper floor would be designed for a capacity of 250. Reversing these two floors would result in the portion of the stairways that serves the upper floor to be designed for a capacity of 150 and the stairways that serve the lower floor to be designed for 250. Requiring the egress component to be designed for the largest tributary occupant load accommodates the worst-case situation.

Also note that the capacity of the exits is based on the occupant load of one floor. The occupant loads are not combined with other floors for the exit design. It is assumed that the peak demand or flow of occupants from more than one floor level at a common point in the means of egress will not occur simultane-
ously, except as provided for in Sections 1005.6 (Egress convergence) and 1004.1.1.2 (Adjacent levels).

1005.5. Distribution of egress capacity. Where more than one exit, or access to more than one exit, is required, the means of egress shall be configured such that the loss of any one exit, or access to one exit, shall not reduce the available capacity to less than 50 percent of the required capacity.

- It is critical that the distribution of egress capacity is examined. Where multiple means of egress are required, the loss of any one path can not reduce the available capacity to less than 50 percent. The 50-percent minimum of the required egress capacity results in a fairly uniform distribution of egress paths. This requirement does not, however, require that the capacities be equally distributed when more than two means of egress are provided. An egress design with a dramatic imbalance of egress component capacities relative to occupant load distribution should be reviewed closely to avoid a needless delay in egressing a story or area. The balancing of the means of egress components, in accordance with the distribution of the occupant load, is reasonable and, in some cases, necessary for facilities having mixed occupancies with dramatically different occupant loads.

1005.6 Egress convergence. Where the means of egress from stories above and below converge at an intermediate level, the capacity of the means of egress from the point of convergence shall not be less than the sum of the required capacities for the two adjacent stories.

- Convergence of occupants can occur whenever the occupants of an upper floor travel down and occupants of a lower floor travel up and meet at a common, intermediate egress component on the route to the exit discharge. The intermediate component may or may not be another occupiable floor and, most often, is an exit door [see Figures 1005.6(1) and 1005.6(2)].

The entire premise of egress convergence is based on the assumption of simultaneous notification (i.e., all occupants of all floors begin moving toward the exits at the same time). As illustrated in Figure 1005.6(3), the occupants of the first floor will have exited the building by the time most of the occupants of the second floor have reached the exit discharge door. However, as illustrated in Figure 1005.6(1), the occupants of a basement will reach the discharge door simultaneously with the second-floor occupants, thereby creating a bottleneck and the need for sizing the affected component for a larger combined occupant load.

An egress convergence situation can also be created when an intermediate floor level is not present, as illustrated in Figure 1005.6(2). Again, under the assumption of simultaneous notification, occupants of both floors would reach the exit discharge door at approximately the same time, invoking the requirements for increased egress capacity.
MEANS OF EGRESS

Figure 1005.6(1)
EGRESS CONVERGENCE AT FIRST STORY

Figure 1005.6(2)
EGRESS CONVERGENCE AT INTERMEDIATE LEVEL
1005.7 Encroachment. Encroachments into the required means of egress width shall be in accordance with the provisions of this section.

This section addresses maximum encroachment into the required width along the path of travel for means of egress. Types of encroachment are door leaves, door hardware, handrails, trim and protruding objects. These requirements are referenced for aisles (Section 1017.1), corridors (Section 1018.3), exit passageways (Section 1023.2) and the exit discharge (Section 1027.4.1). Along stairways, handrail projections are permitted per Section 1012.8.

1005.7.1 Doors. Doors, when fully opened, shall not reduce the required width by more than 7 inches (178 mm). Doors in any position shall not reduce the required width by more than one-half.

Exceptions:

1. Surface-mounted latch release hardware shall be exempt from inclusion in the 7-inch maximum (178 mm) encroachment where:
   1.1. The hardware is mounted to the side of the door facing away from the adjacent wall where the door is in the open position; and
   1.2. The hardware is mounted not less than 34 inches (865 mm) nor more than 48 inches (1219 mm) above the finished floor.

2. The restrictions on door swing shall not apply to doors within individual dwelling units and sleeping units of Group R-2 occupancies and dwelling units of Group R-3 occupancies.

Projections or restrictions in the required width can impede and restrict occupant travel, causing egress to occur less efficiently than expected. The swinging of a door, such as from a room into a corridor, and any handrails along the route are permitted projections.

Historically this section has looked at doors on one wall at a time. Doors located across the hall from one another are not considered additive when considering protrusion limits. Doors would not typically be opened to the full extent at exactly the same moment, nor can they remain open at 90 degrees and totally blocking the hall because of the maximum limitation of 7 inches (178 mm) when fully open (typically approaching 180 degrees). Regarding door encroachment there are two tests. The arc created by the door's outside edge cannot project into more than one-half of the required corridor width. When opened to its fullest extent, the door cannot project more than 7 inches (178 mm) into the required width, which is the dimension of the leaf thickness excluding the hardware as shown in Figure 1005.7.1. Door hardware encroachment is addressed separately in Exception 1. These projections are permitted because they are considered to be temporary and do not significantly impede the flow. Occupants will compensate for the projection by a reduction in the natural cushion they retain between themselves and a boundary, known as the edge effect.
MEANS OF EGRESS

Per Exception 2, the door swing restrictions do not apply within dwelling units since the occupant load is very low. Based on the intent of this section, other situations that could be approved by the official having jurisdiction would be situations where the opening door would not block the egress, such as the door at the end of a corridor, or the room was not typically occupied, such as a janitor's closet.

The provision in Exception 1 indicates that hardware facing the corridor when the door is fully open need not be considered when determining the allowable door encroachment into a corridor of 7 inches (178 mm) maximum. The allowance is applicable provided the hardware is mounted within height range of 34 inches to 48 inches (865 to 1220 mm) which is consistent with the range for means of egress door hardware height as established in Section 1008.1.9.2. Where hardware extends across a door, such as panic hardware, the 4-inch (102 mm) projection in the door opening is addressed in Section 1008.1.1.1.

1005.7.2 Other projections. Handrail projections shall be in accordance with the provisions of Section 1012.8. Other nonstructural projections such as trim and similar decorative features shall be permitted to project into the required width a maximum of 1/2 inches (38 mm) on each side.

Handrails are not required along corridors, level aisles, exit passageways and exit corridors; however, if provided, Section 1012.8 would be applicable. Handrails are sometimes provided along the hallways in hospitals or nursing homes to aid the residents. Bumper guards along the walls are not handrails.

Items such as baseboards, chair rails, pilasters, etc., are limited to protruding over the required width of the corridor a maximum of 1/2 inches (38 mm); however, once again, Section 1003.3.3 would be applicable when the corridor was wider than required.

1005.7.3 Protruding objects. Protruding objects shall comply with the applicable requirements of Section 1003.3.

- This section is a reminder that protruding objects are applicable when looking at encroachments into a confined path of travel. The difference, however, is that door and other projections are applied to the required minimum width, while protruding object provisions apply to paths of travel even when wider than required.

SECTION 1006
MEANS OF EGRESS ILLUMINATION

1006.1 Illumination required. The means of egress, including the exit discharge, shall be illuminated at all times the building space served by the means of egress is occupied.

Exceptions:

1. Occupancies in Group U.
2. Aisle accessways in Group A.
3. Dwelling units and sleeping units in Groups R-1, R-2 and R-3.
4. Sleeping units of Group I occupancies.

All portions of the means of egress must be illuminated by artificial lighting during the entire time a building is occupied, so that the paths of exit travel are always visible and available for evacuation of the occupants during emergencies. The code makes a special point of noting that the exit discharge must also be provided with adequate illumination so that occupants can safely find the public way should the emergency occur at night.

Three of the exceptions are for occupancies where the constant illumination of the means of egress would interfere with the use of space, such as sleeping areas or theater aisles during a performance.

![Figure 1005.7.1](image-url)

For 1: 1 inch = 25.4 mm, 1 degree = 0.01745 rad.
Bear in mind that means of egress lighting is not emergency lighting. For emergency lighting requirements, see Sections 1006.3 and 1006.3.1.

The highrise provisions in Section 403 utilize the means of egress lighting and emergency lighting in this section. High-rise buildings also require a secondary backup system of luminous egress path markings within enclosed exit stairways (Section 1024). Section 1024.5 requires the enclosed exit stairways to be illuminated for 60 minutes prior to the daily occupancy so that the self-luminous stripes can charge.

1006.2 Illumination level. The means of egress illumination level shall not be less than 1 footcandle (11 lux) at the walking surface.

Exception: For auditoriums, theaters, concert or opera halls and similar assembly occupancies, the illumination at the walking surface is permitted to be reduced during performances to not less than 0.2 footcandle (2.15 lux), provided that the required illumination is automatically restored upon activation of a premises' fire alarm system where such system is provided.

The intensity of lighting along the entire means of egress, including open plan spaces, aisles, corridors and passageways, exit stairways, exit doors and places of exit discharge at the walking surface or floor level must not be less than 1 foot-candle (11 lux). One foot-candle (11 lux) is approximately the same lighting level as found outdoors at twilight. It has been found that even this relatively low level of lighting renders enough visibility for occupants to evacuate a building safely.

It is important to note that this lighting level is measured at the floor in order to make the floor surface visible. Levels of illumination above the floor may be higher or lower, thus allowing lights along steps to be used rather than general area lighting.

The exception addresses occupancies where low light level is needed for the function of the space. The level of intensity of aisle lighting in such spaces may be reduced to 0.2 foot-candle (2.15 lux), but only during the time of a performance. This intensity of illumination is sufficient to distinguish the aisles and stairs leading to the egress doors and not be a source of distraction during a performance. It is not the intent of the exception to require a fire alarm system but to require a connection to the egress lighting where a fire alarm system is provided.

1006.3 Emergency power for illumination. The power supply for means of egress illumination shall normally be provided by the premises' electrical supply.

In the event of power supply failure, an emergency electrical system shall automatically illuminate all of the following areas:

1. Aisles and unenclosed egress stairways in rooms and spaces that require two or more means of egress.

2. Corridors, interior exit stairways and ramps and exit passageways in buildings required to have two or more exits.

3. Exterior egress components at other than their levels of exit discharge until exit discharge is accomplished for buildings required to have two or more exits.

4. Interior exit discharge elements, as permitted in Section 1027.1, in buildings required to have two or more exits.

5. Exterior landings as required by Section 1008.1.6 for exit discharge doorways in buildings required to have two or more exits.

The emergency power system shall provide power for a duration of not less than 90 minutes and shall consist of storage batteries, unit equipment or an on-site generator. The installation of the emergency power system shall be in accordance with Section 2702.

The means of egress must be illuminated, especially in times of emergency when the occupants must have a lighted path of exit travel in order to evacuate the building safely. The code is very specific in the description of the areas that are required to be illuminated by the emergency [not standby (see Section 2702.2.4)] power system.

The locations include:

1. Dedicated egress routes in larger rooms or spaces. For example, an aisle in an open office plan but not within individual offices that egress through the open area. Exit access stairways from a mezzanine or from a second floor (as permitted by Section 1009.3) must also be illuminated.

2. Essential portions of the interior egress system, such as exit stairways, ramps and corridors in larger buildings, must be illuminated. Exit passageways are used in facilities with long travel distances, such as malls, or are an extension of the exit stairway enclosure.

3. Means of egress systems that use exit balconies (see Section 1019) or open exterior exit stairways or ramps (see Section 1027) need emergency exit illumination along these components until egress at grade is "reached" or "achieved."

4. Interior exit discharge elements, such as lobbies and vestibules (see Section 1027.1), where stairways discharge into these elements instead of directly to the exterior of a building.

5. Exterior portions of the exit discharge. Note that only the portion of the exterior discharge that is immediately adjacent to the building exit discharge door is required to have emergency illumination and not the entire exterior discharge path to the public way.
So that there will be a continuing source of electrical energy for maintaining the illumination of the means of egress when there is a loss of the main power supply, the means of egress lighting system must be connected to an emergency electrical system that consists of storage batteries, unit equipment or an on-site generator. This emergency power-generating facility must be capable of supplying electricity for at least 90 minutes, thereby giving the occupants sufficient time to leave the premises. In most cases, where the loss of the main electrical supply is attributed to a malfunction in the distribution system of the electric power company, experience has shown that such power outages do not usually last as long as 90 minutes.

1006.3.1 Illumination level under emergency power. Emergency lighting facilities shall be arranged to provide initial illumination that is at least an average of 1 footcandle (11 lux) and a minimum at any point of 0.1 footcandle (1 lux) measured along the path of egress at floor level. Illumination levels shall be permitted to decline to 0.6 footcandle (6 lux) average and a minimum at any point of 0.06 footcandle (0.6 lux) at the end of the emergency lighting time duration. A maximum-to-minimum illumination uniformity ratio of 40 to 1 shall not be exceeded.

- This section provides the criteria of the illumination levels of the emergency lighting system. The initial average level for the main egress paths is the same as for the overall means of egress illumination in Section 1006.2. The reduction of illumination recognizes the performance characteristics over time of some types of power supplies, such as batteries. The minimum levels are sufficient for the occupants to egress from the building. In addition, the emergency lighting system is a secondary system that is spaced along the main egress routes. It will not provide the same level of general lighting over the route as what can be provided by the building lighting system.

- The maximum illumination uniformity ratio of 40 means that the variation in the illumination levels is not to exceed that number. For example, a minimum of 0.06 foot-candle (0.6 lux) would establish a maximum illumination of 2.4 foot-candle (24 lux) in an adjacent area. This is to establish a variation limit such that the means of egress can be seen as a person walks from bright to darker areas along the egress path.

SECTION 1007
ACCESSIBLE MEANS OF EGRESS

1007.1 Accessible means of egress required. Accessible means of egress shall comply with this section. Accessible spaces shall be provided with not less than one accessible means of egress. Where more than one means of egress are required by Section 1015.1 or 1021.1 from any accessible space, each accessible portion of the space shall be served by not less than two accessible means of egress.

Exceptions:

1. Accessible means of egress are not required in alterations to existing buildings.

2. One accessible means of egress is required from an accessible mezzanine level in accordance with Section 1007.3, 1007.4 or 1007.5.

3. In assembly areas with sloped or stepped aisles, one accessible means of egress is permitted where the common path of travel is accessible and meets the requirements in Section 1028.8.

- Access Board is revising and updating its accessibility guidelines for buildings and facilities covered by the Americans with Disabilities Act of 1990 (ADA) and the Architectural Barriers Act of 1968 (ABA). The final ADA/ABA Guidelines, published by the Access Board in July 2004, serve as the basis for the minimum standards when adopted by other federal agencies responsible for issuing enforceable standards. The plan is to eventually use this new document in place of the Uniform Federal Accessibility Standard (UFAS) and ADAAG. The U.S. Department of Justice officially adopted the new federal requirements on September 15, 2010. The new name is the 2010 Standard for Accessible Design otherwise known as the 2010 Standard. The 2010 Standard, Section 201/F207, references the 2000 edition of the IBC with 2001 Supplement, as well as 2003 edition of the IBC, for accessible means of egress requirements. The International Code Council® (ICC®) is very proud to be recognized for its work regarding accessible means of egress in this manner. Refer to the Access Board web site (www.access-board.gov) for more specific information and the current status of this adoption process. Due to the date of the publication and the adoption process, later editions of the IBC are not specifically referenced; however, none of the later editions reduced the accessible means of egress requirements found in the referenced IBC editions so they should be able to be considered as providing equivalent or better accessibility.

The accessible means of egress locations may not be near the accessible route used for ingress into the building (see Sections 1104 and 1105). For example, a two-story building requires one accessible route to connect all accessible spaces within the building. The accessible route to the second level is typically by an elevator. During a fire emergency, persons with mobility impairments on the second level should move to the exit stairways for assisted rescue, not back the way they came in via the elevator. Signage at the elevator will direct occupants to an exit stairway.

This section establishes the minimum requirements for means of egress facilities serving all
MEANS OF EGRESS

spaces that are required to be accessible to people with physical disabilities. Previously, attention had been focused on response to the civil-rights-based issue of providing adequate access for people with physical disabilities into and throughout buildings. Concerns about life safety and evacuation of people with mobility impairments were frequently cited as reasons for not embracing widespread building accessibility, in the best interest of the disabled community.

The provisions for accessible means of egress are predominantly, though not exclusively, intended to address the safety of persons with a mobility impairment. These requirements reflect the balanced philosophy that accessible means of egress are to be provided for occupants who have gained access into the building but are incapable of independently utilizing the typical means of egress facilities, such as the exit stairways. By making such provisions, the code now addresses means of egress for all building occupants, with and without physical disabilities.

Any space that is not required by the code to be accessible in accordance with Chapter 11 is not required to be provided with accessible means of egress. This may include an entire story, a portion of a story, a mezzanine or an individual room. For example, a mechanical penthouse is not required to be accessible in accordance with Section 1103.2.9; therefore, the mechanical penthouse is not required to have an accessible means of egress.

In new construction and additions, accessible means of egress are required in the same number as the general means of egress, up to a maximum of two. For example, in buildings, stories or spaces required by Section 1015.1 or 1021 to have three or more exits or exit access doors, a minimum of two accessible means of egress is required. The number of exits or exit access doors is based on occupant load; therefore, no matter how large the total occupant load of the space, two fully complying accessible means of egress are considered to provide sufficient capacity for those building occupants with a mobility impairment.

The accessibility requirements are based on the required means of egress from both individual spaces and the building as a whole. Therefore, the facilities with multiple large assembly rooms, such as banquet halls or multiplex theaters where the second exit from the space is often a door directly to the outside, may require additional accessible means of egress from the building due to space requirements.

While there are no dispersion requirements specific to accessible means of egress or travel distance limitations where there is no area of refuge requirement (see Sections 1007.3, 1007.4 and 1007.6), the code requires exits to be distinct and independent (Section 1021.1). Therefore, if a stairway and elevator, both being used for accessible means of egress were adjacent to each other, this would only count as one accessible means of egress.

An accessible means of egress is required to provide a continuous path of travel to a public way. This principle is consistent with the general requirements for all means of egress, as reflected in Section 1003.1 and in the definition of "Means of egress" in Chapter 2. This section also emphasizes the intent that accessible means of egress must be available to a person with a mobility impairment, such as a person using a wheelchair, scooter or walker. Some mobility impairments do not allow for self-evacuation along a stairway; therefore, utilization of the exit and exit discharge may require assistance. The safety and fire evacuation plans (see Section 1001.4 of the code and Section 404 of the IFC) require planning for all occupants of a building. This assistance is typically with the fire department or other trained personnel, either along the exit stairways or in buildings five stories or taller, with the elevator system or a combination of both (see commentary, Section 1007.2.1). It is required that accessible routes, areas of refuge and exterior areas of rescue assistance are indicated on these plans. These plans must be approved by the local fire official and reviewed annually.

The exceptions address special situations where accessible means of egress requirements need special consideration. Note that these are exceptions for accessible means of egress; not an exception for accessible entrance requirements (see Section 1105).

Exception 1 indicates that existing buildings that are undergoing alterations are not required to be provided with accessible means of egress as part of that alteration. In many cases, meeting the requirements for accessible means of egress, especially the 48-inch (1219 mm) clear stair width required in nonsprinklered buildings, would be considered technically infeasible. However, if an accessible means of egress was part of the original construction, it must be maintained in accordance with Section 3411.2.

Exception 2 is a special consideration for mezzanines. The size of mezzanines is limited to a portion of the space below. Most are open to the space below; thus, with same atmosphere and line of sight, fire recognition is quicker than in a two-story situation. If the elevator used for ingress has not gone into fire department recall, that system could be used for self-evacuation. There are three different scenarios:

1. If the mezzanine is exempted from accessibility, such as a mechanical mezzanine (see Section 1103.2.9), or small enough not to be required to be accessed by an accessible route (see Section 1104.4, Exception 1), no accessible means of egress is required.

2. If a mezzanine is required to be accessible (see Section 1104.4) and does meet the provisions
MEANS OF EGRESS

for spaces with one means of egress (see Section 1015.1), the exit access stairway must meet the provisions of Section 1007.3.

3. If a mezzanine is required to be accessible (see Section 1104.4) and is required to have two means of egress, at least one of the means of egress stairways must meet the provisions of Section 1007.3.

While under Scenarios 2 and 3 it is optional to have the elevator meet the requirements of Section 1007.4, the provisions for standby power at elevators are based on fire department assisted rescue. This is an expensive option that would likely never be used during a fire event. Where platform lifts can be used in new construction (see Section 1109.8), they are so limited that it is not likely that they will provide the accessible route to a mezzanine. If they do, Section 1007.5 does allow for platform lifts to serve as part of the accessible route for accessible means of egress when they have standby power.

Exception 3 is in consideration of the practical difficulties of providing accessible routes in assembly areas with sloped floors and stepped aisles. Rooms with more than 50 persons are required to have two means of egress; therefore, each accessible seating location is required to have access to two accessible means of egress. Depending on the slope of the seating arrangement, providing an accessible route to both distinct exits can be difficult to achieve, especially in small theaters. A maximum travel distance of 30 feet (9144 mm) for ambulatory persons moving from the last seat in dead-end aisles or from box-type seating arrangements to where they have access to a choice of means of egress routes has been established in Section 1028.8. In accordance with Exception 3, persons using wheelchair seating spaces have the same maximum 30-foot (9144 mm) travel distance from the accessible seating locations to a cross aisle or out of the room to an adjacent corridor or space where two choices for accessible means of egress are provided. Note that there are increases in travel distance for smoke-protected seating and small spaces, such as boxes, galleries or balconies. For additional information, see Section 1028.8.

1007.2 Continuity and Components. Each required accessible means of egress shall be continuous to a public way and shall consist of one or more of the following components:

1. Accessible routes complying with Section 1104.
2. Interior exit stairways complying with Sections 1007.3 and 1022.
3. Interior exit access stairways complying with Sections 1007.3 and 1009.3.
4. Exterior exit stairways complying with Sections 1007.3 and 1026 and serving levels other than the level of exit discharge.
5. Elevators complying with Section 1007.4.
6. Platform lifts complying with Section 1007.5.
7. Horizontal exits complying with Section 1025.
8. Ramps complying with Section 1010.
9. Areas of refuge complying with Section 1007.6.
10. Exterior area for assisted rescue complying with Section 1007.7.

This section identifies the various building features that can serve as elements of an accessible means of egress. Accessible routes are readily recognizable as to how they can provide accessible means of egress; however, some nontraditional principles have been established for the total concept of accessible means of egress. This is evident in that stairways and elevators are also identified as elements that can comprise part of an accessible means of egress. For example, elevators are generally not available for egress during a fire, while stairways are not independently usable by a person using a wheelchair. The concept of accessible means of egress includes the idea that evacuating people with a mobility impairment may require the assistance of others. In some situations, provisions are also included for creating an area of refuge or exterior areas of rescue assistance wherein people can safely await either further instructions or evacuation assistance. Larger refuge areas can also be established by utilizing horizontal exits. All of these elements can be arranged in the manner prescribed in this section to provide accessible means of egress.

1007.2.1 Elevators required. In buildings where a required accessible floor is four or more stories above or below a level of exit discharge, at least one required accessible means of egress shall be an elevator complying with Section 1007.4.

Exceptions:

1. In buildings equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2, the elevator shall not be required on floors provided with a horizontal exit and located at or above the levels of exit discharge.
2. In buildings equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2, the elevator shall not be required on floors provided with a ramp conforming to the provisions of Section 1010.

* Elevators are the most common and convenient means of providing access to the upper floors in multistory buildings. As such, elevators represent a prime candidate for accessible means of egress from such buildings, especially in light of the difficulties involved in carrying a person up or down a stairway for multiple levels. The primary consideration for elevators as an accessible means of egress is that the elevator will be available and protected during a fire event to allow for fire department assisted rescue. Typically it is not the intent that people use the elevator for self-evacuation due to the hazards associated with smoke in the elevator shaft or the elevator taking people to the floor with a direct fire hazard. There are some
new technological advances for "fire service access elevators" and "occupant evacuation elevators" that are discussed in Sections 403, 3007 and 3008.

This section addresses where an elevator must serve as part of an accessible means of egress. See Section 1104 for when elevators are required for the accessible route into a building. By a reference to Section 1007.4, both an area of refuge and a standby source of power for the elevator is required. The standby power requirement establishes a higher degree of reliability that the elevator will be available and usable by reducing the likelihood of power loss caused by fire or other conditions of power failure.

The code defines "Exit Discharge, Level of" as the story at which an exit terminates. In buildings having four or more stories above or below the level of exit discharge, it is unreasonable to rely solely on exit stairways for all of the required accessible means of egress. This is the point at which complete reliance on assisted evacuation down the stairs will not be effective or adequate because of the limited availability of either experienced personnel who are trained to carry people safely (i.e., fire fighters) or the availability of special devices (i.e., self-braking stairway descent equipment or evacuation chairs). In this case, the code requires that at least one elevator, serving all floors of the building, is to serve as one of the required accessible means of egress. This should not represent a hardship, since elevators are typically provided in such buildings for the convenience of the occupants.

On a flat site, "buildings with four or more stories above the level of exit discharge" would typically be a five-story building. The level of exit discharge is the entire first story level (not merely the plane or level of the first floor); therefore, the fifth floor is the fourth story above the level of exit discharge. In a building with multiple basements, a story four stories below the level of exit discharge would be the fourth basement level. The actual vertical distance is the same from the fifth floor above grade down to discharge, as it is from the fourth floor below grade up to discharge. The verbiage is such that a building built on a sloped site can take into consideration that people may be exiting the building from different levels on different sides of the building (see Figure 1007.2.1).

Exception 1 establishes that accessible egress elevator service to floor levels at or above the level of

---

**Figure 1007.2.1**

**ELEVATOR REQUIRED FOR ACCESSIBLE MEANS OF EGRESS**
exit discharge is not necessary under specified conditions. The conditions are that the building is equipped throughout with an automatic sprinkler system in accordance with NFPA 13 or NFPA 13R (see Section 903.3.1.1 or 903.3.1.2) and that floors not served by an accessible egress elevator are provided with a horizontal exit. The presence of an automatic sprinkler system significantly reduces the potential fire hazard and provides for increased evacuation time. The combination of automatic sprinklers and a horizontal exit provides adequate protection for the occupants despite their distance to the level of exit discharge. This exception does not apply to floor levels below the level of exit discharge, since such levels are typically below grade and do not have the added advantage of exterior openings that are available for fire-fighting or rescue purposes. This option is most often utilized when a defend-in-place approach to occupant protection is utilized, such as in a hospital, nursing home or jail. Keep in mind that the horizontal exit (see Section 1025) creates large refuge areas that have separation requirements and capacity requirements that exceed area of refuge requirements.

Exception 2 specifies that a building sprinklered throughout in accordance with NFPA 13 or NFPA 13R (see Section 903.3.1.1 or 903.3.1.2), with ramp access to each level, such as in a sports stadium, is not required to also have an elevator for accessible means of egress. The reasoning behind this is that the issue of carrying people down stairways does not occur because the ramps may be utilized instead.

1007.3 Stairways. In order to be considered part of an accessible means of egress, a stairway between stories shall have a clear width of 48 inches (1219 mm) minimum between handrails and shall either incorporate an area of refuge within an enlarged floor-level landing or shall be accessed from either an area of refuge complying with Section 1007.6 or a horizontal exit. Exit access stairways that connect levels in the same story are not permitted as part an accessible means of egress.

Exceptions:

1. The clear width of 48 inches (1219 mm) between handrails is not required in buildings equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2.

2. Areas of refuge are not required at stairways in buildings equipped throughout by an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2.

3. The clear width of 48 inches (1219 mm) between handrails is not required for stairways accessed from a horizontal exit.

4. Areas of refuge are not required at stairways serving open parking garages.

5. Areas of refuge are not required for smoke protected seating areas complying with Section 1028.6.2.

6. The areas of refuge are not required in Group R-2 occupancies.

This section addresses stairways between floor levels or to a mezzanine level. The last sentence indicates that steps that connect raised areas are not permitted to be part of an accessible means of egress. People with mobility impairments cannot be asked to wait at the top of steps that may be anywhere in the building; they must be able to get to the stairways where the fire department will be coming into the building.

Stairways (exit or exit access) between floor levels, while not part of an accessible route, can serve as part of the accessible means of egress when they are used as part of an assisted evacuation route. The starting point for these requirements is that the stairways must be 48 inches (1219 mm) clear width between handrails; and either include or be accessed directly by a location where people can wait for assisted evacuation. This place to wait can be either an "area of refuge" (see Section 1007.6) or a "refuge area" created by a horizontal exit (see Section 1025).

There are many mobility impairments that can limit or negate a person's ability to walk up and down the stairs. The taller the building, the higher the percentage of the population that will be affected. For example, an elderly person or a person with a broken foot may be able to get down a couple of flights, but not from an upper floor in a high-rise.

Note that this section is for exit stairways as addressed in Sections 1022 and 1026 and exit access stairways as addressed in Section 1009. Therefore, exit access stairways between stories could be considered part of an accessible means of egress, but not exit access steps within the same level, such as steps in a corridor or room leading to an exit or exit access doorway. Interior exit stairways are enclosed; however, there are allowances in Section 1009 for exit access stairways and Section 1026 for exterior exit stairways to be permitted to be open in certain circumstances.

The dimension of 48 inches (1219 mm) clear width between handrails is sufficient to enable two or three persons to carry a person up or down to the level of exit discharge where access to a public way is afforded.

The enclosed exit stairway, in combination with an area of refuge, can provide for safety from fire in one of two ways. One approach is for the fire-resistance rated stairway enclosure to afford the necessary safety. To accomplish this, the landing within the stairway enclosure must be able to contain the wheelchair. The concept is that the person in the wheelchair will remain on the stairway landing for a period of time awaiting further instructions or evacuation assistance; therefore, the stairway landing must be able to accommodate the wheelchair without obstructing the use of the stairway by other egressing occupants. An enlarged, story-level landing is required within the stairway enclosure and must be of
sufficient size to accommodate the number of wheelchairs [see Section 1007.6 and Figure 1007.3(1)].

The other approach is to utilize an enclosed exit stairway that is accessed from an area of refuge complying with Section 1007.6. Under this approach, the stairway is made safe by virtue of its access being in an area that is separated and protected from the point of fire origin. An area of refuge can be created by constructing a vestibule adjacent and with direct access to the stair enclosure [see Section 1007.6 and Figure 1007.3(2)]. This is similar in theory to the approach of an enlarged landing within the stairway enclosure. Again, the general mean of egress path must be available past the wheelchair spaces.

In the case of a horizontal exit [see Figure 1007.3(3)], each floor area on either side of the exit is considered a refuge area (see commentary, Section 1025.1) by virtue of the construction and separation requirements for horizontal exits. The discharge area is always assumed to be the nonfire side and therefore, is protected from fire. Therefore, any stairs within this refuge area are not required to have areas of refuge.

Exceptions may be combined. They can be for either the area of refuge or the 48-inch (1219 mm) stairway width requirement. It is very important to note that an exception for the area of refuge in Section 1007.3 or 1007.4 is not an exception for the accessible means of egress. The accessible route must be available to the stairway or elevator so that people with mobility impairments and emergency responders can meet up as soon as possible.

The exceptions are applicable to all stairways between stories (i.e., exit access, interior exit and exterior exit). While interior exit access stairways are part of the travel distance measurements, they do provide means of egress between floor levels; therefore, the same stairway that serves the ambulatory population for between floor levels can also serve as part of the accessible means of egress. Open exit access stairway requirements for mezzanines and in assembly seating arrangements are addressed in Exceptions 2 and 3 to Section 1007.1.

Exceptions 1 and 2 are in recognition of the increased level of safety and evacuation time that is afforded in a sprinklered occupancy. The expectation is that a supervised system will reduce the threat of fire by reliably controlling and confining the fire to the immediate area of origin. There is also the additional safety of the sprinkler system requirements for automatic notification when the system is activated. This has been substantiated by a study of accessible means of egress conducted for the General Services Administration (GSA). A report issued by the National

![Diagram: Accessible Means of Egress Stairway with Enlarged Story-Level Landing](image)

For: 1 inch = 25.4 mm.

Figure 1007.3(1)
ACCESSIBLE MEANS OF EGRESS STAIRWAY WITH ENLARGED STORY-LEVEL LANDING
Institute for Standards and Technology (NIST), NIST IR 4770, *Staging Areas for Persons with Mobility Limitations*, concluded that the operation of a properly designed sprinkler system eliminates the life threat to all building occupants, regardless of their individual physical abilities and is a superior form of protection as compared to areas of refuge. It was deemed that the ability of a properly designed and operational automatic sprinkler system to control a fire at its point of origin and to limit production of toxic products to a level that is not life-threatening to all occupants of the building, including persons with disabilities, eliminates the need for areas of refuge.

Exceptions 1 and 3 deal with stairway width. Exceptions 2, 4, 5 and 6 are exceptions for the area of refuge. These are not exceptions for the accessible route to the exit, just the area of refuge at the exit.

Exception 1 allows the stairway width to go back to the base requirements in Section 1009.4 in buildings sprinklered in accordance with NFPA 13 or NFPA 13R for both unenclosed and enclosed exit and exit access stairways (see Sections 1009, 1020 and 1026). Exception 1 is often used in conjunction with Exceptions 2. With the sprinkler system in place, there is more opportunity for the fire department to bring in evacuation chairs or possibly bring people to the elevator for evacuation, thus the extra width for carrying someone down the stairway is not needed. This is safer for both emergency responders and the evacuees.

Exception 2 is for the area of refuge for all exit access stairways (see Section 1009) and exit stairways, interior and exterior (see Sections 1022 and 1026), where the building is sprinklered throughout with an NFPA 13 or 13R system. Again, this is not an exception for the accessible route to the exit, just the area of refuge at the exit.

Exception 3 allows the stairway width to go back to the base requirements in Section 1009.3 when the stairway is within the refuge area created by a horizontal exit. This exception considers that the extra exiting time will permit the egress down the stairway to be more deliberate. Horizontal exits are often used in hospitals or jails when the defense scenario is defend in place rather than evacuation.

Exceptions 4 and 5 are for structures where the natural ventilation of the products of combustion that will be afforded by the exterior openings or smoke protection required of such structures (see Sections 406.3, 909 and 1028.6.2). The most immediate hazard for occupants in a fire incident is exposure to smoke and fumes. Floor areas in open parking structures communicate sufficiently with the outdoors such that the need for protection from smoke is not neces-
sary; therefore, open parking garages are exempted from the requirements for an area of refuge (see also the exception to Section 1007.6.2). It is because of this level of natural ventilation that parking garage exit stairways are not required to be enclosed (see Section 1009.3, Exception 6). The logic for exterior sports facilities and smoke-protected seating is the same: if there is no accumulation of smoke, there is no need for areas of refuge, even when a sprinkler system is not included (see Section 1009.3, Exception 7).

Exception 6 is in recognition of the dwelling unit separation and fire-resistant-rated corridors in Group R-2 facilities (see Sections 420 and 1018). Effectively, each dwelling unit can serve as a protected area. Since the current text requires all Group R structures to be sprinklered (see Section 903.2.8), Exceptions 2 and 3 could also be utilized.

1007.4 Elevators. In order to be considered part of an accessible means of egress, an elevator shall comply with the emergency operation and signaling device requirements of Section 2.27 of ASME A17.1. Standby power shall be provided in accordance with Chapter 27 and Section 3003. The elevator shall be accessed from either an area of refuge complying with Section 1007.6 or a horizontal exit.

Exceptions:

1. Elevators are not required to be accessed from an area of refuge or horizontal exit in open parking garages.

2. Elevators are not required to be accessed from an area of refuge or horizontal exit in buildings and facilities equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2.

3. Elevators not required to be located in a shaft in accordance with Section 712 are not required to be accessed from an area of refuge or horizontal exit.

4. Elevators are not required to be accessed from an area of refuge or horizontal exit for smoke protected seating areas complying with Section 1028.6.2.

Elevators are the most common and convenient means of providing access to upper and lower floors in multistory buildings. As such, elevators represent a prime candidate for accessible means of egress from such buildings, especially in light of the difficulties involved in carrying a person in a wheelchair up or down a stairway. The primary consideration for elevators as an accessible means of egress is that the elevator will be available and protected during a fire event. See Sections 403, 3007 and 3008 for new provisions in high-rise buildings for "fire service access elevators" and "occupant evacuation elevators."

This section addresses the use of an elevator as part of an accessible means of egress by requiring both a backup source of power for the elevator and access to the elevator from an area of refuge or a horizontal exit. For situations where elevators are required to be part of one of the accessible means of egress, see Section 1007.2.1. Note that an elevator lobby that is off a fire-resistance-rated corridor must also comply with Section 713.14.1. The backup power requirement establishes a higher degree of reliability that the elevator will be available and usable by reducing the likelihood of power loss caused by
MEANS OF EGRESS

fire or other conditions. Requiring access from an area of refuge or a horizontal exit affords the same degree of fire safety as described for stairways (see commentary, Section 1007.3). Additionally, the reference to Chapter 27 and Section 3003 clarifies that the elevator will comply with the emergency operation features that relate to operating an elevator under fire conditions (see commentary, Sections 2702.2.2, 2702.2.2.19 and 3003). Elevators on an accessible route are also required to meet the accessibility provisions of ICC A117.1 (see commentary, Sections 1109.7 and 3001.3).

Exception 2 is for the area of refuge for all elevators where the building is sprinklered throughout with an NFPA 13 or 13R system. Again, this is not an exception for the accessible route to the exit, just the area of refuge at the elevator with standby power. Exception 2 is in recognition of the increased level of safety and evacuation time that is afforded in a sprinklered occupancy. The expectation is that a supervised system will reduce the threat of fire by reliably controlling and confining the fire to the immediate area of origin. There is also the additional safety of the sprinkler system requirements for automatic notification when the system is activated. This has been substantiated by a study of accessible means of egress conducted for the GSA. NIST IR 4770 concluded that the operation of a properly designed sprinkler system eliminates the life threat to all building occupants, regardless of their individual physical abilities and is a superior form of protection as compared to areas of refuge. It was deemed that the ability of a properly designed and operational automatic sprinkler system to control a fire at its point of origin and to limit production of toxic products to a level that is not life threatening to all occupants of the building, including persons with disabilities, eliminates the need for areas of refuge.

If a level in an open parking garage contains accessible parking spaces or is part of the route to and from those spaces, that level is required to have accessible means of egress. Exception 1, for open parking structures, is in recognition of the natural ventilation of the products of combustion that will be afforded by the exterior openings of such structures (see Section 406.15.2). The most immediate hazard for occupants in a fire incident is exposure to smoke and fumes. Floor areas in open parking structures are sufficiently exposed to the outdoors; thus, the need for protection from smoke is not necessary. Therefore, open parking garages are exempt from the requirements for an area of refuge or horizontal exit to access an elevator that is utilized as part of the accessible means of egress. The same idea holds true for smoke-protected seating areas, in accordance with Exception 4. The protection offered by the smoke control system allows for adequate evacuation time before there is danger from smoke and fume accumulation.

Exception 3 allows for elevators that are not required to be enclosed by Section 712 to not have an area of refuge or be accessed by a horizontal exit. If there is no shaft enclosure around the elevator, construction of a smoke-tight compartment immediately in front of the elevator doors would be very difficult. While there are many items listed under Section 712, combined with the height requirements in Section 1007.2.1, typically this would be elevators in atriums or in open and enclosed parking garages. Again, the nature of the location adjacent to an atrium or with the open ramps in parking garages would minimize the chances of smoke accumulation at the elevators.

1007.5 Platform lifts. Platform (wheelchair) lifts shall not serve as part of an accessible means of egress, except where allowed as part of a required accessible route in Section 1109.7, Items 1 through 9. Standby power shall be provided in accordance with Chapter 27 for platform lifts permitted to serve as part of a means of egress.

• Previously, there have been concerns about whether a platform lift will be reliably available at all times. However, ASME A 18.1, the standard for platform lifts, no longer requires key operation. It is important to note that platform lifts are not prohibited by the code. They simply cannot be counted as a required accessible means of egress in other than locations where they are allowed as part of the accessible route into a space (see commentary, Section 1109.8). When platform lifts are utilized as part of an accessible means of egress, they must be equipped with standby power. Note that platform lifts cannot be used to meet accessible means of egress requirements for a situation that utilizes Section 1109.8, Item 10. Accessible means of egress must be provided at other locations.

In existing buildings undergoing alterations, platform lifts are allowed as part of an accessible route into a building (see commentary, Section 3411.8.3) at any location as long as they are compliant with ASME A18.1. Note that accessible means of egress are not required in existing buildings undergoing an alteration or a change of occupancy (see Sections 1007.1 and 3411.6).

1007.5.1 Openness. Platform lifts on an accessible means of egress shall not be installed in a fully enclosed hoistway.

• Platform lifts utilized as part of an accessible means of egress must be open to permit others in the building to view the user and allow communication between the rider and others in the building so as to reduce the possibility of entrapment during an emergency evacuation. Lifts are now permitted to penetrate floors by ASME A18.1, and thus may be in fire-rated enclosures to maintain the separation between different floors. Even when fire separation is not an issue, nothing prevents the designer from installing a lift in a fully enclosed shaft. The openness requirement is in recognition that platform lifts do not have the fire-fighter service or two-way communication required in elevators. Current text is silent on whether the platform lift being within the same enclosure as
the exit stairway would provide enough visibility to allow this platform lift to be considered open; however, with everyone evacuating in the stairway and the fire department entering through the stairway, the risk of possible entrapment on the platform lift and not being found quickly is extremely minimal.

1007.6 Areas of refuge. Every required area of refuge shall be accessible from the space it serves by an accessible means of egress. The maximum travel distance from any accessible space to an area of refuge shall not exceed the travel distance permitted for the occupancy in accordance with Section 1016.1. Every required area of refuge shall have direct access to a stairway complying with Sections 1007.3 or an elevator complying with Section 1007.4. Where an elevator lobby is used as an area of refuge, the shaft and lobby shall comply with Section 1022.10 for smokeproof enclosures except where the elevators are in an area of refuge formed by a horizontal exit or smoke barrier.

- Areas of refuge, when provided, are an important component of the fire and safety evacuation plans for the buildings. These areas must be included in the plans required by Section 1001.4 of the code and Section 404 of the IFC.

An area of refuge is of no value as part of an accessible means of egress if it is not accessible. The code states an obvious but essential requirement: the path that leads to an area of refuge must qualify as an accessible means of egress. This provision is required so that there will be an accessible route leading from every accessible space to each required area of refuge. For consistency in principle with the general means of egress design concepts, the code also limits the travel distance to the area of refuge.

The limitation is the same distance as specified in Section 1016.2 for maximum exit access travel distance. This equates the maximum travel distance required to reach an exit with the maximum distance required to reach an area of refuge. It should be noted that an area of refuge is not necessarily an exit in the classic sense. For example, when the area of refuge is an enlarged, story-level landing within an exit stairway, the area of refuge is within the exit and the maximum travel distance for both the conventional exit and the accessible area of refuge is measured to the same point (the entrance to the exit stairway). If the area of refuge is a vestibule immediately adjacent to an enclosed exit stairway, the maximum travel distance for the required accessible means of egress is measured to the entrance of the area of refuge and, for the travel distance to the exit, to the entrance of the exit stairway (see Figure 1007.6). In the case of accessible means of egress with an elevator, the maximum travel distance may end up being measured along two different paths, with the only consistency between the conventional means of egress and the accessible means of egress being the maximum travel distance (see Figure 1007.6). The travel distance within an area of refuge is not directly regulated, but will be limited by the general provisions for maximum exit access travel distance, which are always applicable.

In summary, the code takes a reasonably consistent approach for both conventional and accessible means of egress by limiting the distance one must travel to reach a safe area from which further egress to a public way is available.

To ensure that there is continuity in an accessible

![Figure 1007.6](image-url)
means of egress, the code requires that every area of refuge have direct access to either an exit stairway (see Section 1007.3) or an elevator (see Section 1007.4). This, again, may be viewed as stating the obvious, but it is necessary so that the egress layout does not involve entering an area of refuge and then having to leave that protected area before gaining access to a stairway or elevator. Once an occupant reaches the safety of an area of refuge, that level of protection must be continuous until the vertical transportation element (the stairway or elevator) is reached.

If one chooses to comply with the accessible means of egress requirements by providing an accessible elevator with an area of refuge in the form of an elevator lobby, the elevator shaft and the lobby are required to be constructed in accordance with Sections 713.14 and 1022.10. The elevator lobby must be protected from smoke moving up through the shaft by the elevator lobbies having an additional vestibule for access or pressurization of the shafts and lobbies (see Section 909.20). Elevator hoistway door assemblies are, by nature, not substantially air tight. Significant quantities of air can move throughout the shaft and adjacent lobby because of stack effect, especially in tall buildings. The requirements provide additional assurance that the elevator will not be rendered unavailable because of smoke movement into the elevator shaft. If the elevator is in a refuge area that is formed by the use of a horizontal exit (i.e., fire walls or fire barriers in accordance with Section 1025.2) or smoke compartments formed by smoke barriers (see Sections 407.5 and 408.6), it is presumed that the refuge area is relatively free from smoke; therefore, the extra protection of Sections 713.14 and 1022.10 would not be needed.

1007.6.1 Size. Each area of refuge shall be sized to accommodate one wheelchair space of 30 inches by 48 inches (762 mm by 1219 mm) for each 200 occupants or portion thereof, based on the occupant load of the area of refuge and areas served by the area of refuge. Such wheelchair spaces shall not reduce the required means of egress width. Access to any of the required wheelchair spaces in an area of refuge shall not be obstructed by more than one adjoining wheelchair space.

The number of wheelchair spaces that are required to be provided in an area of refuge is intended to represent broadly the expected population of the average building. As one point of measurement, a 1977 survey conducted by the National Center for Health indicated that one in 333 civilian, noninstitutionalized persons uses a wheelchair. The 1990 ADA currently utilizes the criterion of one space for each 200 occupants, based on the space served by the area of refuge. Given the variations and difficulties involved in accurately predicting a representative ratio for application to all occupancies, it was concluded that a requirement for one space for each 200 occupants based on the area of refuge itself, plus the areas served by the area of refuge, represents a reasonable criterion. Very few buildings would ever require more than four wheelchair spaces on a floor, since nearly all buildings with an occupant load greater than 400 per floor would be sprinklered and using Exception 2 in Section 1007.3.

Arrangement of the required wheelchair spaces is critical so as not to interfere with the means of egress for ambulatory occupants (see Section 1009.8). Since the design concept is that wheelchair occupants will move to the area of refuge and await further instructions or evacuation assistance, the spaces must be located so as not to reduce the required means of egress width of the stairway, door, corridor or other egress path through the area of refuge.

In order to provide for orderly maneuvering of wheelchairs, this section states that access to any of the required wheelchair spaces cannot be obstructed by more than one adjoining wheelchair space. For example, this precludes an arrangement that three or more wheelchairs could be stacked down a dead-end corridor. This also effectively limits the difficulty any given wheelchair occupant would have in reaching or leaving a given wheelchair space, as well as providing easier access to all wheelchair spaces by persons providing evacuation assistance.

1007.6.2 Separation. Each area of refuge shall be separated from the remainder of the story by a smoke barrier complying with Section 709 or a horizontal exit complying with Section 1025. Each area of refuge shall be designed to minimize the intrusion of smoke.

Exception: Areas of refuge located within an enclosure for exit access stairways or interior exit stairways.

- The minimum standard for construction of an area of refuge is a smoke barrier, in accordance with Section 709. This establishes a minimum degree of performance by means of a 1-hour fire-resistance rating, including opening protectives and a minimum degree of performance against the intrusion of smoke into an enclosed area of refuge, as specified in Sections 709.4 and 709.5. By nature of the connection to the stair enclosure or elevator shaft, the normal smoke barrier requirement for extension from exterior wall to exterior wall is replaced by connection to the shaft enclosure.

An alternative is to provide a refuge area created by a horizontal exit complying with Section 1025. Horizontal exits are formed by fire walls or fire barriers with a minimum fire-resistance rating of 2 hours. The horizontal exit separation must extend vertically through all levels of the building, unless floor assemblies have a fire-resistance rating of not less than 2 hours with no unprotected openings (see Section 1025.2). The other provisions for horizontal exits for additional egress elements, opening protection and capacity must also be complied with.

This section does not require an area of refuge within an exit stairway to be designed to prevent the intrusion of smoke. This was based on a study of areas of refuge conducted by NIST for the GSA,
which concluded that a story-level landing within a fire-resistance-rated exit stairway would provide a satisfactory staging area for evacuation assistance.

1007.6.3 Two-way communication. Areas of refuge shall be provided with a two-way communication system complying with Sections 1007.8.1 and 1007.8.2.

- If a building includes areas of refuge at the stairway or elevators, each area of refuge must include a two-way communication system. If the building uses one of the exceptions for areas of refuge, Section 1007.8 would still require a two-way communication system at the elevator. This way anyone needing assistance can communicate with a person at a constantly attended location to request evacuation assistance. This system is an important part of the fire and safety evacuation plans required by Section 1001.4 of the code and Section 404 of the IFC. See Sections 1007.8.1 and 1007.8.2 for specific requirements for this system.

1007.7 Exterior area for assisted rescue. Exterior areas for assisted rescue shall be accessed by an accessible route from the area served. Exterior areas for assisted rescue shall be permitted in accordance with Section 1007.7.1 or 1007.7.2.

- Section 1007.2 requires the accessible means of egress to have an accessible route along the path for exit access, exit and exit discharge. In exterior locations where this is not feasible, one of the options is an exterior area of assisted rescue.

Exterior areas of assisted rescue are intended to be open-air locations for persons with physical disabilities to wait for assisted rescue. There must be an interior or exterior accessible route along the path of travel for exit access to this location. This allows a person unable to negotiate the exit discharge to get to a location where they can be quickly discovered by the fire department or other emergency responders.

In most situations, interior areas of refuge are not a positive alternative. Tenants tend to use such areas as convenient storage areas. Where persons with mobility impairment can wait for assisted rescue outside of the building, they are effectively protected from interior smoke and fumes—the deadliest of the fire hazards. Being immediately visible at an exit should also result in a shorter period of time before assisted rescue is achieved.

Exterior areas for assisted rescue, when provided, are an important component of the fire and safety evacuation plans for the buildings. These areas must be included in the plans required by Section 1001.4 of the code and Section 404 of the IFC.

The option under Section 1007.7.1 is commonly used on the ground level for the second exit out the back of a building or tenant space. This will be either a single-story building, or the first level of a multi-story building, where the secondary exit discharge is not accessible due to changes in elevation around the perimeter.

The option under Section 1007.7.2 deals with outdoor assembly seating spaces where the path of the means of egress is essentially open to the outside. Per Section 1009.3, Exception 7, and Section 1016.3, Exception 2, the stairways are exit access stairways, but the travel distance measurement is stopped at the top riser rather than including the travel down the stairway. This is similar to an open parking garage. Since there will be a limited chance for the accumulation of smoke in the assembly area, there is not a need for areas of refuge, even though the building is not sprinklered. This allowance is consistent with Section 1007.3, Exception 5 and Section 1007.4, Exception 4, which exempts smoke-protected seating areas from providing areas of refuge at exit stairways.

1007.7.1 Level of exit discharge. Where the exit discharge does not include an accessible route from an exit located on a level of exit discharge to a public way, an exterior area of assisted rescue shall be provided on the exterior landing in accordance with Sections 1007.7.3 through 1007.7.6.

- Due to site constraints, such as easements, slopes and ground surfaces, an accessible route from a second exit is not always practical. The option under Section 1007.7.1 is commonly used on the ground level for the second exit out the back of a building or tenant space. This will be either a single-story building or the first level of a multi-story building, where the secondary exit discharge is not accessible due to changes in elevation around the perimeter. Examples of this issue are:

Example 1:
A strip mall would have accessible entrances to each tenant in the front (Section 1106.6). Many have service entrances or loading bays across the back, so the second exit door leads to steps. Providing a ramp for accessible exit discharge could be extensive due to the elevation change; block access to the loading docks; get damaged by the maneuvering trucks or there might not be space on a narrow alley.

Example 2:
An office building has a second exit that leads to a concrete stoop and the exit discharge is sloped, is uneven or may be blocked by snow. This is just as impassable for a person using a wheelchair as a series of steps. Providing a sidewalk all the way to the front of the building may not be practical due to adjacent buildings or the fact that you could be travelling adjacent to a burning building.

Sections 1007.7.3 through 1007.7.6 provide criteria for a safe place to wait temporarily for assistance. These address size, separation/protection, openness and any steps leading from the exterior area for assisted rescue. If this is an exterior exit stairway (i.e., more than one story of vertical travel), the provisions in Section 1007.3 would be applicable.

1007.7.2 Outdoor facilities. Where exit access from the area serving outdoor facilities is essentially open to the outside, an exterior area of assisted rescue is permitted as an alternative to an area of refuge. Every required exterior area of assisted rescue shall have direct access to an interior exit stairway.
exterior stairway, or elevator serving as an accessible means of egress component. The exterior area of assisted rescue shall comply with Sections 1007.7.3 through 1007.7.6 and shall be provided with a two-way communication system complying with Sections 1007.8.1 and 1007.8.2.

- If ramps are provided from a level, this section is not applicable since ramps can serve as part of the accessible means of egress (Section 1007.2, Item 8).

Accessibility into the outdoor arena or grandstand is addressed in Section 1108.2, which, in conjunction with ICC A117.1, requires an accessible route to accessible seating locations dispersed throughout the seating bowl. The vertical portion of the route into the space will be by elevators, platform lifts or ramps.

The option under Section 1007.7.2 deals with outdoor assembly seating spaces where the path of the means of egress is essentially open to the outside. These large seating areas will require two accessible means of egress. Stairways in outdoor facilities are considered exit access stairways (Section 1009.3, Exception 7). In these facilities, exit access travel distance is measured to the top riser (Section 1016.3, Exception 2). The path of travel to exits is limited to 50 feet (15 240 mm), starting from the accessible seat location and following back along the same route an occupant entered from. Once the occupant gets to that point, he or she needs two separate distinct routes to the two accessible means of egress. This allowance is consistent with Section 1007.3, Exception 5 and Section 1007.4, Exception 4, which exempts smoke-protected seating areas from providing areas of refuge at exit stairways.

If a person with mobility impairment needs to move to the stairways or elevator for assisted evacuation, the area where they will be waiting must meet the provisions of Sections 1007.7.3 through 1007.7.6.

1007.7.3 Size. Each exterior area for assisted rescue shall be sized to accommodate wheelchair spaces in accordance with Section 1007.6.1.

- The exterior area for assisted rescue must have an enlarged landing area with space for at least one wheelchair for every 200 occupants that will be using that exit. The wheelchair spaces must be located so that they do not obstruct the general means of egress. If these spaces are confined by walls, guards or edges, they must also meet the alcove provisions in ICC A117.1 so that persons using wheelchairs can maneuver into the space [see Figure 1007.7.3].

1007.7.4 Separation. Exterior walls separating the exterior area of assisted rescue from the interior of the building shall have a minimum fire-resistance rating of 1 hour, rated for exposure to fire from the inside. The fire-resistance-rated exterior wall construction shall extend horizontally 10 feet (3048 mm) beyond the landing on either side of the landing or equivalent fire-resistance-rated construction is permitted to extend out perpendicular to the exterior wall 4 feet (1219 mm) minimum on the side of the landing. The fire-resistance-rated construction shall extend vertically from the ground to a point 10 feet (3048 mm) above the floor level of the area for assisted rescue or to the roof line, whichever is lower. Openings within such fire-resistance-rated exterior walls shall be protected in accordance with Section 716.

- The protection provided by an exterior area for assisted rescue would be equivalent to that required for an interior area of refuge. Note that there is no exception for the exterior area of assisted rescue for buildings that contain sprinkler systems. The separation requirements are similar to exterior exit stairways, rated walls and protected openings for 10 feet (3048 mm) above, below and to the sides of the landing (see Sections 1022.7 and 1026.6). The exceptions for exterior exit stairway protection in Section 1026.6 would not be applicable where the area includes an exterior area for assisted rescue (see Figure 1007.7.4).

The current separation requirements address typical rear exit situations. Other locations may require alternative protection measures to "shield" an exterior area for assisted rescue. The principle of "wing" walls (as used at a fire wall extension) suggests an alternative to 1/4-hour opening protectives at dock doors adjacent to an exterior area for assisted rescue.

An exterior area of assisted rescue in an open-air stadium is difficult to protect. Since the intent is for some level of protection from a possible fire, a fire-resistance rated floor in the structural bay where an exterior area for assisted rescue is provided may be part of an appropriate solution.

Note that providing a rescue location 10 feet (3048 mm) away from an exterior wall does not serve as a viable alternative to a fire-resistance-rated exterior wall. Persons waiting for assistance must have a minimum level of shielding from a fire in the building.

1007.7.5 Openness. The exterior area for assisted rescue shall be open to the outside air. The sides other than the separation walls shall be at least 50 percent open, and the open area shall be distributed so as to minimize the accumulation of smoke or toxic gases.

- The openness criteria for exterior areas of assisted rescue are similar to the requirements for exterior balconies. The purpose is to ensure that a person at an exterior area of rescue assistance is not in danger from smoke and fumes. The criteria are to address the situation where the rescue area is open to outside air, but a combination of roof overhangs and perimeter walls or guards could still trap enough smoke that the safety of the occupants would be jeopardized.

1007.7.6 Stairway. Stairways that are part of the means of egress for the exterior area for assisted rescue shall provide a clear width of 48 inches (1219 mm) between handrails.

Exception: The clear width of 48 inches (1219 mm) between handrails is not required at stairways serving buildings equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2.

- Any steps that lead from an exterior area for assisted rescue to grade must have a clear width of 48 inches
(1219 mm) between handrails. The additional width is to permit adequate room to assist a mobility impaired person down the steps and to a safe location.

If the building is sprinklered, the exception allows for the stairway to utilize the minimum widths required in Section 1009.4. This is consistent with Section 1007.3, Exceptions 1 and 3.

1007.8 Two-way communication. A two-way communication system shall be provided at the elevator landing on each accessible floor that is one or more stories above or below the story of exit discharge complying with Sections 1007.8.1 and 1007.8.2.

Exceptions:

1. Two-way communication systems are not required at the elevator landing where the two-way communication system is provided within areas of refuge in accordance with Section 1007.6.3.

2. Two-way communication systems are not required on floors provided with ramps conforming to the provisions of Section 1010.

Unless provided in areas of refuge, in multistory buildings a two-way communication system must be located at the elevator landing of each accessible floor level other than the level of exit discharge. The system is intended to offer a means of communication to individuals with mobility impairment, either permanent or temporary, who need assistance during an emergency situation. Such a system can be useful not only in the event of a fire but also in the case of a natural or technologic disaster by providing emergency responders with the location of individuals who will require assistance in being safely evacuated from floor levels above or below the discharge level. Again, two-way communication is for all elevator lobbies in sprinklered buildings, not just elevators that serve as part of an accessible route. The ability of emergency responders to locate persons needing assistance quickly is an important part of the fire- and safety-plan. The two-way communication system is a critical element in that plan.

Exception 1 exempts the requirement for locating the communication systems at the elevator landings where the building is provided with complying areas of refuge. Since areas of refuge are required by Section 1007.6.3 to be equipped with two-way communication systems, there is limited need to provide such additional systems at the elevator landings. However, where multistory buildings are not provided with areas of refuge, such as in the case with most sprinklered buildings, the installation of communications systems at the elevator landings is important to those individuals unable to negotiate egress stairways during an emergency. As a result, both sprinklered and nonsprinklered multistory buildings will be provided with the means for two-way communication at all accessible floor levels other than the level of exit discharge.

For Sl: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

Figure 1007.7.3
EXTERIOR AREA OF RESCUE ASSISTANCE—PLAN VIEW
MEANS OF EGRESS

Exception 2 applies to floor levels that utilize ramps as vertical accessible means of egress elements. Where complying ramps are available for independent evacuation, such as occurs in a sports stadium, the two-way communication system is not required at the elevator landings.

A two-way communication system is required at exterior areas for assisted rescue in outdoor facilities (see Section 1007.7.2). The current language in Exception 1 does not allow for two-way communication systems at the elevator lobbies to be removed if two-way communication systems are available at exterior areas of assisted rescue.

Because of immediate visibility of a person at an exterior area of rescue assistance provided at ground level (i.e., level of exit discharge) and the high chance of vandalism at that location, two-way communication systems are not required.

If the option of horizontal exits is utilized, the code does not currently address if a two-way communication system should be provided within a refuge area without an elevator. Since the horizontal exit is not typically recognizable by a person not familiar with the building plan, the most logical location for the two-way communication, if provided, would seem to be adjacent to the exit stairway that was located within the refuge area.

1007.8.1 System requirements. Two-way communication systems shall provide communication between each required location and the fire command center or a central control point location approved by the fire department. Where the central control point is not constantly attended, a two-way communication system shall have a timed automatic telephone dial-out capability to a monitoring location or 9-1-1. The two-way communication system shall include both audible and visible signals.

- Use of an elevator, stair enclosure or other area of refuge as part of an accessible means of egress requires a person to wait for evacuation assistance or relevant instructions. The two-way communication system allows this person to inform emergency personnel of his or her location and to receive additional instructions or assistance as needed.

The arrangement and design of the two-way communication system is specified in Section 1007.8.1. In addition to the required locations specified in Section 1007.6.3 for areas of refuge, Section 1007.8 for elevator landings, or Section 1007.7.2 for exterior areas of assisted rescue in outdoor stadiums, a communication device is also required to be located in a high-rise building's fire command center or at a central control point whose location is approved by the fire department (see Sections 403.5.1 and 907.2.13.2). "Central control point" is not a defined term. However, given the intent and function of the two-way communication system, a central control point is a location where an individual answers the call for assistance and either provides or requests aid for a person who needs help. A suitable central control point is often not available in low-rise buildings or in a high-rise building where the central control point may not be manned on a 24-hour basis. In order that a caller may reach an appropriate emergency location, such as the fire department, the fire department must approve the configuration of the system. A central control point could be the lobby of a building constantly staffed by a security officer, a public safety answering point such as a 9-1-1 center or a central supervising station in a Group I occupancy. There could be a combination solution—such as a system configured to automatically call 9-1-1 when the central control point within the building is not manned. The communication system provides visual signals for the hearing impaired and audible signals to assist the vision impaired.

![Diagram of exterior area of rescue assistance](image-url)

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

Figure 1007.7.4
EXTERIOR AREA OF RESCUE ASSISTANCE—ELEVATION
1007.8.2 Directions. Directions for the use of the two-way communication system, instructions for summoning assistance via the two-way communication system and written identification of the location shall be posted adjacent to the two-way communication system.

- Guidance to the users of the two-way communication system is also specified. Operating instructions for the two-way communication system must be posted and the instructions are to include a means of identifying the physical location of the communication device. If a signal from a two-way communication system terminates to a public safety answering point, such as a fire department communication center, current 9-1-1 telephony technology only reports the address of the location of the emergency—it does not report a floor or area from the address reporting the emergency. The "identification of the location" posted adjacent to the communication system should ensure that most discrete location information can be provided to the central control point. This will aid emergency responders, especially in high-rise buildings or corporate campuses with multiple multistory structures.

1007.9 Signage. Signage indicating special accessibility provisions shall be provided as shown:

1. Each door providing access to an area of refuge from an adjacent floor area shall be identified by a sign stating: AREA OF REFUGE.
2. Each door providing access to an exterior area for assisted rescue shall be identified by a sign stating: EXTERIOR AREA FOR ASSISTED RESCUE.

Signage shall comply with the ICC A117.1 requirements for visual characters and include the International Symbol of Accessibility. Where exit sign illumination is required by Section 1011.3, the signs shall be illuminated. Additionally, raised character and Braille signage complying with ICC A117.1 shall be located at each door to an area of refuge and exterior area for assisted rescue in accordance with Section 1011.4.

- Signage enables an occupant to become aware of an area of refuge and/or the exterior area for rescue assistance. The assistance areas must provide signage on or above the door stating either "AREA OF REFUGE" or "EXTERIOR AREA FOR ASSISTED RESCUE" and includes the International Symbol of Accessibility. The approach that the code takes for identification of the area of refuge is comparable to the general provisions for identification of exits, including the requirement for lighted signage. Raised letters and Braille stating "EXIT" is also required adjacent to the door for the benefit of persons with a visual impairment.

The current text does not clearly indicate how to identify a refuge area formed by a horizontal exit. In hospitals and jails, where this option is typically utilized, the location of the horizontal exits is part of the staff training for the fire safety and evacuation plans.

1007.10 Directional signage. Directional signage indicating the location of the other means of egress and which are accessible means of egress shall be provided at the following:

1. At exits serving a required accessible space but not providing an approved accessible means of egress.
2. At elevator landings.
3. Within areas of refuge.

- The additional signage required by this section is intended to advise persons of the location of all means of egress and which also serve as accessible means of egress. Since not all of the exits will necessarily be accessible means of egress, it is appropriate to provide this information at exit stairways and, particularly, at all elevators, whether they are or are not part of an accessible means of egress. Directional signage is not required to meet raised character or Braille signage requirements.

1007.11 Instructions. In areas of refuge and exterior areas for assisted rescue, instructions on the use of the area under emergency conditions shall be posted. The instructions shall include all of the following:

1. Persons able to use the exit stairway do so as soon as possible, unless they are assisting others.
2. Information on planned availability of assistance in the use of stairs or supervised operation of elevators and how to summon such assistance.
3. Directions for use of the two-way communications system where provided.

- The instructions provided at the exterior area of rescue assistance and the areas of refuge will differ. The required instructions on the proper use of the area of refuge and the communication system provide a higher degree of assurance that the communication system will accomplish the intended function and occupants will behave as expected. A two-way communication system will not be of much value if a person in that area does not know how to operate it. Also, since the area of refuge is required by Section 1007.9 to be identified as such, ambulatory occupants may mistakenly conclude that they should remain in that area. The instructions remind ambulatory occupants that they should continue to egress as soon as possible.

For an exterior area of assisted rescue at grade level, a two-way communication system is not required so this portion of the instructions is not needed. However, instructions for any ambulatory persons to move to the exit discharge is still required, as well as information on how assistance will be provided at this location.

Since each building's means of egress and fire and safety evacuation plans are unique, specific requirements for verbiage are not indicated, but will depend on the situation.
MEANS OF EGRESS

SECTION 1008
DOORS, GATES AND TURNSTILES

1008.1 Doors. Means of egress doors shall meet the requirements of this section. Doors serving a means of egress system shall meet the requirements of this section and Section 1020.2. Doors provided for egress purposes in numbers greater than required by this code shall meet the requirements of this section.

Means of egress doors shall be readily distinguishable from the adjacent construction and finishes such that the doors are easily recognizable as doors. Mirrors or similar reflecting materials shall not be used on means of egress doors. Means of egress doors shall not be concealed by curtains, drapes, decorations or similar materials.

The general requirements for doors are in this section and the following subsections. The reference to Section 1020.2 is intended to emphasize that exterior exit doors must lead to a route that will allow a path to a public street or alley (see definition for "Public way"). Doors need to be easily recognizable for immediate use in an emergency condition. Thus, the code specifies that doors are not to be hidden in such a manner that a person would have trouble seeing where to egress.

1008.1.1 Size of doors. The minimum width of each door opening shall be sufficient for the occupant load thereof and shall provide a clear width of 32 inches (813 mm). Clear openings of doorways with swinging doors shall be measured between the face of the door and the stop, with the door open 90 degrees (1.57 rad). Where this section requires a minimum clear width of 32 inches (813 mm) and a door opening includes two door leaves without a mullion, one leaf shall provide a clear opening width of 32 inches (813 mm). The maximum width of a swinging door leaf shall be 48 inches (1219 mm) nominal. Means of egress doors in a Group I-2 occupancy used for the movement of beds shall provide a clear width not less than 41 1/2 inches (1054 mm). The height of door openings shall not be less than 80 inches (2032 mm).

Exceptions:

1. The minimum and maximum width shall not apply to door openings that are not part of the required means of egress in Group R-2 and R-3 occupancies.
2. Door openings to resident sleeping units in Group I-3 occupancies shall have a clear width of not less than 28 inches (711 mm).
3. Door openings to storage closets less than 10 square feet (0.93 m²) in area shall not be limited by the minimum width.
4. Width of door leaves in revolving doors that comply with Section 1008.1.4.1 shall not be limited.
5. Door openings within a dwelling unit or sleeping unit shall not be less than 78 inches (1981 mm) in height.
6. Exterior door openings in dwelling units and sleeping units, other than the required exit door, shall not be less than 76 inches (1930 mm) in height.
7. In other than Group R-1 occupancies, the minimum widths shall not apply to interior egress doors within a dwelling unit or sleeping unit that is not required to be an Accessible unit, Type A unit or Type B unit.
8. Door openings required to be accessible within Type B units shall have a minimum clear width of 31.75 inches (806 mm).

The size of a door opening determines its capacity as a component of egress and its ability to fulfill its function in normal use. A door opening must meet certain minimum criteria as to its width and height in order to be used safely and to provide accessibility to people with physical disabilities. Doorways that are not in the means of egress are not limited in size by this section. However, doors that are used for egress purposes, including additional doors over and above the number of means of egress required by the code, are required to meet the requirements of this section unless one of the exceptions applies.

The minimum clear width of an egress doorway for occupant capacity is based on the portion of the occupant load (see Section 1004.1) intended to utilize the doorway for egress purposes multiplied by the egress width per occupant from Section 1005.1. The capacity of a 32-inch (813 mm) clear width door is 32/0.2 = 160 occupants. The 0.15-inch (3.81 mm) allowance for capacity is permitted in sprinklered buildings (32/0.15 = 213 occupants). The clear width of a swinging door opening is the horizontal dimension measured between the face of the door and the door stops when the door is in the 90-degree (1.57 rad) position [see Figure 1008.1.1(1)].

Using the face of the door as the measurement point is consistent with the provisions of ICC A117.1 and the ADAAG Review Advisory Committee. Further, this measurement is not intended to prohibit other projections into the required clear width, such as latching or panic hardware [see the commentary to Section 1008.1.1.1 and Figure 1008.1.1(2) for further discussion on the specific projections allowed in the required clear width]. For nonswinging means of egress doors, such as a sliding door, the clear width is to be measured from the face of the door jambs.

The minimum clear width in a doorway of 32 inches (813 mm) is to allow passage of a wheelchair as well as persons utilizing walking devices or other support apparatus. Similarly, because of the difficulties that a person with physical disabilities would have in opening a pair of doors simultaneously, the 32-inch (813 mm) minimum must be provided by a single door leaf.

Note that in some cases, with standard door construction and hardware, a 36-inch-wide (914 mm) door is the narrowest door that can be used while still providing the minimum clear width of 32 inches (813 mm). A standard 34-inch-wide (864 mm) door has less than a 32-inch (813 mm) clear opening depending on the thickness of the opposing doorstop, the door thickness and the type of hinge. The building designer must verify that the swinging door specified...
Means of Egress

will in fact provide the required clear width.

A minimum clear width of 41\(\frac{1}{2}\) inches (1054 mm) is required for doors in any portion of Group I-2 where patients may need to be moved in beds. This is especially important for evacuating patients from the area in the event of a fire.

The maximum width for a means of egress door leaf in a swinging door is 48 inches (1219 mm) because larger doors are difficult to handle and are of sizes that typically are not fire tested. The maximum width only applies to swinging doors and not to horizontal sliding doors.

Minimum door heights are required to provide clear headroom for the users. A minimum height of 80 inches (2032 mm) has been empirically derived as sufficient for most users. Note that although the clear height of a doorway is not specified, typical door frame dimensions will render an opening very close to 80 inches (2032 mm) in clear height. The exception in Sections 1003.3.1 and 1008.1.1.1 allows for door closers and doorstops to be as low as 78 inches (1981 mm).

Exception 1 is very limited in scope and is primarily intended to permit decorative-type doors, e.g., café doors, in dwelling units. This exception addresses spaces that are provided with two or more doors when only one means of egress is required. These nonrequired doors are exempted from the minimum and maximum dimensions.

Exception 2 permits the continued use of doors to resident sleeping rooms (cells) in jails (Group I-3) to be a minimum of 28 inches (711 mm), according to current practices.

Exception 3 is for all occupancies. This exception permits doors to storage closets less than 10 square feet (0.9 m²) in area to be less than 32 inches (813 mm). This provision is intended to include those closets that can be reached in an arm's length and thus do not require full passage into the closet to be functional.

Exception 4 permits the door leaves in a revolving door assembly to comply with Section 1008.1.1.1, which provides for adequate egress width when the revolving door is collapsed into a bookfold position.

Exception 5 permits the doorway within a dwelling or sleeping unit to be a minimum of 78 inches (1981 mm) in clear height. This is deemed acceptable because of the familiarity persons in a dwelling or sleeping unit usually have with the egress system and the lack of adverse injury statistics relating to such doors. Note that this exception does not apply to exterior doors of a townhouse or the main entrance doors leading to the hallway in hotels or apartment buildings. However, exterior doors could use the limited exception for doorstops and closers in Sections 1003.3.1 and 1008.1.1.1.

Exception 6 permits exterior doorways to a dwelling or sleeping unit, except for the required exit door, to be a minimum of 76 inches (1930 mm) in clear height. Accordingly, the required exterior exit door to a dwelling or sleeping unit must be 80 inches (2032 mm) in height (exterior doors are not within the scope of Exception 5), but other exterior doors are allowed to be a height of only 76 inches (1930 mm). This provision allows for the continued use of 76-inch-high (1930 mm) sliding patio doors and swinging doors sized to replace such doors.

Exception 7 allows interior means of egress doors within dwelling or sleeping units to have a clear width less than 32 inches (813 mm). If the dwelling or sleeping unit is required to be an Accessible, Type A or B unit, this exception is not applicable. ICC A117.1 requires door openings within Accessible and Type A units to be 32-inches (813 mm) clear and doors within Type B units to be 31\(\frac{1}{4}\) inches (806 mm) clear. This exception is not applicable to Group R-1. The requirement for all doorways within a Group R-1 unit to be sized to provide access to persons with physical disabilities is applicable to both entrance doors to the units and all doors to rooms in the unit (i.e., bathroom door). Because of the social interaction and visitation that often occur in lodging facilities, a door opening sized for accessibility (e.g., wheel-chairs, walkers, canes, crutches) is deemed necessary to allow people with disabilities to visit a friend's, colleague's or relative's unit. In addition, wider doors provide an additional benefit to all persons handling luggage and bulky items, or for the situation when an Accessible unit is not available. This requirement for Group R-1 occupancies is consistent with the 2010 Standard.

Exception 8 addresses the clear width of doors within a Type B dwelling or sleeping unit. The 31\(\frac{1}{4}\) inch (806 mm) dimension effectively allows for 2 foot, 10 inch (864 mm) doors to be used inside the unit. Again, note that the exterior door to the garden-style apartments or the main door to the hallway from units in an apartment building are not covered by this exception. ICC A117.1 requires the exterior doors of Type B dwelling units to provide a 32-inch (813 mm) clear width. This is consistent with the correlative text in ICC A117.1 for Type B units. Refer to Chapter 11 for additional information related to Type B dwelling and sleeping units.

1008.1.1 Projections into clear width. There shall not be projections into the required clear width lower than 34 inches (864 mm) above the floor or ground. Projections into the clear opening width between 34 inches (864 mm) and 80 inches (2032 mm) above the floor or ground shall not exceed 4 inches (102 mm).

Exception: Door closers and door stops shall be permitted to be 78 inches (1980 mm) minimum above the floor.

This section of the code provides specific allowances for projection into the required clear widths of means of egress doors. These allowances directly correspond with the method of measuring the required clear width of the door as specified in Section 1008.1.1. A reasonable range of projections for door hardware and trim has been established by these requirements. The use of the means of egress door
by a wheelchair occupant will not be significantly impacted by small projections located in inconspicuous areas. The key to these allowances is their location. Projections are allowed at a height between 34 inches (864 mm) and 80 inches (2032 mm). Below the 34-inch (864 mm) height, the code does not permit any projections since they would decrease the available width for wheelchair operation. The full 32-inch (813 mm) width must be provided at this location. At 34 inches (864 mm) and higher, projections of up to and including 4 inches (102 mm) are permitted. The 4-inch (102 mm) projection is consistent with the allowances of Section 1003.3.3. This section permits door hardware, such as panic hardware, to extend into the clear width, yet maintain accessibility for persons with physical disabilities [see Figure 1008.1.1(2)].

Allowance must be made for door closers and stops, since their design and function necessitates placement within the door opening. The minimum headroom clearance for door closers and stops is allowed to be 78 inches (1981 mm) [see Figure 1003.3.1(1)]. The 2-inch (51 mm) projection into the doorway height is reasonable since these devices are normally mounted away from the center of the door opening, thus minimizing the potential for contact with a person moving through the opening. This is consistent with the exception in Section 1003.3.1.

While this section deals with door hardware projection within the clear door opening width, door hard-
ware projection into the required width of corridors, aisles, exit passageways and exit discharge is addressed in Section 1005.7.1.

1008.1.2 Door swing. Egress doors shall be of the pivoted or side-hinged swinging type.

Exceptions:

1. Private garages, office areas, factory and storage areas with an occupant load of 10 or less.
2. Group I-3 occupancies used as a place of detention.
3. Critical or intensive care patient rooms within suites of health care facilities.
4. Doors within or serving a single dwelling unit in Groups R-2 and R-3.
5. In other than Group H occupancies, revolving doors complying with Section 1008.1.4.1.
6. In other than Group H occupancies, horizontal sliding doors complying with Section 1008.1.4.3 are permitted in a means of egress.
7. Power-operated doors in accordance with Section 1008.1.4.2.
8. Doors serving a bathroom within an individual sleeping unit in Group R-1.
9. In other than Group H occupancies, manually operated horizontal sliding doors are permitted in a means of egress from spaces with an occupant load of 10 or less.

Doors shall swing in the direction of egress travel where serving a room or area containing an occupant load of 50 or more persons or a Group H occupancy.

Generally, egress doors are required to be the side-swinging type. The swinging hardware can be either a hinge or a pivot type (see the definition for "Balanced door"). Side swinging doors are familiar to all occupants in the method of operation. Door designs with pivots are permitted by this section since the door action itself has little difference between the side-hinged-type door.

The code has several conditions where it allows doors that are not side-hinged-swinging types.

Examples of the doors permitted in Exception 1 are overhead garage doors and horizontal sliding doors. Exception 1 allows doors other than the swinging type for the listed uses where the number of occupants is very low.

Exception 2 allows for the sliding-type doors that are commonly used in prisons and jails.

Exception 3 allows for sliding doors between the nursing areas and patient rooms in critical care and intensive care suites. Patients are not typically moving around on their own in these areas; visitors are extremely limited, the glass doors allow a better view for nurse supervision and the sliding option allows for equipment locations unaffected by door swing. See also Sections 407, 1008.1.9.6 and 1008.1.9.8 for these types of areas.

Exception 4 allows for sliding-type doors or pocket-type doors within or serving individual units in a non-transient residential occupancy. Residents are typically familiar with the door operation. The use of sliding doors on the interior of dwelling units is permitted by the Fair Housing Accessibility Guidelines (FHAG) and by ICC A117.1 for Accessible, Type A and Type B units.

Exception 5 allows for revolving doors that meet the requirements of Section 1008.1.4.1. Revolving doors are not permitted for egress from high-hazard spaces.

Exceptions 6 and 7 allow for power-operated swinging or power-operated horizontal sliding doors that meet the requirements of Section 1008.1.4.2 or 1008.1.4.3. These exceptions are intended to allow wide span openings to be used in a means of egress. This is to enhance the movement of the general population as well as people with mobility impairments to areas of safety without obstructions, since the specified doors afford simple operation by persons for both typical and emergency operation.

Exception 8 allows for pocket doors between the bathrooms and living or sleeping space within hotel rooms. Since the bathroom is most commonly placed immediately inside the entrance to the room, a side-swinging door could be an obstruction for a person entering carrying suitcases. Familiarity with these types of doors and minimal occupant loads makes this situation acceptable.

Exception 9 partially overlaps the allowances in Exception 1 for horizontal sliding doors by matching the 10 or less occupant load, but extends the use to all other groups except for high hazard. For example, some emergency rooms or clinics use patio-type horizontal sliding doors to separate patient care rooms while still allowing visual supervision, or pocket doors may be used for access to a bathroom within a private office. The allowance for such a door will provide greater design flexibility and efficiency, while at the same time maintaining an acceptable level of safety.

A side-hinged door must swing in the direction of egress travel where the required occupant capacity of the room is 50 or more. As such, a room with two doors and an occupant load of 99 would require both doors to swing in the direction of egress travel, even though each door has a calculated occupant usage of less than 50. At this level of occupant load, the possibility exists that, in an emergency situation, a compact line of people could form at a closed door that swings in a direction opposite the egress flow. This could delay or eliminate the first person's ability to open the door inward with the rest of the queue behind the person.

In a Group H occupancy, the threat of rapid fire buildup, or worse, is such that any delay in egress caused by door swing may jeopardize the opportunity for all occupants to evacuate the premises. For this reason, all egress doors in Group H occupancies are to swing in the direction of egress.
1008.1.3 Door opening force. The force for pushing or pulling open interior swinging egress doors, other than fire doors, shall not exceed 5 pounds (22 N). For other swinging doors, as well as sliding and folding doors, the door latch shall release when subjected to a 15-pound (67 N) force. The door shall be set in motion when subjected to a 30-pound (133 N) force. The door shall swing to a full-open position when subjected to a 15-pound (67 N) force.

- The ability of all potential users to be physically capable of opening an egress door is a function of the forces required to open the door. The 5-pound (22 N) maximum force for pushing and pulling interior swinging doors without closers that are part of the means of egress inside a building is based on that which has been deemed appropriate for people with a physical limitation due to size, age or disability. The operating force is permitted to be higher for all exterior doors, interior swinging doors that are not part of the means of egress, doors that are part of the means of egress but also serve as opening protectives in fire-resistance-rated walls (i.e., fire doors), sliding doors and folding doors. This recognizes that doors with closers, particularly fire doors, require greater operating forces in order to close fully in an emergency where combustion gases may be exerting pressure on the door assembly. Similarly, exterior doors are exempted because air pressure differentials and strong winds may prevent doors from being fully automatically closed. A maximum force of 15 pounds (67 N) is required for operating the latching mechanism. Once unlatched, a maximum force of 30 pounds (133 N) is applied to the latch side of the leaf to start the door in motion by overcoming its stationary inertia. Once in motion, it must not take more than 15 pounds (67 N) of force to keep the door in motion until it reaches its full open position and the required clear width is available. To conform to this requirement on a continual basis, door closers must be adjusted periodically and door fits must also be checked and adjusted when necessary.

1008.1.3.1 Location of applied forces. Forces shall be applied to the latch side of the door.

- See the commentary for door opening forces in Section 1008.1.3.

1008.1.4 Special doors. Special doors and security grilles shall comply with the requirements of Sections 1008.1.4.1 through 1008.1.4.4.

- This section simply defines the scope of the code requirements for special doors such as revolving doors, power-operated swinging doors, power-operated horizontal sliding doors and security grilles.

1008.1.4.1 Revolving doors. Revolving doors shall comply with the following:

1. Each revolving door shall be capable of collapsing into a bookfold position with parallel egress paths providing an aggregate width of 36 inches (914 mm).

2. A revolving door shall not be located within 10 feet (3048 mm) of the foot or top of stairs or escalators. A dispersal area shall be provided between the stairs or escalators and the revolving doors.

3. The revolutions per minute (rpm) for a revolving door shall not exceed those shown in Table 1008.1.4.1.

4. Each revolving door shall have a side-hinged swinging door which complies with Section 1008.1 in the same wall and within 10 feet (3048 mm) of the revolving door.

5. Revolving doors shall not be part of an accessible route required by Section 1007 and Chapter 11.

- Revolving doors must comply with all five provisions.

  Item 1: One of the causes contributing to the loss of lives in the 1942 Cocoanut Grove fire in Boston was that the revolving doors at the club’s entrance could not collapse for emergency egress and there was not an alternative means of egress adjacent to the revolving doors. Thus, in the panic of the fire, the door became jammed and the club’s occupants were trapped.

As a result of this fire experience, all revolving doors, including those for air structures, now are required to be equipped with a collapse feature. A bookfold operation is where all leaves collapse parallel to each other and to the direction of egress [see Figure 1008.1.4.1(1)]. A bookfold operation creates two openings of approximately equal width. The sum of the widths is not to be less than 36 inches (914 mm) so that a stream of pedestrians may use each side of the opening.

Item 2: If a stairway or escalator delivers users to a landing in front of a revolving door at a greater rate than the capacity of the door, a compact line of people will develop. Lines of people formed on a stairway or escalator create an unsafe situation, since stairways and escalators are not intended to be used as standing space for persons who may be waiting to use the revolving doors. Therefore, to avoid congestion at a revolving door that under normal operation has a maximum delivery capacity of users, a dispersal area is required between the stairways or escalators and the revolving doors to allow for the queuing of people as they enter the door. Accordingly, to create a dispersal area for users of a revolving door, the door is not to be placed closer than 10 feet (3048 mm) from the foot or top of a stairway or escalator.

Item 3: Door speeds also directly relate to the capacity of a revolving door, which is calculated by multiplying the number of leaves (wings) by the revolutions per minute (rpm). For example, if you have a four-leaf door moving at 10 rpm, the door will allow 40 people to move in either direction in 1 minute.

Item 4: In case a revolving door malfunctions or becomes obstructed, the adjacent area is to be equipped with a conventional side-hinged door to provide users with an immediate alternative way to
exit a building. The side-hinged door is intended to be used as a relief device for people lined up to use the revolving door or who desire to avoid it because of a physical disability or other reason. It also can be used when the revolving door is obstructed or out of service. The swinging door is to be immediately adjacent to the revolving door so that its availability is obvious [see Figure 1008.1.4.1(2)]. A single swinging door can be located between side-by-side revolving doors in order to comply with this provision.

Item 5: While some revolving doors may be considered part of a means of egress, they cannot be considered part of a required accessible route for either ingress or egress. This requirement is consistent with ICC A117.1, which also prohibits revolving gates and turnstiles along the only accessible route. The side-swinging door required by Item 4 can serve as the accessible entrance or exit required by Sections 1007 and 1105.

A route through a hinged or sliding door differs remarkably from that provided through a revolving door. For a revolving door, the route includes a turn into the doorway, an arcing path of travel as the door revolves, followed by a change of direction when leaving the door. Items that may cause difficulty for anyone with mobility impairments could involve the overall doorway diameter, the number of leaves and their relative angle, and the configuration of the return walls surrounding the revolving door. Additionally, the speed of the door movement if motorized, or the force required for movement if not motorized, would be a concern for anyone who needed to keep both hands on their device to move forward (e.g., walker or wheelchair).

Automatic revolving doors, if large enough, may be usable by many people who use wheelchairs. How-

2012 INTERNATIONAL BUILDING CODE® COMMENTARY 10-43
however, the intent of this section is that these types of
doors not be the only means of passage at an
entrance or exit. An alternative door in full compliance
with this section is considered necessary because some
people with disabilities may be uncertain of the
usability, or may not have enough strength or speed
to use them. Although manufacturers have developed
safety criteria, certain questions remain, such as the
appropriate maximum and minimum speeds.

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

- Door speeds also directly relate to the capacity of a
revolving door, which are calculated by multiplying
the number of leaves (wings) by the revolutions per
minute (rpm). For example, if you have a four-leaf
door moving at 10 rpm, the door will allow 40 people
to move in either direction in 1 minute.

**1008.1.4.1.1 Egress component.** A revolving door used as a
component of a *means of egress* shall comply with Section
1008.1.4.1 and the following three conditions:

1. Revolving doors shall not be given credit for more than
50 percent of the required egress capacity.
2. Each revolving door shall be credited with no more
than a 50-person capacity.
3. Each revolving door shall be capable of being collapsed
when a force of not more than 130 pounds (578 N) is
applied within 3 inches (76 mm) of the outer edge of a
wing.

- A revolving door can be incorporated, to a very limited extent, in a means of egress. Compliance with
these three additional conditions is required.

Condition 1 limits the exit capacity that revolving
doors can provide in a building. This is so that 50 per-
cent of the capacity has conventional egress compo-
nents and is not dependent on mechanical devices or
fail-safe mechanisms.

Condition 2 limits the capacity of any one revolving
door for the same reasons as stated in Condition 1.
Each revolving door is therefore limited to a 50-per-
sen capacity.

Condition 3 limits the collapse force to 130 pounds
(578 N), as opposed to the 180-pound (792 N) value
listed in Section 1008.1.4.1.2. Revolving doors used
as means of egress are not permitted to have the col-
lapse force exceed 130 pounds (578 N) under any
circumstances.

**1008.1.4.1.2 Other than egress component.** A revolving
door used as other than a component of a *means of egress*
shall comply with Section 1008.1.4.1. The collapsing force of
a revolving door not used as a component of a *means of
egress* shall not be more than 180 pounds (801 N).

**Exception:** A collapsing force in excess of 180 pounds
(801 N) is permitted if the collapsing force is reduced to
not more than 130 pounds (578 N) when at least one of the
following conditions is satisfied:

1. There is a power failure or power is removed to the
device holding the door wings in position.
2. There is an actuation of the *automatic sprinkler sys-
tem* where such system is provided.
3. There is an actuation of a smoke detection system
which is installed in accordance with Section 907 to
provide coverage in areas within the building which
are within 75 feet (22 860 mm) of the revolving
doors.
4. There is an actuation of a manual control switch, in an
approved location and clearly defined, which
reduces the holding force to below the 130-pound
(578 N) force level.

- This section addresses revolving doors that are not
used to serve any portion of the occupant egress
capacity. For example, where adjacent side-hinged
doors have more than the required egress capacity, the
revolving door would not be part of the required
means of egress.

The maximum collapse force of 180 pounds (792
N), applied within 3 inches (76 mm) of the outer edge of a
wing, is based on industry standards to accom-
mmodate normal use conditions and other forces that
may act on the leaves, such as that caused by wind
or air pressure. An exception for revolving doors that
are not a component of a required means of egress
allows the collapse force to exceed 180 pounds (792
N) in normal operating conditions provided that a
force of not more than 130 pounds (578 N) is required
whenever any one of the listed conditions is satisfied.

**1008.1.4.2 Power-operated doors.** Where *means of egress*
doors are operated by power, such as doors with a photoelec-
tric-actuated mechanism to open the door upon the approach
of a person, or doors with power-assisted manual operation,
the design shall be such that in the event of power failure, the
door is capable of being opened manually to permit *means of
egress* travel or closed where necessary to safeguard *means of
egress*. The forces required to open these doors manually
shall not exceed those specified in Section 1008.1.3, except
that the force to set the door in motion shall not exceed 50
pounds (220 N). The door shall be capable of swinging from any position to the full width of the opening in which such door is installed when a force is applied to the door on the side from which egress is made. Full-power-operated doors shall comply with BHMA A156.10. Power-assisted and low-energy doors shall comply with BHMA A156.19.

Exceptions:

1. Occupancies in Group I-3.

2. Horizontal sliding doors complying with Section 1008.1.4.3.

3. For a bi-parting door in the emergency breakout mode, a door leaf located within a multiple-leaf opening shall be exempt from the minimum 32-inch (813 mm) single-leaf requirement of Section 1008.1.1, provided a minimum 32-inch (813 mm) clear opening is provided when the two bi-parting leaves meeting in the center are broken out.

- For convenience purposes, power-operated doors are intended to facilitate the normal nonemergency flow of persons through a doorway. Where a power-operated or assisted door is also required to be an egress door, the door must conform to the requirements of this section. The essential characteristic is that the door is to be manually operable from any position to its full open position at any time, with or without a power failure or a failure of a door mechanism. Hence, both swinging and horizontal sliding doors, complying with this section, may be used, provided the door can be operated manually from any position as a swinging door and that the minimum required clear width for egress capacity is not less than 32 inches (813 mm). Note that the opening forces of Section 1008.1.3 are applicable, except that the 30-pound (133 N) force needed to set the door in motion is increased to 50 pounds (220 N) as an operational tolerance in the design of the power-operated door.

In accordance with Exception 1, power-operated doors in detention and correctional occupancies (Group I-3) are not required to be manually operable by the occupants (inmates) for security reasons, but otherwise are required to conform to Section 408.

Exception 2 states that power-operated horizontal doors that meet the requirements of this section are not required to meet the requirements of Section 1008.1.4.3 (i.e., power-operated horizontal sliding doors that are not capable of swing operation in the event of power failure). This is consistent with the option offered in Section 1008.1.2 by Exceptions 6 and 7.

Exception 3 allows an individual leaf of a four-panel bi-parting door to be less than 32 inches (813 mm) wide, provided 32 inches (813 mm) of clear space is available when the two center bi-parting leaves are broken out as part of the emergency breakaway feature.

1008.1.4.3 Horizontal sliding doors. In other than Group H occupancies, horizontal sliding doors permitted to be a component of a means of egress in accordance with Exception 6 to Section 1008.1.2 shall comply with all of the following criteria:

1. The doors shall be power operated and shall be capable of being operated manually in the event of power failure.

2. The doors shall be operable by a simple method from both sides without special knowledge or effort.

3. The force required to operate the door shall not exceed 30 pounds (133 N) to set the door in motion and 15 pounds (67 N) to close the door or open it to the minimum required width.

4. The door shall be operable with a force not to exceed 15 pounds (67 N) when a force of 250 pounds (1100 N) is applied perpendicular to the door adjacent to the operating device.

5. The door assembly shall comply with the applicable fire protection rating and, where rated, shall be self-closing or automatic closing by smoke detection in accordance with Section 716.5.9.3, shall be installed in accordance with NFPA 80 and shall comply with Section 716.

6. The door assembly shall have an integrated standby power supply.

7. The door assembly power supply shall be electrically supervised.

8. The door shall open to the minimum required width within 10 seconds after activation of the operating device.

- Horizontal sliding doors are permitted in the means of egress, in other than rooms or areas of Group H, under the conditions set forth in this section. Horizontal sliding doors are not permitted to be used in Group H occupancies because of the potential for delaying or impeding egress from those areas and the additional risk to occupants in hazardous occupancies. Note that this section regulates egress doors that do not meet all of the requirements of Section 1008.1.4.2 (e.g., a power-operated horizontal sliding door that does not have "breakout" capabilities to allow the door panels to swing if power is lost).

Such doors permitted in other groups are typically in the open position and close either because of a fire or to provide some degree of separation, often for security purposes to restrict movement to certain parts of a building. When in the closed position, the doors must be easily operated with forces similar to the limitations for swinging doors.

All eight of the criteria listed in this section must be
MEANS OF EGRESS

met for a horizontal sliding door since there is a concern that it must be able to be easily opened under all conditions.

Additionally, the door must be openable even if a force of 250 pounds (1100 N) is being applied perpendicular to it, as may occur if a group of people were pushing on it.

Since the doors are manually operable, they need not automatically open or close during a loss of power; however, a standby power supply must be provided. The primary power supply must be supervised so that an alarm is received at a constantly attended location (such as a security desk) on loss of the primary power. If the doors are also serving as fire doors, they must be automatic or self-closing in accordance with Section 716.

Since the maximum swinging door leaf width limitations of Section 1008.1.1 do not apply, a maximum opening time of 10 seconds is permitted. It should be noted, however, that the door need not open fully within the 10 seconds; rather, it must open to the required width. For example, if the door is protecting an opening that is 10 feet (3048 mm) wide, but the minimum required width of the opening is 32 inches (813 mm) (as determined by Section 1008.1.1), the door need only open 32 inches (813 mm) within the 10-second criterion. In fact, the door may have controls such that the automatic opening feature only opens the door to a width of 32 inches (813 mm). If additional width is required, it can be accomplished by manual means and, possibly, by an additional activation of the operating device.

1008.1.4.4 Security grilles. In Groups B, F, M and S, horizontal sliding or vertical security grilles are permitted at the main exit and shall be openable from the inside without the use of a key or special knowledge or effort during periods that the space is occupied. The grilles shall remain secured in the full-open position during the period of occupancy by the general public. Where two or more means of egress are required, not more than one-half of the exits or exit access doorways shall be equipped with horizontal sliding or vertical security grilles.

- This section really functions as an exception to several sections, including Sections 1008.1.2 (Door swing) and 1008.1.9.3 (Locks and latches) and permits the use of these security grilles under conditions that are similar to those found in Section 402 for covered mall buildings. These security grilles will be open when the space is occupied and will, therefore, not obstruct any egress path. Since the building may be partially used (i.e., team practice in a football stadium) when not fully occupied, no more than one-half of the exits from the building can be through security grilles.

1008.1.5 Floor elevation. There shall be a floor or landing on each side of a door. Such floor or landing shall be at the same elevation on each side of the door. Landings shall be level except for exterior landings, which are permitted to have a slope not to exceed 0.25 unit vertical in 12 units horizontal (2-percent slope).

Exceptions:

1. Doors serving individual dwelling units in Groups R-2 and R-3 where the following apply:

   1.1. A door is permitted to open at the top step of an interior flight of stairs, provided the door does not swing over the top step.

   1.2. Screen doors and storm doors are permitted to swing over stairs or landings.

2. Exterior doors as provided for in Section 1003.5, Exception 1, and Section 1020.2, which are not on an accessible route.

3. In Group R-3 occupancies not required to be Accessible units, Type A units or Type B units, the landing at an exterior doorway shall not be more than 71/4 inches (197 mm) below the top of the threshold, provided the door, other than an exterior storm or screen door, does not swing over the landing.

4. Variations in elevation due to differences in finish materials, but not more than 1/8 inch (12.7 mm).

5. Exterior decks, patios or balconies that are part of Type B dwelling units, have impervious surfaces and that are not more than 4 inches (102 mm) below the finished floor level of the adjacent interior space of the dwelling unit.

- Changes in floor surface elevation at a door, however small, often are slip or trip hazards. This is because persons passing through a door, including those who may have some mobility impairments, usually do not expect changes in floor surface elevation or are not able to recognize them because of the intervening door leaf. Under emergency conditions, a fall in a doorway could result not only in injury to the falling occupant but also interruption of orderly egress by other occupants. The exterior landing is allowed to slope to drain.

The size of this landing is set by Section 1008.1.6. In accordance with Exception 4, the floor surface elevation of the landing is to be at the same elevation plus or minus 1/2 inch (12.7 mm) (see Figure 1008.1.5).

Note that some of the exceptions indicate which direction the door swings to allow the exceptions while others do not limit the door swing direction.

Exception 1, which applies to nontransient residential occupancies, recognizes that occupants are familiar with the stair and landing arrangements. In Exception 1.1, an interior stairway can start immediately at the door, provided the door leaf does not swing over the stairway. Exception 1.2 clarifies that a screen door or storm door would not be considered the main door prohibited from swinging over the stairway by Exception 1.1.
Exception 2 references two other locations. Section 1003.5. Exception 1, permits a 7-inch (178 mm) change in elevation at exterior doors in Groups F, H, R-2, R-3, S and U if they are not on an accessible route. The door could swing in either direction for this exception and may actually be required to swing out in accordance with Section 1008.1.2. A reference to Section 1020.2 does not address a change in elevation but does address exterior exit doors.

In accordance with Exception 3, for a residential unit, the step-down is limited to 7/4 inches (197 mm) measured from the top of the threshold rather than the interior floor surface. In addition, the exterior door cannot swing over the exterior landing. A screen door or storm door could swing over the exterior landing. This is consistent with the exception to Section 1008.1.7.

Exception 4 addresses a change in floor finish material (see Figure 1008.1.5).

In accordance with Exception 5, Type B dwelling or sleeping units are not required to have level landings on both sides of some of the exterior doors. Please note that this exception is not applicable for the primary entrance door to the unit (see Section 1105.1.6). Exterior doors that open out onto an exterior deck, patio or balcony are allowed a 4-inch (102 mm) step down. Type B units are established by Chapter 11 for residential occupancies containing four or more dwelling or sleeping units. In order to use this exception, the exterior decks, patios or balconies must be of solid and impervious construction, such as concrete or wood. A 4-inch (102 mm) step from inside the unit down to the exterior surfaces is allowed for weather purposes. This allowance is consistent with the provisions of ICC A117.1 and FHA.

**1008.1.6 Landings at Doors.** Landings shall have a width not less than the width of the stairway or the door, whichever is greater. Doors in the fully open position shall not reduce a required dimension by more than 7 inches (178 mm). When a landing serves an occupant load of 50 or more, doors in any position shall not reduce the landing to less than one-half its required width. Landings shall have a length measured in the direction of travel of not less than 44 inches (1118 mm).

**Exception:** Landing length in the direction of travel in Groups R-3 and U and within individual units of Group R-2 need not exceed 36 inches (914 mm).

✦ Door landings are at either side of the door. Landings can overlap floor surfaces within a room or corridor, overlap an exterior porch or balcony, or share the landings for stairways. The 7-inch (178 mm) encroachment and one-half required width limitations are consistent with Section 1005.7 for door encroachment. Section 1005.7 deals with egress width and is referenced from aisles (see Section 1017.1), corridors (see Section 1018.3), exit passageways (see Section 1023.2) and egress courts (see Section 1027.4.1).

This section also is intended to address landings at the entrance door to enclosed stairways (also see Section 1009.8 for stairway landings). The width of a landing at a door in a stairway is to be not less than the width of the stairway or the door, whichever is greater [see Figure 1009.8(4) for an example of these provisions].

No matter what size the door or stair landing is, door landings are to have the floor elevation requirements of Section 1008.1.5 extending at least 44 inches (1118 mm) in the direction of egress travel.

The reduction in landing length from 44 inches minimum to 36 inches minimum for certain residential occupancies allowed by the exception is in recognition of their low occupant load.

**1008.1.7 Thresholds.** Thresholds at doorways shall not exceed 3/4 inch (19.1 mm) in height above the finished floor or landing for sliding doors serving dwelling units or 1/8 inch

---

**Figure 1008.1.5**

DOOR LANDINGS

For SI: 1 inch = 25.4 mm.
MEANS OF EGRESS

(12.7 mm) above the finished floor or landing for other doors. Raised thresholds and floor level changes greater than 1/4 inch (6.4 mm) at doorways shall be beveled with a slope not greater than one unit vertical in two units horizontal (50-percent slope).

Exception: In occupancy Group R-2 or R-3, threshold heights for sliding and side-hinged exterior doors shall be permitted to be up to 7/4 inches (197 mm) in height if all of the following apply:

1. The door is not part of the required means of egress.
2. The door is not part of an accessible route as required by Chapter 11.
3. The door is not part of an Accessible unit, Type A unit or Type B unit.

A threshold is a potential tripping hazard and a barrier to accessibility by people with mobility impairments. For these reasons, thresholds for all doorways, except exterior sliding doors serving dwelling units, are to be a maximum of 1/4 inch (12.7 mm) high. Exterior sliding doors serving dwelling units, however, are permitted to be 1/4 inch (19.1 mm) high because of practical design considerations, concern for deterioration of the doorway because of snow and ice buildup and lack of adequate drainage in severe climates. Raised threshold and floor level changes at doorways without beveled edge treatment [see Figure 1008.1.7(1)] are limited to 1/4 inch (6.3 mm) high vertically.

Figures 1008.1.7(2), 1008.1.7(3) and 1008.1.7(4) illustrate configurations where the change in elevation is between 1/4 inch (6.4 mm) and 1/4 inch (12.7 mm). The slope of required beveled edges cannot exceed one unit vertical in two units horizontal (1:2 or 50-percent slope) but lesser slopes are fully compliant. This kind of threshold treatment provides for minimum obstructions for wheelchair users and limits the trip hazard for those with other mobility disabilities.

The exception permits a 7/4-inch (197 mm) threshold at both side-swinging and sliding exterior doors in Group R-2 and R-3 buildings. However, this door cannot be part of the required means of egress out of a building; cannot be part of an accessible route required into a building or unit (see Sections 1104 and 1105) and cannot serve an Accessible, Type A or Type B unit. The result would be that this exception would be permitted at the "back door," stoop or patio in single-family homes (see Section 1103.2.4) or upper floor balconies within individual apartments in buildings without elevators (see Section 1107). This terminology is consistent with the 7/4-inch (197 mm) step down in Section 1008.1.5, Exception 3; however, this exception is to the threshold requirements, not the landing elevations.

1008.1.8 Door arrangement. Space between two doors in a series shall be 48 inches (1219 mm) minimum plus the width of a door swinging into the space. Doors in a series shall swing either in the same direction or away from the space between the doors.

Exceptions:

1. The minimum distance between horizontal sliding power-operated doors in a series shall be 48 inches (1219 mm).

**Figure 1008.1.7(4)**
DOOR THRESHOLD HEIGHT LIMITATIONS

10-48

2012 INTERNATIONAL BUILDING CODE® COMMENTARY
2. Storm and screen doors serving individual dwelling units in Groups R-2 and R-3 need not be spaced 48 inches (1219 mm) from the other door.

3. Doors within individual dwelling units in Groups R-2 and R-3 other than within Type A dwelling units.

- Door arrangement is required to be such that an occupant's use of means of egress doorway is not hampered by the operation of a preceding door located in the same line of travel so that the occupant flow can be smooth through the openings. Successive doors in a single egress path (i.e., in a series) can cause such interference. The 4-foot (1219 mm) clear distance between doors when the first door is open at 90 degrees allows an occupant, including a person using a wheelchair, to move past one door and its swing before beginning the operation of the next door [see Figure 1008.1.8(1)]. Note that where doors in a series are not arranged in a straight line, the intent of the code is to provide sufficient space to enable occupants to negotiate the second door without being encumbered by the first door's swing arc. To facilitate accessibility, the space between doors should provide sufficient clear space for a wheelchair [30 inches by 48 inches (762 mm by 1219 mm)] beyond the arc of the door swing [see Figure 1008.1.8(2)]. Additionally, the approach and access provisions of ICC A117.1 must be considered for all doors along an accessible route.

The exception is to permit horizontal sliding power-operated doors (see Sections 1008.1.4.2 and 1008.1.4.3) to be designed with a lesser distance between them in a series arrangement because they are customarily designed to open simultaneously or in sequence such that movement through them is unhampered. Storm and screen doors on residential dwelling units need not be spaced at 48 inches (1219 mm) since it would be impractical, and they do not operate the same as doors in a series. Doors within dwelling units of Group R-2 or R-3 that are not Type A dwelling units (see Section 1107) are also permitted to have a lesser distance between doors, because the accessibility provisions do not apply. There are requirements in Chapter 10 of the ICC A117.1 for door arrangements within Accessible and Type A dwelling and sleeping units.

1008.1.9 Door operations. Except as specifically permitted by this section egress doors shall be readily openable from the egress side without the use of a key or special knowledge or effort.

- When installed for security purposes, locks and latches can intentionally prohibit the use of an egress door and thus interfere with or prevent the egress of occupants at the time of a fire. While the security of property is important for many, the life safety of occupants is essential for everyone. Where security and life safety objectives conflict, alternative measures, such as those permitted by each of the exceptions in Section 1008.1.9.3, may be applicable.

Egress doors are permitted to be locked, but must be capable of being unlocked and readily openable from the side from which egress is to be made. The outside of a door can be key locked as long as the inside—the side from which egress is to be made—can be unlocked without the use of tools, keys or special knowledge or effort. For example, an unlocking operation that is integral with an unlatching operation is acceptable.

Examples of special knowledge would be a combination lock or an unlocking device or deadbolt in an unknown, unexpected or hidden location. Special effort would dictate the need for unusual and unexpected physical ability to unlock or make the door fully available for egress.

Where a pair of egress door leaves is installed, with or without a center mullion, the general requirement is that each leaf must be provided with its own releasing or unlatching device so as to be readily openable. Door arrangements or devices that depend on the release of one door before the other can be opened are not to be used except as permitted by Section 1008.1.9.4.
MEANS OF EGRESS

1008.1.9.1 Hardware. Door handles, pulls, latches, locks and other operating devices on doors required to be accessible by Chapter 11 shall not require tight grasping, tight pinching or twisting of the wrist to operate.

- Any doors that are located along an accessible route for ingress or egress must have door hardware that is easy to operate by a person with limited mobility. This would include all elements of the door hardware used in typical door operation, such as door levers, locks, security changes, etc. This requirement is also an advantage for persons with arthritis in their hands. Items such as small, full-twist thumb turns or smooth circular knobs are examples of hardware that is not acceptable.

Some people with disabilities are unable to grasp objects with their hands or twist their wrists. Such people are unable to operate, or have great difficulty in operating, door hardware other than lever-operated mechanisms, push-type mechanisms and U-shaped door pulls. Door hardware that can be operated with a closed fist or a loose grip accommodates the greatest range of users. Hardware operated by simultaneous hand and finger movement requires greater dexterity and coordination and should be avoided for doors along an accessible route (see Figure 1008.1.9.1).

![Figure 1008.1.9.1 DOOR HARDWARE](image)

1008.1.9.2 Hardware height. Door handles, pulls, latches, locks and other operating devices shall be installed 34 inches (864 mm) minimum and 48 inches (1219 mm) maximum above the finished floor. Locks used only for security purposes and not used for normal operation are permitted at any height.

Exception: Access doors or gates in barrier walls and fences protecting pools, spas and hot tubs shall be permitted to have operable parts of the release of latch on self-latching devices at 54 inches (1370 mm) maximum above the finished floor or ground, provided the self-latching devices are not also self-locking devices operated by means of a key, electronic opener or integral combination lock.

- The requirements in this section place the door hardware at a level that is usable by most people, including a person using a wheelchair. The exception allows security locks to be placed at any height. An example would be an unframed glass door at the front door of a tenant space in a mall that has the lock near the floor level. The lock is only used when the store is not open for business. Such locks are not required for the normal operation of the door.

The exception permits a special allowance for security latches at pools, spas and hot tubs. The concern is that the 48-inch (1219 mm) maximum height would place the security latch within reach of children. The 54-inch (1372 mm) maximum height is intended to override the maximum 48-inch (1219 mm) reach range in ICC A117.1. This compromise addresses concerns for children's safety and still maintains accessibility to a reasonable level. This same exception is found in Section 1109.13, Exception 7, for the accessibility requirements for operable parts. This is consistent with the 2010 Standard and ANSI/NSPI-8 1996, Model Barrier Code for Residential Swimming Pools, Spas, and Hot Tubs.

1008.1.9.3 Locks and latches. Locks and latches shall be permitted to prevent operation of doors where any of the following exists:

1. Places of detention or restraint.
2. In buildings in occupancy Group A having an occupant load of 300 or less, Groups B, E, M and S, and in places of religious worship, the main exterior door or doors are permitted to be equipped with key-operated locking devices from the egress side provided:
   2.1. The locking device is readily distinguishable as locked;
   2.2. A readily visible durable sign is posted on the egress side on or adjacent to the door stating: THIS DOOR TO REMAIN UNLOCKED WHEN BUILDING IS OCCUPIED. The sign shall be in letters 1 inch (25 mm) high on a contrasting background; and
   2.3. The use of the key-operated locking device is revokable by the building official for due cause.
3. Where egress doors are used in pairs, approved automatic flush bolts shall be permitted to be used, provided that the door leaf having the automatic flush bolts has a doorknob or surface-mounted hardware.
4. Doors from individual dwelling or sleeping units of Group R occupancies having an occupant load of 10 or less are permitted to be equipped with a night latch, dead bolt or security chain, provided such devices are operable from the inside without the use of a key or tool.
5. Fire doors after the minimum elevated temperature has disabled the unlatching mechanism in accordance with listed fire door test procedures.

- Where security and life safety objectives conflict, alternative measures, such as those permitted by each of the exceptions, may be applicable.

Exception 1 is needed for jails and prisons or locations where someone must be kept inside for their own safety (i.e., dementia wards, psychiatric wards).

Exception 2 permits a locking device, such as a double-cylinder dead bolt, on the main entrance door.
It must be immediately apparent that these doors are locked. For example, such locking devices may have an integral indicator that automatically reflects the "locked" or "unlocked" status of the device. In addition, a sign must be provided that clearly states that the door is to be unlocked when the building is occupied. The sign on the door not only reminds employees to unlock the door, but also advises the public that an unacceptable arrangement exists if one finds the door locked. Ideally, the individual who encounters the locked door will notify management and possibly the building official. Note that the use of the key-locking device is revocable by the building official. The locking arrangement is not permitted on any door other than the main exit and, therefore, the employees, security and cleaning crews will have access to other exits without requiring the use of a key. This allowance is not limited just to multiple-exit buildings but also to small buildings with one exit. This option is an alternative to the panic hardware required by Section 1008.1.10.

In Exception 3, an automatic flush bolt device is one that is internal to the inactive leaf of a pair of doors. The device has a small "knuckle" that extends from the inactive leaf into an opening in the active leaf. When the active leaf is opened, the bolt is automatically retracted. When the active leaf is closed, the knuckle is pressed into the inactive leaf by the active leaf, extending the flush bolt(s), in the head or sill of the inactive leaf (see Figure 1008.1.9.3).

Automatic flush bolts on one leaf of a pair of egress doors are acceptable, provided the leaf with the automatic flush bolts is not equipped with a doorknob or other hardware that would imply to the user that the door leaf is unlatched independently of the companion leaf.

Exception 4 addresses the need for security in residential dwelling and sleeping units such as hotel rooms, apartments, dormitory rooms or townhouses. The occupants are familiar with the operation of the indicated devices, which are intended to be relatively simple to operate without the use of a key or tool. Note that this exception only applies to the door leading from individual dwelling or sleeping units in a building. This exception would not be applicable for doors locked as part of a security system in a multi-unit building.

Exception 5 is in recognition of listed procedures for fire doors, which include the disabling of the locking mechanism.

1008.1.9.4 Bolt locks. Manually operated flush bolts or surface bolts are not permitted.

 Exceptions:

1. On doors not required for egress in individual dwelling units or sleeping units.

2. Where a pair of doors serves a storage or equipment room, manually operated edge- or surface-mounted bolts are permitted on the inactive leaf.

3. Where a pair of doors serves an occupant load of less than 50 persons in a Group B, F or S occupancy, manually operated edge- or surface-mounted bolts are permitted on the inactive leaf. The inactive leaf shall contain no doorknobs, panic bars or similar operating hardware.

4. Where a pair of doors serves a Group B, F or S occupancy, manually operated edge- or surface-mounted
MEANS OF EGRESS

bolts are permitted on the inactive leaf provided such inactive leaf is not needed to meet egress width requirements and the building is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1. The inactive leaf shall contain no doorknobs, panic bars or similar operating hardware.

5. Where a pair of doors serves patient care rooms in Group I-2 occupancies, self-latching edge- or surface-mounted bolts are permitted on the inactive leaf provided that the inactive leaf is not needed to meet egress width requirements and the inactive leaf contains no doorknobs, panic bars or similar operating hardware.

This section is applicable to doors that are intended and required to be for means of egress purposes or are identified as a means of egress, such as by an "Exit" sign or other device. Doors, as well as a second leaf in a doorway that is provided for a purpose other than means of egress, such as for convenience or building operations, should be arranged or identified so as not to be mistaken as a means of egress. The use of manually operated flush bolts or surface bolts on means of egress doors have traditionally been prohibited due to the inability of users to quickly identify and operate such devices under emergency conditions.

This section prohibits installation of manually operated flush and surface bolts except in limited situations. The exceptions allowing the use of such hardware are intended to expand the use of manually operated edge- or surface-mounted bolts under specified conditions while maintaining an appropriate degree of safety for the building occupants.

Exception 1 allows bolt locks at some doors within an individual dwelling or sleeping unit. Even then, such bolts may only be used on doors not required for egress (see Section 1008.1.9.3, Exception 4, for security of doors from individual dwelling and sleeping units). Flush and surface bolts represent locking devices that are difficult to operate because of their location and operation (see Figure 1008.1.9.4).

Exception 2 provides for edge-mounted or surface-mounted bolts on the inactive leaf of a pair of doors from storage or equipment areas. Double doors are often provided to allow for the easy removal or replacement of large pieces of equipment or bulk movement of goods.

Exceptions 3 and 4 offer two options for limited doors in Group B, F and S occupancies. Again, the wider door is sometimes needed for the movement of equipment. Automatic flush bolts and removable center posts can be easily damaged and difficult to maintain in areas of frequent door usage. Revisions to the requirements for door hardware on such pairs of doors will increase building functionality while maintaining a very high degree of occupant safety.

In Exception 3, the number of occupants within the space must be less than 50, the active leaf must meet means of egress requirements and the inactive leaf must not have any operating hardware so that it could be mistaken for an egress door.

In accordance with Exception 4, if the Group B, F or S building is sprinklered throughout with an NFPA 13 system, the room served by the double door can have any occupant load if the inactive leaf is not needed for egress and has no operating hardware.

Exception 5 is in recognition of the clinical needs for movement of equipment into some patient sleeping and treatment rooms in hospital and nursing home environments. Again, the inactive leaf must not be needed for means of egress or have any operating hardware. This is consistent with Section 407.1.1, which allows for staff to operate patient sleeping and treatment room doors during emergency events. The doors would still have to meet smoke barrier opening protective requirements. The clear width of 41 1/2 inches (1054 mm) requirements in Section 1008.1.1 would still have to be met with the active door leaf.

Figure 1008.1.9.4
TYPICAL MANUAL BOLT HARDWARE

1008.1.9.5 Unlatching. The unlatching of any door or leaf shall not require more than one operation.

Exceptions:

1. Places of detention or restraint.
2. Where manually operated bolt locks are permitted by Section 1008.1.9.4.
3. Doors with automatic flush bolts as permitted by Section 1008.1.9.3, Exception 3.
4. Doors from individual dwelling units and sleeping units of Group R occupancies as permitted by Section 1008.1.9.3, Exception 4.

- The code prohibits the use of multiple locks or latching devices on a door, which would be a safety hazard in an emergency situation. The exceptions address loca-tions where multiple locks or latching devices are acceptable. See the referenced sections for additional commentary.

1008.1.9.5.1 Closet and bathroom doors in Group R-4 occupancies. In Group R-4 occupancies, closet doors that latch in the closed position shall be openable from inside the closet, and bathroom doors that latch in the closed position shall be capable of being unlocked from the ingress side.

- The intent of this provision is to address possible entrapment concerns in group homes. If a closet door has a door latch, the closet door must be openable from both inside and outside. This will ensure that someone cannot get stuck inside a closet by accident. If a closet does not latch, no interior hardware is required. In case a resident needs assistance in a bathroom, the bathroom door must have a type of hardware that would allow the door to be unlocked from the outside by staff. This requirement is unique to Group R-4. There are not similar requirements for Group I-1 assisted living facilities or Group I-2 nursing homes; however, some facilities install such devices to increase patient safety. Section 2902.3.5 and the equivalent section in the International Plumbing Code® (IPC®) (Section 403.3.6) prohibits the door leading from multistall bathrooms from being lockable from the inside.

1008.1.9.6 Special locking arrangements in Group I-2. Approved special egress locks shall be permitted in a Group I-2 occupancy where the clinical needs of persons receiving care require such locking. Special egress locks shall be permitted in such occupancies where the building is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 or an approved automatic smoke or heat detection system installed in accordance with Section 907, provided that the doors are installed and operate in accordance with Items 1 through 7.

1. The doors unlock upon actuation of the automatic sprinkler system or automatic fire detection system.
2. The doors unlock upon loss of power controlling the lock or lock mechanism.
3. The door locks shall have the capability of being unlocked by a signal from the fire command center, a nursing station or other approved location.
4. A building occupant shall not be required to pass through more than one door equipped with a special egress lock before entering an exit.
5. The procedures for the operation(s) of the unlocking system shall be described and approved as part of the emergency planning and preparedness required by Chapter 4 of the International Fire Code.

6. All clinical staff shall have the keys, codes or other means necessary to operate the locking devices.

7. Emergency lighting shall be provided at the door.

Exception: Items 1 through 4 shall not apply to doors to areas where persons, which because of clinical needs, require restraint or containment as part of the function of a psychiatric treatment area.

- The intent of these provisions is to address the special safety needs for wards that may include dementia or Alzheimer’s patients/residents. Due to concerns over possible elopement, there must be a balance between maintaining a safe and secure environment for patients/residents and emergency evacuation requirements. Items 1 through 3 deal with the delayed egress locks would be automatically unlocked. Item 4 states that no occupant shall have to pass through more than one such locking system to get out of the building. Items 5 and 6 deal with staff and fire department awareness of the issues. Item 7 requires emergency lighting at the delayed egress door to ensure visibility for unlocking during a possible power outage. The exception allows for the automatic unlocking to not be included as a requirement in the psychiatric treatment area in hospitals or nursing homes due to additional safety concerns for the residents.

1008.1.9.7 Delayed egress locks. Approved, listed, delayed egress locks shall be permitted to be installed on doors serving any occupancy except Group A, E and H occupancies in buildings that are equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 or an approved automatic smoke or heat detection system installed in accordance with Section 907, provided that the doors unlock in accordance with Items 1 through 6 below. A building occupant shall not be required to pass through more than one door equipped with a delayed egress lock before entering an exit.

1. The doors unlock upon actuation of the automatic sprinkler system or automatic fire detection system.
2. The doors unlock upon loss of power controlling the lock or lock mechanism.
3. The door locks have the capability of being unlocked by a signal from the fire command center.
4. The initiation of an irreversible process which will release the latch in not more than 15 seconds when a force of not more than 15 pounds (67 N) is applied for 1 second to the release device. Initiation of the irreversible process shall activate an audible signal in the vicinity of the door. Once the door lock has been released by the application of force to the releasing device, relocking shall be by manual means only.

Exception: Where approved, a delay of not more than 30 seconds is permitted.

5. A sign shall be provided on the door located above and within 12 inches (305 mm) of the release device read-
MEANS OF EGRESS

6. Emergency lighting shall be provided at the door.

- This locking system is called delayed egress due to Item 4, which allows for an alarm to sound before someone is able to egress. These types of locks are permitted for situations where there are concerns about internal security, and one such delay is not considered detrimental to occupant evacuation. They are permitted for doors in means of egress serving occupancies other than those in Groups A, E and H. The arrangements are not permitted in assembly or educational occupancies because the resulting delay in egress is not acceptable given the greater number of occupants who may be unfamiliar with the space or of a young age. Such a delay would also be inconsistent with Section 1008.1.10, which requires the installation of panic hardware on doors in such uses. Also, the delay from Group H would be unreasonable given the potential for rapid fire buildup in such areas.

Because of the delay caused by the controlled locking device in the egress door, the building must be provided throughout with compensating fire protection features to promptly warn occupants of a fire condition. All of the listed conditions must be met in order to permit use of such a locking device.

Item 1 interconnects the lock with an automatic sprinkler system in accordance with NFPA 13 or, alternatively, an automatic fire detection system in accordance with Section 907, which is required to be installed throughout the building. Such systems are to provide occupants with an early warning of a fire event, and thus additional time for egress. Note that the provision for an automatic fire detection system does not include the use of single- or multiple-station detectors. Also note that actuation of the automatic sprinkler or fire detection system is to unlock the control device so as to permit the egress door to be readily and immediately openable.

Item 2 is so that the control device is “fail safe.” Since the operation of the device is dependent on electrical power, in the event of electrical power loss to the lock or locking mechanism, the egress doors must be readily and immediately openable from the side from which egress is to be made.

Item 3 specifies that the door must be capable of being manually unlocked by a signal sent from a fire command center. Personnel at that location are intended to be the first alerted to an emergency event and are expected to take appropriate action to unlock all egress doors equipped with special locking arrangements. This will permit the locks to be deactivated prior to the sprinklers or smoke detection system detecting the problem or in case of other nonfire emergencies such as an earthquake.

Item 4 specifies the operational characteristics of the locking control device that is similar to a panic device. A user must apply a minimum 15-pound (67 N) force to the release device for at least 1 second, at which time an audible alarm will sound and the device will automatically start to unlock the door. The 1-second duration is to prevent initiation of the unlocking process because of an inadvertent bump or accidental contact against the device. The unlocking cycle is irreversible; once it is started, it does not stop. Once the cycle starts, the door is required to be unlocked in no more than 15 seconds. When the door is unlocked at the end of the 15-second delay, it stays unlocked until someone comes to the door and manually relocks it. A method of automatically relocking the door from a remote location such as a central control station or security office is not permitted; therefore, the first users to the door may face a delay, but after that other users would be able to exit immediately.

The exception will permit the building official to allow the time delay prior to opening to be increased beyond the basic 15 seconds, but never to the point where the delay would exceed 30 seconds.

The sign required by Item 5 informs the user of the type of unlocking device and that the door will become available for egress. An undesirable consequence of the door not unlocking immediately is if the user assumes it will never be available and then proceeds to another exit door.

Item 6 provides emergency lighting at the door so that the user can read the sign required by Item 5.

1008.1.9.8 Access-controlled egress doors. The entrance doors in a means of egress in buildings with an occupancy in Groups A, B, E, I-2, M, R-1 or R-2, and entrance doors to tenant spaces in occupancies in Groups A, B, E, I-2, M, R-1 or R-2, are permitted to be equipped with an approved entrance and egress access control system, listed in accordance with UL 294, which shall be installed in accordance with all of the following criteria:

1. A sensor shall be provided on the egress side arranged to detect an occupant approaching the doors. The doors shall be arranged to unlock by a signal from or loss of power to the sensor.

2. Loss of power to that part of the access control system which locks the doors shall automatically unlock the doors.

3. The doors shall be arranged to unlock from a manual unlocking device located 40 inches to 48 inches (1016 mm to 1219 mm) vertically above the floor and within 5 feet (1524 mm) of the secured doors. Ready access shall be provided to the manual unlocking device and the device shall be clearly identified by a sign that reads "PUSH TO EXIT." When operated, the manual unlocking device shall result in direct interruption of power to the lock—indeed, independent of the access control system electronics—and the doors shall remain unlocked for a minimum of 30 seconds.

4. Activation of the building fire alarm system, if provided, shall automatically unlock the doors, and the doors shall remain unlocked until the fire alarm system has been reset.
MEANS OF EGRESS

5. Activation of the building automatic sprinkler or fire detection system, if provided, shall automatically unlock the doors. The doors shall remain unlocked until the fire alarm system has been reset.

6. Entrance doors in buildings with an occupancy in Group A, B, E or M shall not be secured from the egress side during periods that the building is open to the general public.

Doors can be protected by controlled egress or free egress. A controlled egress door requires permission from the access control system to allow someone to enter or exit through the door. This type is used where entry and exit must be logged or where areas on both sides of the passage must be controlled. An entrance door that was locked or controlled from the exterior, but allowed free egress at any time, such as with a panic bar or other standard hardware, would not be an access controlled egress door. This locking arrangement is for situations where both the ingress and egress out of the door is controlled by some type of entry system, such as a key pad or card swipe.

Security in buildings is a major concern to owners and occupants from the perspective of property preservation and personal physical safety. Since many occupancies are partially occupied around the clock, after normal business hours or on weekends, it is necessary that an adequate level of security be provided without jeopardizing the egress capabilities of the occupants.

This section permits the building entrance doors in a means of egress and entrance doors to tenant spaces in occupancies of Groups A, B, E, I-2, M, R-1 and R-2 to be secured while maintaining them as a means of egress. Items 1 through 6 provide additional life safety measures to permit easier egress during normal and emergency situations. Occupancies in Groups F, S and H are not included here because of their increased hazard due to an increase in fuel load and other potentially life-threatening activities. The required listing UL 294 is for access control system units and addresses requirements for construction, performance and operation of these systems.

Item 1 requires that such doors be provided with an automatic exit sensor typically operating on an infrared, microwave or sonic principle. This sensor is required to automatically release the lock upon an occupant approaching the door from the egress side or when there is a loss of power to the sensor. This provision is written as "performance-based," where any means of sensor design can be utilized to allow the doors to unlock in an emergency situation. It is important to note that, during loss of power, the doors would be required to be "fail-safe" (prioritizing safety over security). The current text does not indicate to what distance the sensor should be set. Since Item 3 sets the exit button at within 5 feet (1524 mm) from the door, it would seem that the sensor would be set for a distance less than the location of the manual exit device.

Item 2 requires that if there is a loss of power to the access control system itself, the doors must unlock. Access controlled egress doors are held secure with fail-safe devices (such as magnetic locks and electric door-strikes) so that these doors will automatically unlock when power to the locking device is interrupted. In some instances, the access controller may be powered from a different source than the locking device itself. In these cases, a loss of power to the access controller (while power remains applied to the locking device) must also cause the egress door to automatically unlock.

Item 3 requires that there be a manual exit device, such as a push button, within 5 feet (1524 mm) of the door, mounted 40 to 48 inches (1016 to 1219 mm) above the floor, unobstructed and with a clearly identifiable sign that says "PUSH TO EXIT." When operated, the manual exit device is to interrupt (independent of the access control electronics) the power to the lock directly and cause the doors to remain unlocked for a minimum of 30 seconds.

Items 4 and 5 require the building fire alarm system, automatic fire detection system or sprinkler system, if provided, to be interfaced with the access control system to unlock automatically the doors on activation. The doors are to remain unlocked until the fire alarm system is reset. This is so that the building entrance doors with controlled access will remain unlocked and open until the fire fighters responding to the alarm have entered.

Item 6 requires that during the hours the building is open to the general public, doors equipped with an access control system will not require the use of the system from the egress side in Group A, B, E and M occupancies. Thus, the building entrance doors in these occupancies are allowed to be secured from both directions only during off hours when the building occupant load will generally be reduced. In Groups I-2, R-1 and R-2, there is no restriction on the time period that access-controlled egress doors may be used, because the staff and residents of the building are expected to be familiar with the building entrance and locking systems. Hence, with a building access control system, the number of individuals who are not familiar with the building is limited, and they are usually accompanied by staff or a resident.

To summarize, it is important to keep in mind that an egress door equipped with an access control system must always allow egress whether power is present or not. The egress door must be "fail-safe" and must assume this "fail-safe" condition when power is removed from any part of the access control system. In other words, if the access control system loses power, the egress door must be capable of being opened. People must be kept from being involuntarily locked inside buildings.

1008.1.9.9 Electromagnetically locked egress doors. Doors in the means of egress in buildings with an occupancy in
MEANS OF EGRESS

Group A, B, E, M, R-1 or R-2, and doors to tenant spaces in Group A, B, E, M, R-1 or R-2, shall be permitted to be electromagnetically locked if equipped with listed hardware that incorporates a built-in switch and meet the requirements below:

1. The listed hardware that is affixed to the door leaf has an obvious method of operation that is readily operated under all lighting conditions.
2. The listed hardware is capable of being operated with one hand.
3. Operation of the listed hardware directly interrupts the power to the electromagnetic lock and unlocks the door immediately.
4. Loss of power to the listed hardware automatically unlocks the door.
5. Where panic or fire exit hardware is required by Section 1008.1.10, operation of the listed panic or fire exit hardware also releases the electromagnetic lock.

In limited occupancy groups, doors that are electromagnetically locked during building occupancy are now permitted to be utilized in the means of egress if equipped with listed hardware that incorporates a built-in switch that meets specified conditions.

As a general rule, means of egress door hardware shall be operable by manual operation to provide for occupant control of the egress system. Locking devices are typically prohibited as they can interfere or prevent efficient egress through the door during an emergency situation. However, owner concerns that must be considered sometimes require a greater degree of security. In specific occupancies, doors in the means of egress are now permitted to be electromagnetically locked if equipped with listed hardware that incorporates a built-in switch that interrupts the power supply to the electromagnetic lock and unlocks the door. The use of this type of locking system provides for a greater degree of security than that offered by other methods addressed in the code, including delayed egress locking systems and egress access control systems.

The allowance for electronically locked egress doors is limited to low- and moderate-hazard occupancies where security can be a major concern. The listed hardware that incorporates a built-in switch has been tested by Underwriters Laboratories (UL). When the occupant prepares to use the door hardware, the method of operating the hardware must be obvious, even under poor lighting conditions. The operation shall be accomplished through the use of a single hand. This is consistent with the general requirement that the door be readily operable without the use of special knowledge or effort. The unlocking of the door must occur immediately on the operation of the hardware by interrupting the power supply to the electromagnetic lock. This requirement is the same when the type of hardware is fire or panic hardware. As an additional safeguard, the loss of power to the hardware shall automatically unlock the door.

Where these special provisions are utilized, the requirements of Section 1008.1.10 regarding panic hardware remain applicable. In Group A and E occupancies having occupant loads of 50 or more, the door hardware must also comply with the requirements for panic hardware.

1008.1.9.10 Locking arrangements in correctional facilities. In occupancies in Groups A-2, A-3, A-4, B, E, F, I-2, I-3, M and S within correctional and detention facilities, doors in means of egress serving rooms or spaces occupied by persons whose movements are controlled for security reasons shall be permitted to be locked when equipped with egress control devices which shall unlock manually and by at least one of the following means:

1. Activation of an automatic sprinkler system installed in accordance with Section 903.3.1.1;
2. Activation of an approved manual alarm box; or
3. A signal from a constantly attended location.

Correctional facilities can include a variety of uses where detainees may be gathered for eating, recreational activities, education, technical training, job training, etc. Correctional facilities can also contain types of support services, such as stores, storage areas or hospital area. Security is still a concern within these areas. This provision will allow the correctional facility to maintain security on all areas. Most commonly the doors would be opened by staff from a central control point under Item 3, but Items 1 and 2 allow for other alternatives in lower security facilities. This provision is not intended to apply to these groups when located outside of a detention or correctional facility.

1008.1.9.11 Stairway doors. Interior stairway means of egress doors shall be openable from both sides without the use of a key or special knowledge or effort.

Exceptions:

1. Stairway discharge doors shall be openable from the egress side and shall only be locked from the opposite side.
2. This section shall not apply to doors arranged in accordance with Section 403.5.3.
3. In stairways serving not more than four stories, doors are permitted to be locked from the side opposite the egress side, provided they are openable from the egress side and capable of being unlocked simultaneously without unlatching upon a signal from the fire command center, if present, or a signal by emergency personnel from a single location inside the main entrance to the building.
4. Stairway exit doors shall be openable from the egress side and shall only be locked from the opposite side in Group B, F, M and S occupancies where the only interior access to the tenant space is from a single exit stair where permitted in Section 1021.2.
5. Stairway exit doors shall be openable from the egress side and shall only be locked from the oppo-
Based on adverse fire experience where occupants have become trapped in smoke-filled stairway enclosures, stairway doors generally must be arranged to permit reentry into the building without the use of any tools, keys or special knowledge or effort. For security reasons, this restriction does not apply to the discharge door from the stairway enclosure to the outside or into an exit passageway (Exception 1). Section 403 for high-rise buildings permits the locking of the doors from the stairway side, provided the doors are capable of being unlocked from a fire command station and there is a communication system within the stairway enclosure that allows contact with the fire command station (Exception 3).

Exception 3 addresses the need for security. The exception is limited to four-story buildings to provide a short travel distance to the stairway discharge door for the building occupants. In addition, to allow quick entrance for fire fighters and emergency responders, a means of simultaneously unlocking all of the doors by emergency personnel must be provided. This provision further requires that the stairway doors be unlocked without unlatching. Stairway doors will typically be fire door assemblies, and their continued latching is necessary to maintain the integrity of the fire-resistive separation for the exit enclosure. The remote unlatching signal shall be initiated from the fire command station, if provided, or a single point of signal initiation at an approved location inside the building's main entrance.

Exceptions 4 and 5 allow for stairways in single exit buildings to have doorways that lead to multiple tenants and dwelling units. For security reasons, those doors can remain locked from the stairway side so no one can enter another tenant space or dwelling unit from the exit stairway.

1008.1.10 Panic and fire exit hardware. Doors serving a Group H occupancy and doors serving rooms or spaces with an occupant load of 50 or more in a Group A or E occupancy shall not be provided with a latch or lock unless it is panic hardware or fire exit hardware.

Exception: A main exit of a Group A occupancy in compliance with Section 1008.1.9.3, Item 2.

Electrical rooms with equipment rated 1,200 amperes or more and over 6 feet (1829 mm) wide that contain overcurrent devices, switching devices or control devices with exit or exit access doors shall be equipped with panic hardware or fire exit hardware. The doors shall swing in the direction of egress travel.

Doors that are part of a means of egress from the locations listed in this section shall not be provided with a latch or lock unless it is panic hardware or fire exit hardware. (See the commentary for the definitions for "Fire exit hardware" or "Panic hardware" and Sections 1008.1.10.1 and 1008.1.10.2).

Panic hardware is also required for all Group H occupancies because of the physical hazards of these spaces. Panic hardware is required on all doors that provide means of egress to rooms and spaces of assembly and educational (Groups A and E) occupancies with an occupant load of 50 or more. This would include large assembly spaces in mixed-use buildings. These uses are characterized by higher occupant load densities. Whereas doors from an assembly or educational room with an occupant load of less than 50 do not require panic hardware, a door that provides means of egress for two or more such rooms would require panic hardware when the combination of spaces has a total occupant load of 50 or more.

The exception is to clarify that the provisions for key-locking hardware at the main exit in Group A occupancies are permitted instead of panic hardware at those specific locations. (For the Group A exception, see the commentary to Section 1008.1.9.3, Item 2.)

Certain electrical rooms are required to have panic hardware. This provision is consistent with the requirement for panic hardware in the NFPA 70: National Electrical Code® (NEC). This requirement is applicable only where multiple conditions are present. The type of room regulated creates a potentially hazardous environment. In the event of an electrical accident, the more immediate egress provided by the panic hardware is desirable.

1008.1.10.1 Installation. Where panic or fire exit hardware is installed, it shall comply with the following:

1. Panic hardware shall be listed in accordance with UL 305;
2. Fire exit hardware shall be listed in accordance with UL 10C and UL 305;
3. The actuating portion of the releasing device shall extend at least one-half of the door leaf width; and
4. The maximum unlatching force shall not exceed 15 pounds (67 N).

As its name implies, panic hardware is special unlatching and unlocking hardware that is intended to simplify the unlatching and unlocking operation to a single 15-pound (67 N) force applied in the direction of egress (see Figure 1008.1.10.1). In a panic situation with a rush of persons trying to utilize a door, the conventional devices, such as doorknobs or thumb turns, may cause sufficient delay so as to create a crush at the door and prevent or slow the opening operation.

The locational specifications for the activating panel or bar are based on ready availability and access to the unlatching device. Note that the section requires the activating portion to extend at least one-half the width of the door leaf. Panic and fire exit hardware must be listed. UL 305, Standard for Safety Panic Hardware, includes construction and perfor-
Means of Egress

Performance requirements dealing with endurance, emergency operation, elevated ambient exposure and low-temperature impact tests to ensure that the panic device operates properly. (For panic hardware on a balanced door, see Section 1008.1.10.2.) The activation device must be mounted between 34 inches and 48 inches (864 mm and 1219 mm) high in accordance with Section 1008.1.9.2. Section 1008.1.1.1 was specifically added to allow the panic hardware to extend the full width of the door as long as it does not protrude more than 4 inches (102 mm) into the door clear width.

Standard panic hardware or "listed panic hardware" is not approved for use on fire door assemblies. Panic hardware and fire exit hardware can be similar in appearance.

Where a fire door, such as an exit stairway, is required to be equipped with panic hardware, the hardware must accomplish the dual objectives of panic hardware and continuity of the enclosure in which it is located—thus the reference to UL 10C, Standard for Safety Positive Pressure Fire Tests of Door Assemblies. In this case, fire exit hardware is to be provided that meets both objectives and requirements, since panic hardware is not tested for use on fire doors. There are standard test procedures designed to evaluate the performance of panic and fire exit hardware from the panic standpoint as well as from a fire protection standpoint. "Fire door assemblies" are defined in Section 716.5 as a combination of doors, frame, hardware and other accessories required to provide a specific degree of fire and smoke barrier protection to the opening in a fire wall, fire barrier, fire partition, smoke barriers or exterior wall required to have a fire-resistance rating.

Fire doors must close and positively latch in order to protect exit stairways, corridors and other areas of the building from the spread of smoke and fire. Additionally, fire doors are required to self-close and automatically latch after each use. Positive latching of fire doors is not related to the locking of the door and should never be confused with locking or security issues.

The requirement for positive latching means that dogging devices are not permitted on fire exit hardware. A dogging device is an option on the hardware that allows for the panic hardware to be locked in the fully depressed position. A dogging device mechanically defeats the latching feature of panic hardware preventing the door from positively latching when in the closed position. The dogging device is typically manually activated with a small wrench or tool and is activated through a hole adjacent to the activation bar. Dogging capability is often provided on exterior doors that are intended as building entrances.

Fire exit hardware must be labeled. Typical locations are on either end of the hardware. Information on the label must include the words "listed" and "fire exit hardware" and indicate a control or serial number. The label on the fire door itself should indicate that it is a fire door suitable for use with fire exit hardware.

1008.1.10.2 Balanced doors. If balanced doors are used and panic hardware is required, the panic hardware shall be the
push-pad type and the pad shall not extend more than one-half the width of the door measured from the latch side.

- The provisions for balanced doors ensure that the occupants push only on the latch side of the door since the hinge side of a balanced door pivots "against" the direction of egress (see the commentary for the definition of "Door, balanced" in Chapter 2).

1008.2 Gates. Gates serving the means of egress system shall comply with the requirements of this section. Gates used as a component in a means of egress shall conform to the applicable requirements for doors.

Exception: Horizontal sliding or swinging gates exceeding the 4-foot (1219 mm) maximum leaf width limitation are permitted in fences and walls surrounding a stadium.

- This section specifies that all of the requirements for doors also apply to gates, except gates that surround a stadium are allowed to exceed 4 feet (1219 mm) in width. Usually a large gate is required to adequately serve a stadium crowd for egress purposes.

1008.2.1 Stadiums. Panic hardware is not required on gates surrounding stadiums where such gates are under constant immediate supervision while the public is present, and where safe dispersal areas based on 3 square feet (0.28 m²) per occupant are located between the fence and enclosed space. Such required safe dispersal areas shall not be located less than 50 feet (15 240 mm) from the enclosed space. See Section 1027.5 for means of egress from safe dispersal areas.

- Panic hardware is impractical for large gates that surround stadiums. Normally, these gates are opened and closed by the stadium's ground crew that is constantly in attendance during the use of such gates. The safe dispersal area requirement provides for the safety of the crowd if for some reason the gate is not open. The safe dispersal area is to be between the stadium enclosure and the surrounding fence and the area to be occupied is not to be closer than 50 feet (15 240 mm) to the stadium enclosure.

1008.3 Turnstiles. Turnstiles or similar devices that restrict travel to one direction shall not be placed so as to obstruct any required means of egress.

Exception: Each turnstile or similar device shall be credited with no more than a 50-person capacity where all of the following provisions are met:

1. Each device shall turn free in the direction of egress travel when primary power is lost, and upon the manual release by an employee in the area.
2. Such devices are not given credit for more than 50 percent of the required egress capacity.
3. Each device is not more than 39 inches (991 mm) high.

Figure 1008.1.10.1—continued
EXAMPLES OF TYPICAL PANIC HARDWARE
MEANS OF EGRESS

4. Each device has at least 16½ inches (419 mm) clear width at and below a height of 39 inches (991 mm) and at least 22 inches (559 mm) clear width at heights above 39 inches (991 mm).

Where located as part of an accessible route, turnstiles shall have at least 36 inches (914 mm) clear at and below a height of 34 inches (864 mm), at least 32 inches (813 mm) clear width between 34 inches (864 mm) and 80 inches (2032 mm) and shall consist of a mechanism other than a revolving device.

This section provides for a limited use of turnstiles to serve as a means of egress component. The exception to this section limits each turnstile to a maximum of 50 persons of egress capacity. The turnstile must comply with all four listed items to be considered to serve any part of the occupant load for means of egress. The turnstiles must rotate freely both when there is a loss of power and when they are manually released. Note that the 50-person limit applies to each individual turnstile. These provisions are similar to the revolving door provisions in Section 1008.1.4.1.

If turnstiles are located along an accessible route, the route for persons using mobility devices must be something other than a revolving device, such as a swinging gate. A common example would be the turnstiles for automatic ticket taking, such as at the entrance to a mass transit platform.

1008.3.1 High turnstile. Turnstiles more than 39 inches (991 mm) high shall meet the requirements for revolving doors.

Where a turnstile is higher than 39 inches (991 mm), the restriction to egress is much like a revolving door. Thus, the egress limitations for revolving doors in Section 1008.1.4.1 apply to this type of turnstile. If a high turnstile does not meet the revolving door requirements for doors that are an egress component, it is not to be included as serving a portion of the means of egress. It would be necessary to provide doors in these areas for egress. High turnstiles may not be part of an accessible route for ingress or egress.

1008.3.2 Additional door. Where serving an occupant load greater than 300, each turnstile that is not portable shall have a side-hinged swinging door which conforms to Section 1008.1 within 50 feet (15 240 mm).

This section addresses a common egress condition for sports arenas where a number of turnstiles are installed for ticket taking. Portable turnstiles are moved from the egress path for proper exiting capacity. Permanent turnstiles are not considered as providing any of the required egress capacity when serving an occupant load greater than 300, no matter how many turnstiles are installed. Doors are required to provide occupants with a path of egress other than through the turnstiles. The doors are to be located within 50 feet (15 240 mm) of the turnstiles.

SECTION 1009 STAIRWAYS

1009.1 General. Stairways serving occupied portions of a building shall comply with the requirements of this section.

It is important for stairway safety that all stairways meet the provisions in this section. This would include all elevation changes using stairways; everything from one riser to multiple flights and landings between stories (see the definitions for "Stair" and "Stairway" in Chapter 2). These provisions will be applicable for interior exit access stairways, interior exit stairways, and exterior exit stairways, as well as any steps along the paths for exit access or exit discharge. It is intended that this section be applicable to required stairways as well as what can be called "convenience" stairways.

Section 1009.2 references Section 1022 for enclosures for exit stairways.

Section 1009.3 provides criteria for enclosures for exit access stairways between stories.

Sections 1009.4 through 1009.10 provide criteria for the stairway itself, including exit access stairways between levels less than stories and for mezzanines.

Special provisions are provided for curved stairways (Section 1009.11), spiral stairways (Section 1009.12), alternating tread devices (Section 1009.13) and ship ladders (Section 1009.14).

Section 1009.15 references Section 1012 for handrail requirements.

Sections 1009.16 and 1009.17 indicates when stairways need to provide access to the roof or elevator equipment.

1009.2 Interior exit stairways. Interior exit stairways shall lead directly to the exterior of the building or shall be extended to the exterior of the building with an exit passageway conforming to the requirements of Section 1023, except as permitted in Section 1027.1.

Exit stairways are stairways that provide a protected path of travel between the exit access and the exit discharge. Exit stairways are required to be enclosed and protected in accordance with Section 1022 (Section 1009.2.2). The exit discharge from the enclosed interior exit stairway can be directly to the outside through an exterior exit doorway; through a doorway in a horizontal exit (Section 1027.1. Exception 3); to the outside through an exit passageway (Section 1023) or, in limited situations, to the outside through a lobby or vestibule (Section 1027.1, Exceptions 1 and 2). This requirement is repeated in Sections 1022.1 and 1022.3.

Provisions are similar for interior exit ramps (Section 1010.2).
1009.2.1 Where required. Interior exit stairways shall be included, as necessary, to meet one or more means of egress design requirements, such as required number of exits or exit access travel distance.

- The number of means of egress from a story is specified in Section 1021.2. On the upper stories of most multistory buildings, this will be met by protected interior or exterior exit stairways (see Sections 1022 and 1026). Travel distance measurements for exit access ends at the entrance to the enclosure for the interior exit stair tower or the exterior door leading to the exterior exit stairway (Section 1016.3).

In limited situations, the means of egress can include interior exit access stairways located along the interior exit access route prior to arrival at an exit element (i.e., exterior exit door, an interior or exterior exit stairway or a horizontal exit). The exit access travel distance will include travel along any exit access stairway.

1009.2.2 Enclosure. All interior exit stairways shall be enclosed in accordance with the provisions of Section 1022.

- Section 1022 provides criteria for the protection and enclosure of interior exit stairways. This includes provisions for enclosure by fire-resistance-rated walls (i.e., fire barriers or horizontal assemblies); protection for door, openings, penetrations and joints in that enclosure; exterior walls; signage within the stairway as well as high-rise requirements for exit stairways within pressurized smokeproof enclosures.

1009.3 Exit access stairways. Floor openings between stories created by exit access stairways shall be enclosed.

Exceptions:

1. In other than Group I-2 and I-3 occupancies, exit access stairways that serve, or atmospherically communicate with, only two stories are not required to be enclosed.

2. Exit access stairways serving and contained within a single residential dwelling unit or sleeping unit in Group R-1, R-2 or R-3 occupancies are not required to be enclosed.

3. In buildings with only Group B or M occupancies, exit access stairway openings are not required to be enclosed provided that the building is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1, the area of the floor opening between stories does not exceed twice the horizontal projected area of the exit access stairway, and the opening is protected by a draft curtain and closely spaced sprinklers in accordance with NFPA 13.

4. In other than Group B and M occupancies, exit access stairway openings are not required to be enclosed provided that the building is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1, the floor opening does not connect more than four stories, the area of the floor opening between stories does not exceed twice the horizontal projected area of the exit access stairway, and the opening is protected by a draft curtain and closely spaced sprinklers in accordance with NFPA 13.

5. Exit access stairways within an atrium complying with the provisions of Section 404 are not required to be enclosed.

6. Exit access stairways and ramps in open parking garages that serve only the parking garage are not required to be enclosed.

7. Stairways serving outdoor facilities where all portions of the means of egress are essentially open to the outside are not required to be enclosed.

8. Exit access stairways serving stages, platforms and technical production areas in accordance with Sections 410.6.2 and 410.6.3 are not required to be enclosed.

9. Stairways are permitted to be open between the balcony, gallery or press box and the main assembly floor in occupancies such as theaters, places of religious worship, auditoriums and sports facilities.

10. In Group I-3 occupancies, exit access stairways constructed in accordance with Section 408.5 are not required to be enclosed.

- Section 1010.2 references this section for interior exit access ramps. For simplicity in the commentary to Sections 1009.3 through 1009.3.1.8, when interior exit access stairways are mentioned, let it be understood that the same rules apply to interior exit access ramps.

The enclosure requirements are for "interior exit access stairways" that are between stories. Exit access stairways between elevation changes on the same story or serving mezzanines do not serve different stories; therefore, the enclosure requirements in this section are not applicable. The general provisions for stairways, starting with Sections 1009.4, would be applicable.

The primary difference between "interior exit access stairways" and "interior exit stairways" is how exit access travel distance is measured (Section 1016.3). Where a designer chooses to use an exit access stairway, the exit access travel distance includes travel along the slope of the exit access stairway, similar to stairways leading from an open mezzanine or steps at a change in level on a floor.

The base requirement is that exit access stairways between floors are protected in a similar manner as exit stairways. The enclosure is needed because a stairway penetrates the floor/ceiling assemblies between the levels, thus creating a vertical opening or shaft. In cases of fire, a vertical opening may act as a chimney, causing smoke, hot gases and light-burning products to flow upward (buoyant force). If an opening is unprotected, these products of combustion will be forced by positive pressure differentials to
spread horizontally into the building spaces. There are exceptions for shaft protection around openings in Section 712.1 or exit access stairways as permitted in this section in Exceptions 1 through 10.

Exit access stairways are not required to discharge directly to the exterior as are interior exit stairways (see Sections 1009.2 and 1022.3). Instead, exit access stairways are part of the route that leads to the exit (i.e., exterior exit door, horizontal exit or enclosed interior exit stairway). See the commentary to Sections 1009.3.1 through 1009.3.1.8 for a discussion of other differences in protection permitted for the enclosure of exit access stairways versus exit stairways.

While this section does not state that exit access stairways cannot be used for any purpose other than means of egress (see Section 1022.1), the provisions for no obstructions in the path of travel or reduction of the capacity for means of egress (Section 1003.6) are applicable. If one of the exceptions eliminating enclosures for a stairway is utilized, the exit access stairway openings would still have to meet the exit and exit access door separation requirement specified in Section 1015.2 for the space or floor.

Exception 1 allows an open exit access stairway when the opening is only between two floors. There cannot be any other unprotected openings that connect to other floors since this could create a staggered stack effect for the movement of smoke between multiple stories. In two-story buildings, this would allow for open stairways between the basement and ground level or between the first and second floors. Another example would be an open exit access stairway between the fifth and sixth floors of a building, provided there were no other unprotected openings between the fourth and fifth floor or the sixth and seventh floors. This is consistent with Section 712.1.8 for openings between two stories. This exception would not be permitted in jails or institutional facilities, like nursing homes or hospitals. These spaces commonly use smoke compartmentation for protection with defend-in-place evacuation plans.

In Exception 2, for residential occupancies, the exit access stairway within a single-family home or townhouse are not required to be enclosed because of the small occupant load and resident familiarity with the space. Examples of "within an individual dwelling or sleeping unit" would be a two-story hotel suite or a multistory apartment unit. Literally, a congregate residence would not be considered an individual dwelling unit; however, since small facilities often operate similarly to a single-family home, consideration for this exception is by the local code official on a case-by-case basis (see Section 1021.2, Exception 6, which allows a single exit in Group R-3 and R-4 congregate residences. These congregate residences are limited to 16 occupants in Sections 308.3.2, 310.5 and 310.6). Live/work units call for the egress to be designed for the "function served," and vertical openings are not required to be enclosed (Section 419.3 and 419.4); therefore, it is appropriate to allow open exit access stairways to serve the dwelling portion of the live/work unit. Note that Section 712.1.2 limits any vertical opening within dwelling units, including stairways, to four stories or less.

Exception 3 is limited to business and mercantile buildings sprinklered throughout with an NFPA 13 system. The size of the opening is limited to twice the size of the stairway footprint. The opening must be protected with a draft curtain and closely spaced sprinklers (see Figure 1009.3). This allows for such an opening to extend the entire height of the building; however, to serve as part of the means of egress, the exit access stairway must still be able to meet the exit access travel distance. This exception is similar to what is permitted for escalators and stairways that were not needed for exit or exit access purposes (see Sections 712.1.3 and 712.1.3.1). The power-operated automatic shutter permitted in Section 712.1.3.2 would not be an option for exit access stairways since they must be available for exit access travel.

Exception 4 is similar to Exception 3, but for groups other than business and mercantile. The requirements are the same for the sprinkler system, draft curtain and opening size (see Figure 1009.3); however, there is the additional limitation of a maximum of four stories. To be considered part of the exit access, the travel distance limitation would still be applicable.

Exception 5 allows for exit access stairways to travel down through an atrium. Atriums often penetrate more than two floors. Atriums must meet the provisions in Section 404 for sprinklers, fire alarms, smoke control, enclosure, limitations on flame spread and smoke development of interior finishes and the reduction in the normal exit access travel distance. In no case can the exit access travel distance through the atrium, including travel along the stairway, be more than 200 feet (60 960 mm).

In Exception 6, exit access stairways located in open parking structures are exempt from the enclosure requirements because of the ease of accessibility by the fire services, the natural ventilation of such structures, the low level of fire hazard, the small number of people using the structure at any one time and the excellent fire record of such structures. Section 1016.3, Exception 1, permits the exit access travel distance to be measured to the top step of the exit access stairway in open parking garages. In essence, open parking garages using this exception do not have exit stairways.

In Exception 7, stairways in outdoor facilities (i.e., Group A-5) in which the means of egress is essentially open to the outside need not be enclosed because of the ability to vent the fire to the outside. The criteria specified in Section 1026.3 could be used to determine if the stairway is "essentially open." Section 1016.3, Exception 2, permits the exit access travel distance to be measured to the top step of the
exit access stairway in outdoor facilities. In essence, outdoor facilities using this exception do not have exit stairways.

Regarding Exception 8, due to the open nature of stages and platforms, exit access stairways from the side of a stage, spaces under the stage and any supporting technical production areas are not required to be enclosed (see Sections 410.6.2 and 410.6.3). A travel distance increase is permitted for technical production areas (see Section 410.6.3.2).

Exception 9 addresses the unique situation for large indoor assembly seating areas. Since press boxes, galleries and balconies all have the same atmosphere and fire recognition ability as the rest of the seating, the stairways serving these spaces are protected by the same system as the seating (i.e., open to the interior volume and smoke protected; open to the outside); therefore, it is logical to treat the access to these spaces the same as the seating bowl.

Exception 10, for observation and security needs in detention facilities, exit access stairways within a housing unit are not required to be enclosed (see Section 408.5.1). Section 1022.2 also includes a limited exception for enclosure of exit stairways within jails.

1009.3.1 Construction. Where required, enclosures for exit access stairways shall be constructed in accordance with this section. Exit access stairway enclosures shall be constructed as fire barriers in accordance with Section 707 or horizontal assemblies in accordance with Section 711, or both.

This section requires that all interior exit stairways are to be enclosed with rated walls (i.e., fire barriers) and floor/ceiling assemblies (i.e., horizontal assemblies). The fire-resistance rating required depends on the number of connected stories and the required fire-resistance rating of the penetrated floors (see Section 1009.3.2). The fire-resistance requirements for enclosures for exit access stairways are consistent with

---

**Figure 1009.3**

DRAFT CURTAIN, EXCEPTIONS 3 AND 4
those for shaft enclosures and enclosures for exit stairways.

The enclosure is needed because exit access stairways penetrate the floor/ceiling assembly, thus creating a vertical opening or shaft. In cases of fire, a vertical opening may act as a chimney, causing smoke, hot gases and light-burning products to flow upward (buoyant force). If an opening is unprotected, these products of combustion will be forced by positive pressure differentials to spread horizontally into the building spaces. There are exceptions for shaft protection around stairways and ramps that are not part of a means of egress in Section 712, exit access stairways as permitted in Section 1009.3 or exit stairways as permitted in Section 1022.2. The enclosure of interior stairways or ramps with construction having a fire-resistance rating is intended to prevent the spread of fire from floor to floor. Another important purpose is to provide a safe path of travel for the building occupants and to serve as a protected means of access to the fire floor by fire department personnel. For this reason, Sections 1009.3.1.4 through 1009.3.1.7 limit the penetrations and openings permitted in the enclosure for an exit access stairway.

1009.3.1.1 Materials. Exit access stairway enclosures shall be of materials permitted by the building type of construction.

- This section is a reminder that walls that enclose an exit access stairway must be consistent with the type of construction required in Chapter 6. This agrees with Section 1009.9, which states that the stairway components themselves must also be consistent with the type of construction.

1009.3.1.2 Fire-resistance rating. Exit access stairway enclosures shall have a fire-resistance rating of not less than 2 hours where connecting four stories or more, and not less than 1 hour where connecting less than four stories. The number of stories connected by the exit access stairway enclosures shall include any basements, but not any mezzanines. Exit access stairway enclosures shall have a fire-resistance rating not less than the floor assembly penetrated, but need not exceed 2 hours.

- The enclosure for an exit access stairway must have a fire-resistance rating of at least 1 hour. The fire-resistance rating of the enclosure must be increased to 2 hours if the stairway connects four or more stories or if it penetrates a floor system with a fire-resistance rating of 2 hours or more (see Table 602 for Type I construction). Note that the criteria are based on the number of stories connected by the stairway and not the height of the building. For example, a building that has three stories located entirely above the grade plane and a basement would require an enclosure with a 2-hour fire-resistance rating if the stairway connects all four stories. Where the floor construction penetrated by the enclosure for the exit access stairway has a fire-resistance rating, the enclosure must have the same minimum rating. For example, an enclosure that penetrates a 2-hour floor assembly must have a minimum fire-resistance rating of 2 hours, regardless of the number of stories the enclosure connects. The fire-resistance rating of an enclosure need never exceed 2 hours. If the floor assembly penetrated requires a minimum 3-hour fire-resistance rating, the enclosure rating is only required to be 2-hour fire-resistance rated.

1009.3.1.3 Continuity. Exit access stairway enclosures shall have continuity in accordance with Section 707.5 for fire barriers or Section 711.4 for horizontal assemblies as applicable.

- This is a reminder that fire barriers and horizontal assemblies enclosing the exit access stairway need to be supported by construction that is consistent with the required fire-resistance rating for the enclosure. Typically, this includes beams, girders and columns that support the structural bay that contains the exit access stairway.

1009.3.1.4 Openings. Openings in an exit access stairway enclosure shall be protected in accordance with Section 716 as required for fire barriers. Doors shall be self- or automatic-closing by smoke detection in accordance with Section 716.5.9.3.

- In order for fire doors to be effective, they must be in the closed position; therefore, the preferred arrangement is to install self-closing doors. Recognizing that operational practices often require doors to be open for an extended period of time, automatic-closing doors are permitted as long as this opening will not pose a threat to occupant safety and the doors will be self-latching. Automatic-closing devices enable the opening to be protected during a fire condition. The basic requirement for closing devices and specific requirements for automatic-closing and self-closing devices are given in NFPA 80. Automatic-closing doors that provide protected openings into exits are also required to close on the actuation of smoke detectors or loss of power to the smoke detectors (see Section 716.5.9.3).

1009.3.1.4.1 Prohibited openings. Openings other than those necessary for the purpose of the exit access stairway enclosure shall not be permitted in exit access stairway enclosures.

- The only openings that are permitted in fire-resistance-rated enclosure for exit access stairways are doors that lead into the enclosure that are necessary for egress and doors leading out of the enclosure. This restriction on openings essentially prohibits the use of windows in an exit enclosure except for those on an exterior wall. Requirements for protection on windows or doors on the exterior wall are addressed in Section 1009.1.3.8. The only exception would be window assemblies that have been tested as wall assemblies in accordance with ASTM E 119 or UL 263. The objective of this provision is to minimize the possibility of fire spreading into an enclosure and endangering the occupants or even preventing the use of the exit access at a time when it is most needed. While this section does not specifically limit
the doors to those from normally occupied spaces as indicated for enclosures for exit stairways or state that elevators should not open into this enclosure (see Section 1022.4), the concern would be the same. The limitation on openings from normally occupied areas is intended to reduce the probability of a fire occurring in an unoccupied area, such as a storage closet, that has an opening into the enclosure for the exit stairway, possibly resulting in fire spread into the exit stairway. Other spaces that are not normally occupied include, but are not limited to, toilet rooms, electrical/mechanical equipment rooms and janitorial closets. The difficulty with elevator doors is keeping in compliance with opening protective criteria in a fire barrier, but still operating effectively as elevator doors. For additional information on elevator lobbies and doors, see the commentary to Sections 713.14 and 1018.6.

1009.3.1.5 Penetrations. Penetrations in an exit access stairway enclosure shall be protected in accordance with Section 714 as required for fire barriers.

- Section 714 addresses through and membrane penetrations for fire-resistance-rated wall and floor/ceiling assemblies. The intent is to maintain the integrity of the enclosure for the exit access stairway. This section and Section 1009.3.1.7 are meant to work together. Penetrations in exterior walls are addressed in Section 1009.3.1.8.

1009.3.1.5.1 Prohibited penetrations. Penetrations other than those necessary for the purpose of the exit access stairway enclosure shall not be permitted in exit access stairway enclosures.

- Penetrations into the enclosure can include sprinkler systems, lighting and electrical systems and ductwork. In general, only portions of the building service systems that serve the enclosure for the exit access stairway are allowed to penetrate the enclosure. If two enclosures for exit access stairways are adjacent to one another, or adjacent to an enclosure for an exit stairway, there must be no penetrations between them, thereby limiting the chances of smoke being in both stairwells.

1009.3.1.6 Joints. Joints in an exit access stairway enclosure shall comply with Section 715.

- The linear voids at joints between fire-resistant wall and floor/ceiling assemblies and where an enclosure would intersect with an exterior wall must be filled so that the integrity of the enclosure is maintained (see Section 715).

1009.3.1.7 Ducts and air transfer openings. Penetrations of an exit access stairway enclosure by ducts and air transfer openings shall comply with Section 717.

- Where ducts penetrate a fire-resistance-rated enclosure, the opening must be protected with an approved fire and smoke damper (see Section 717.5.3). This section and Section 1009.3.1.5 are intended to work together.

1009.3.1.8 Exterior walls. Where exterior walls serve as a part of an exit access stairway enclosure, such walls shall comply with the requirements of Section 705 for exterior walls and the fire-resistance-rated enclosure requirements shall not apply.

- This section does not require the exterior wall of the enclosure for the exit access stairway to be rated the same as the walls between the stairway and the interior of the building; however, if the exterior wall is located close to a lot line or an adjacent building, Table 602 and Section 705 could require the exterior wall to be rated and would put a limit on the openings in that wall. The intent is to limit possible ignition from an adjacent building. Buildings with exterior walls 30 feet (9145 mm) or more from the lot line are not required to be rated due to fire separation distances. This is different than exterior load-bearing walls that are required to have a fire-resistance rating because of the type of construction (see Table 601).

- Exterior walls of enclosures for exit stairways may have additional requirements for situations when the exterior wall of the stairway is not flush with the exterior wall of the building (see Section 1022.7).

1009.4 Width. The width of stairways shall be determined as specified in Section 1005.1, but such width shall not be less than 44 inches (1118 mm). See Section 1007.3 for accessible means of egress stairways.

Exceptions:

1. Stairways serving an occupant load of less than 50 shall have a width of not less than 36 inches (914 mm).
2. Spiral stairways as provided for in Section 1009.12.
3. Aisle stairs complying with Section 1028.
4. Where an incline platform lift or stairway chairlift is installed on stairways serving occupancies in Group R-3, or within dwelling units in occupancies in Group R-2, a clear passage width not less than 20 inches (508 mm) shall be provided. If the seat and platform can be folded when not in use, the distance shall be measured from the folded position.

- To provide adequate space for occupants traveling in opposite directions and to permit the intended full egress capacity to be developed, minimum dimensions are dictated for means of egress stairways. A minimum width of 44 inches (1118 mm) is required for stairway construction to permit two columns of users to travel in the same or opposite directions. The reference to Section 1005.1 is for the determination of stairway width based on occupant load. The larger of the two widths is to be used.

- Exception 1 recognizes the relatively small occupant loads of less than 50 that permit a staggered file of users when traveling in the same direction. When traveling in opposite directions, one column of users must stop their ascent (or descent) to permit the opposite column to continue. Again, considering the relatively small occupant loads, any disruption of
MEANS OF EGRESS

orderly flow will be infrequent. The use of this exception is limited to buildings where the occupant load of each upper story and/or basement is less than 50.

Exception 2 permits a spiral stairway to have a minimum width of 26 inches (660 mm) when it conforms to Section 1009.12, on the basis that the configuration of a spiral stairway will allow nothing other than single-file travel.

Exception 3 provides for the aisle stair widths that are specified in Section 1028.

Exception 4 addresses the use of inclined platform lifts or stairway chairlifts for individual dwelling units. For clarification on the types of lifts, see the commentary to Section 1109.7. Both types of lifts may be installed to aid persons with mobility impairments in their homes. The code and ASME A18.1 allow a reduction in the width of the stair to a minimum of 20 inches (508 mm) of clear passageway to be maintained on a stairway where a lift is located. If a portion of the lift, such as a platform or seat, can be folded, the minimum clear dimension is to be measured from the folded position. If the lift cannot be folded, then the 20 inches (508 mm) is measured from the fixed position. The track for these lifts typically extends 9 to 12 inches (229 to 305 mm) from the wall, making the 20-inch (508 mm) clear measurement actually 24 to 27 inches (610 to 686 mm) from the edge of the track.

The code does not have any specific provisions for where incline platform lifts are utilized along stairways in locations other than within dwelling units. Section 1109.7 limits the use of platform lifts in new construction to areas with minor occupant loads or where elevators and ramps are impractical. Section 3411.8.3 allows for platform lifts anywhere in existing buildings in order to gain accessibility for persons with mobility impairments. When in the closed and off position, the platform lifts should not block the clear width required for the stairway, or use of the handrails. The industry is currently working on different options to address the concern that the lift may be in operation during an event that requires evacuation.

1009.5 Headroom. Stairways shall have a minimum headroom clearance of 80 inches (2032 mm) measured vertically from a line connecting the edge of the nosings. Such headroom shall be continuous above the stairway to the point where the line intersects the landing below, one tread depth beyond the bottom riser. The minimum clearance shall be maintained the full width of the stairway and landing.

Exceptions:

1. Spiral stairways complying with Section 1009.12 are permitted a 78-inch (1981 mm) headroom clearance.

2. In Group R-3 occupancies; within dwelling units in Group R-2 occupancies; and in Group U occupancies that are accessory to a Group R-3 occupancy or accessory to individual dwelling units in Group R-2 occupancies; where the nosings of treads at the side of a flight extend under the edge of a floor opening through which the stair passes, the floor opening shall be allowed to project horizontally into the required headroom a maximum of 4 3/4 inches (121 mm).

This headroom requirement is necessary to avoid an obstruction to orderly flow and to provide visibility to the users so that the desired path of travel can be planned and negotiated. Height is a vertical measurement above every point along the stairway stepping and walking surfaces, with minimum height measured vertically from the tread nosing or from the surface of a landing or platform up to the ceiling [see Figure 1009.5(1)].

Sections 1003.2 and 1208.2 require a minimum ceiling height within a room of 7 feet, 6 inches (2307 mm). A bulkhead or doorway at the bottom of the stairway would be allowed to meet the minimum headroom height of 80 inches (2032 mm), as permitted in Section 1003.3.

Exception 1, allowing for a clear headroom of 6 feet, 6 inches (1981 mm) for spiral stairs, correlates with the provisions of Section 1009.12.

Exception 2 recognizes a common method of stairwell construction in which the stringer on the open side of a stair is supported by the same floor joists or wall that supports the edge of the opening through which the stairway passes to the floor above, thus resulting in the stairway being wider at the lower portion than at the top portion. In this case, headroom is not required for a distance of up to 4 3/4 inches (121 mm) measured horizontally from the edge of the opening above to the handrail or guard system, which limits the clear width on the lower open sides of the stairway. The 4 3/4 inches (121 mm) maximum is derived from the finished width of a typical 2 by 4 supporting wall and is not critical to obstructing orderly flow or visibility in the desired path of travel [see Figure 1009.5(2)].

1009.6 Walkline. The walkline across winder treads shall be concentric to the direction of travel through the turn and located 12 inches (305 mm) from the side where the winders are narrower. The 12-inch (305 mm) dimension shall be measured from the widest point of the clear stair width at the walking surface of the winder. If winders are adjacent within the flight, the point of the widest clear stair width of the adjacent winders shall be used.

This requirement is essential for smooth, consistent travel on stairs that turn with winder treads. It provides a standard location for the regulation of the uniform tread depth of winders. Due to the wide range of anthropometrics of stairway users, there is no one line that all persons will travel on stairs; however, the code recognizes a standard location of a walkline is essential to design and enforcement. Each footfall of the user through the turn can be associated with an arc to describe the path traveled. As a user ascends or descends the flight, the turning at each step should be consistent through the turn. The walkline is established concentric, or having the same center (approx-
imately parallel) as the arc of travel of the user. The
tread depth dimension at the walkline is one of two
tread depths across the width of the stair at which
winder tread depth is regulated, cited in Section
1009.7.2. The second is the minimum tread depth.
Regulation at these two points controls the angularity
of the turn and the configuration of the flight. In order
to establish consistently shaped winders, tread
depths must always be measured concentric to the
arc of travel. The walkline is unique as the only line or
path of travel where winder tread depth is controlled
by the same minimum tread depth as rectangular
treads. However, Exception 2 of Section 1009.7.4
recognizes winder tread depth need not be compared
to rectangular tread depths for dimensional uniformity
in the same flight because the location of the walkline

For St: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

Figure 1009.5(1)
STAIRWAY HEADROOM REQUIREMENTS

Figure 1009.5(2)
EXAMPLE OF SECTION 1009.2, EXCEPTION 2
MEANS OF EGRESS

is chosen for the purpose of providing a standard and cannot be specific to the variety of actual paths followed by all users. This specific line location is determined by measuring along each nosing edge 12 inches (305 mm) from the extreme of the clear width of the stair at the surface of the winder tread or the limit of where the foot might be placed in use of the stair. If adjacent winders are present, the point of the widest clear stair width at the surface of the tread in the group of adjacent consecutive winders is used to provide the reference from which the 12-inch (305 mm) dimension will be measured along each nosing. The tread depth may be determined by measuring between adjacent nosings at these determined intersections of the nosings with the walkline. It is important to note that the clear stair width is only that portion of the stair width that is clear for passage. Portions of the stair beyond the clear width are not consequential to use of the stair, consistent travel or location of the walkline.

1009.7 Stair treads and risers. Stair treads and risers shall comply with Sections 1009.7.1 through 1009.7.5.3.

❖ The provisions for treads and risers contribute to the efficient use of the stairway, facilitating smooth and consistent travel. This section provides dimensional ranges and tolerances for the component elements to allow the flexibility required to design and construct a stair or a flight of stairs which are elements of a stairway. The allowed proportion of maximum riser height and minimum tread depth provide for a maximum angle of ascent but there is no maximum tread depth to consider with the minimum riser height that would define a minimum angle for a stairway. Nor is the proportion of riser height to tread depth compared with the limitations of the length of the user’s stride on stairways that is significantly foreshortened from the user’s stride on the level. For this reason, care should be taken when incorporating larger tread depths and controlling the point at which a tread might be wide enough to require more than one step to cross, which can vary significantly when considering ascent and descent movement patterns. Especially in areas where all segments of the public might use the stairs, those persons requiring two smaller sequential steps to cross the tread would progress at significantly different rates than those that might be able to stretch or jump and lead to dangerous complications, especially in egress. Of equal significance is the use of shorter risers without increasing tread depth resulting in a proportion that could cause overstepping. With these same limitations for proportion in mind however, by controlling the minimum depth of rectangular treads and the minimum depth and angularity of winder treads these components can control the configuration of the plan of a flight of stairs to provide for smooth and consistent travel.

Section 1009.7.1 provides for consistent identification of the surfaces that are to be measured. This is as critical to the users’ experience throughout the built environment as it is to determining all the dimensions in this section as they must relate to each other and the ultimate design and construction of a safe stairway.

The remaining sections address the uniformity and essential attributes of the tread and riser. Of particular note is the nosing or leading edge of the tread. The nosing shape and projection affect the determination of the tread depth and the riser height and are regulated at all steps throughout the stairway, including the nosings at landings to provide for smooth and consistent travel. Furthermore, the line connecting the nosings is used to determine handrail height, guard height and headroom, causing consistent nosings to be a dependent integral of every element of the stairway design, construction and regulation.

1009.7.1 Dimension reference surfaces. For the purpose of this section, all dimensions are exclusive of carpets, rugs or runners.

❖ Carpets, rugs and runners, like furniture, are frequently changed by the occupants and are not regulated by the code. For this reason it is essential that the riser height and tread depth be regulated exclusive of these transitory surfaces to provide an enforceable standard. This practice minimizes the possible variation due to the removal of nonpermanent carpeting throughout the life of a structure and provides a standard enforcement methodology that will provide consistency across the build environment for all users. When owners or occupants add carpeting, rugs or runners, they need to add it to all tread and landing surfaces in the stairway. It is important that the tread and landing surfaces are consistent and comply with the code prior to the addition of carpet. This methodology of enforcement makes it unnecessary to reconstruct floor and stair elevations in the stairway when nonpermanent carpet surfaces are changed that do not require a building permit and eliminates the resulting variations in the built environment that will not comply with the tolerance in Section 1009.7.4 (see Figure 1009.7.1).

1009.7.2 Riser height and tread depth. Stair riser heights shall be 7 inches (178 mm) maximum and 4 inches (102 mm) minimum. The riser height shall be measured vertically between the nosings of adjacent treads. Rectangular tread depths shall be 11 inches (279 mm) minimum measured horizontally between the vertical planes of the foremost projection of adjacent treads and at a right angle to the tread’s nosing. Winder treads shall have a minimum tread depth of 11 inches (279 mm) between the vertical planes of the foremost projection of adjacent treads at the intersections with the walkline and a minimum tread depth of 10 inches (254 mm) within the clear width of the stair.

Exceptions:

1. Alternating tread devices in accordance with Section 1009.13.
2. Ship ladders in accordance with Section 1009.14.
3. **Spiral stairways** in accordance with Section 1009.12.

4. **Aisle stairs** in assembly seating areas where the stair pitch or slope is set, for sightline reasons, by the slope of the adjacent seating area in accordance with Section 1028.11.2.

5. In Group R-3 occupancies; within dwelling units in Group R-2 occupancies; and in Group U occupancies that are accessory to a Group R-3 occupancy or accessory to individual dwelling units in Group R-2 occupancies; the maximum riser height shall be $\frac{7}{14}$ inches (197 mm); the minimum tread depth shall be 10 inches (254 mm); the minimum winder tread depth at the walkline shall be 10 inches (254 mm); and the minimum winder tread depth shall be 6 inches (152 mm). A **nosing** projection not less than $\frac{3}{14}$ inch (19.1 mm) but not more than $\frac{3}{14}$ inches (32 mm) shall be provided on **stairways** with solid risers where the tread depth is less than 11 inches (279 mm).

6. See Section 3404.1 for the replacement of existing stairways.

7. In Group I-3 facilities, **stairways** providing access to guard towers, observation stations and control rooms, not more than 250 square feet (23 m²) in area, shall be permitted to have a maximum riser height of 8 inches (203 mm) and a minimum tread depth of 9 inches (229 mm).

- The riser height—the vertical dimension from tread surface to tread surface or tread surface to landing surface—is typically limited to no more than 7 inches (178 mm) nor less than 4 inches (102 mm). The minimum tread depth—the horizontal distance from the leading edge (nosing) of one tread to the leading edge (nosing) of the next adjacent tread or landing—

![Tread Depth Measurement](image)

![Tread/Riser Dimensions](image)

*For SI: 1 inch = 25.4 mm.*

- The minimum tread depth of 11 inches (279 mm) is intended to accommodate the largest shoe size found in 95 percent of the adult population, allowing for an appropriate overhang of the foot beyond the tread nosing while descending a stairway. Tread depths under 11 inches (279 mm) could cause a larger overhang (depending on the size of the foot) and could force users with larger feet to descend a stairway increasing the angle of their foot to the line of travel. Based on the probability of adequate foot placement, the rate of misstep with various step sizes and consideration for the user's
comfort and energy expenditure, it was agreed that the 11-inch (279 mm) minimum tread depth and maximum 7-inch (178 mm) riser height resulted in the reasonable proportion of riser height and tread depth for stairway construction. A minimum riser height of 4 inches (102 mm) is considered to allow the visual identification of the presence of the riser in ascent or descent.

The precise location of rectangular tread depth and riser measurements is to be perpendicular to the tread’s nosing or leading edge. This is to duplicate the user’s anticipated foot placement in traveling the stairway.

The size for a winder tread is also considered for proper foot placement along the walkline [see Figure 1009.11 and the commentary for Section 1009.6]. The dimensional requirements are consistent with the straight tread.

The exceptions apply only to the extent of the text of each exception. For example, the entire text of Section 1009.7.2 is set aside for spiral stairways conforming to Section 1009.12 (see Exception 3). However, Exception 5 allows a different maximum riser and minimum tread under limited conditions, but retains the minimum riser height and measurement method of Section 1009.7.2.

The requirements for dimensional uniformity are found in Section 1009.7.4.

Exceptions 1 and 2 are for unique elements of vertical egress. Section 1009.7.2 is not applicable to these elements because of their construction issues and limited application. For a discussion on alternating tread devices, see Section 1009.13. For ships ladders, see Section 1009.14.

Exception 3 is for spiral staircases, a unique type of stairway. Section 1009.7.2 is not applicable to this stair type, again because of construction issues and limited applications. For a discussion on spiral staircases, see Section 1009.12.

Exception 4 provides a practical exception where assembly facilities are designed for viewing. See Sections 1028.11 through 1028.11.3 for assembly aisle stair-limiting dimensions.

Exception 5 allows revisions to the 7 inches/11 inches (178 mm/279 mm) riser/tread requirements for Group R-3 and any associated utility (such as barns, connected garages or detached garages) and within individual units of Group R-2 and their associated utility areas (such as attached garages). This change is allowed because of the low occupant load and the high degree of occupant familiarity with the stairways. When this exception is taken for stairways that have solid risers, each tread is required to have a nosing projection with a minimum dimension of 1/4 inch (19.1 mm) and maximum dimension of 1/2 inch (32 mm) where the tread depth is less than 11 inches (279 mm). Nosing projections are created where the nosing of the tread above extends beyond the trailing edge of the tread below or when a solid riser is angled under the tread above and connected to the trailing edge of the tread below. Nosing projections are not required for residential stairs with open risers and 10-inch (254 mm) treads. A nosing projection provides a greater stepping surface for those ascending the stairway. For users descending the stairway, the nosing projection allows the toe of the foot to be placed further away from the riser above, providing the necessary clearance for the heel of the foot as it swings down in an arc to its position on the tread [see Figure 1009.7.3].

Exception 6 allows for the replacement of an existing stair. Where a change of occupancy would require compliance with current standards, this exception allows a stairway that may be steeper than that permitted, provided it does not constitute a hazard (see Section 3404.1). This language is consistent with that found for existing stairways in the International Existing Building Code® (IEBC®).

Exception 7 allows steeper stairs in spaces of not more than 250 square feet (23 m²) in correctional facilities (Group I-3) with a maximum riser height of 8 inches (203 mm) and a minimum tread depth of 9 inches (229 mm) because of the minimal occupant load and the familiarity of the users with the stairway. Although not stated in this exception, utilizing a nosing projection to provide effective tread depth, as stated in Exception 5 for tread depths less than 11 inches (279 mm), is a good design practice.

**1009.7.3 Winder treads.** Winder treads are not permitted in means of egress stairways except within a dwelling unit.

**Exceptions:**

1. Curved stairways in accordance with Section 1009.11.
2. Spiral stairways in accordance with Section 1009.12.

The intent of this section is to coordinate the general provisions for stairway tread and riser dimensions in Section 1009.7.2 with the provisions for winder treads permitted in curved and spiral stairways (see Sections 1009.11 and 1009.12). Winders are permitted in means of egress stairways within dwelling units where occupant loads are smaller and do not block visual clues that prompt the autonomic adjustments in the gait of the user as well as increased familiarity (see Figure 1009.7.3 and Section 1009.7.2, Exception 5). This is consistent with provisions in the International Residential Code® (IRC®).

Winders are used to change the direction of a flight by introducing a consistent incremental turn associated with each tread. The risk of injury in the use of stairways constructed with winders is considered to be greater than for stairways constructed as straight runs where users may be restricted by the presence of other users limiting visual clues or influencing the rate of travel. Additional user attention in the turn and the aid of the turn in arresting falls similar to turns at
landings is also understood to negate this.

The employment of winders in stairway construction may necessitate the change of the user’s gait in both ascent and descent where the tread depth of the winder is not equal to the tread depth of any rectangular treads in the same flight. For example, a person descending a straight flight of stairs will develop a particular gait conforming to the proportion of the riser height and tread depth that will be consistent throughout the flight. However, in a flight that includes winders and rectangular treads the user must accommodate a change in the proportion of the riser height and tread depth if the winder tread depth increases or decreases as determined by the path of travel chosen. Visual clues are important to the users’ autonomic responses to alter the path of travel, the length of the stride, or a combination of both that may result in nonconcentric movement. To ensure users of the visual clues necessary to alter their gait and limit the need to alter the path of travel in conditions of higher occupant loading, flights with winders must meet the specific safety provisions listed for curved or spiral stairways unless they are within a dwelling unit.

2. Consistently shaped winders, complying with Section 1009.7, differing from rectangular treads in the same stairway flight.

Where the bottom or top riser adjoins a sloping public way, walkway or driveway having an established grade and serving as a landing, the bottom or top riser is permitted to be reduced along the slope to less than 4 inches (102 mm) in height, with the variation in height of the bottom or top riser not to exceed one unit vertical in 12 units horizontal (8 percent slope) of stairway width. The nosings or leading edges of treads at such nonuniform height risers shall have a distinctive marking stripe, different from any other nosing marking provided on the stair flight. The distinctive marking stripe shall be visible in descent of the stair and shall have a slip-resistant surface. Marking stripes shall have a width of at least 1 inch (25 mm) but not more than 2 inches (51 mm).

- Dimensional uniformity in the design and construction of stairways contributes to safe stairway use. When ascending or descending a stair, users establish a gait based on the autonomic expectation or "feel" that each step taken will be at the same height and will land in approximately the same position on the tread as the previous steps in the pattern. A substantial change in tread or riser dimensions in a stairway flight in excess of the allowed dimensional tolerance can break the rhythm and cause a misstep, stumbling or physical strain that may result in a fall or serious injury. Therefore, this section limits the dimensional variations to a tolerance of 1/16 inch (9.5 mm) between the largest and smallest riser or tread dimension in a flight of stairs. A “flight” of stairs is defined as a run of stairs between landings.

For special conditions of construction and as a practical matter, this section allows some greater variations in stairway tread and riser dimensions than the general limitations specified above. Exception 1 addresses conditions where the seating in assembly facilities is on a sloping gradient (for sightline purposes), and the aisle stairs become an integral part of the arrangement. Exception 2 addresses winder treads, which must be consistent along the walkline [see Figure 1009.4.7(1)] when compared to other winder treads in the same flight but are not required to meet the tolerance when compared to the uniform dimension of rectangular treads in the same flight.

This section also addresses the situation where the bottom riser of a flight of stairways meets a sloped landing, such as a public way, walk or driveway [see Figure 1009.4.7(2)]. Because the sidewalk landing is sloped perpendicular to the stairway run, stopping off the bottom tread on one side will result in a higher riser than stepping off the bottom tread on the other side. This is permitted provided the bottom riser is marked so that someone using the stairs will be aware of the hazard of a nonuniform riser.

1009.7.5 Nosing and riser profile. The radius of curvature at the leading edge of the tread shall be not greater than 1/36 inch (14.3 mm). Beveling of nosings shall not exceed 1/16 inch (14.3 mm). Risers shall be solid and vertical or sloped under...
MEANS OF EGRESS

the tread above from the underside of the nosing above at an
angle not more than 30 degrees (0.52 rad) from the vertical.

- The profiles of treads and risers contribute to stairway
  safety. The radius or bevel of the nosing eases the
  otherwise square edge of the tread and prevents
  irregular chipping and wear that can become a main-
  tenance issue and seriously affect the safe use of the
  stair. In addition, it eliminates a sharp square edge
  that will cause greater injury in falls and provides a
  certain contrast from the other surfaces of the stair for
  easier visual location of the start of the tread surface.
  The \( \frac{3}{16} \) -inch (14.3 mm) limit of beveling and maxi-
  mum radius of curvature at the leading edge of the
  tread is intended to allow descending foot placement
  on a surface that does not pitch the foot forward or
  allow the ball of the foot to slide off the treads and
  ascending foot placement to slide onto the tread with-
  out catching on a square edge. This section also
  states that risers shall be solid; however, Section
  1009.7.5.3 specifically states exceptions to this
  requirement that are to be applied. The sloping of ris-
  ers allows the step profile to have a nosing projection
  without a lip that might cause a foot to catch when
  dragged up the face of the riser. Such designs are
  subject to the maximum nosing projection stated in
  Section 1009.7.5.1 that must be considered when
  choosing the angle to slope the riser.

![Figure 1009.7.4(1)]( CONSISTENTLY SHAPED WINDERS)

![Figure 1009.7.4(2)]( SLOPED LANDING)
1009.7.5.1 Nosing projection size. The leading edge (nosing) of treads shall project not more than 1 1/4 inches (32 mm) beyond the tread below.

- A nosing projection allows the descending foot to be placed further forward on the tread and the heel to then clear the nosing of the tread above as it swings down in an arc, landing on a tread that is effectively deeper than if no nosing projection is used. Nosing projections are so common in stair design that they are usually only noticed by users when they are absent since the lack of nose projection can affect one's gait. Treads with vertical risers are allowed with or without a nosing projection. A nosing projection may also be accommodated by slanting the riser under the tread above. The nosing projection is limited to 1 1/4 inch (32 mm) maximum. Treads designed with rounding or bevel on the underside would reduce the chance that a user's toe might catch while ascending the stairway [see Figure 1009.7.5.1].

1009.7.5.2 Nosing projection uniformity. All nosing projections of the leading edges shall be of uniform size, including the projections of the nosings leading edge of the floor at the top of a flight.

- See the commentary to Section 1009.7.5.1

1009.7.5.3 Solid risers. Risers shall be solid.

Exceptions:

1. Solid risers are not required for stairways that are not required to comply with Section 1007.3, provided that the opening between treads does not permit the passage of a sphere with a diameter of 4 inches (102 mm).

2. Solid risers are not required for occupancies in Group I-3 or in Group F, H and S occupancies other than areas accessible to the public. There are no restrictions on the size of the opening in the riser.

3. Solid risers are not required for spiral stairways constructed in accordance with Section 1009.12.

4. Solid risers are not required for alternating tread devices constructed in accordance with Section 1009.13.

- The code does not address when a riser could contain openings and still be considered "solid." Exception 1 allows the use of open risers on all stairs that are not part of an accessible means of egress. Where the riser is allowed to be open, the opening is limited to be consistent with the requirements for guards [see Figure 1009.7.5.3]. The code does not reference ICC A117.1 for stairways, because stairways are not part of an accessible route; however, the code and standard provide opening limitations in tread surfaces. Section 1009.6.1 does allow for treads to have a maximum opening that allows for a 1 1/4-inch (32 mm) sphere.

Exception 2 recognizes that open risers are commonly used for stairs in occupancies such as detention facilities, storage, industrial and high-hazard areas for practical reasons. In detention facilities, open risers provide a greater degree of security and supervision because of the fact that people cannot effectively conceal themselves behind the stair. Factories, high-hazard buildings and storage facilities have areas where workers may need the open risers to decrease the chance of spillage, water or snow accumulating on the stairs.

Exceptions 3 and 4 recognize open risers as necessary for adequate foot placement in spiral stairways and alternating tread devices. The 4-inch (102 mm) opening limitations of Exception 1 are not applicable to these stairs.

---

**Figure 1009.7.5.1**

Tread/Riser Profile (SOLID RISER)

For SI: 1 inch = 25.4 mm, 1 degree = 0.01745 rad.

---

2012 INTERNATIONAL BUILDING CODE® COMMENTARY 10-73
1009.8 Stairway landings. There shall be a floor or landing at the top and bottom of each stairway. The width of landings shall not be less than the width of stairways they serve. Every landing shall have a minimum width measured perpendicular to the direction of travel equal to the width of the stairway. Where the stairway has a straight run the depth need not exceed 48 inches (1219 mm). Doors opening onto a landing shall not reduce the landing to less than one-half the required width. When fully open, the door shall not project more than 7 inches (178 mm) into a landing. When wheelchair spaces are required on the stairway landing in accordance with Section 1007.6.1, the wheelchair space shall not be located in the required width of the landing and doors shall not swing over the wheelchair spaces.

Exception: Aisle stairs complying with Section 1028.

A level portion of a stairway provides users with a place to rest in their ascent or descent, to enter a stairway and to adjust their gait before continuing. Landings also break up the run of a stairway especially at a turn to aid in the arrest of falls that may occur (see Section 1009.10).

The minimum size (width and depth) of all landings in a stairway is determined by the actual width of the stairway. If Section 1009.4 requires a stairway to have a width of at least 44 inches (1118 mm) and the stairway is constructed with that minimum width, then all landings serving that stairway must be at least 44 inches (1118 mm) wide and 44 inches (1118 mm) deep [see Figure 1009.8(1)]. If a stairway is constructed wider than required, landings must increase accordingly so as to not create a bottleneck situation in the egress travel. However, when a stairway is configured so that it has a straight run, the depth of the landing between flights in the direction of egress...
travel is not required to exceed 48 inches (1219 mm), even though the actual width of the stair may exceed 48 inches (1219 mm) [see Figure 1009.8(2)].

It is not the intent of this section to require that a stairway landing be shaped as a square or rectangle. A landing turning the stairway 90 degrees (1.57 rad) or more with a curved or segmented outside periphery would be permitted, as long as the landing provides an area described by an arc with a radius equal to the actual stairway width [see Figure 1009.8(3)]. In this case, the space necessary for means of egress will be available.

The last portion of the requirement limits the extent to which doors that swing on to landings may interfere or encroach upon the required landing space. This limits the arc of the door swing on a landing, so that the effect on the means of egress is minimized [see Figure 1009.8(4)]. This is consistent with a door opening into an exit access corridor in Section 1005.7. For safety reasons and to ensure the means of egress is continually available for everyone, where an area of refuge/wheelchair space must be located on a landing, the wheelchair spaces must not be within the required landing width and the entrance door to the stair enclosure may not swing over the wheelchair spaces [see Figure 1007.3(1)].

Exception 1 provides for aisle stairs where the requirements are in Section 1028.

**1009.9 Stairway construction.** All stairways shall be built of materials consistent with the types permitted for the type of construction of the building, except that wood handrails shall be permitted for all types of construction.

- In keeping with the different levels of fire protection provided by each of the five basic types of construction designated in Chapter 6, the materials used for
stairway construction must meet the appropriate combustibility/noncombustibility requirements indicated in Section 602 for the particular type of construction of the building in which the stairway is located. This is required whether or not the stair is part of the required means of egress. Any structure supporting the stairway and the stairway enclosure must be fire-resistance rated consistent with the construction type; however, the stairway components inside the enclosure need only comply with the material limits for the type of construction.

If desired, wood handrails may be used on the basis that the fuel load contributed by this combustible component of stairway construction is insignificant and will not pose a fire hazard.

1009.9.1 Stairway walking surface. The walking surface of treads and landings of a stairway shall not be sloped steeper than one unit vertical in 48 units horizontal (2-percent slope) in any direction. Stairway treads and landings shall have a solid surface. Finish floor surfaces shall be securely attached.

Exceptions:

1. Openings in stair walking surfaces shall be a size that does not permit the passage of a 2-inch-diameter (12.7 mm) sphere. Elongated openings shall be placed so that the long dimension is perpendicular to the direction of travel.

2. In Group F, H and S occupancies, other than areas of parking structures accessible to the public, openings in treads and landings shall not be prohibited provided a sphere with a diameter of 1 7/8 inches (29 mm) cannot pass through the opening.

* It is the intent of this section that both landing and stair treads be solid and level with firmly attached surface materials; however, the 1:48 slope should be adequate to allow for drainage to limit the chance for an accumulation of water where someone might slip.

The exceptions permit the use of open grate-type material or slotted grill for stairway treads and landings in two different situations.

Exception 1 allows for a maximum 1/2-inch (12.7 mm) opening on stairway treads in public areas and serving any use (see Figure 1009.9.1). This is very beneficial on exterior stairways where snow, ice or water may accumulate. The 1/2-inch (12.7 mm) limitation is consistent with ICC A117.1 and federal accessibility requirements. The opening limitation is small enough that most shoe heels will not get stuck. If a slotted grill pattern is used, the slots must run side to side on the stairway tread, not front to back.

Exception 2 is applicable in factory, industrial, storage and high-hazard occupancies. This provision is intended to apply primarily to stairs that provide access to areas not required to be accessible, such as attics and basements.
as pits, catwalks, tanks, equipment platforms, roofs or mezzanines. Walking surfaces with limited-size openings are typically used because open grate-type material is less susceptible to accumulation of dirt, debris or moisture, as well as being more resistant to corrosion. Most commercially available grate material is manufactured with a maximum nominal 1-inch (25 mm) opening; therefore, the limitation that the openings not allow the passage of a sphere of 1 1/8 inch (29 mm) diameter allows the use of most material as well as accounting for manufacturing tolerances.

1009.9.2 Outdoor conditions. Outdoor stairways and outdoor approaches to stairways shall be designed so that water will not accumulate on walking surfaces.

- Outdoor stairways and approaches to stairways are to be constructed with a slope that complies with Section 1009.9.1 or are required to be protected such that walking surfaces do not accumulate water. While not specifically stated, any interior locations, such as near a pool, should also have the stair designed to limit the accumulation of water in order to maintain slip resistance (see Section 1003.4).

Where exterior stairways are used in moderate or severe climates, there may also be a concern to protect the stairway from accumulations of snow and ice to provide a safe path of egress travel at all times, including winter. Maintenance of the means of egress in the IFC requires an unobstructed path to allow for full instant use in case of a fire or emergency (see Section 1030.2 of the IFC). Typical methods for protecting these egress elements include roof overhangs or canopies; heated slabs; grated treads and landings; or when approved by the building official, a reliable snow removal maintenance program.

1009.9.3 Enclosures under interior stairways. The walls and soffits within enclosed usable spaces under enclosed and unenclosed stairways shall be protected by 1-hour fire-resistance-rated construction or the fire-resistance rating of the stairway enclosure, whichever is greater. Access to the enclosed space shall not be directly from within the stair enclosure.

**Exception:** Spaces under stairways serving and contained within a single residential dwelling unit in Group R-2 or R-3 shall be permitted to be protected on the enclosed side with 1 1/2-inch (12.7 mm) gypsum board.

- This section addresses the fire hazard of storage under an interior stairway, whether it is an exit access stairway or exit stairway. The stairway must be protected from a storage area under it, even if the stair is not required to be enclosed. The section also requires that the storage area not open into a stairway enclosure. This limits the potential of a fire that starts in the storage area from affecting the means of egress. The exception provides specific criteria for separation for storage areas under an interior stairway for the indicated residential occupancies.

1009.9.4 Enclosures under exterior stairways. There shall be no enclosed usable space under exterior exit stairways unless the space is completely enclosed in 1-hour fire-resistance-rated construction. The open space under exterior stairways shall not be used for any purpose.

- If the space under an exterior stairway is to be used, such as for storage, the area below the stairway must be separated from the stairway with walls and a ceiling with a fire-resistance rating of at least 1 hour. If the space under the exterior stairway is open, it must remain free and clear. A fire occurring in this space would jeopardize the use of the stairway for exiting during an emergency.

1009.10 Vertical rise. A flight of stairs shall not have a vertical rise greater than 12 feet (3658 mm) between floor levels or landings.

**Exceptions:**

1. **Aisle stairs** complying with Section 1028.

2. **Alternating tread devices** used as a means of egress shall not have a rise greater than 20 feet (6096 mm) between floor levels or landings.

3. **Spiral stairways** used as a means of egress from technical production areas.

- Between landings and platforms, the vertical rise is to be measured from one landing walking surface to another (see Figure 1009.10). The limited height provides a reasonable interval for users with physical limitations to rest on a level surface and also serves to alleviate potential negative psychological effects of long and uninterrupted stairway flights.

Exception 1 provides for aisle stairs in assembly occupancies to be regulated by Section 1028 and not by this section.

Exception 2 allows for 20 feet (6096 mm) between landings for alternating tread devices given their limited application and low occupant loads. In addition,
Exception 2 recognizes that additional vertical rise is needed for steeper devices used where space is often too restrictive for a landing.

Exception 3 allows for spiral stairways that only serve technical production areas to eliminate intermediate landings regardless of height. These stairways typically have limited use and serve areas such as catwalks or lighting booths in stadiums and theaters. In addition, there is the technical difficulty of maintaining proper headroom in a spiral stairway with an intermediate landing.

1009.11 Curved stairways. Curved stairways with winder treads shall have treads and risers in accordance with Section 1009.7 and the smallest radius shall not be less than twice the required width of the stairway.

Exception: The radius restriction shall not apply to curved stairways for occupancies in Group R-3 and within individual dwelling units in occupancies in Group R-2.

- Curved stairway construction consists of a series of winder treads that form a stairway configuration. Options are many, including circular, S-shaped, oval, elliptical, hourglass, etc. The commentary to Section 1009.7.3 regarding the possible event of nonconcentric movement on stairways with winders also applies to curved stairways. This type of stairway is allowed to be used as a component of a means of egress when tread and riser dimensions meet the requirements or exceptions of Section 1009.7. This section also requires that the shorter radius must be equal to or greater than twice the required width of the stairway to limit the degree of turning thereby expediting egress from higher occupancies (see Figure 1009.11).

The exception for residential units eliminates the minimum radius requirement where the occupants are familiar with the extent of the turning of the stair through the curve.

1009.12 Spiral stairways. Spiral stairways are permitted to be used as a component in the means of egress only within dwelling units or from a space not more than 250 square feet (23 m²) in area and serving not more than five occupants, or from technical production areas in accordance with Section 410.6.

A spiral stairway shall have a 7 1/2-inch (191 mm) minimum clear tread depth at a point 12 inches (305 mm) from the narrow edge. The risers shall be sufficient to provide a headroom of 78 inches (1981 mm) minimum, but riser height shall not be more than 9 1/2 inches (241 mm). The minimum stairway clear width at and below the handrail shall be 26 inches (660 mm).

- Spiral stairways can be used within an individual dwelling unit; from small spaces in other occupancies and from technical production areas in spaces such as theaters. Spiral stairways are permitted to provide access between the levels within a live/work unit (Section 419.3.2).

Spiral stairways are generally constructed with a fixed center pole that serves as either the primary or the only means of support from which pieshaped treads radiate to form a winding stairway. The term "spiral" in the geometrical sense describes a curve that diminishes in radius and relates to the form of the stair as viewed in perspective from above or below; however, "spiral" does not describe the actual geometry of the stair. The unique turning of spiral stairs allows the center pole to act as the guard at the inside of the stair and the typically narrow width requires users to choose a walkline along the outer perimeter near the only required handrail. On spiral stairways of larger widths, where two users can pass and restrict access to the single handrail, the provision of a handrail at both sides should be considered.

The commentary to Section 1009.7.3 regarding the possible event of nonconcentric movement on stairways with winders also applies to spiral stairways. The nature of stairway construction is such that it does not serve well when used in emergencies that require immediate evacuation, nor does a spiral stairway configuration permit the handling of a large occupant load in an efficient and safe manner. Furthermore, it is impossible for fire service personnel to use a spiral stairway at the same time and in a direction opposite that being used by occupants to exit the premises, possibly causing a serious delay in fire-fighting operations. Therefore, this section allows only very limited use of spiral stairways when part of
a required means of egress. Spiral stairways may be used in any occupancy as long as such stairways are not a component of a required means of egress.

Spiral stairways are required to have dimensional uniformity. The stairway must have a clear width of at least 26 inches (660 mm) at and below the handrail. The depth of the treads must not be less than $7\frac{1}{2}$ inches (191 mm) measured at a point that is 12 inches (305 mm) out from the narrow edge (see Figure 1009.12). Riser heights are required to be the same throughout the stairway, but are not to exceed $9\frac{1}{2}$ inches (241 mm). Minimum headroom of 6 feet, 6 inches (1981 mm) is required.

**1009.13 Alternating tread devices.** *Alternating tread devices* are limited to an element of a means of egress in buildings of Groups F, H and S from a mezzanine not more than 250 square feet (23 m²) in area and which serves not more than five occupants; in buildings of Group I-3 from a guard tower, observation station or control room not more than 250 square feet (23 m²) in area and for access to unoccupied roofs.

- This type of device is constructed in such a way that each tread alternates with each adjacent tread so that the device consists of a system of right-footed and left-footed treads (see Figure 1009.13).

  The use of center stringer construction, half-treads and an incline that is considerably steeper than allowed for ordinary stairway construction makes the alternating tread device unique. However, because of its structural feature, only single-file use of the device
MEANS OF EGRESS

(between handrails) is possible, thus preventing the occupants from passing one another. The pace of occupant travel is set by the slowest user, a condition that could become critical in an emergency situation. Furthermore, it is impossible for fire service personnel to use an alternating tread device at the same time and in a direction opposite to that being used by occupants to exit the premises, possibly causing a serious delay in fire-fighting operations. For these reasons, this section greatly restricts the use of alternating tread devices as a means of egress. Alternating tread devices may be used in any occupancy as long as such stairways are not a component of a required means of egress.

Alternating tread devices are considered a modest improvement to ladder construction and, therefore, can be used as an unoccupied roof access in accordance with the requirements of Section 1009.16.

1009.13.1 Handrails of alternating tread devices. Handrails shall be provided on both sides of alternating tread devices and shall comply with Section 1012.

- For the safety of occupants, this section references the dimensional requirements for handrail locations to be used in conjunction with the special construction features of alternating tread devices provided in Section 1009.13. Because of the steepness of these devices, handrails on both sides are essential for safe functional use and additional clearances are required so that hand movement will not be encumbered by obstructions.

1009.13.2 Treads of alternating tread devices. Alternating tread devices shall have a minimum tread depth of 3 inches (127 mm), a minimum projected tread depth of 8 1/2 inches (216 mm), a minimum tread width of 7 inches (178 mm) and a maximum riser height of 9 1/2 inches (241 mm). The tread depth shall be measured horizontally between the vertical planes of the foremost projections of adjacent treads. The riser height shall be measured vertically between the leading edges of adjacent treads. The riser height and tread depth provided shall result in an angle of ascent from the horizontal of between 50 and 70 degrees (0.87 and 1.22 rad). The initial tread of the device shall begin at the same elevation as the platform, landing or floor surface.

Exception: Alternating tread devices used as an element of a means of egress in buildings from a mezzanine area not more than 250 square feet (23 m²) in area which serves not more than five occupants shall have a minimum tread depth of 3 inches (76 mm) with a minimum projected tread depth of 10 1/2 inches (267 mm). The rise to the next alternating tread surface shall not exceed 8 inches (203 mm).

- Alternating tread stairways (see Section 1009.13) are required to have tread depths of at least 5 inches (127 mm). Tread projections are not to be less than 3 1/2 inches (89 mm) when measured from tread nosing to tread nosing [next adjacent tread to the left or right to provide a minimum projected tread depth of 8 1/2 inches (216 mm)] (see Figure 1009.13).

The risers are to be not more than 9 1/2 inches (241 mm) when measured from tread to alternating tread (next adjacent tread to the left or right). The rise between treads on the same side would be 19 inches (482 mm) maximum. Applying the limiting dimensions stated above results in a device with a very steep incline that is common to ladders; however, because the device may be walked facing down in descent it is considered a type of stairway in the code.

Tread widths are required to be a minimum of 7 inches (178 mm) or more. With a center support, the total width will be more than 15 inches (381 mm). Although no maximum width of the tread is stated, the device must be of a width to provide for functional use of both handrails at the same time in ascent and descent. For this same reason handrail heights for alternating tread devices are modified from those stairways in Section 1012.2.

Just using the dimensions could result in an alternating tread device with an angle of over 75 degrees (1.3 rad). In any case, the overall angle of the device must be between 50 and 70 degrees (0.87 and 1.22 rad).

For alternating tread devices used as a means of egress from small-area mezzanines as prescribed in the exception, the treads must project at least 7 1/2 inches (191 mm) as compared to the 3 1/2 inches (89 mm) stated above; treads are to be at least 3 inches (76 mm) in depth [compared to 5 inches (127 mm)] and risers are not to exceed 8 inches (203 mm) in height [compared to 9 1/2 inches (241 mm)].

1009.14 Ship ladders. Ship ladders are permitted to be used in Group I-3 as a component of a means of egress to and from control rooms or elevated facility observation stations not more than 250 square feet (23 m²) with not more than three occupants and for access to unoccupied roofs.

Ship ladders shall have a minimum tread depth of 5 inches (127 mm). The tread shall be projected such that the total of the tread depth plus the nosing projection is no less than 8 1/2 inches (216 mm). The maximum riser height shall be 9 1/2 inches (241 mm).

Handrails shall be provided on both sides of ship ladders. The minimum clear width at and below the handrails shall be 20 inches (508 mm).

- Ship ladders are of similar gradient or pitch to alternating tread devices; however, the treads span the full width like that of a ladder rather than being staggered to either side (see Figure 1009.14). Also similar is the need for handrails on both sides to assist in ascent and descent and the absence of a maximum width. (see Section 1009.13). Ship ladders can be used in correctional facilities for access to small control rooms, observation stations and unoccupied roofs.

Where approved by the code official, ship ladders could be used for access to unoccupied roofs in other occupancies (see Sections 1009.16 and 1009.16.1).

1009.15 Handrails. Stairways shall have handrails on each side and shall comply with Section 1012. Where glass is used
to provide the handrail, the handrail shall also comply with Section 2407.

Exceptions:

1. **Handrails for aisle stairs** provided in accordance with Section 1028.13.

2. **Stairways within dwelling units and spiral stairways** are permitted to have a handrail on one side only.

3. Decks, patios and walkways that have a single change in elevation where the landing depth on each side of the change of elevation is greater than what is required for a landing do not require handrails.

4. In Group R-3 occupancies, a change in elevation consisting of a single riser at an entrance or egress door does not require handrails.

5. Changes in room elevations of three or fewer risers within dwelling units and sleeping units in Groups R-2 and R-3 do not require handrails.

- Handrails are required along each side of a flight of stairs; however, handrails are not required along stairway landings. Handrail continuity and extensions that will overlap the landings are addressed in Sections 1012.4 and 1012.6.

- Handrails have four recognized functions in stairway use. First, they serve to guide persons in ascent and descent, especially important for those with low vision, and in cases of fire where vision might be obscured by smoke, handrails serve as guides directing the user along the path of egress travel. Second, they provide a tool for the user to exert stabilizing forces longitudinally (along the length of the rail), vertically and, most importantly, transversely (perpendicular) to the rail as the body transfers weight from side to side with each leg swing of the unique gait used on stairs. Third, they provide for pulling when arms are used to augment legs in ascent of steeper angles or when such climbing strategies result in more efficient use of the strengths of the user. Fourth, they are a tool that can be utilized to help in the arrest of a fall. In these capacities handrails serve to aid in the use of the stairway and are required on both sides of stairways in compliance with Section 1012 to allow passing users unencumbered access to a handrail. Finally, when glass is the material used to provide the handrail, it must comply with Section 2407.

- Note that if the handrail extension is at a location that could be considered a protruding object, the handrail must return to the post at a height of less than 27 inches (686 mm) above the floor. Handrails along the stair runs are not considered protruding objects.

- The exceptions state conditions where handrails are only required on one side or are not needed at all. Stepped aisles with assembly seating are addressed specifically in Section 1028 (see Exception 1). By nature or their construction, spiral stairways can only have a single handrail (see Exception 2). In accordance with Exceptions 2 and 5, within dwelling units, all stairways can have a handrail on one side only.

---

**Figure 1009.14**

**TYPICAL SHIP LADDER**

For SI: 1 inch = 25.4 mm.
and stairs with three or fewer rises are not required to have any handrails. Since "stair" is defined as one or more risers, Exceptions 3 and 4 are necessary. Exception 4 exempts the single step at the front or back door of a Group R-3 dwelling unit (i.e., townhouse). Decks, patios and walkways often move down with the grade. When there are single steps, either off the patio or deck to grade, or along the surface, a handrail is not required (Exception 3, see Figure 1009.15). Many of these exceptions dealing with residential units are consistent with the IRC.

1009.16 Stairway to roof. In buildings four or more stories above grade plane, one stairway shall extend to the roof surface, unless the roof has a slope steeper than four units vertical in 12 units horizontal (33-percent slope). In buildings without an occupied roof, access to the roof from the top story shall be permitted to be by an alternating tread device.

❖ Because of safety considerations, roofs used for habitable purposes such as roof gardens, observation decks, sporting facilities (including jogging or walking tracks and tennis courts) or other similar uses, must be provided with conventional stairways that will serve as required means of egress. Access by ladders or an alternating tread device for such uses is not permitted.

In buildings four or more stories high, roofs that are not used for habitable purposes must be provided with ready access by conventional stairways or by an alternating tread device (see Section 1009.13). If this stair is also to provide access to an elevator penthouse on the roof, see additional requirements in Section 1009.17. Two reasons for this are access for roof or rooftop equipment repair and fire department access during a fire event. Sloping roofs with a rise greater than 4 inches (102 mm) for every 12 inches (305 mm) in horizontal measurement (4:12) are exempt from the requirements of this section because of the steepness of the construction and the inherent dangers to life safety.

While it is not specifically required that roof access be through an exit stairway enclosure, since part of the intent is for fire department access to the roof, it is strongly advised. Section 1022.9 requires signage at the level of exit discharge indicating whether the stairway has roof access.

1009.16.1 Roof access. Where a stairway is provided to a roof, access to the roof shall be provided through a penthouse complying with Section 1509.2.

Exception: In buildings without an occupied roof, access to the roof shall be permitted to be a roof hatch or trap door not less than 16 square feet (1.5 m²) in area and having a minimum dimension of 2 feet (610 mm).

❖ The purpose of the penthouse or stairway bulkhead requirement in this section is to protect the walking surface of the stairway to the roof. The exception provides for situations when roof access is only needed for service or maintenance purposes, and where the access may be permitted by alternatives such as alternating tread devices, ship ladders or ladders.

1009.16.2 Protection at roof hatch openings. Where the roof hatch opening providing the required access is located within 10 feet (3049 mm) of the roof edge, such roof access or roof edge shall be protected by guards installed in accordance with the provisions of Section 1013.

❖ While guards are required at the edge of a normally occupied roof by Section 1013, there is also a safety concern for roof areas that need to be accessed by service personnel, inspectors and emergency responders. This requirement for guards provides a minimum measure of safety when the roof access is close to the room edge. This is consistent with the requirements at mechanical equipment in Sections 1013.6 and 1013.7.

1009.17 Stairway to elevator equipment. Roofs and penthouses containing elevator equipment that must be accessed for maintenance are required to be accessed by a stairway.

❖ The requirement for a stair to the roof for maintaining elevator equipment correlates the code with ASME A17.1/CSA B44, Safety Code for Elevators and Escalators. This referenced standard (see Section 3001.2) has required stairs and a door to access elevator equipment since 1955. More specifically, Section 2.27.3.2.1 of ASME A17.1/CSA B44 states the following: "A stairway with a swinging door and platform at the top level, conforming to 2.7.3.3 shall be provided from the top floor of the building to the roof level. Hatch covers as a means of access to the roofs shall not be permitted." Alternating tread devices or ladders are not permitted as an alternative to the stairway for access to the elevator penthouse. This provision is more specific; therefore, while not prohibiting using the same stairway for access to the roof and the elevator penthouse (see Sections 1009.16 and 1009.16.1), access to that elevator penthouse must be via a stairway with door access, not an alternating tread device and hatch.
SECTION 1010
RAMPs

1010.1 Scope. The provisions of this section shall apply to ramps used as a component of a means of egress.

Exceptions:

1. Other than ramps that are part of the accessible routes providing access in accordance with Sections 1108.2 through 1108.2.4 and 1108.2.6, ramped aisles within assembly rooms or spaces shall conform with the provisions in Section 1028.11.

2. Curb ramps shall comply with ICC A117.1.

3. Vehicle ramps in parking garages for pedestrian exit access shall not be required to comply with Sections 1010.4 through 1010.10 when they are not an accessible route serving accessible parking spaces, other required accessible elements or part of an accessible means of egress.

Ramps provide an alternative method of vertical means of access to or egress from a building. Ramps are required for access to building areas for persons who are mobility impaired (see Chapter 11) and for small changes in floor elevations that are a safety hazard in themselves (see Section 1003.5). All ramps intended for pedestrian usage, whether required or otherwise provided, must comply with the requirements of this section. The code considers any walking surface that has a slope steeper than one unit vertical in 20 units horizontal (5-percent slope) to be a ramp (see the definition for "Ramp" in Chapter 2).

Exception 1 clarifies that in assembly rooms with sloped floors, ramps other than the routes utilized to and from accessible wheelchair seating locations (see Section 1108.2) are permitted to be designed in accordance with the sloped aisle provisions for assembly with fixed seating in Section 1028.

Exception 2 references specific curb cut requirements found in Section 406 of ICC A117.1.

Exception 3 addresses parking garages. An accessible route is required to and from any accessible parking space, and all ramp provisions must be followed. However, ramps that provide access to and from nonaccessible spaces in the remainder of the parking garage need only comply with the provisions for slope and guard requirements. This permits non-accessible portions of garages to be constructed as a continuous slope. Ramps that are strictly for vehicles, such as jump ramps, are not required to meet any of the ramp provisions.

1010.2 Enclosure. All interior exit ramps shall be enclosed in accordance with the applicable provisions of Section 1022. Exit access ramps shall be enclosed in accordance with the provisions of Section 1009.3 for enclosure of stairways.

The protection/separation and exit access travel distance requirements for stairways and ramps are the same.

Ramps that are part of a means of egress between stories inside a building can be either exit access ramps or exit ramps. Exit ramps are ramps that provide a protected enclosed path of travel between the "exit access" and the "exit discharge." Exit ramps follow the same protection requirements as exit stairways in Section 1022. Exit access ramps can be ramps between levels on the same story or they can be ramps between stories. Section 1009.3 requires exit access stairways and ramps to be enclosed, but then provides an extensive series of exceptions. For example, ramps between stories in an outdoor facility, such as a baseball stadium, are considered exit access ramps that are not required to be enclosed (see Section 1009.3, Exception 7). The key difference between the two types is how exit access travel distance is measured. For exit ramps, the exit access travel distance is measured from the entrance to the enclosure for an exit ramp. For exit access ramps, exit access travel distance includes all travel along the ramp to an exterior door, a horizontal exit or, an enclosure for an exit. Travel distance is defined in Section 1016.3. There are exceptions for how travel distance is measured for open parking garages and outdoor facilities.

Once a level of protection is provided by an enclosure for an exit ramp, that level of protection must be maintained to an exterior door leading to the outside, to an exit passageway, through a horizontal exit or in limited situations, through a lobby or vestibule (see Section 1022.3).

Exterior exit ramps are addressed separately in Section 1026.

1010.3 Slope. Ramps used as part of a means of egress shall have a running slope not steeper than one unit vertical in 12 units horizontal (8-percent slope). The slope of other pedestrian ramps shall not be steeper than one unit vertical in eight units horizontal (12.5-percent slope).

Exception: Aisle ramp slope in a room or space used for assembly purposes shall comply with Section 1028.11.

Maximum slope is limited to facilitate the ease of ascent and to control the descent of persons with or without a mobility impairment. The maximum slope of a ramp in the direction of travel is limited to one unit vertical in 12 units horizontal (1:12) (see Figure 1010.3). Ramps in existing buildings may be permitted to have a steeper slope at small changes in elevation (see Section 3411.8.5 or Sections 410.8.5 and 705.1.4 of the IEBCC). An example of a ramp that is not part of a means of egress and, therefore, allowed to be a maximum slope of 1:8, is an industrial access ramp that provides access to a raised floor level around a piece of equipment.

The exception is a reference to spaces with assembly seating commonly found in sports facilities, theaters and lecture halls. However, the ramps that are part of an accessible route for ingress or egress are still required to meet the 1:12 maximum slope. Only the ramps used elsewhere in the assembly space
may utilize the 1:8 maximum slope permitted in Section 1028.11.

1010.4 Cross slope. The slope measured perpendicular to the direction of travel of a ramp shall not be steeper than one unit vertical in 48 units horizontal (2-percent slope).

- The limitation of one unit vertical in 48 units horizontal on the slope across the direction of travel is to prevent a severe cross slope that would pitch a user to one side (see Figure 1010.3).

1010.5 Vertical rise. The rise for any ramp run shall be 30 inches (762 mm) maximum.

- Because pushing a wheelchair up a ramp requires a great deal of energy, landings must be situated so that a person can rest after each 30-inch (762 mm) elevation change (see Figure 1010.3).

1010.6 Minimum dimensions. The minimum dimensions of means of egress ramps shall comply with Sections 1010.6.1 through 1010.6.3.

- These minimum dimension requirements allow the ramp to function as a means of egress and an accessible route.

1010.6.1 Width. The minimum width of a means of egress ramp shall not be less than that required for corridors by Section 1018.2. The clear width of a ramp between handrails, if provided, or other permissible projections shall be 36 inches (914 mm) minimum.

- The requirements for the width of a means of egress ramp are 36 inches (914 mm) minimum, similar to that established by Section 1018.2 for corridors. Note that the clear width of 36 inches (914 mm) is required between the handrails and any other obstructions (i.e., handrail supports, curbs) for proper clearance for a person in a wheelchair. This is different from stairways where handrails are permitted to project into the required width. The 36-inch (914 mm) minimum clear width between handrails is consistent with ICC A117.1 and the federal 2010 Standard.

1010.6.2 Headroom. The minimum headroom in all parts of the means of egress ramp shall not be less than 80 inches (2032 mm).

- The requirement for headroom on any part of an egress ramp is identical to the requirement of a conventional (nonspiral) stairway (see Section 1009.5). General headroom heights along the means of egress are addressed in Section 1003.2.

1010.6.3 Restrictions. Means of egress ramps shall not reduce in width in the direction of egress travel. Projections into the required ramp and landing width are prohibited.

---

**Figure 1010.3**

TYPICAL MEANS OF EGRESS RAMP

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.
Doors opening onto a landing shall not reduce the clear width to less than 42 inches (1067 mm).

- The purpose of not allowing ramps to reduce in width in the direction of egress travel is to prevent a restriction that would interfere with the flow of occupants out of a facility. This would include ramp landings in accordance with Section 1010.7.2. Handrails are the only exception in accordance with Sections 1010.6.1 and 1012.8.

Doors that open onto a ramp landing, including those at the top and bottom landings, must not reduce the clear width to less than 42 inches (1067 mm). This is a more restrictive provision than for corridors that would permit the reduction to one-half the required width (see Section 1005.7). Since one of the purposes of a ramp is to accommodate persons with physical disabilities, it must provide the additional clear width for access by those confined to wheelchairs without the interference or potential blockage caused by the swing of a door (see Figures 1010.3 and 1010.6.3).

1010.7 Landings. Ramps shall have landings at the bottom and top of each ramp. Points of turning, entrance, exit and at doors. Landings shall comply with Sections 1010.7.1 through 1010.7.5.

- Landings must be provided to allow users of a ramp to rest on a level floor surface and to adjust to the change in floor surface pitch.

Landings are required at the top and bottom of each ramp run (see Figure 1010.7). In addition, Section 1010.5 requires a landing every 30 inches (762 mm) of vertical rise of the ramp. The requirements for landings allow those occupants of the structure the ability to negotiate all changes in direction, and prepare themselves to either ascend or descend the ramp and to rest. If there is a door at the top or the bottom of the ramp, there are additional requirements in Section 1010.6.3 for door swing over the landing and Section 405 of ICC A117.1 for maneuvering space and turning space at the door.

1010.7.1 Slope. Landings shall have a slope not steeper than one unit vertical in 48 units horizontal (2-percent slope) in any direction. Changes in level are not permitted.

- Landings must be almost flat. This allows persons confined to a wheelchair to come to a complete stop without having to activate the brake or hold themselves stationary at the landing. The maximum slope or cross slope of the landing in any direction is 1:48 (see Figure 1010.3). This minimum slope is to allow for drainage to limit the accumulation of water on the landing surface.

1010.7.2 Width. The landing shall be at least as wide as the widest ramp run adjoining the landing.

- The width of all landings must be consistently as wide as the widths of the ramp runs leading to them. Means of egress ramps cannot be reduced in width in the direction of egress travel. This is also applicable to the landings connecting the ramp runs (see Figure 1010.7).
1010.7.3 Length. The landing length shall be 60 inches (1525 mm) minimum.

Exceptions:

1. In Group R-2 and R-3 individual dwelling and sleeping units that are not required to be Accessible units, Type A units or Type B units in accordance with Section 1107, landings are permitted to be 36 inches (914 mm) minimum.

2. Where the ramp is not part of an accessible route, the length of the landing shall not be required to be more than 48 inches (1220 mm) in the direction of travel.

 Vander The landings for ramps must be at least 60 inches (1524 mm) long (see Figure 1010.7). This allows persons confined to wheelchairs a sufficient distance to stop and rest along with any persons who may be assisting them. This requirement is directly applicable to straight-run ramps that may require an intermediate landing at every 30 inches (762 mm) of vertical rise (see Figure 1010.3). If the landing is also to be used to negotiate a change in the ramp’s direction, Section 1010.7.4 is applicable. If a door overlaps the landing, Section 1010.6.3 is applicable. The exceptions provide for smaller landings in dwelling and sleeping units where the ramp is not part of an accessible route. This is consistent with requirements in the IRC.

1010.7.4 Change in direction. Where changes in direction of travel occur at landings provided between ramp runs, the landing shall be 60 inches by 60 inches (1524 mm by 1524 mm) minimum.

Exception: In Group R-2 and R-3 individual dwelling or sleeping units that are not required to be Accessible units, Type A units or Type B units in accordance with Section 1107, landings are permitted to be 36 inches by 36 inches (914 mm by 914 mm) minimum.

When a change in direction is made in the ramp at a landing, the landing must be a square of at least 60 inches (1524 mm). This allows the person confined to a wheelchair enough room to negotiate the turn with minimal effort. The length of the landing may need to exceed 60 inches (1524 mm) to match the widths of the two ramp runs. In any case, the landing would still need to be 60 inches (1524 mm) wide (see Figures 1010.6.3 and 1010.7). If a door overlaps the landing, Section 1010.6.3 is applicable. It is not the intent of this provision to prohibit curved ramps. As long as the cross slope meets the limitations in Section 1010.4, the curved ramp is permitted.

The exception provides for smaller landings in dwelling and sleeping units where the ramp is not part of an accessible route. This is consistent with requirements in the IRC.

1010.7.5 Doorways. Where doorways are located adjacent to a ramp landing, maneuvering clearances required by ICC A117.1 are permitted to overlap the required landing area.

This section specifies that the area required for maneuvering to open the door and the area of the landing are allowed to overlap. It is not necessary to provide the sum of the two area requirements (see Figure 1010.6.3). Requirements for maneuvering space and turning space at the top and bottom of ramps are found in Section 405 of ICC A117.1. ICC A117.1 requires a turning space at the top or bottom landing of a ramp where the door may be locked. This allows people to turn around to travel back along the ramp.

1010.8 Ramp construction. All ramps shall be built of materials consistent with the types permitted for the type of con-
struction of the building, except that wood handrails shall be permitted for all types of construction.

- Material requirements for the type of construction as required by Section 602 for floors are also the material requirements for ramp construction.

1010.8.1 Ramp surface. The surface of ramps shall be of slip-resistant materials that are securely attached.

- As the pace of exit travel becomes hurried during emergency situations, the probability of slipping on smooth or slick floor surfaces increases. To minimize the hazard, all floor surfaces in the means of egress are required to be slip resistant. The use of hard floor materials with highly polished, glazed, glossy or finely finished surfaces should be avoided. This is consistent with Section 1003.4.

Field testing and uniform enforcement of the concept of slip resistance is not practical. One method used to establish slip resistance is that the static coefficient of friction between leather [Type 1 (Vegetable Tanned) of Federal Specification KK-L-165C] and the floor surface is greater than 0.5. Laboratory test procedures such as ASTM D 2047 can determine the static coefficient of resistance. Bulletin No. 4 entitled "Surfaces" issued by the U.S. Access Board (ATBCB) contains further information regarding slip resistance.

1010.8.2 Outdoor conditions. Outdoor ramps and outdoor approaches to ramps shall be designed so that water will not accumulate on walking surfaces.

- Outdoor ramps, landings and the approaches to the ramp must be sloped so that surfaces do not accumulate water so as to provide a safe path of egress travel at all times. While not specifically stated, any interior locations, such as near a pool, should also have the ramps designed to limit the accumulation of water in order to maintain slip resistance (see Sections 1003.4 and 1010.8.1).

Where exterior ramps are used in moderate or severe climates, there may also be a concern to protect the ramp from accumulations of snow and ice to provide a safe path of egress travel at all times, including inclement weather. Maintenance of the means of egress in the IFC requires an unobstructed path to allow for full instant use in case of a fire or emergency (see Section 1030.2 of the IFC). Typical methods for protecting these egress elements include roof overhangs or canopies, heated slabs and, when approved by the building official, a reliable snow removal maintenance program.

1010.9 Handrails. Ramps with a rise greater than 6 inches (152 mm) shall have handrails on both sides. Handrails shall comply with Section 1012.

Exception: Handrails for ramped aisles provided in accordance with Section 1028.13.

- To aid in the use of a ramp, handrails are to be provided. Handrails are intended to provide the user with a graspable surface for guidance and support. All ramps with a vertical rise greater than 6 inches (152 mm) between landings are to be provided with handrails on both sides [see Figures 1010.9(1) and 1012.2]. General strength requirements for handrails are found in Section 1012 with a reference to Section 1607.8. Note that if the handrail extension is at a location that could be considered a protruding object, the handrail extension must return to the post at a height of less than 27 inches (686 mm) above the floor. Handrails along the ramp runs are not considered protruding objects.

Depending on the configuration of the ramp and the adjacent walking surface, ramps may require a combination of handrails, edge protection and guards. See Figures 1010.9(1), 1010.9(2), 1010.9(3) and 1010.9(4) for an illustration of some of the alternatives.

For SI: 1 inch = 25.4 mm.

Figure 1010.9(1)

MEANS OF EGRESS

Figure 1010.9(2)
RAMP WITH HANDRAIL AND BARRIER

Figure 1010.9(3)
RAMP WITH HANDRAIL AND CURB

Figure 1010.9(4)
RAMP WITH HANDRAIL AND GUARD

For SI: 1 inch = 25.4 mm.
1010.10 Edge protection. Edge protection complying with Section 1010.10.1 or 1010.10.2 shall be provided on each side of ramp runs and at each side of ramp landings.

Exceptions:

1. Edge protection is not required on ramps that are not required to have handrails, provided they have flared sides that comply with the ICC A117.1 curb ramp provisions.

2. Edge protection is not required on the sides of ramp landings serving an adjoining ramp run or stairway.

3. Edge protection is not required on the sides of ramp landings having a vertical drop off of not more than \(\frac{1}{2}\) inch \((12.7 \text{ mm})\) within 10 inches \((254 \text{ mm})\) horizontally of the required landing area.

4. In assembly spaces with fixed seating, edge protection is not required on the sides of ramps where the ramps provide access to the adjacent seating and aisle accessways.

- This section of the code now addresses the comprehensive requirements for edge protection for all ramps. It must be noted that edge protection is not the same as the requirements for guards. The presence of a guard does not necessarily provide adequate edge protection and the presence of adequate edge protection does not satisfy the requirements for a guard. Edge protection is necessary to prevent the wheels of a wheelchair from leaving the ramp surface or becoming lodged between the edge of the ramp and any adjacent construction. For example, a ramp may be located relatively adjacent to the exterior wall of a building. However, between the ramp edge and the exterior wall, there is a strip of earth for landscape purposes. Without adequate edge protection, persons confined to wheelchairs could possibly have their wheels run off the side of the ramp into the landscape, causing them to tip. These requirements are consistent with Section 405 of ICC A117.1 and those in the federal 2010 Standard.

Exception 1 allows a ramp to have minimal edge protection as long as its vertical rise is 6 inches \((152 \text{ mm})\) or less. The exception is predicated on the ramp not needing any handrails, which is established by the provisions of Section 1010.9. Such a ramp would only need flared sides or returned curbs. Edge protection without handrails or guards could be a tripping hazard for ambulatory persons. For specific details of these types of edge protection, the provisions of Section 406 of ICC A117.1 for curb ramps must be followed.

Exception 2 reiterates that edge protection is not literally required entirely around a ramp landing. Obviously, edge protection is not required along that portion of the landing that directly adjoins a ramp run; it is only required along the the edges of the landing with a dropoff (other than steps of ramp runs).

Exception 3 states that edge protection is not required for those sides of a ramp landing directly adjacent to the ground surface that gently slopes away from the edge of the landing. If the grade adjacent to the ramp landing slopes no more than 1/2:10 (which equates to 1:20) away from the landing, additional edge protection is not required. Such a gradual slope would not be detrimental to persons confined to wheelchairs as they negotiate the ramp landing. Note that this exception is limited to landings, not the ramp surface itself. The ramp must meet the edge protection in Section 1010.10.1 or 1010.10.2.

Exception 4 allows for no edge protection along ramps that serve fixed seating on the side where the seats are located. If curbs were provided they would be a tripping hazard for people coming in and out of the aisle accessways between the seats.

Depending on the configuration of the ramp and the adjacent walking surface, ramps may require a combination of handrails, edge protection and guards. See Figures 1010.9(1), 1010.9(2), 1010.9(3) and 1010.9(4) for illustrations of some alternatives.

1010.10.1 Curb, rail, wall or barrier. A curb, rail, wall or barrier shall be provided to serve as edge protection. A curb must be a minimum of 4 inches \((102 \text{ mm})\) in height. Barriers must be constructed so that the barrier prevents the passage of a 4-inch-diameter \((102 \text{ mm})\) sphere, where any portion of the sphere is within 4 inches \((102 \text{ mm})\) of the floor or ground surface.

- Edge protection for ramps and ramp landings may be achieved with a built-up curb or other barrier, such as a rail, wall or guard. The barrier must be located near the surface of the ramp and landing such that a 4-inch-diameter \((102 \text{ mm})\) sphere cannot pass through any openings. An example of an effective barrier would be the bottom rail of a guard system. If the bottom rail is located less than 4 inches \((102 \text{ mm})\) above the ramp and landing surface, edge protection has been provided. If a curb option is used, the curb must be a minimum of 4 inches \((102 \text{ mm})\) high. The curb or barrier prevents the wheel of a wheelchair from running off the edge of the surface and provides people with visual disabilities a toe stop at the edge of the walking surface (see Figure 1010.10.1).

1010.10.2 Extended floor or ground surface. The floor or ground surface of the ramp run or landing shall extend 12 inches \((305 \text{ mm})\) minimum beyond the inside face of a handrail complying with Section 1012.

- An alternative to providing some type of barrier at the edge of the ramp (see Section 1010.10.1) is to make the ramp surface wider than the handrails provided at either side. The combination of the wider surface and the handrail barrier would assist in preventing a wheelchair or crutch tip from moving very far off the ramp during a temporary slip (see Figure 1010.10.1).

1010.11 Guards. Guards shall be provided where required by Section 1013 and shall be constructed in accordance with Section 1013.

- To protect the user from falls to surfaces below, guards are to be provided where the sides of a ramp or landing are more than 30 inches \((762 \text{ mm})\) above
MEANS OF EGRESS

the adjacent grade. Guards are to be constructed in accordance with Section 1013, including the minimum height of 42 inches (1067 mm) [see Figure 1010.9(4)].

Depending on the configuration of the ramp and the adjacent walking surface, ramps may require a combination of handrails, edge protection and guards. See Figures 1010.9(1), 1010.9(2), 1010.9(3) and 1010.9(4) for illustrations of some alternatives.

SECTION 1011
EXIT SIGNS

1011.1 Where required. Exits and exit access doors shall be marked by an approved exit sign readily visible from any direction of egress travel. The path of egress travel to exits and within exits shall be marked by readily visible exit signs to clearly indicate the direction of egress travel in cases where the exit or the path of egress travel is not immediately visible to the occupants. Intervening means of egress doors within exits shall be marked by exit signs. Exit sign placement shall be such that no point in an exit access corridor or exit passageway is more than 100 feet (30 480 mm) or the listed viewing distance for the sign, whichever is less, from the nearest visible exit sign.

Exceptions:

1. Exit signs are not required in rooms or areas that require only one exit or exit access.
2. Main exterior exit doors or gates that are obviously and clearly identifiable as exits need not have exit signs where approved by the building official.
3. Exit signs are not required in occupancies in Group U and individual sleeping units or dwelling units in Group R-1, R-2 or R-3.
4. Exit signs are not required in dayrooms, sleeping rooms or dormitories in occupancies in Group I-3.
5. In occupancies in Groups A-1 and A-5, exit signs are not required on the seating side of vomitories or openings into seating areas where exit signs are provided in the concourse that are readily apparent from the vomitories. Egress lighting is provided to identify each vomitory or opening within the seating area in an emergency.

WHERE AN OCCUPANCY HAS TWO OR MORE REQUIRED EXITS OR EXIT ACCESSES, THE MEANS OF EGRESS MUST BE PROVIDED WITH ILLUMINATED SIGNS THAT READILY IDENTIFY THE LOCATION OF, AND INDICATE THE PATH OF TRAVEL TO, THE EXITS. THE SIGNS MUST BE ILLUMINATED WITH LETTERS READING “EXIT.” THE ILLUMINATION MAY BE INTERNAL OR EXTERNAL TO THE SIGN. THE SIGNS SHOULD BE VISIBLE FROM ALL DIRECTIONS IN THE EXIT ACCESS ROUTE. IN CASES WHERE THE SIGNS ARE NOT VISIBLE TO THE OCCUPANTS BECAUSE OF LIGHTS IN THE CORRIDOR OR FOR OTHER REASONS, ADDITIONAL ILLUMINATED SIGNS MUST BE PROVIDED INDICATING THE DIRECTION OF EGRESS TO AN EXIT. “EXIT” SIGNS MUST BE LOCATED SO THAT, WHERE REQUIRED, THE NEAREST ONE IS WITHIN 100 FEET (30 480 MM), OF THE SIGN’S LISTED VIEWING DISTANCE. UL 924 PERMITS EXIT SIGNS TO BE LISTED WITH A VIEWING DISTANCE OF LESS THAN 100 FEET (30 480 MM) (SEE SECTION 1011.5). WHEN A SIGN IS LISTED FOR A VIEWING DISTANCE OF LESS THAN 100 FEET (30 480 MM) THE LABEL ON THE SIGN WILL INDICATE THE APPROPRIATE VIEWING DISTANCE. IF SUCH A SIGN IS USED, THE SPACING OF THE SIGNS SHOULD BE BASED ON THE LISTED VIEWING DISTANCE.

Typically, once an occupant enters an exit enclosure, exit signs are no longer needed; however, in buildings with more complicated egress layouts, it is possible that the direction for egress travel within the exit is not immediately apparent. For example, exit passageways can be part of the path of exit travel at the level of exit discharge or transfer floors. Evacuees may hesitate or be confused when the vertical travel becomes horizontal travel, which may result in a delay in evacuation. In these situations, exit signs may be needed within the exit enclosure (see Figure 1011.1).

The exceptions identify conditions where exit signs are not necessary since they would not increase the safety of the egress path.

For Exceptions 1 and 3, the assumption is that the occupants are familiar enough with the space to know the way out and/or the exits are obvious; in addition, in most cases, the way out is the same as the way in.
In accordance with Exception 2, when the exit is identifiable in itself and is also the main exterior door through which the occupants entered the building, "Exit" signs are not required. For example, a two-story Group B building has a main employee/customer entrance. The entrance consists of a storefront arrangement with glass doors and sidelights. The entrance is centrally located within the building. These main exterior exit doors can be quickly observed as being an exit and would not need to be marked with an "Exit" sign.

In accordance with Exception 4, "Exit" signs are not required in detainee living and sleeping room areas of Group I-3 buildings. In cases of emergency, occupants in Group I-3 are escorted by staff to the exits and to safety. "Exit" sign materials can also be potential weapons when they are accessible to the detainees.

In the Group A-4 and A-5 occupancies described in Exception 5, the egress path is obvious and thus exit signs are not needed. Additionally, because of the configuration of the vomitories, the "Exit" signs are not readily visible to the persons immediately adjacent to or above the vomitory.

1011.2 Floor-level exit signs in Group R-1. Where exit signs are required in Group R-1 occupancies by Section 1011.1, additional low-level exit signs shall be provided in all areas serving guestrooms in Group R-1 occupancies and shall comply with Section 1011.5.

The bottom of the sign shall be not less than 10 inches (254 mm) nor more than 12 inches (305 mm) above the floor level. The sign shall be flush mounted to the door or wall. Where mounted on the wall, the edge of the sign shall be within 4 inches (102 mm) of the door frame on the latch side.

Due to people sleeping and that most residents are transient (and thus unfamiliar with the space) in hotels (i.e., Group R-1), for the routes for emergency exiting leading from the guestrooms, low level "EXIT" signs must be provided. When smoke at the ceiling obscures the exit signs required by Section 1011.1, these signs will serve as a backup identification of the exit door. By the reference to Section 1011.5, these signs must be internally illuminated and listed and labeled in accordance with UL 924. It is not the intent of this section to require low level "EXIT" signs in the guestrooms. The low level "EXIT" signs are required only in areas where Section 1011.1 requires "EXIT" signs and only leading from the guestroom area, not throughout the entire hotel.

The "EXIT" signs must be mounted on the exit door itself or to the side of the exit door on the latch side. The height of the bottom of the exit sign will allow for exit signs not to conflict with accessible route requirements. ICC A117.1 requires doors on an accessible route to have a smooth surface for the bottom 10 inches (254 mm) so that someone could use the footplates on their wheelchair to assist in opening the door.

The requirements do not indicate what low level signage is appropriate for "EXIT" signs that provide direction rather than at the exit. It is also not clear on how an "EXIT" sign on a door will be visible from down the corridor if the door is perpendicular to the direction of the hallway.

---

**Figure 1011.1**

EXIT SIGNS WITHIN AN EXIT ENCLOSURE
1011.3 Illumination. Exit signs shall be internally or externally illuminated.

Exception: Tactile signs required by Section 1011.4 need not be provided with illumination.

This section simply provides the scope for illumination of regulated "Exit" signs. "Exit" signs must be illuminated so that they are readily apparent in situations where the lights may be off or the building has lost power. "Exit" signs with raised letters and Braille are specifically addressed in Section 1011.4.

1011.4 Raised character and Braille exit signs. A sign stating EXIT in raised characters and Braille and complying with ICC A117.1 shall be provided adjacent to each door to an area of refuge, an exterior area for assisted rescue, an exit stairway, an exit ramp, an exit passageway and the exit discharge.

"Tactile" is defined as "used for the sense of touch;" therefore, signage that has either raised letters or Braille is considered tactile. For exit signage, both raised letters and Braille are required. ICC A117.1 includes requirements for the sign and the correct placement. Typically the sign is placed at about 4 feet, 6 inches (1375 mm) above the floor and on the wall at the latch side of the door. While not required to be illuminated by these provisions or to meet the visibility provisions in ICC A117.1, high contrast raised letters would be advantageous for a person with partial sight.

This signage is needed to indicate which doors are serving as exits for those persons with visual impairments. Signs are needed on the required exit doors in the building: including at doors leading to an interior or exterior exit stairway or ramp; doors leading to an exit passageway; within the exit enclosures leading to the outside or to an exit passageway; and exit doors that lead directly to the outside.

While an area of refuge may be located within an enclosure for an exit stairway, Section 1007.3 also allows the area of refuge to be located immediately outside of the enclosure for the exit stairway. In this situation, exit signage with raised letters and Braille would be required both at the door leading into the area of refuge and the door leading to the exit stairway. Exterior areas for assisted rescue are typically located immediately outside of an exit door (see Section 1007.7).

This is not intended to preclude the signage from including additional information as long as "Exit" is first. For example, labeling the door to the exit enclosure as "Exit Stairway" would indicate to the visually impaired person that once they moved through the door they would be dealing with vertical travel. This could be considered an additional safety feature. This section is also referenced in Section 1110.3.

1011.5 Internally illuminated exit signs. Electrically powered, self-luminous and photoluminescent exit signs shall be listed and labeled in accordance with UL 924 and shall be installed in accordance with the manufacturer’s instructions and Chapter 27. Exit signs shall be illuminated at all times.

All exit signage must be listed and labeled as indicated in UL 924, Standard for Safety of Emergency Lighting and Power Equipment. Listed "Exit" signs are required by UL 924 to meet the same graphics, illumination and power sources defined in Sections 1011.6.1 through 1011.6.3 for externally illuminated signs. Internal illumination may be electrically powered or be of a self-luminous or photoluminescent product. Electrically powered would include LED, incandescent, fluorescent and electroluminescent types of signs. If a sign is photoluminescent, the "charging" source must be continually available (see the definitions in Chapter 2 for "Photoluminescent" and "Self-luminous"). "Exit" signs must be illuminated at all times, including when the building may not be fully occupied. If a fire occurs late at night, there may be cleaning crews or persons working overtime in the building who will need to be able to find the exits. The reference to Chapter 27 is so the signs will be equipped with a connection to an emergency power supply.

1011.6 Externally illuminated exit signs. Externally illuminated exit signs shall comply with Sections 1011.6.1 through 1011.6.3.

Externally illuminated exit signage must meet the graphic, illumination and emergency power requirements in the referenced sections. The requirements are the same as for internally illuminated signage.

1011.6.1 Graphics. Every exit sign and directional exit sign shall have plainly legible letters not less than 6 inches (152 mm) high with the principal strokes of the letters not less than \(\frac{3}{8}\) inch (19.1 mm) wide. The word "EXIT" shall have letters having a width not less than 2 inches (51 mm) wide, except the letter "I," and the minimum spacing between letters shall not be less than \(\frac{3}{16}\) inch (9.5 mm). Signs larger than the minimum established in this section shall have letter widths, strokes and spacing in proportion to their height.

The word "EXIT" shall be in high contrast with the background and shall be clearly discernible when the means of exit sign illumination is or is not energized. If a chevron directional indicator is provided as part of the exit sign, the construction shall be such that the direction of the chevron directional indicator cannot be readily changed.

Every "Exit" sign and directional sign located in the exit access or exit route is required to have a color contrast vivid enough to make the signs readily visible, even when not illuminated. Letters must be at least 6 inches (152 mm) high and their stroke not less than \(\frac{3}{8}\) inch (19.1 mm) wide (see Figure 1011.6.1). The sizing of the letters is predicated on the readability of the wording from a distance of 100 feet (30 480 mm).

While red letters are common for "Exit" signs,
sometimes green on black is used in auditorium areas with low lighting levels, such as theaters, because that color combination tends not to distract the audience's attention. It is more important that the "Exit" sign be readily visible with respect to the background.

"Exit" signs may be larger than the minimum size specified; however, the standardized proportion of the letters must be maintained. Externally illuminated signage that is smaller could use the requirements in UL 924 for guidance; however, sign spacing would need to be adjusted, and alternative approval would be through the building official having jurisdiction.

A "chevron directional indicator" is the same as a directional arrow. The language is intended to be consistent with UL 924.

power sources for a duration of not less than 90 minutes, in case of primary power loss, are not required to be connected to an emergency electrical system.

"Exit" signs must be illuminated on a continuous basis so that when a fire emergency occurs, occupants will be able to identify the locations of the exits. The reliability of the power sources supplying the electrical energy required for maintaining the illumination of exit signs is important. When power interruptions occur, "Exit" sign illumination must be obtained from an emergency power system. This does not imply that the sign must be internally illuminated. Whatever illumination system is used, whether internal or external, it must be connected to a system designed to pick up the power load required by the "Exit" signs after loss of the normal power supply.

Where self-luminous signs are used, connection to the emergency electrical supply system is not required.

The IFC requirements for emergency power for emergency egress lighting and exit signage in existing buildings only requires a 60-minute time duration. This is not a conflict, but rather recognition of the loss of battery storage capability over a length of time.

SECTION 1012
HANDRAILS

1012.1 Where required. Handrails for stairways and ramps shall be adequate in strength and attachment in accordance with Section 1607.8. Handrails required for stairways by Section 1009.15 shall comply with Sections 1012.2 through 1012.9. Handrails required for ramps by Section 1010.9 shall comply with Sections 1012.2 through 1012.8.

Handrails are required at stairways and ramps. In all situations, they must be designed in accordance with the structural requirements in Section 1607.8. There are, however, distinct differences in how the handrail requirements are applied in stairways and ramps. The specific section references allow for this consideration. Stairways and their handrails are not part of an accessible route and are not subject to the stairway technical requirements in ICC A117.1. Handrails are also very distinct from guards, even though they are sometimes incorrectly called "guardrails." The "handrail" is the element that is grasped during vertical travel, for guidance, stabilization, pulling and as an aid in arresting a possible fall. Guards are located near the side of an elevated walking surface to minimize the possibility of a fall to a lower level and are discussed in Section 1013. In residential applications, however, the top rail of a guard when located at handrail height may also serve as a handrail.

1012.2 Height. Handrail height, measured above stair tread nosings, or finish surface of ramp slope, shall be uniform, not less than 34 inches (864 mm) and not more than 38 inches (965 mm). Handrail height of alternating tread devices and
ship ladders, measured above tread nosings, shall be uniform, not less than 30 inches (762 mm) and not more than 34 inches (864 mm).

Exceptions:

1. When handrail fittings or bendings are used to provide continuous transition between flights, the fittings or bendings shall be permitted to exceed the maximum height.

2. In Group R-3 occupancies; within dwelling units in Group R-2 occupancies; and in Group U occupancies that are associated with a Group R-3 occupancy or associated with individual dwelling units in Group R-2 occupancies; when handrail fittings or bendings are used to provide continuous transition between flights, transition at winder treads, transition from handrail to guard, or when used at the start of a flight, the handrail height at the fittings or bendings shall be permitted to exceed the maximum height.

- It has been demonstrated that for safe use, the height of handrails must not be less than 34 inches (864 mm) nor more than 38 inches (965 mm) above the leading edge of stairway treads, landings or other walking surfaces (see Figure 1012.2). This requirement is applicable for all uses, including handrails within a dwelling unit.

The fundamental stairway requirements are not appropriate for alternating tread devices and ship ladders since they differ significantly from other types of stairways. The permitted range for handrail height for alternating tread devices and ship ladders allows for a lower height above the tread nosings. The minimum required height is reduced from 34 inches (864 mm) to 30 inches (762 mm), with a maximum permitted height of 34 inches (864 mm). The special features of an alternating tread device or ship ladder result in differences of handrail use, such as different arm posture, the hand gripping the handrail near a higher part of the body and the use of handrails under the arms for stabilization when descending. Therefore, a lower handrail height is more appropriate.

The exceptions allow for the use of common fittings and bendings to provide for continuous transition of the handrail at specified turns and pitch changes in the stairway where the fitting or bending might exceed the maximum handrail height. In some cases, there is no reference for the height when the fitting or handrail might extend beyond the nosings at the intersection of adjoining flights. Exception 1 applies to all stairways between flights. This typically occurs at the center handrail at the landings on a dogleg or switchback stairway configuration. Although the handrails are not required on the landing, the code requirement for handrail extensions or for handrail continuity often creates the need for some type of transition, especially at turns (see also Section 1012.6). This exception would allow for an easing or gooseneck riser over the landing to be used for a smooth transition of the handrail. The use of the new exceptions may permit a more gradual variation in the height even though it will allow for portions of the handrail to exceed the normal 38-inch (965 mm) maximum height. The belief is that handrail continuity is more important than staying within the height limitation.

Exception 2 applies to dwelling units with the intent to allow transition elements at common locations, such as the start of the flight, at winder treads or from handrail to guard at landings. Combined with the guard height reduction in Section 1013.3, Exception 1, the end result may be fewer transition pieces. This is consistent with provisions in the IRC.

![Figure 1012.2 Handrail Requirements](image)

**Figure 1012.2**

**HANDRAIL REQUIREMENTS**

1012.3 Handrail graspability. All required handrails shall comply with Section 1012.3.1 or shall provide equivalent graspability.

Exception: In Group R-3 occupancies; within dwelling units in Group R-2 occupancies; and in Group U occupancies that are accessory to a Group R-3 occupancy or accessory to individual dwelling units in Group R-2 occupancies; handrails shall be Type I in accordance with
Section 1012.3.1, Type II in accordance with Section 1012.3.2 or shall provide equivalent graspability.

- The ability of grasping a handrail firmly and sliding the hand along the rail’s gripping surface without meeting obstructions are important factors in the safe use of stairways and ramps. These properties are largely a function of the shape of the handrail. Handrails for stairways and ramps must meet the specifications of Section 1012.3.1 or be determined to have grasping properties and attributes equivalent to profiles allowed in Section 1012.3.1. Such determinations of equivalence are an allowed option made by local building officials based on the profile presented and the building official’s evaluation of its properties. A complete evaluation will consider the four basic functions of a handrail: guidance, stabilization, pulling and aid in arresting a fall. The determination is best made by comparative use on stairs or ramps of properly mounted samples. Handrails that meet neither Type I or Type II characteristics may be considered to have equivalent graspability. Complete evaluation will also consider the mounting of the handrail and understanding the interference of handrail mounts on the gripping surfaces of smaller profiles that may require access to the bottom surface to obtain a grasp that is just as effective in use as being mounted on the stairway. For a discussion of this, see Section 1012.4.

The exception allows for an alternative, Type II handrail, within residential units and their associated structures. A handrail on common stairways within an apartment building or on the steps to the front door of a townhouse could not use this exception unless approved by the building official as being equivalent to Type I. The residential allowance is consistent with the IRC.

1012.3.1 Type I. Handrails with a circular cross section shall have an outside diameter of at least 1-1/4 inches (32 mm) and not greater than 2 inches (51 mm). Where the handrail is not circular, it shall have a perimeter dimension of at least 4 inches (102 mm) and not greater than 6-1/4 inches (160 mm) with a maximum cross-sectional dimension of 2-1/4 inches (57 mm) and minimum cross-sectional dimension of 1 inch (25 mm). Edges shall have a minimum radius of 0.01 inch (0.25 mm).

- Handrails have traditionally been regulated as either circular or noncircular rails. The noncircular rails have previously been limited to a maximum perimeter dimension of 6-1/4 inches (160 mm), with other limitations addressing minimum perimeter and minimum and maximum cross-sectional dimensions. These handrails shapes are now referred to as Type I handrails.

Type I handrails include circular cross sections with an outside diameter of at least 1-1/4 inches (32 mm) but not greater than 2 inches (51 mm). This limits the perimeter of the cross section such that the gripping surface incorporates the bottom of the rail. A handrail with either a very narrow or a large cross section is not grasappable in a power grip by all able-bodied users and certainly not by those with hand-strength or flexibility deficiencies. A power grip typically accesses the bottom surface of the handrail, such as around a bar. A pinching grip is not as effective when there is a need to arrest a fall. An example of a pinching grip would be where a 2x4 stud on edge was used as a handrail. This would not comply with graspability concerns.

Noncircular Type I cross sections must meet the alternative noncircular criteria in this section, and the bottom of the rail must be considered part of the suitable gripping surface. Of note is that this criteria now includes a minimum cross section of 1 inch (25 mm) to provide for designs that reduce the interference of fingers and an opposing thumb that occurs when small objects are tightly grasped. Edges must be slightly rounded and not sharp. An example is shown in Figure 1012.3.1.

Ramp requirements in ICC A117.1 are referenced as part of the accessible route requirements in Chapter 11. Current handrail provisions are largely coordinated with the Type I handrail requirements in this section. Section 103 of ICC A117.1 would also permit alternative handrail shapes if they provided equivalent or better graspability.

![Figure 1012.3.1
EXAMPLE OF TYPE I ALTERNATIVE HANDRAIL CONFIGURATION](image)

For SI: 1 inch = 25.4 mm.

1012.3.2 Type II. Handrails with a perimeter greater than 6-1/4 inches (160 mm) shall provide a grasappable finger recess area on both sides of the profile. The finger recess shall begin within a distance of 5/16 inch (19 mm) measured vertically from the tallest portion of the profile and achieve a depth of at least 1/16 inch (8 mm) within 1/8 inch (22 mm) below the widest portion of the profile. This required depth shall continue for at least 1/4 inch (10 mm) to a level that is not less than 1/4 inches (45 mm) below the tallest portion of the profile. The minimum
width of the handrail above the recess shall be $1\frac{1}{4}$ inches (32 mm) to a maximum of $2\frac{3}{4}$ inches (70 mm). Edges shall have a minimum radius of 0.01 inch (0.25 mm).

- Handrail profiles having a perimeter dimension greater than $6\frac{3}{4}$ inches (160 mm), identified as Type II handrails, are acceptable within dwelling units and their associated structures when complying with all of the specific dimensional requirements.

Research has shown that Type II handrails have grabability that is essentially equal to or greater than the graspability of handrails meeting the long-accepted and codified shape and size now defined as Type I.

The key features of the graspability of Type II handrails are graspable finger recesses on both sides of the handrail. These recesses allow users to firmly grip a properly proportioned grasping surface on the top of the handrail, ensuring that the user can tightly retain a power-span grip on the handrail for all forces that are associated with attempts to arrest a fall.

This class of handrails incorporates a grip surface with controlled recesses for the purchase of the fingers and opposing thumb. These handrail shapes allow the use of the power-span grip that need not encompass the bottom surfaces of the rail allowing the design of taller cross sections that can eliminate the interference of mountings and provide a completely uninterrupted gripping surface for the user. The limits of the position and depth of the required recesses represent the minimum standard. Optimizing the design within the parameters with larger recesses and complete finger clearance from mountings will enhance the performance of these profiles. Although this standard allows design flexibility, it is important to follow the specifications accurately to comply. Each drawing in Figure 1012.3.2 illustrates the requirements of each sentence for clarity.

**1012.4 Continuity.** Handrail gripping surfaces shall be continuous, without interruption by newel posts or other obstructions.

**Exceptions:**

1. *Handrails within dwelling units* are permitted to be interrupted by a newel post at a turn or landing.

2. Within a dwelling unit, the use of a volute, turnout, starting easing or starting newel is allowed over the lowest tread.

3. Handrail brackets or balusters attached to the bottom surface of the handrail that do not project horizontally beyond the sides of the handrail within $1\frac{1}{4}$ inches (38 mm) of the bottom of the handrail shall not be considered obstructions. For each $\frac{1}{2}$ inch (12.7 mm) of additional handrail perimeter dimension above 4 inches (102 mm), the vertical clearance dimension of $1\frac{1}{4}$ inches (38 mm) shall be permitted to be reduced by $\frac{1}{4}$ inch (3 mm).

4. Where handrails are provided along walking surfaces with slopes not steeper than 1:20, the bottoms of the handrail gripping surfaces shall be permitted to be obstructed along their entire length where they are integral to crash rails or bumper guards.

- Handrails must be usable for their entire length without requiring the users to release their grasp. Typi-
cally, when using the handrail while traveling the means of egress, an individual’s arm is extended to lead the body with the hand forming a loose grip on the top and sides of the rail. If handrails are to be of service to users, they must be uninterrupted and continuous. Oversize newels, changes in the guard system, or excessive supports at the bottom of small perimeter handrails can cause interruption of the handrail, requiring the occupants to release their grip [see Figure 1012.4(1)]. Exception 1 allows the interruption of the handrail by a newel post at the intersection of two handrail sections at a turn within a flight or at a landing in dwelling units; however, this exception is not applicable to curved or spiral stairs. Exception 2 provides for familiar and historical handrail details, often combined with guards, that have been used for decades in dwelling units without substantiated incidence to the safety of the occupants. Exception 3 provides specifications for the attachment of brackets and balusters to the bottom of handrails to provide for minimum finger clearance such that they will not be considered obstructions. This method of handrail support limits interruptions of the grip surfaces at the bottom of smaller perimeter shapes that otherwise would deter or impede the user’s ability to attain a stabilizing grip that is essential to safe stairway use. Larger handrail sizes permit shorter brackets since geometrically the finger clearance is still maintained [see Figure 1012.4(2)]. For example, a Type II handrail may elevate the fingertips completely above the supports, allowing the rail to be mounted by other means that do not obstruct when providing the clear-

---

For SI: 1 inch = 25.4 mm.
MEANS OF EGRESS

ances specified. Exception 4 allows for products that serve dual purposes, such as the bumper guard/handrail found in hospitals and nursing homes along corridors, to have a continuous bottom support. Since these are only permitted on slopes that are less than what is defined as a ramp, the handrails are more for assistance in mobility or balance rather than to arrest a fall.

1012.5 Fittings. Handrails shall not rotate within their fittings.

- Fittings are those component pieces of a continuous handrail that are shaped or bent and attached to the longer sections of straight or curved handrail to provide for transition at changes in pitch, direction or to provide for termination of a continuous handrail. Fittings and handrails must be securely joined to ensure a stable handrail that does not allow any portion to rotate when grasped.

1012.6 Handrail extensions. Handrails shall return to a wall, guard or the walking surface or shall be continuous to the handrail of an adjacent stair flight or ramp run. Where handrails are not continuous between flights, the handrails shall extend horizontally at least 12 inches (305 mm) beyond the top riser and continue to slope for the depth of one tread beyond the bottom riser. At ramps where handrails are not continuous between runs, the handrails shall extend horizontally above the landing 12 inches (305 mm) minimum beyond the top and bottom of ramp runs. The extensions of handrails shall be in the same direction of the stair flights at stairways and the ramp runs at ramps.

Exceptions:

1. Handrails within a dwelling unit that is not required to be accessible need extend only from the top riser to the bottom riser.

2. Aisle handrails in rooms or spaces used for assembly purposes in accordance with Section 1028.13.

3. Handrails for alternating tread devices and ship ladders are permitted to terminate at a location vertically above the top and bottom risers. Handrails for alternating tread devices and ship ladders are not required to be continuous between flights or to extend beyond the top or bottom risers.

The purpose of return requirements at handrail ends is to prevent a person from catching an article of clothing or satchel straps or from being injured by falling onto the extended end of a handrail.

The length that a handrail extends beyond the top and bottom of a stairway, ramp or intermediate landing where handrails are not continuous to another stair flight or ramp run is an important factor for the safety of the users. An occupant must be able to grasp securely a handrail beyond the last riser of a stairway or the last sloped segment of a ramp. Handrail terminations that bend around a corner do not provide this stability; therefore, the handrail must extend in the direction of the stair flight or ramp run. The handrail extensions are not required where a user could keep his or her hand on the handrail, such as the continuous handrail at the landing of a switchback stairway or ramp (see Section 1012.2, Exception 1).

For stairways, handrails must be extended 12 inches (305 mm) horizontally beyond the top riser and sloped a distance of one tread depth beyond the bottom riser. For ramps, handrails must be extended 12 inches (305 mm) horizontally beyond the last sloped ramp segment at both the top and bottom locations. These handrail extensions are not required at the top and bottom on both sides of stairways and ramps, but also at other places where handrails are not continuous, such as landings and platforms. These requirements are intended to reflect the current provisions of ICC A117.1 (see Figure 1012.2) and the 2010 Standard. Note that if the handrail extension is at a location that could be considered a protruding object, the handrail must return to the post at a height of less than 27 inches (686 mm) above the floor (see Sections 1003.3.2 and 1003.3.3).

In accordance with Exception 1, handrail extensions are not required where a dwelling unit is not required to meet any level of accessibility (i.e., Accessible unit, Type A unit or Type B unit). Handrail extensions are permitted to end at a newel post or turnaround. Exception 2 provides for handrails along ramped or stepped aisles in assembly seating configurations, such as in sports facilities, theaters and lecture halls. It is necessary to have discontinuous handrails in assembly aisles to provide for circulation. Such discontinuous handrails must still extend the full run of the aisle stairs or ramp. Exception 3 allows for the unique construction considerations for alternating tread devices and ship ladders. Again, usage of these devices is very limited. Since alternative tread devices and ship ladders are typically utilized as a safer alternative to a vertical ladder, they are often located in tight spaces where traditional-type stairs cannot be used or are not required. With a much steeper angle than traditional stairs and differing usage, the practicality of the handrail extensions and continuity provisions was not deemed appropriate.

1012.7 Clearance. Clear space between a handrail and a wall or other surface shall be a minimum of 11/2 inches (38 mm). A handrail and a wall or other surface adjacent to the handrail shall be free of any sharp or abrasive elements.

- A clear space is needed between a handrail and the wall or other surface to allow the user to slide his or her hand along the rail with fingers in the gripping position without contacting the wall surface, which could have an abrasive texture. In climates where persons may be expected to be wearing heavy gloves during the winter, an open design with greater clearance would be desirable at an exterior stairway, or a stairway directly inside the entrance to a building. [See Figures 1012.4(2) and 1012.8(2) for an illustration of handrail clearance.]
1012.8 Projections. On ramps, the clear width between handrails shall be 36 inches (914 mm) minimum. Projections into the required width of stairways and ramps at each side shall not exceed 4 1/2 inches (114 mm) at or below the handrail height. Projections into the required width shall not be limited above the minimum headroom height required in Section 1009.5. Projections due to intermediate handrails shall not constitute a reduction in the egress width.

- Handrails may not project more than 4 1/2 inches (114 mm) into the required width of a stairway, so that the clear width of the passage will not be seriously reduced [see Figure 1012.8(1)]. This is consistent with Section 1003.3.3. This projection may exist below the handrail height as well [see Figure 1012.8(2)]. The projection can be greater on stairways or ramps exceeding minimum width requirements.

The requirement for some stairs to have center handrails (Section 1012.9) could result in a single or double handrail down the center of the flight of stairs.

Figure 1012.8(1)
TYPICAL HANDRAIL ARRANGEMENT

Figure 1012.8(2)
PROJECTION OF HANDRAIL

For St: 1 inch = 25.4 mm.
MEANS OF EGRESS

Since these stairways are 60 inches (1525 mm) or wider, a center handrail would typically not be an obstruction and, therefore, would not reduce the capacity of the stairway. Schools and large assembly spaces commonly put in center handrails to aid in the flow up and down the stairs during peak usage times.

1012.9 Intermediate handrails. Stairways shall have intermediate handrails located in such a manner that all portions of the stairway width required for egress capacity are within 30 inches (762 mm) of a handrail. On monumental stairs, handrails shall be located along the most direct path of egress travel.

- In order to always be available to the user of the stairway, the maximum horizontal distance to a handrail from within the required width must not exceed 30 inches (762 mm). People tend to walk close to handrails, and if intermediate handrails are not provided for very wide stairways, the center portion of such stairways will normally receive less use. More importantly, in emergencies, the center portions of wide stairways with handrails would enhance egress travel rather than delay it by overcrowding at the sides with the handrails. This would especially be true under panic conditions where the use of wide interior stairways could become particularly hazardous.

The distance to the handrail applies to the "required width" of the stairway. If a stairway is greater than 60 inches (1524 mm) in width, but only 60 inches (1524 mm) total width is required based on occupant load (see Section 1005.3.1), intermediate handrails are not required. Adequate safety is provided since every user is within 30 inches (762 mm) of a handrail.

Monumental stairways are typically provided for architectural effect and may or may not be considered required egress stairs. The criteria for monumental egress stairways deal with the very wide stairway in relation to the required width. While handrails on both sides of the stairway may be sufficient to accommodate the required width, the handrails may not be near the stream of traffic or even apparent to the user. In this case, the handrails are to be placed in a location more reflective of the egress path (see Figure 1012.9).

SECTION 1013 GUARDS

1013.1 General. Guards shall comply with the provisions of Sections 1013.2 through 1013.7. Operable windows with sills located more than 72 inches (1.83 m) above finished grade or other surface below shall comply with Section 1013.8.

- Guards required along dropoffs must comply with the provisions for height, strength and opening limitations. Special provisions are provided for unique locations, such as screened-in porches, around mechanical equipment on platforms or roofs and at hatch openings.

Where there are operable windows on upper floors, there is a concern over the possibility of a child falling; thus, the placement of this requirement is in the guard section. Such windows must comply with Section 1013.8.

1013.2 Where required. Guards shall be located along open-sided walking surfaces, including mezzanines, equipment platforms, stairs, ramps and landings that are located more than 30 inches (762 mm) measured vertically to the floor or grade below at any point within 36 inches (914 mm) horizontally to the edge of the open side. Guards shall be ade-
MEANS OF EGRESS

quate in strength and attachment in accordance with Section 1607.8.

Exception: Guards are not required for the following locations:

1. On the loading side of loading docks or piers.
2. On the audience side of stages and raised platforms, including steps leading up to the stage and raised platforms.
3. On raised stage and platform floor areas, such as runways, ramps and side stages used for entertainment or presentations.
4. At vertical openings in the performance area of stages and platforms.
5. At elevated walking surfaces appurtenant to stages and platforms for access to and utilization of special lighting or equipment.
6. Along vehicle service pits not accessible to the public.
7. In assembly seating where guards in accordance with Section 1028.14 are permitted and provided.

Where one or more sides of a walking surface are open to the floor level or grade below, a guard system must be provided to minimize the possibility of occupants accidentally falling to the surface below [see Figure 1013.2(1)]. A guard is required only where the difference in elevation between the higher walking surface and the surface below is greater than 30 inches (762 mm). When the ground slopes away from the edge, the vertical distance from the walking surface to the grade or floor below must also be more than 30 inches (762 mm) on the lowest point within a 36-inch (914 mm) radius measured horizontally from the edge of the open-sided walking surface [see Figure 1013.2(2)].

The loads for guard design are addressed in Section 1007 and are typically 50 psf (222 N) along the top with a 200-pound (90.72 kg) concentrated force. If glazing is used as part of a guard system, or windows are located adjacent to stairways or ramps, the guard must also comply with Section 1013.2.1 (see Sections 1013.2.2, 1607.8 and 2407).

Most of the exceptions identify situations when guards are not practical, such as along loading docks, stages and their approaches and vehicle service pits. Exception 7 references the lower guards permitted at locations where a line of sight for assembly spaces is part of the considerations.
1013.2.1 Glazing. Where glass is used to provide a guard or as a portion of the guard system, the guard shall also comply with Section 2407. Where the glazing provided does not meet the strength and attachment requirements of Section 1607.8, complying guards shall also be located along glazed sides of open-sided walking surfaces.

- Glazing in guards may be infill or structural. The loads for guard design in Section 1013.2, which references Section 1607, are typically 50 psf (222 N) along the top with a 200-pound (90.72 kg) concentrated force. Two different situations are addressed with glazing: where glazing is installed in a guard on the side of a stairway, ramp or landing; or when a stairway, ramp or landing is immediately adjacent to a window where the glazing has not been designed to resist the forces from a fall (see Sections 1607.8 and 2407 and Figure 1013.2.1).

1013.3 Height. Required guards shall not be less than 42 inches (1067 mm) high, measured vertically as follows:

1. From the adjacent walking surfaces;
2. On stairs, from the line connecting the leading edges of the tread nosings; and
3. On ramps, from the ramp surface at the guard.

Exceptions:

1. For occupancies in Group R-3 not more than three stories above grade in height and within individual dwelling units in occupancies in Group R-2 not more than three stories above grade in height with separate means of egress, required guards shall not be less than 36 inches (914 mm) in height measured vertically above the adjacent walking surfaces or adjacent fixed seating.

2. For occupancies in Group R-3, and within individual dwelling units in occupancies in Group R-2, guards
on the open sides of stairs shall have a height not less than 34 inches (864 mm) measured vertically from a line connecting the leading edges of the treads.

3. For occupancies in Group R-3, and within individual dwelling units in occupancies in Group R-2, where the top of the guard also serves as a handrail on the open sides of stairs, the top of the guard shall not be less than 34 inches (864 mm) and not more than 38 inches (965 mm) measured vertically from a line connecting the leading edges of the treads.

4. The guard height in assembly seating areas shall comply with Section 1028.14.

5. Along alternating tread devices and ship ladders, guards whose top rail also serves as a handrail, shall have height not less than 30 inches (762 mm) and not more than 34 inches (864 mm), measured vertically from the leading edge of the device tread nosing.

Guard height must not be less than 42 inches (1067 mm) in height as measured vertically from the top of the guard down to the sloped line connecting the leading edge of the tread along steps or to an adjacent walking surface for floors and ramps [see Figures 1013.2(1), 1013.3 and 1010.9(4)]. Experience has shown that 42 inches (1067 mm) or more provides adequate height to minimize accidental falls in occupancies where crowding is more likely to occur. This puts the top of the guard above the center of gravity of the average adult. The height requirement is not intended to consider such items as planters or loose furniture next to the dropoff as walking surfaces. Because of safety concerns, the designer often chooses to install a barrier where there is a dropoff of less than 30 inches (762 mm). Decorative barriers may be utilized to support handrails or serve as part of the edge protection along a ramp. Where nonrequired guards/barriers are provided, provisions for guard height, openings and strength may be used for design, but are not required. It is common practice to follow the strength provisions, but not always the opening or height provisions for nonrequired guards.

Exception 1 measures the guard height differently. In Group R-2 and R-3 units that are three stories or less, where there is a fixed seat along the edge of deck or balcony, it is reasonable to consider the additional exposure for young children that may use the seat as standing or walking surfaces. In this situation, the guard height is measured from the top of the seat surface [see Figure 1013.2(3)]. Within dwelling units the incidence of the exposure to crowds and to egress from higher occupancy spaces is extremely limited, thus a minimum guard height of 36 inches (914 mm) is appropriate. Exception 1 is consistent with provisions in the IRC.

Where the minimum guard height requirement is 42 inches (1067 mm), where both a guard and handrail are required, the handrail cannot be the top of the guard, but must be placed along the inside face of the guard.

Exceptions 2 and 3 are for nontransient residential occupancies and only address guard heights along the stairways, not at other dropoffs, such as balconies or second-floor landings. For Group R-2, these guard height exceptions are only permitted for stairways within individual dwelling units, not common stairways within the building. The handrail provisions allow some residential stairways to only have one handrail (see Section 1009.15). Exceptions 2 and 3 allow for a reduced guard height when the guard is also used as a handrail and when it just serves the purpose of a guard along a stairway. The reduced allowable guard height along stairways is consistent
with current construction practice. Unless a dwelling could comply with Exception 1, the guard height along other dropoffs would have to be 42 inches (1067 mm) measured from the floor.

Exception 4 references the lower guards permitted at limited locations where a line of sight for assembly spaces is part of the consideration.

Exception 5 permits a reduction in guard heights based on the limited used and unique design considerations for alternating tread devices and ship ladders (see Sections 1009.13 and 1009.14).

1013.4 Opening limitations. Required guards shall not have openings which allow passage of a sphere 4 inches (102 mm) in diameter from the walking surface to the required guard height.

Exceptions:

1. From a height of 36 inches (914 mm) to 42 inches (1067 mm), guards shall not have openings which allow passage of a sphere 4 7/8 inches (111 mm) in diameter.

2. The triangular openings at the open sides of a stair, formed by the riser, tread and bottom rail shall not allow passage of a sphere 6 inches (152 mm) in diameter.

3. At elevated walking surfaces for access to and use of electrical, mechanical or plumbing systems or equipment, guards shall not have openings which allow passage of a sphere 21 inches (533 mm) in diameter.

4. In areas that are not open to the public within occupancies in Group I-3, F, H or S, and for alternating tread devices and ship ladders, guards shall not have openings which allow passage of a sphere 21 inches (533 mm) in diameter.

5. In assembly seating areas, guards at the end of aisles where they terminate at a fascia of boxes, balconies and galleries shall not have openings which allow passage of a sphere 4 inches in diameter (102 mm) up to a height of 26 inches (660 mm). From a height of 26 inches (660 mm) to 42 inches (1067 mm) above the adjacent walking surfaces, guards shall not have openings which allow passage of a sphere 8 inches (203 mm) in diameter.

6. Within individual dwelling units and sleeping units in Group R-2 and R-3 occupancies, guards on the open sides of stairs shall not have openings which allow passage of a sphere 4 7/8 inches (111 mm) in diameter.

The opening limitations in a guard are based on anthropometric research that indicates children in the 99th percentile that have developed to the point of being able to crawl will have chest depth and head size of at least 4 7/8 inches. Both the 4-inch (102 mm) and the 4 7/8-inch (111 mm) sphere rules are intended to provide an additional margin of safety. Note that the opening limitations are stated as preventing the passage of a sphere, requiring the openings to be smaller than the dimension stated.

Exception 1 allows the 4 7/8-inch (203 mm) opening limitation at heights where falling through the guard is not a risk for children of early development that cannot access the opening [i.e., above 36 inches (914 mm) in height].

Exception 2 allows a 6-inch (152 mm) opening limitation at openings formed by the riser, tread and bottom rail of guards at the open side of a stairway. The geometry of these openings is such that the entire body cannot pass through the triangular opening, and further limiting such openings is impractical to achieve with a sloped bottom member in the guard without intersecting the tread nosings (see Figure 1013.3).

Exceptions 3 and 4 address areas where the presence of small children is unlikely and often prohibited. Guards along walkways leading to electrical, mechanical and plumbing systems or equipment and in occupancies in Groups I-3, F, H and S may be constructed in such a way that a sphere 21 inches (533 mm) in diameter will not pass through any of the openings [see Figure 1013.4(1)]. This requirement allows the use of one horizontal intermediate member with the standard top-of-guard height of 42 inches (1067 mm).

Exception 5, for the guard infill near the top of the aisle guard in assembly seating areas, is provided to reduce sightline problems in limited locations.

Exception 6 recognizes a standard construction practice within residential units. In practicality this allows a stairway with the 7-inch riser height/11-inch tread depth (178 mm riser height/279 mm tread depth) step geometry to have two common 1 1/4-inch
(32 mm) balusters per stair tread instead of three. Where the 7\(\frac{1}{4}\)-inch riser height/10-inch tread depth (197 mm riser height/254 mm tread depth) step geometry (see Section 1009.7.2, Exception 5) is utilized, the two balusters would meet the 4-inch (102 mm) opening limitation and most profiled or turned balusters would meet the 4\(\frac{3}{8}\)-inch (111 mm) sphere rule.

The provisions of guards are to minimize accidental falls through or over a guard. Opening limitations do not prohibit the use of horizontal members or ornamentation infill as guard components. Research has shown that no practical design for guard infill, including solid panels, can prevent climbing; but good design practices can greatly reduce the opportunity for small children to "climb" the guard [see Figure 1013.4(2)].

The purpose of this requirement is to protect workers from falls off of roofs or from open-sided walking surfaces when doing maintenance work on equipment. The guard opening is allowed to be up to 21 inches (533 mm) since children are not likely to be in such areas. This requirement allows the use of horizontal intermediate members.

1013.7 Roof access. Guards shall be provided where the roof hatch opening is located within 10 feet (3048 mm) of a roof edge or open side of a walking surface and such edge or open side is located more than 30 inches (762 mm) above the floor, roof or grade below. The guard shall be constructed so as to prevent the passage of a sphere 21 inches (533 mm) in diameter.

The code already requires guards around equipment on the roof; this section is intended to provide the same level of safety at the opening that the service personnel are using to access the roof (see Figure 1013.7).

1013.8 Window sills. In Occupancy Groups R-2 and R-3, one- and two-family and multiple-family dwellings, where the opening of the sill portion of an operable window is located more than 72 inches (1829 mm) above the finished grade or other surface below, the lowest part of the clear opening of the window shall be at a height not less than 36 inches (915 mm) above the finished floor surface of the room in which the window is located. Operable sections of windows shall not permit openings that allow passage of a 4-inch-diameter (102 mm) sphere where such openings are located within 36 inches (915 mm) of the finished floor.

Exceptions:

1. Operable windows where the sill portion of the opening is located more than 75 feet (22 860 mm) above the finished grade or other surface below and that are provided with window fall prevention devices that comply with ASTM F 2006.

2. Windows whose openings will not allow a 4-inch-diameter (102 mm) sphere to pass through the opening when the window is in its largest opened position.

3. Openings that are provided with window fall prevention devices that comply with ASTM F 2090.

4. Windows that are provided with window opening control devices that comply with Section 1013.8.1.

The window limitations specified here are intended for Group R-2 and R-3 units. These facilities have the highest potential for infants and toddlers being present for an extended period of time. The requirement is intended to provide a level of protection to children and to help limit the chances of them falling through window openings. In most cases, these provisions are not applicable to first-floor windows. Typically, the 72 inches (1829 mm) to finished grade would make these provisions applicable for windows starting at
MEANS OF EGRESS

the second floor. For windows in bedrooms that may also be required to serve as emergency escape and rescue openings, see Section 1029.

There are basically five options offered:

One option is to locate the window so that any opening is at least 36 inches (915 mm) above the floor. By raising the lowest operable portion of a window to 36 inches (915 mm) or more, the sill height is above the center of gravity of smaller children. The National Ornamental & Miscellaneous Metals Association (NOMMA) commissioned a paper on child safety related to falls. The report indicates that the standing center of gravity of children aged 2 to 3.5 years is 24.1 inches (612 mm) [50th percentile is 22.2 inches (564 mm)] and of children aged 3.5 to 4.5 years is 25.2 inches (640 mm) [50th percentile is 23.6 inches (599 mm)]. The 36-inch (915 mm) sill height was chosen to reduce the ability of a child to climb onto the sill, enabling the fall through the opening. Windows that are also to serve as emergency escape windows must also comply with Section 1029.3 sill height requirements for 44 inches (1118 mm) maximum. Note that Section R612.2 of the IRC requires a minimum sill height of 24 inches (610 mm).

A second option (last sentence and Exception 2) would be for windows with an opening lower than 36 inches (915 mm) to limit the opening to 4 inches (102 mm) maximum. This opening size is consistent with the guard opening provisions (see Section 1013.4). Many awning or hopper-type casement windows have control arms that limit the opening width.

The third option offered (Exception 1) allows for fall prevention devices to be installed in accordance with ASTM F 2006. The limitation for window sills over 75 feet (22.860 mm) is for consistency with Section 1.3 of ASTM F 2006, which states: "This safety specification applies only to devices intended to be applied to windows installed at height of more than 75 feet above the ground level in multiple family dwellings. This safety specification is not intended to apply to windows below 75 feet (22.860 mm) because all windows below 75 feet (22.860 mm) that are operable could be used as a possible secondary means of escape."

ASTM F 2090 includes window fall prevention devices (Exception 3) and window opening control devices (Exception 4 and Section 1013.8.1). This standard is specifically written for window openings within 75 feet (22.860 mm) of grade and specifically allows for windows to be used for emergency escape and rescue. Both the code and IRC reference ASTM F 2090, Specification for Window Fall Prevention Devices with Emergency Escape (Egress Release Mechanisms). This standard was updated in 2008 to address window opening control devices. Opening control devices allow for normal operation to result in a 4-inch (102 mm) maximum opening (Section 1013.8 and Section R612.4.1 of the IRC). This control device can be released from the inside to allow the window to be fully opened in order to comply with the emergency escape provisions in both the code (Section 1029.2) and IRC (Section R310.1.1).

**1013.8.1 Window opening control devices.** Window opening control devices shall comply with ASTM F 2090. The

**Figure 1013.7**
PROTECTION AT ROOF-HATCH OPENING

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.
window opening control device, after operation to release the control device allowing the window to fully open, shall not reduce the minimum net clear opening area of the window unit to less than the area required by Section 1029.2.

❖ See the commentary to Section 1013.8.

SECTION 1014
EXIT ACCESS

1014.1 General. The exit access shall comply with the applicable provisions of Sections 1003 through 1013. Exit access arrangement shall comply with Sections 1014 through 1019.

❖ Sections 1014 through 1019 include the design requirements for exit access and exit access components. The general requirements that also apply to the exit access are in Sections 1003 through 1013.

The following sections are included under exit access:
• Section 1014 deals with egress through intervening spaces, as well as travel and separation of the common path of travel to the exit.
• Section 1015 provides information on the number of doors and the separation for exit and exit access doors.
• Section 1016 lists the total exit access travel distance from an occupied space to an exit. This distance includes the common path of travel addressed in Section 1014.3.
• Section 1017 takes a look at requirements for aisles and aisle accessways in business and mercantile occupancies. Aisle and aisle accessways in spaces used for assembly purposes are specifically addressed in Section 1028.
• Section 1018 deals with another type of confined part of the exit access path – corridors.
• Section 1019 addresses egress balconies, where the path of travel to the exterior exit stairway is partially open to the exterior.

1014.2 Egress through intervening spaces. Egress through intervening spaces shall comply with this section.

1. Egress from a room or space shall not pass through adjoining or intervening rooms or areas, except where such adjoining rooms or areas and the area served are accessory to one or the other, are not a Group H occupancy and provide a discernible path of egress travel to an exit.

Exception: Means of egress are not prohibited through adjoining or intervening rooms or spaces in a Group H, S or F occupancy when the adjoining or intervening rooms or spaces are the same or a lesser hazard occupancy group.

2. An exit access shall not pass through a room that can be locked to prevent egress.

3. Means of egress from dwelling units or sleeping areas shall not lead through other sleeping areas, toilet rooms or bathrooms.

4. Egress shall not pass through kitchens, storage rooms, closets or spaces used for similar purposes.

Exceptions:

1. Means of egress are not prohibited through a kitchen area serving adjoining rooms constituting part of the same dwelling unit or sleeping unit.

2. Means of egress are not prohibited through stockrooms in Group M occupancies when all of the following are met:
   a. The stock is of the same hazard classification as that found in the main retail area;
   b. Not more than 50 percent of the exit access is through the stockroom;
   c. The stockroom is not subject to locking from the egress side; and
   d. There is a demarcated, minimum 44-inch-wide (1118 mm) aisle defined by full- or partial-height fixed walls or similar construction that will maintain the required width and lead directly from the retail area to the exit without obstructions.

❖ This section allows adjoining spaces to be considered a part of the room or space from which egress originates, provided that there are reasonable assurances that the continuous egress path will always be available. The code does not limit the number of intervening or adjoining rooms through which egress can be made, provided that all other code requirements (i.e., travel distance, number of doorways, etc.) are met. An exit access route, for example, may be laid out such that an occupant leaves a room or space, passes through an adjoining space, enters an exit access corridor, passes through another room and, finally, into an exit [see Figure 1014.2(2)] as long as all other code requirements are satisfied.

The intent of Item 1 is not that the accessory space be limited to the 10-percent area in Section 508.2.1., but that the spaces be interconnected so that doors between the spaces will not risk being blocked or locked. For example, a conference room and managers’ offices could exit through the secretary’s office to reach the exit access corridor; or several office spaces could exit through a common reception/lobby area. Requiring occupants to egress from an area and pass through an adjoining Group H that can be characterized by rapid fire buildup, or worse, places them in an unreasonable risk situation [see Figure 1014.2(1)]; therefore, this illustrated egress path would be prohibited. As an exception to Item 1, in facilities that may contain a Group H area, buildings of Group H, S or F can exit through adjoining rooms or spaces that have the same or lesser hazard. For
example, a person exiting from a Group H storage room (see Section 415) could egress either through a similar Group H storage area or through the factory to get to an exit, but the person in the factory could not egress through the Group H storage rooms to get to the outside.

As expressed in Item 2, a common code enforcement problem is a locked door in the egress path. Twenty-five workers perished in September 1991 when they were trapped inside the Imperial Food Processing Plant in Hamlet, North Carolina, partially because of locked exit doors. As long as the egress door is readily openable in the direction of egress travel without the use of keys, special knowledge or effort (see Section 1008.1.9.5), the occupants can move unimpeded away from a fire emergency. Relying on an egress path through an adjacent dwelling unit to be available at all times is not a reasonable expectation. Egress through an adjacent business tenant space can be unreasonable given the security and privacy measures the adjacent tenant may take to secure such a space. However, egress through a reception area that serves a suite of offices of the same tenant is clearly accessible and is permitted.

Item 3 addresses concerns along the path of egress travel within individual dwelling or sleeping units. The concern once again is possible locking devices. Egress for one bedroom should not be through another bedroom or bathroom.

The concern in Item 4 is that kitchens, storage rooms and similar spaces may be subject to locking or blockage of the exit access path. This is not a gen-

![Diagram of egress prohibited through Group H areas](image1)

**Figure 1014.2(1)**
**EGRESS PROHIBITED THROUGH GROUP H AREAS**

![Diagram of egress through adjoining rooms and spaces](image2)

**Figure 1014.2(2)**
**EGRESS THROUGH ADJOINING ROOMS AND SPACES**
eral provision for all Group S occupancies; therefore, it is not the intent of this provision to address the situation of egress for offices through an associated warehouse space. Item 4, Exception 1, does not apply this same prohibition to areas within dwelling or sleeping units. However, for other spaces, a customer means of egress should not be through the working portions of a commercial kitchen behind a restaurant or the stock storage area of a storage room behind a mercantile occupancy. A dedicated path must be established through such space. The four items listed in Item 4, Exception 2, are intended to provide measurable criteria to increase the likelihood that the exit access path of travel would always be available and identifiable through the stock room of a store. It is not acceptable to just mark the path on the floor. Whatever defines the route must permanently establish the egress path in a manner to maintain the minimum required unobstructed width.

1014.2.1 Multiple tenants. Where more than one tenant occupies any one floor of a building or structure, each tenant space, dwelling unit and sleeping unit shall be provided with access to the required exits without passing through adjacent tenant spaces, dwelling units and sleeping units.

Exception: The means of egress from a smaller tenant space shall not be prohibited from passing through a larger adjoining tenant space where such rooms or spaces of the smaller tenant occupy less than 10 percent of the area of the larger tenant space through which they pass; are the same or similar occupancy group; a discernible path of egress travel to an exit is provided; and the means of egress into the adjoining space is not subject to locking from the egress side. A required means of egress serving the larger tenant space shall not pass through the smaller tenant space or spaces.

- Where a floor is occupied by multiple tenants, each tenant must be provided with full and direct access to the required exits serving that floor without passing through another tenant space. Tenants typically lock the doors to their spaces for privacy and security. Should an egress door that is shared by both tenants be locked, occupants in one of the spaces could be trapped and unable to reach a secondary exit. Therefore, an egress layout where occupants from one tenant space travel through another tenant space to gain access to one of the required exits from that floor is prohibited.

This limitation is so that occupants from all tenant spaces will have unrestricted access to the required egress elements while maintaining the security and privacy of the individual tenants. This limitation is based on one of the fundamental principles of egress: to provide a means of egress where all components are capable of being used by the occupants without keys, tools, special knowledge or effort (see Section 1008.1.9.5).

A common practice is to have a bank or small restaurant located within a large grocery store or department store. These can be separate tenants. In these situations, the small tenants are not open when the main store is closed. The intent of the exception is to allow those small tenants to egress through the large tenant. Since there may be times when the larger tenant is open and the smaller is closed (e.g., bank holidays), the larger tenant cannot exit through the smaller tenant.

1014.3 Common path of egress travel. The common path of egress travel shall not exceed the common path of egress travel distances in Table 1014.3.

- Common path of egress travel does not apply to stories or buildings with one exit. The definition for "Common path" indicates the provisions are only applicable when access to two or more exits is required. See Section 1021.2 for travel limitations for
MEANS OF EGRESS

single-exit one-, two- and three-story buildings and Section 1015.1 for spaces with one exit.

The common path of travel is the distance measured from the most remote point in a space to the point in the exit path where the occupant has access to two required exits in separate directions. The distance limitations are applicable to all paths of travel that lead out of a space or building where two exits are required. An illustration of this distance is found in Figure 1014.3. The illustration reflects two examples of a common path of travel where the occupants at points A and B are able to travel in only one direction before they reach a point at which they have a choice of two paths of travel to the required exits from the building. Note that from point A, the occupants have two available paths, but these merge to form a single path out of the space. This is also considered a common path of travel. The common path of travel is considered part of the overall travel distance limitations in Section 1016.1.

While a Group R-3 occupancy is typically a single-exit space, it is included in the table to address mixed-use buildings.

TABLE 1014.3. See next column.

- In nonsprinklered business, storage and utility buildings, the length of the common path of egress travel is greater for single-exit spaces when the occupant load for that space is 30 or less. While some of the groups listed are not permitted to be built as new buildings without being fully sprinklered, the provisions are included for existing buildings that are not sprinklered throughout. Business, factories and nontransient residential buildings get an increase in the common path of travel in recognition of the additional fire safety offered by a fully sprinklered building.

Notes a and b indicate if the travel distance increase is based on an NFPA 13 or NFPA 13R sprinkler system being provided throughout the building.

The reference in Note c to Section 1028.8 is to allow for the unique common path of travel requirements in spaces with assembly seating, such as in a lecture room or sports facility.

Note d is an allowance for the common path of travel in an open parking garage to be 100 feet (30 480 mm) when the occupant load is greater than 30 and there is no sprinkler system provided. This is in recognition of the minimal possibility of smoke accumulation due to the openness requirements and the low fuel loads for open parking garages.

As indicated in Note e, while Group R-3 dwellings are typically only required to have one exit (see Section 1021.2, Exception 2), there can be a situation where a Group R-3 unit is included in a mixed-use building. In these situations, the travel distance limitations for common path of travel in the table are applicable.

Note f is a reference to the common path of travel provisions specific to Group I-2 care rooms and suites that are specifically addressed in Section 407.4.

For SI: 1 foot = 304.8 mm.
a. Buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1.
b. Buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2. See Section 903 for occupancies where automatic sprinkler systems are permitted in accordance with Section 903.3.1.2.
c. For a room or space used for assembly purposes having fixed seating, see Section 1028.8.
d. The length of a common path of egress travel in a Group S-2 open parking garage shall not be more than 100 feet (30 480 mm).
e. The length of a common path of egress travel in a Group R-3 occupancy located in a mixed occupancy building.
f. For the distance limitations in Group I-2, see Section 407.4.

SECTION 1015
EXIT AND EXIT ACCESS DOORWAYS

1015.1 Exits or exit access doorways from spaces. Two exits or exit access doorways from any space shall be provided where one of the following conditions exists:

1. The occupant load of the space exceeds one of the values in Table 1015.1.

Exceptions:

1. In Group R-2 and R-3 occupancies, one means of egress is permitted within and from individual dwelling units with a maximum occupant load of 20 where the dwelling unit is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2.

2. Care suites in Group I-2 occupancies complying with Section 407.4.3.

3. The common path of egress travel exceeds one of the limitations of Section 1014.3.

3. Where required by Section 1015.3, 1015.4, 1015.5, or 1015.6.

Where a building contains mixed occupancies, each individual occupancy shall comply with the applicable requirements for that occupancy. Where applicable, cumulative
occupant loads from adjacent occupancies shall be considered in accordance with the provisions of Section 1004.1.

- This section dictates the minimum number of paths of travel an occupant is to have available to avoid a fire incident in the occupied room or space. While providing multiple egress doorways from every room is unrealistic, a point does exist where alternative egress paths must be provided based on the number of occupants at risk, the distance any one occupant must travel to reach a doorway and the relative hazards associated with the occupancy of the space. Generally, the number of egress doorways required from any room or space coincides with the occupant load threshold criteria set forth for the minimum number of exits required in a building (see Section 1021.1).

In accordance with Item 1, the limiting criteria in Table 1015.1 for rooms or spaces permitted to have a single exit access doorway are based on an empirical judgment of the associated risks.

If the occupants of a room are required to egress through another room, as permitted in Section 1014.2, the rooms are to be combined to determine if multiple doorways are required from the combined rooms. For example, if a suite of offices shares a common reception area, the entire suite with the reception area must be considered in the occupant load and the travel distance criteria. The same logic would hold true for a space with a mezzanine.

It should be noted that where two doorways are required, the remoteness requirement of Section 1015.2 is applicable.

Item 1, Exception 1, allows for individual dwelling units to be considered a space with one means of egress, provided they meet the common path of travel requirements in Section 1014.3. Single-exit buildings must meet the provisions for buildings in Section 1021.2 (see the commentary to Section 1021.2 for comparison examples). If the building is sprinklered with an NFPA 13 or 13R system, the occupant load for the unit can be 20 (4,000-square foot apartment/200 square feet per occupant = 20 occupants), whereas if the unit complies with the table, the occupant load is limited to 10 people per unit (2,000-square-foot apartment/200 square feet per occupant = 10 occupants).

Item 1, Exception 2, allows for hospital patient rooms and care suites to egress in accordance with the specific criteria in Section 407.4; including the common path of egress travel provisions (Table 1014.3, Note f). Other areas in Group I-2 occupancies are addressed in Table 1015.1.

Item 2 sets the limits for a single means of egress based on travel distance. Where the common path of travel exceeds any one of the limits in Section 1014.3, two egress paths are required for safe egress from the space.

Item 3 addresses when two means of egress may be required in boiler, incinerator and furnace rooms; refrigerator machinery rooms or refrigerated rooms and spaces; and day care rooms with toddlers and infants.

Special provisions for stages, platforms and their associated technical production areas, previously in this section, are now specifically addressed in Section 410.

The final paragraph reinforces the cumulative occupant load requirements in Section 1004.1.

### Table 1015.1

- The table represents an empirical judgment of the risks associated with a single means of egress from a room or space based on the occupant load in the room, the travel distance to the exit access door and the inherent risks associated with the occupancy (such as occupant mobility, occupant familiarity with the building, occupant response and the fire growth rate). The number 49 is for consistency with other occupant load thresholds, such as panic hardware (see Section 1008.1.10).

Since the occupants of Groups I and R may be sleeping and, therefore, not able to detect a fire in its early stages without staff supervision or room detectors, the number of occupants in a single egress room or space is limited to 10. See the exceptions to Section 1015.1, Item 1, for Group R-2 and R-3 individual units and Group I-2 patient rooms and care suites.

Because of the potential for rapidly developing hazardous conditions, the single egress condition in Groups H-1, H-2 and H-3 is limited to a maximum of three persons. Because the materials contained in Groups H-4 and H-5 do not represent the same fire hazard potential as those found in Groups H-1, H-2 and H-3, the occupant load for spaces with one means of egress is increased.

Because of the reduced occupant density in Group S and the occupants' normal familiarity with the building, the single egress condition is permitted with an occupant load of 29.

**1015.1.1 Three or more exits or exit access doorways.**

Three exits or exit access doorways shall be provided from any space with an occupant load of 501 to 1,000. Four exits or exit access doorways shall be provided from any space with an occupant load greater than 1,000.

- This section is correlated with Section 1021.4 for conditions where three or more exits are required from a story.
MEANS OF EGRESS

1015.2 Exit or exit access doorway arrangement. Required exits shall be located in a manner that makes their availability obvious. Exits shall be unobstructed at all times. Exit and exit access doorways shall be arranged in accordance with Sections 1015.2.1 and 1015.2.2.

- Exits need to be unobstructed and obvious at all times for the safety of occupants to evacuate the building in an emergency situation. This is consistent with the requirements in Section 1008.1 for exit or exit access doors to not be concealed by curtains, drapes, decorations or mirrors. Whether the doors from the space are exit access doors leading to a hallway or actual exit doors leading to an exit enclosure or directly to the outside, they must be located in accordance with the next two sections.

1015.2.1 Two exits or exit access doorways. Where two exits or exit access doorways are required from any portion of the exit access, the exit doors or exit access doorways shall be placed a distance apart equal to not less than one-half of the length of the maximum overall diagonal dimension of the building or area to be served measured in a straight line between exit doors or exit access doorways. Interlocking or scissor stairs shall be counted as one exit stairway.

Exceptions:

1. Where interior exit stairways are interconnected by a 1-hour fire-resistance-rated corridor conforming to the requirements of Section 1018, the required exit separation shall be measured along the shortest direct line of travel within the corridor.

2. Where a building is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2, the separation distance of the exit doors or exit access doorways shall not be less than one-third of the length of the maximum overall diagonal dimension of the area served.

- This section provides a method to determine, quantitatively, remoteness between exits and exit access doors based on the dimensional characteristics of the space served. This measure has been common practice for some years with significant success. Very simply, the method involves determining the maximum dimension between any two points in a floor or a room (e.g., a diagonal between opposite corners in a rectangular room or building or the diameter in a circular room or building). If two doors or exits are required from the room or building (see Sections 1015.1 and 1021.2), the straight-line distance between the center of the thresholds of the doors must be at least one-half of the maximum dimension [see Figure 1015.2.1(1)].

While technical proof is not available to substantiate this method of determining remoteness, it has been found to be realistic and practical for most building designs. Buildings with exits in a center core and occupied spaces around the perimeter are addressed in Exception 1.

If a scissor stairway is utilized, regardless of the separation of the two entrances, the scissor stair may only be counted as one exit. Two independent stairways within the same enclosure could result in both stairways being usable in an emergency where smoke penetrates the single enclosure (see the definition for "Scissor stairways" in Chapter 2). Interlocking stairways that occur over the same building footprint but are within separate enclosures are not "scissor stairways" and can count as two independent exits. Due to concern about smoke migration, careful review of the construction details and verification that they meet all the provisions for fire barriers and horizontal assemblies must be made. Of special concern would be the provisions for continuity, penetrations and joints.

Where exit access stairways are permitted to be unenclosed, the remoteness measurement for doorways shall begin at the center of the top riser of the unenclosed stairways; this is consistent with the exit access travel distance measurement in Section 1016.3. When enclosure is provided, distances are measured to the door of the enclosure.

In Exception 1, a method of permitting the distance between exits to be measured along a complying corridor connecting the enclosure for the exit stairway or ramp has served to mitigate the disruption to this design concept [see Figure 1015.2.1(2)].

As reflected in Exception 2, the protection provided by an automatic sprinkler system can reduce the threat of fire buildup so that the reduction in remoteness to one-third of the diagonal dimension is not unreasonable, based on the presumption that it provides the occupants with an acceptable level of safety from fire [see Figure 1015.2.1(3)]. The automatic sprinkler system must be installed throughout the building in accordance with NFPA 13 or 13R. This reduced separation (one-third diagonal) may also be used when applying the requirements of Exception 1.

In applying the provisions of this section, it is important to recognize any convergence of egress paths that may exist. Figure 1015.2.1(4) illustrates an assembly room with remotely located exit access doors, but the doors from the entire space are not considered remote in accordance with this section.

1015.2.2 Three or more exits or exit access doorways. Where access to three or more exits is required, at least two exit doors or exit access doorways shall be arranged in accordance with the provisions of Section 1015.2.1.

- When there are three or more required exits from a building or exit access doors from a room, they are to be analyzed identically to the method described in Section 1015.2.1. Two of the exits or exit access
doors must meet the remoteness test. Any additional exits or doors can be located anywhere within the floor plan that meets the code requirements, including independence, accessibility, capacity and continuity.

There is no specific separation requirement provided in Section 1015.2.2 for the third exit, but the exits must be located so that one fire event will not block two exits; so two doors immediately adjacent would not be acceptable. The appropriate separation is subjective and would be partially dependent on the layout of the space. Using some other provisions in the code for guidance can help. Section 1005.5 states that multiple means of egress need to be sized such that the loss of any one will not reduce the capacity below 50 percent. This intent is repeated for an assembly space with more than 300 occupants. Sections 1028.2 and 1028.3 can require this space to have a main exit that accommodates one-half of the total occupant load and then require the balance of the exits (means of egress) to provide for the remaining one-half of the occupant load. The "main exit" is typically the result of a single "main entrance" for fee or ticket entry. If there is not a main exit, the exceptions to both Sections 1028.2 and 1028.3 require the means of egress to be "distributed around the perimeter of the building."

Figure 1015.2.1(1)
EXAMPLES OF REMOTENESS BETWEEN EXITS OR EXIT ACCESS DOORS FROM A ROOM OR BUILDING
MEANS OF EGRESS

**Figure 1015.2.1(2)**
REMOTEINESS OF EXITS INTERCONNECTING BY A 1-HOUR FIRE-RESISTANCE-RATED CORRIDOR

EXAMPLE:
DIAGONAL DIMENSION = 134'-0"
MIN. SEPARATION OF EXITS = 134' / 2 = 67'-0"

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

**Figure 1015.2.1(3)**
REMOTEINESS OF EXITS IN A BUILDING WITH AN AUTOMATIC SPRINKLER SYSTEM

EXAMPLE:
DIAGONAL DIMENSION = 134'-0"
MIN. SEPARATION OF EXITS = 134' + 3 = 44'-8"

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.
1015.3 Boiler, incinerator and furnace rooms. Two exit access doorways are required in boiler, incinerator and furnace rooms where the area is over 500 square feet (46 m²) and any fuel-fired equipment exceeds 400,000 British thermal units (Btu) (422 000 KJ) input capacity. Where two exit access doorways are required, one is permitted to be a fixed ladder or an alternating tread device. Exit access doorways shall be separated by a horizontal distance equal to one-half the length of the maximum overall diagonal dimension of the room.

This section requires two exit access doorways for the specified mechanical equipment spaces because of the level of hazards in this type of space. A fixed ladder or an alternating tread device is permitted for service personnel to egress where two doorways are required. The remoteness of the exit access doorways specified in this section provides two paths of travel to exit the room so that if one doorway is not available, the alternate path can be used.

1015.4 Refrigeration machinery rooms. Machinery rooms larger than 1,000 square feet (93 m²) shall have not less than two exits or exit access doorways. Where two exit access doorways are required, one such doorway is permitted to be served by a fixed ladder or an alternating tread device. Exit access doorways shall be separated by a horizontal distance equal to one-half the maximum horizontal dimension of room.

All portions of machinery rooms shall be within 150 feet (45 720 mm) of an exit or exit access doorway. An increase in travel distance is permitted in accordance with Section 1016.1.

Doors shall swing in the direction of egress travel, regardless of the occupant load served. Doors shall be tight fitting and self-closing.

The reasons for these requirements are the same as for Section 1015.3. Travel distance is to be limited in accordance with Section 1016.2. For example, the travel distance limit for a large refrigeration machinery room classified as Group F-1 that has a sprinkler system throughout the entire building in accordance with NFPA 13 would be 250 feet (76 200 mm) based on Table 1016.2. The 150-foot (45 720 mm) maximum distance to an exit or exit access doorway that is specified in this section would not apply in this example. The 150-foot (45 720 mm) travel distance is intended to be applied where a sprinkler system is not installed and to shorten the time that occupants would be exposed to the hazards within the machinery room.

1015.5 Refrigerated rooms or spaces. Rooms or spaces having a floor area larger than 1,000 square feet (93 m²), containing a refrigerant evaporator and maintained at a temperature below 68°F (20°C), shall have access to not less than two exits or exit access doorways.
MEANS OF EGRESS

Travel distance shall be determined as specified in Section 1016.1, but all portions of a refrigerated room or space shall be within 150 feet (45 720 mm) of an exit or exit access doorway where such rooms are not protected by an approved automatic sprinkler system. Egress is allowed through adjoining refrigerated rooms or spaces.

Exception: Where using refrigerants in quantities limited to the amounts based on the volume set forth in the International Mechanical Code.

The commentary for Sections 1015.1 to 1015.4 also applies to this section. The exception is intended to apply if Chapter 11 of the International Mechanical Code (IMC) does not require a separate refrigeration machinery room due to the small amount of refrigerant used (see the commentary to Section 1104 of the IMC for further explanation of the machinery room requirements).

1015.6 Day care means of egress. Day care facilities, rooms or spaces where care is provided for more than 10 children that are 2 1/2 years of age or less, shall have access to not less than two exits or exit access doorways.

Day care occupancies are limited to a maximum of 10 occupants for rooms or spaces with infants and toddlers before two exits are required from a room. This limit is in consideration of needing a quick means of egress for children that would need to be carried or led for evacuation (i.e., children under 2 1/2 years of age).

There is an exception for the Group I-4 classification in Section 308.6.1 that allows day care facilities with up to 100 children 2 1/2 years of age or less with care rooms having direct access to the exterior to be classified as Group E. An exterior door to the outside from infant and toddler rooms can serve as the second exit to meet this section. It is not the intent that a day care classified as Group E, with children 2 1/2 years of age or less, could use the means of egress requirements for Group E for these rooms.

SECTION 1016
EXIT ACCESS TRAVEL DISTANCE

1016.1 General. Travel distance within the exit access portion of the means of egress system shall be in accordance with this section.

"Exit access" is defined as "that portion of a means of egress system that leads from any occupied portion of a building or structure to an exit" (see the commentary for the definition in Chapter 2). Exit access includes rooms, spaces, aisles and corridors that an occupant would travel along to get to an exit. Doors and doorways along this route are exit access doorways, but may sometimes be called "exit doors." True exits for this exit access travel can be: (1) an exterior exit door at grade; (2) the door to an enclosure for an interior exit stairway, ramp or exit passageway; (3) the exit door leading to a exterior exit door or ramp or (4) a door leading through a horizontal exit. How exit access travel distance is measured is one of the key differences between interior exit access stairways/ramps (see Section 1016.3.1) and interior exit stairways/ramps (see Section 1016.3).

It is important to understand the relationship between the common path of travel limitations of Section 1014.3 and the exit access travel distance limitations of this section. Both measurements start at the same location, i.e., the most remote location in any occupied space. Both are measured in the exit access portion of the means of egress system. The common path of travel is measured to the point where the occupant has two distinct paths of travel, which will lead to two distinct exits. Travel distance is measured all the way until the exit is reached. The common path of travel measurement can end within a space or at a corridor where a single means of egress space (Section 1015.1) has its door to a corridor that provides access to two exits.

1016.2 Limitations. Exit access travel distance shall not exceed the values given in Table 1016.2.

The table includes the travel distance measurements for buildings with or without sprinkler systems. "Not Permitted" is in support of the Chapter 9 requirements for all Group I and H occupancies to be sprinklered.

TABLE 1016.2. See page 10-117.

This table reflects the maximum distance a person is allowed to travel from any point in a building floor area to the nearest exit along a natural and unobstructed path. While quantitative determinations or formulas are not available to substantiate the tabular distances, empirical factors are utilized to make relative judgments as to reasonable limitations. Such considerations include the nature and fitness of the occupants; the typical configuration within the space; the level of fire hazard with respect to the specific uses of the facilities, including fire spread and the potential intensity of a fire. The inclusion of an automatic sprinkler system throughout the building can serve to control, confine or possibly eliminate the fire threat to the occupants so an increased travel distance is permitted. Increased travel distances are permitted when an automatic sprinkler system is installed in accordance with NFPA 13 or 13R.

When measuring travel distance, it is important to consider the natural path of travel [see Figure 1016.3(1)]. In many cases, the actual layout of furnishings and equipment is not known or is not identified on the plans submitted with the permit application. In such instances, it may be necessary to measure travel distance using the legs of a triangle instead of the hypotenuse [see Figure 1016.3(2)]. Since most people tend to migrate to more open spaces while egressing, measurement of the natural path of travel typically excludes floor areas within 1 foot (305 mm) of walls, corners, columns and other permanent construction. Where the travel path includes passage through a doorway, the natural
route is generally measured through the centerline of the door openings.

The common path of travel in Section 1014.3 is part of the overall exit access travel distance, with both starting at the same point. Common path of travel stops when the occupant has a choice of at least two exits, and overall travel distance stops when an occupant gets to the closest exit.

Note a is a reference to other travel distance limitations in the code. Notes b and c are simply references to the allowed type of sprinkler system—NFPA 13, 13R or 13D. Note that some travel distance increases are based on the type of sprinkler system provided. For example, a building with an NFPA 13D sprinkler system might meet the sprinkler protection requirement in Chapter 9, but would not be permitted to take the exit access travel distance increases in this table.

### 1016.2.1 Exterior egress balcony increase

**Exit access travel distances** specified in Table 1016.2 shall be increased up to an additional 100 feet (30 480 mm) provided the last portion of the exit access leading to the exit occurs on an exterior egress balcony constructed in accordance with Section 1019. The length of such balcony shall not be less than the amount of the increase taken.

The length of such balcony shall not be less than the amount of the increase taken.

- This section allows an additional travel distance on exterior egress balconies since smoke disperses rapidly. Note that the length of the increase is not to be more than the length of the exterior balcony. For example, if the length of the balcony is 75 feet (22 860 mm), the additional travel distance is limited to 75 feet (22 860 mm). In order for the increase to apply, the exterior balcony must be located at the end of the path of egress travel and not in some other portion of the egress path.

### 1016.3 Measurement

**Exit access travel distance shall be measured** from the most remote point within a story along the natural and unobstructed path of horizontal and vertical egress travel to the entrance to an exit.

**Exceptions:**

1. In open parking garages, exit access travel distance is permitted to be measured to the closest riser of an exit access stairway or the closest slope of an exit access ramp.

2. In outdoor facilities with open exit access components, exit access travel distance is permitted to be measured to the closest riser of an exit access stairway or the closest slope of an exit access ramp.

The length of travel, as measured from the most remote point within a structure to an exit, is limited to restrict the amount of time that the occupant is exposed to a potential fire condition [see Figure 1016.3(1)]. The route must be assumed to be the natural path of travel without obstruction. This commonly results in a rectilinear path similar to what can be experienced in most occupancies, such as a schoolroom or an office with rows of desks [see Figure 1016.3(2)]. The "arc" method, using an "as the crow flies" linear measurement, must be used with caution, as it seldom represents typical floor design and room layout and, in most cases, would not be the natural, unobstructed path.

The travel distance is measured every occupable point on a floor to the closest exit. While each occupant may be required to have access to a second or third exit, the travel distance limitation is only applicable to the distance to the nearest exit. In effect, this means that the distance an occupant must travel to the second or third exit is not regulated.

For exit access travel distances that include vertical elements, such as stairways or ramps, see Section 1016.3.1.

**Exceptions** 1 and 2 provide for a travel distance terminating at the top of an open exit access stairway in an open parking structure, or an open exit access stairway or ramp in outdoor facilities (e.g., stadiums, stadiums, stadiums).
MEANS OF EGRESS

(see Section 1009.3, Exceptions 6 and 7). This is appropriate in view of the low hazard and minimal possible smoke accumulation in these facilities.

The distance of travel within an exit enclosure (e.g., enclosed interior exit stairway or ramp or exit passageway) and in the exit discharge portion of the means of egress is also not regulated. Section 1021.2 permits certain buildings to be provided with a single exit. In instances where there is a single exit, travel distances less than those permitted in Table 1016.1 apply [see Tables 1021.2(1) and 1021.2(2)].

1016.3.1 Exit access stairways and ramps. Travel distance on exit access stairways or ramps shall be included in the exit access travel distance measurement. The measurement along stairways shall be made on a plane parallel and tangent to the stair tread nosings in the center of the stair and landings. The measurement along ramps shall be made on the walking surface in the center of the ramp and landings.

* Travel distance is measured along the exit access path. Exit access travel distance may include travel on an interior stairway or ramp if it is not enclosed and constructed to meet the definition of an exit (see Section 1022). An example of exit access stairways would be an unenclosed exit access stairway from a mezzanine level (see Section 505.2.2), open exit access stairways from a second floor (see Section 1009.3, Exception 1) or steps along the path of travel in a split floor-level situation. An example of an open exit access ramp would be a ramp between levels or ramps leading from the upper levels in an outdoor sports stadium (see Section 1009.3, Exception 7). For the last example, Section 1016.3, Exception 2, allows for the exit access travel distance to be measured to the top of the ramp or stairway rather than down the ramp or stairway and to the exit.

When Section 1009.3 permits an exit access stairway to be unenclosed, the travel distance would also include travel down the open stairway and to an enclosed exit stairway, a horizontal exit or an exit door to the outside. An example of this would be an open exit stairway within an individual dwelling unit (see Section 1009.3, Exception 2) or an open exit stairway from a press box (see Section 1009.3, Exception 9).

![Figure 1016.3(1) Length of Exit Access Travel](image1)

![Figure 1016.3(2) Measuring Travel Distance Using Rectilinear Approach](image2)

For SI: 1 foot = 304.8 mm.
SECTION 1017
AISLES

1017.1 General. Aisles and aisle accessways serving as a portion of the exit access in the means of egress system shall comply with the requirements of this section. Aisles or aisle accessways shall be provided from all occupied portions of the exit access which contain seats, tables, furnishings, displays and similar fixtures or equipment. The required width of aisles shall be unobstructed.

Exception: Encroachments complying with Section 1005.7.

This section addresses aisles and aisle accessways, primarily in occupancies other than assembly seating areas. Current provisions address aisles in all uses, but only address aisle accessways for assembly spaces and mercantile.

"Aisle accessway" is defined in Chapter 2 as "that portion of exit access that leads to an aisle." The term "Aisle" is defined in Chapter 2 as "an exit access component that defines and provides a path of egress travel." Given the many possible configurations of fixtures and furniture, both permanent and moveable, the determination of where aisle accessways stop and aisles begin is often subject to interpretation.

Typically, the aisle accessways lead to the aisles, which in turn lead to the exits. Since the aisle serves as a path for means of egress similar to a corridor, the requirements for doors obstructing the aisle are the same (see Section 1005.7).

A cross reference back to Section 1005.7 from the exceptions for width in corridors (see Section 1018.3), aisles (see Section 1017.1), exit passageways (see Section 1023.2) and exit courts (see Section 1027.4.1) reinforces the fact that the protrusion limits provision is generally applicable for these types of confined routes.

1017.2 Aisles in assembly spaces. Aisles and aisle accessways serving a room or space used for assembly purposes shall comply with Section 1028.

The provisions for aisles and aisle accessways in spaces with assembly seating, such as restaurants, theaters and sports arenas, are unique. See Section 1028 for criteria.

1017.3 Aisles in Groups B and M. In Group B and M occupancies, the minimum clear aisle width shall be determined by Section 1005.1 for the occupant load served, but shall not be less than 36 inches (914 mm).

Exception: Nonpublic aisles serving less than 50 people and not required to be accessible by Chapter 11 need not exceed 28 inches (711 mm) in width.

This requirement establishes aisle width criteria for Group B and M occupancies based on the occupant load served by the aisle. The reference to Section 1005.1 would trigger a requirement for aisles wider than 36 inches (914 mm) when the anticipated occupant load that the aisle served was larger than 180 (36 inches/0.2 = 180 occupants for nonsprinklered buildings and 36 inches/0.15 = 240 occupants in sprinklered buildings). When an aisle allows for access to exits in two directions, the occupant load could be split, similar to corridors. The exception addresses aisles that may be found in an archival file room or stock storage racks.

For mercantile, if fixtures are permanent, such as in a typical grocery store or office cubicles in a business, the aisle provisions would be applicable throughout. In a situation where there were groups of displays separated by aisles, the area within the displays may be considered aisle accessways (see Section 1017.4).

1017.4 Aisle accessways in Group M. An aisle accessway shall be provided on at least one side of each element within the merchandise pad. The minimum clear width for an aisle accessway not required to be accessible shall be 30 inches (762 mm). The required clear width of the aisle accessway shall be measured perpendicular to the elements and merchandise within the merchandise pad. The 30-inch (762 mm) minimum clear width shall be maintained to provide a path to an adjacent aisle or aisle accessway. The common path of egress travel shall not exceed 30 feet (9144 mm) from any point in the merchandise pad.

Exception: For areas serving not more than 50 occupants, the common path of egress travel shall not exceed 75 feet (22 860 mm).

The definition for "Merchandise pad" can be found in Chapter 2. The idea is that a merchandise pad contains the movable displays and aisle accessways. A surrounding aisle or permanent walls or displays would define the extent of the merchandise pad. Large department stores will have numerous merchandise pads (see Figure 1017.3). In accordance with Section 105.2, Item 13, movable cases, counters and partitions not over 5 feet, 9 inches (1753 mm) in
MEANS OF EGRESS

height do not require a building permit to move, add or alter. Every element within a merchandise pad must adjoin a minimum 30-inch-wide (762 mm) aisle accessway on at least one side. Travel within a merchandise pad is limited, with a maximum common path of travel of 30 feet (914 mm). The common path of travel limitation is extended to 75 feet (22 m) in those areas serving a maximum occupant load of 50.

1017.5 Aisles in other than assembly spaces and Groups B and M. In other than rooms or spaces used for assembly purposes and Group B and M occupancies, the minimum clear aisle width shall be determined by Section 1005.1 for the occupant load served, but shall not be less than 36 inches (914 mm).

- Aisles can occur in other occupancies when there is a confined path of travel to the exit access or exit door leading from a space. The reference to Section 1005.1 would trigger a requirement for aisles wider than 36 inches (914 mm) when the anticipated occupant load that the aisle served was larger than 180 (36 inches/0.2 = 180 occupants for nonsprinklered buildings and 36 inches/0.15 = 240 occupants in sprinklered buildings). When an aisle allows for access to exits in two directions, the occupant load could be split, similar to corridors.

SECTION 1018 CORRIDORS

1018.1 Construction. Corridors shall be fire-resistance rated in accordance with Table 1018.1. The corridor walls required to be fire-resistance rated shall comply with Section 708 for fire partitions.

Exceptions:

1. A fire-resistance rating is not required for corridors in an occupancy in Group E where each room that is used for instruction has at least one door opening directly to the exterior and rooms for assembly purposes have at least one-half of the required means of egress doors opening directly to the exterior. Exterior doors specified in this exception are required to be at ground level.

2. A fire-resistance rating is not required for corridors contained within a dwelling or sleeping unit in an occupancy in Group R.

3. A fire-resistance rating is not required for corridors in open parking garages.

4. A fire-resistance rating is not required for corridors in an occupancy in Group B which is a space requiring only a single means of egress complying with Section 1015.1.

5. Corridors adjacent to the exterior walls of buildings shall be permitted to have unprotected openings on unrated exterior walls where unrated walls are permitted by Table 602 and unprotected openings are permitted by Table 705.8.

- The purpose of corridor enclosures is to provide fire protection to occupants as they travel the confined path, perhaps unaware of a fire buildup in an adjacent floor area. The base protection is a fire partition having a 1-hour fire-resistance rating (see Table 1018.1). The table allows a reduction or elimination of the fire-resistance rating depending on the occupant load and the presence of an NFPA 13 or 13R automatic sprinkler system throughout the building.

Section 708 addresses the continuity of fire partitions serving as corridor walls. In addition to allowing the fire partitions to terminate at the underside of a fire-resistance-rated floor/ceiling or roof/ceiling assembly, the supporting construction need not have the same fire-resistance rating in buildings of Type II, III and VB construction as specified in Section 708. If such walls were required to be supported by fire-resistance-rated construction, the use of these construction types would be severely restricted when the corridors are required to have a fire-resistance rating. Section 407.3 requires that corridor walls in Group I-2 occupancies that are required to have a fire-resistance rating must be continuous to the underside of the floor or roof deck above or at a smoke-limiting ceiling membrane. Continuity is required because of the defend-in-place protection strategy utilized in such buildings. Requirements for corridor construction within Group I-3 occupancies are found in Section 408.8. Dwelling unit separation in Groups I-1, R-1, R-2 and R-3 is found in Sections 420.2 and 420.3. Ambulatory care facilities have special requirements in Section 422.2 when some of the patients can be incapable of self-preservation. For additional requirements for an elevator lobby that is adjacent to or part of a corridor, see the commentary to Section 713.14.

Exception 1 indicates a fire-resistance rating is not required for corridors in Group E when any room adjacent to the corridor that is used for instruction or assembly purposes has a door directly to the outside. Because these rooms are provided with an alternative egress path due to the requirement for exterior exits, the need for a fire-resistance-rated corridor is eliminated. This option is typically utilized in nonsprinklered buildings, such as day care facilities, since a sprinkler system would also allow for unrated corridors in Group E (see Table 1018.1). Grade schools and high schools have security concerns that sometimes make the outdoor exit for every classroom not a preferred option.

In accordance with Exception 2, a fire-resistance rating for a corridor contained within a single dwelling unit (e.g., apartment, townhouse) or sleeping unit (e.g., hotel guestroom, assistive living suite) is not required for practical reasons. It is unreasonable to expect fire doors and the associated hardware and
closing devices to be within dwellings and similar occupancies.

Given the relatively smoke-free environment of open parking structures, Exception 3 does not require rated corridors in these types of facilities.

If an office suite is small enough that only one means of egress is required from the suite, Exception 4 indicates that a rated corridor would not be required in that area. The main corridor that connected these suites to the exits would be evaluated in accordance with Table 1018.1.

a. For requirements for occupancies in Group I-2, see Sections 407.2 and 407.3.

b. For a reduction in the fire-resistance rating for occupancies in Group I-3, see Section 408.8.

c. Buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2 where allowed.

The required fire-resistance ratings of corridors serving adjacent spaces are provided in Table 1018.1. The fire-resistance rating is based on the group classification (considering characteristics such as occupant mobility, density and familiarity with the building as well as the fire hazard associated with the classification), the total occupant load served by the corridor and the presence of an automatic sprinkler system.

Where the corridor serves a limited number of people (second column in Table 1018.1), the fire-resistance rating is eliminated because of the limited size of the facility and the likelihood that the occupants would become aware of a fire buildup in sufficient time to exit the structure safely. The total occupant load that the corridor serves is used to determine the requirement for a rated corridor enclosure. The number of occupants served is the total occupants that will move into the corridor to egress. Corridors serving a total occupant load equal to or less than that indicated in the second column of Table 1018.1 are not required to be enclosed with fire-resistance-rated construction. For example, a corridor serving an occupant load of 30 or less in an unsprinklered Group B occupancy is not required to be enclosed with fire-resistance-rated construction. This example is illustrated in Figure 1018.1.

The number of occupants served by the corridor is different than the occupant load number used to determine the corridor width (Section 1018.2). If a corridor leads in two directions to two separate exits, that number is split in half to determine the required occupant load for the corridor width.

The purpose of corridor enclosures is to provide fire protection to occupants as they travel the confined path, perhaps unaware of a fire buildup in an adjacent floor area. The base protection is a fire partition having a 1-hour fire-resistance rating. The table allows a reduction or elimination of the fire-resistance rating depending on the occupant load and the presence of an NFPA 13 or 13R automatic sprinkler system throughout the building.

A common mistake is assuming a building is sprinklered throughout and utilizing the corridor rating reductions, when in fact certain requirements in NFPA 13 would not consider the building sprinklered throughout. For example, a health club installs a sprinkler system, but chooses to eliminate the sprinklers over the swimming pool in accordance with the exception in Section 507.3. Any corridors within the building that serve greater than 30 occupants must be rated because the building would not be considered sprinklered throughout in accordance with NFPA.
MEANS OF EGRESS

13 requirements.

Note that because of the hazardous nature of occupancies in Groups H-1, H-2 and H-3, fire-resistance-rated corridors are required under all conditions. Regardless of the presence of a fire sprinkler system, a 1-hour-rated corridor enclosure is required in high-hazard occupancies with detonation, deflagration, accelerated burning, readily supported combustion or physical hazards. Group H-4 and H-5 occupancies that contain semiconductor fabrication materials or operations constituting a health hazard do not pose the same relative fire or explosion hazard as Group H-1, H-2 or H-3 materials. As such, in Group H-4 or H-5, where the corridor serves a total occupant load of 30 or less, a fire-resistance-rated enclosure is not required. The "not permitted" in the third column is in coordination with Section 903.2.5, which requires all Group H buildings to be fully sprinklered.

The code acknowledges that an automatic sprinkler system can serve to control or eliminate fire development that could threaten the exit access corridor. Most occupancies where sleeping rooms are not present (Groups A, B, E, F, M, S and U) are permitted to have nonfire-resistance-rated corridors if a sprinkler system is installed throughout the building in accordance with NFPA 13.

In residential facilities, the response time to a fire may be delayed because the residents may be sleeping. With this additional safety concern, the requirements for corridors are more restrictive than nonresidential occupancies. If the corridor serves more than 10 occupants, it is required to be rated. If the building is sprinklered throughout with either an NFPA 13 or 13R system, then the rating of the corridor may be reduced to 1/2 hour. Note the exception for fire-resistance-rated corridors within an individual dwelling or sleeping unit in Section 1018.1. Also note that the reduction in the rating of the corridor walls is not permitted when an NFPA 13D sprinkler system is provided.

While all Group I facilities are supervised environments, the level of supervision in Group I-2 and I-4 occupancies would permit assisted evacuation by staff in an emergency; therefore, corridors are not required to be rated. Corridors in Groups I-2 are also regulated by Section 407.3. Due to the lower staff/resident ratio in Group I-1 and the limitation on free egress in Group I-3, corridors must have a 1-hour fire-resistance rating (see Section 408.8 for a reduction in the corridors in Group I-3). The "not permitted" in the third column is in coordination with Section 903.2.6, which requires all Group I buildings to be fully sprinklered.

1018.2 Width. The minimum width of corridors specified in Table 1018.2 shall be as determined in Section 1005.1.

The corridor widths specified in Table 1018.2 are long established minimums originally derived from human dimensions, practical concerns, occupant load and psychological considerations. Additional corridor capacity, when necessary for large crowds, is deter-

mined in accordance with Section 1005.

The number of occupants using a corridor for egress establishes the required capacity of a corridor, as well as for any specific portion of a multileg corridor system. Portions of a corridor system may differ in width for a variety of reasons not related to code minimums. The designer and building official are expected to verify that corridor widths and corridor fire-resistance ratings are in accordance with Sections 1005 and 1018.

The required occupant capacity of a corridor is based on the total occupant load of the rooms and spaces served by the corridor as determined by Section 1004. Where a corridor is served by two exits in opposite directions, the corridor capacity is split to determine the minimum required width of those exits (i.e., exit door, exit stairway) at each end of the corridor. The total occupant load served by a corridor is not split to establish the corridor fire-resistance rating (see Section 1018.1).

For SI: 1 inch = 25.4 mm.

The width of passageways, aisles and corridors is a functional element of building construction that allows the occupants to circulate freely and comfortably throughout the floor area under nonemergency conditions. Under emergency situations, the egress paths must provide the needed width to accommodate the number of occupants that must utilize the corridor for egress.

When the occupant load of the space exceeds 49, the minimum width of the passageway, aisle or corridor serving that space is required to be at least 44 inches (1118 mm) to permit two unimpeded parallel columns of users to travel in opposite directions. When the total occupant load served by a corridor is 49 or less, a minimum width of 36 inches (914 mm) is permitted and the users are expected to encounter some intermittent travel interference from fellow users, but the lower occupant load makes those occasions infrequent and tolerable. The 36-inch (914
mm) minimum width is also required within a dwelling unit.

Passageways that lead to building equipment and systems must be at least 24 inches (610 mm) in width to provide a means to access and service the equipment when needed. Due to the frequency of the servicing intervals and the limited number of occupants in these normally unoccupied areas, a reduced width is warranted. This minimum width criteria applies to many common situations, such as stage lighting and special-effects catwalks; catwalks leading to heating and cooling equipment as well as passageways providing access to boilers, furnaces, transformers, pumps, piping and other equipment.

Except for small buildings, Group E occupancies are required to have minimum 72-inch-wide (1829 mm) corridors where the corridors serve educational areas. This width is needed not only for proper functional use, but also because of the edge effect caused by student lockers and other boundary attractions and objects. Service and other corridors outside of educational areas, such as an administrative area, would be regulated consistent with their use. Note that Section 1018.3 would not allow the wall lockers to overlap the required corridor width.

In Group I-2 occupancies, where the corridor is utilized during a fire emergency for moving patients confined to beds, it is required to be at least 96 inches (2438 mm) in clear width. This width requirement is applicable to all areas where there are patient sleeping rooms, and may also be required in some of the treatment room areas where in-house patients will be brought in in beds or gurneys. This minimum width allows two rolling beds or gurneys to pass in a corridor and permits the movement of a bed/gurney into the corridor through a room door. In Group I-2 and ambulatory care center areas, where the movement of beds is not anticipated, such as administrative and some outpatient areas of a hospital or clinic, the corridor would not be required to be 96 inches (2438 mm) wide. The minimum width would be determined by one of the appropriate applicable criteria. For outpatient medical care, where the patient may be incapable of self-preservation, such as some outpatient surgery areas or dialysis treatment areas, the 72-inch-wide (1829 mm) corridor is required based on Exception 5. This would include Group I surgical areas, areas such as MRI suites or dialysis centers, emergency rooms or Group B ambulatory care centers.

1018.3 Obstruction. The required width of corridors shall be unobstructed.

Exception: Encroachments complying with Section 1005.7.

It is important to maintain required corridor width so that the path of travel to an exit is continually available and unobstructed. Due to the fact that corridors tend to be lined with user passage doors, there are allowances under Section 1005.7. In no case may a door block more than 50 percent of the corridor width. In addition, when fully open, the doors must not protrude more than 7 inches (178 mm). This is consistent with the provisions in aisles, corridors, stairways, ramps, exit passageways and exit discharge courts.

A cross reference back to Section 1005.7 from the exceptions for width in corridors (see Section 1018.3), aisles (see Section 1017.1), exit passageways (see Section 1023.2) and exit courts (see Section 1027.4.1) reinforces the fact that the protrusion limits provision is generally applicable for these types of confined routes.

1018.4 Dead ends. Where more than one exit or exit access doorway is required, the exit access shall be arranged such that there are no dead ends in corridors more than 20 feet (6096 mm) in length.

Exceptions:

1. In occupancies in Group I-3 of Occupancy Condition 2, 3 or 4 (see Section 308.5), the dead end in a corridor shall not exceed 50 feet (15240 mm).

2. In occupancies in Groups B, E, F, I-1, M, R-1, R-2, R-4, S and U, where the building is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1, the length of the dead-end corridors shall not exceed 30 feet (9144 mm).

3. A dead-end corridor shall not be limited in length where the length of the dead-end corridor is less than 2.5 times the least width of the dead-end corridor.

The requirements of this section apply where a space is required to have more than one means of egress according to Section 1015.1.

Dead ends in corridors and passageways can seriously increase the time needed for an occupant, especially if unfamiliar with the space, to locate the exits. More importantly, dead ends will allow a single fire event to eliminate access to all of the exits by trapping the occupants in the dead-end area. A dead end exists whenever a user of the corridor or passageway has only one direction to travel to reach any building exit [see Figure 1018.4(1)]. While a preferred building layout would be one without dead ends, a maximum dead-end length of 20 feet (6096 mm) is permitted and is to be measured from the extreme point in the dead end to the point where occupants have a choice of two directions to separate exits. Having to go back only 20 feet (6096 mm) after coming to a dead end is not such a significant distance as to cause a serious delay in reaching an exit during an emergency situation.

A dead end results whether or not egress elements open into it. A dead end is a hazard for occupants who enter the area from adjacent spaces, travel past an exit into a dead end or enter a dead end with the mistaken assumption that an exit is directly accessible from the dead end.

Note that Section 402.8.6 deals with dead-end dis-
tances in a covered mall and assumes that, with a sufficiently wide mall in relation to its length, alternative paths of travel will be available in the mall itself to reach an exit (i.e., the common mall area is not to be construed as a corridor).

Under special conditions, exceptions to the 20-foot (6096 mm) dead-end limitation apply. Exception 1 is permitted based on the considerations of the functional needs of Group I-3 Occupancy Conditions 2, 3 or 4, the requirements for smoke compartmentalization in Section 408.6 and the requirement for automatic sprinkler protection of the facility in Section 903.2.6.

Exception 2 recognizes the fire protection benefits and performance history of automatic fire sprinkler systems. While the degree of hazard in Group B, E, F, M, S and U occupancies does not initially require an automatic fire suppression system, the length of a dead-end corridor or passageway is permitted to be extended to 50 feet (15240 mm) where an automatic fire sprinkler system in accordance with NFPA 13 is provided throughout the building. This exception is also permitted in Group I-1, R-1, R-2 and R-4 occupancies. In addition, these provisions are consistent with those in the IIBC and IFC in the regulation of dead-end corridors in existing buildings undergoing alterations. Dead-end provisions are not applicable in single-exit spaces; therefore, dead-end provisions are not applicable in Group R-3 occupancies.

Exception 3 addresses the condition presented by "cul-de-sac" elevator lobbies directly accessible from exit access corridors. In such an elevator lobby, lengths of 20 to 30 feet (6096 to 9144 mm) are common for three- or four-car elevator banks. Typically, the width of this elevator lobby is such that the possibility of confusion with a path of egress is minimized. Below the 2'/':1 ratio, the dead end becomes so wide that it is less likely to be perceived as a corridor leading to an exit. For example, based on the 2'/':1 ratio limitation, a 25-foot-long (7620 mm) dead end over 10 feet (3048 mm) in width would not be considered a dead-end corridor [see Figure 1018.4(2)]. For addi-
national elevator lobby requirements, see the commentary to Section 713.14.1.

1018.5 Air movement in corridors. Corridors shall not serve as supply, return, exhaust, relief or ventilation air ducts.

Exceptions:

1. Use of a corridor as a source of makeup air for exhaust systems in rooms that open directly onto such corridors, including toilet rooms, bathrooms, dressing rooms, smoking lounges and janitor closets, shall be permitted, provided that each such corridor is directly supplied with outdoor air at a rate greater than the rate of makeup air taken from the corridor.

2. Where located within a dwelling unit, the use of corridors for conveying return air shall not be prohibited.

3. Where located within tenant spaces of 1,000 square feet (93 m²) or less in area, utilization of corridors for conveying return air is permitted.

4. Incidental air movement from pressurized rooms within health care facilities, provided that the corridor is not the primary source of supply or return to the room.

Two of the most critical elements of the means of egress are the required exit stairways and corridors. Exit stairways serve as protected areas in the building that provide occupants with safe passage to the level of exit discharge. Since required exits and corridors are critical elements in the means of egress, the potential spread of smoke and fire into these spaces must be minimized. The scope of this section is corridors. For requirements for the exits, see Section 1022.

The use of these corridors as part of the air distribution system could render those egress elements unusable. The intent is to have positive pressure in the corridors. Therefore, any air movement condition that could introduce smoke into these vital egress elements is prohibited. It is not the intent of this section to prohibit the air movement necessary for ventilation and space conditioning of corridors, but rather to prevent those spaces from serving as conduits for the distribution of air to, or the collection of air from, adjacent spaces. This restriction also extends to door transoms and door grilles that would allow the spread of smoke into a corridor. This limitation is not, however, intended to restrict slight pressure differences across corridor doors, such as a negative pressure differential maintained in kitchens to prevent odor migration into dining rooms. Note that air distribution via ducted systems located in or above corridors is acceptable since the corridor itself would not be functioning as a duct.

The four exceptions to this section identify conditions where a corridor can be utilized as part of the air distribution system. The exceptions apply only to exit access corridors, not to exit passageways.

Exception 1 addresses the common practice of using air from the corridor as makeup air for small exhaust fans in adjacent rooms. Where the corridor is supplied directly with outdoor air at a rate equal to or greater than the makeup air rate, negative pressure will not be created in the corridor with respect to the adjoining rooms and smoke would generally not be drawn into the corridor.

Regarding Exception 2, it is common practice to locate return air openings in the corridors of dwelling units and draw return air from adjoining spaces through the corridor. Such use of dwelling unit corridors for conveying return air is not considered to be a significant hazard and is permitted. Individual dwelling units are permitted to have unprotected openings between floors. Corridors within dwelling units that serve small occupant loads are short in length and are not required to be fire-resistance rated. For these reasons, the use of the corridor or the space above a corridor ceiling for conveying return air does not constitute an unacceptable hazard.

Exception 3 permits corridors located in small tenant spaces to be used for conveying return air based on the relatively low occupant load and the relatively short length of the corridor. These conditions do not pose a significant hazard. In the event of an emergency, the occupants of the space would tend to simply retrace their steps to the entrance.

Health care facilities require direct pressurization control of certain rooms to provide a clean and sterile environment for patients. For example, operating rooms and pharmacies are required to have positive air pressure in the room, resulting in a general air movement out of the room. This ensures that airborne contaminants do not infect a sterile procedure or supplies. Pressurization is achieved by supplying air at a greater or lesser rate than the return air. Exception 4 recognizes the need of infection control and clarifies that the corridor should not be the primary source of supply return. There should be supply and return air in the room.

1018.5.1 Corridor ceiling. Use of the space between the corridor ceiling and the floor or roof structure above as a return air plenum is permitted for one or more of the following conditions:

1. The corridor is not required to be of fire-resistance-rated construction;

2. The corridor is separated from the plenum by fire-resistance-rated construction;

3. The air-handling system serving the corridor is shut down upon activation of the air-handling unit smoke detectors required by the International Mechanical Code;

4. The air-handling system serving the corridor is shut down upon detection of sprinkler waterflow where the building is equipped throughout with an automatic sprinkler system; or
5. The space between the corridor ceiling and the floor or roof structure above the corridor is used as a component of an approved engineered smoke control system.

- This section identifies five different conditions where the space above the corridor ceiling is permitted to serve as a return air plenum. Since a return air plenum operates at a negative pressure with respect to the corridor, any smoke and gases within the plenum should be contained within that space. Conversely, a supply plenum operates at a positive pressure with respect to the corridor, thus increasing the likelihood that smoke and gases will infiltrate the corridor enclosure. Where any one of the five conditions is present, the use of the corridor ceiling space as a return air plenum is permitted.

Where the corridor is permitted to be constructed without a fire-resistance rating (see Section 1018.1), Item 1 permits the space above the ceiling to be utilized as a return air plenum without requiring it to be separated from the corridor with fire-resistance-rated construction.

Item 2 is only applicable to corridors that are required to be enclosed with fire-resistance-rated construction. Compliance with this item requires the plenum to be separated from the corridor by fire-resistance-rated construction equivalent to the rating of the corridor enclosure itself. Therefore, the ceiling membrane itself must provide the fire-resistance rating required of the corridor enclosure. Section 708.4, Exception 3, is an example of this method of construction.

Items 3 and 4 recognize that the hazard associated with smoke spread through a plenum is minimized if the air movement is stopped. It is not uncommon for an above-ceiling plenum to be utilized as part of the smoke removal system. This practice is permitted by Item 5. Due to the way these systems are designed, the higher equipment ratings and the power supply provisions, this is considered acceptable.

1018.6 Corridor continuity. Fire-resistance-rated corridors shall be continuous from the point of entry to an exit, and shall not be interrupted by intervening rooms. Where the path of egress travel within a fire-resistance-rated corridor to the exit includes travel along unenclosed exit access stairways or ramps, the fire resistance-rating shall be continuous for the length of the stairway or ramp and for the length of the connecting corridor on the adjacent floor leading to the exit.

Exception: Foyers, lobbies or reception rooms constructed as required for corridors shall not be construed as intervening rooms.

- This section requires that where fire protection is offered by a corridor, it is to be continuous from the point of entry into the corridor to an exit. This is to protect occupants from the accumulation of smoke or fire exposure and to allow for sufficient time to evacuate the building. Where a corridor is served by two or more exits, only one of the exits is required to be accessed directly from the corridor. Other exits may be accessed through intervening spaces in accordance with Section 1014.2, provided that there is an opening protective at the end of the corridor to separate the rated corridor from the intervening rooms. Thus, occupants will always have their protected path to an exit, and at the same time allows a reasonable degree of design freedom [see Figures 1018.6(1) and 1018.6(3)].

When a level is permitted to have unenclosed exit access stairways in accordance with Section 1009.3, the corridor protection is required to continue down the exit access stairway to an enclosure for an inte-
rior exit stairway or to an exit door leading to the outside. Since the exit access stairway effectively becomes part of the corridor, doors would not be required at the top and bottom of the open exit access stairway as they are when entering enclosures for exit stairways.

The exception allows a foyer, lobby or reception room to be located on the path of egress from a corridor or as part of the fire-resistance-rated corridor, provided the room has the same fire-resistance-rated walls and doors as required for the corridor. The use of this provision should be viewed as limiting the types of uses that may occur within the protected corridor. Occupied spaces within the corridor should have very limited uses and hazards. Foyers and lobbies are included in this exception based on the low fire hazard of the contents in such rooms [see Figure 1018.6(2)].

Another consideration is corridor continuity at an elevator opening. When an elevator opens into a corridor that is required to be of fire-resistance-rated construction, the opening between the elevator shaft and the corridor must be protected to meet not only the shaft’s fire protection rating but also the additional

---

Figure 1018.6(2)
CORRIDOR CONTINUITY—EXAMPLE 2

---

Figure 1018.6(3)
CORRIDOR CONTINUITY—EXAMPLE 3
smoke and draft protection requirements necessary to limit the spread of smoke into the corridor. This additional smoke and draft control requirement is found in Section 716.5.3.1. Because elevator hoistway doors do not typically comply as smoke- and draft-control assemblies, they would not be able to open directly into a corridor that is required to have protected openings. The provisions in Section 713.14 waiving the requirements for an elevator lobby do not waive the corridor opening protection requirements.

Figure 1018.6(4)
ELEVATOR LOBBY/CORRIDOR OPTION 1

Figure 1018.6(5)
ELEVATOR LOBBY/CORRIDOR OPTION 2
Therefore, to maintain the integrity of the corridor, the elevator hoistway shaft doors opening into such rated corridors will need to be separated from the corridor by one of the following methods of protection:

1. A lobby needs to be provided with the appropriate doors [see Figure 1018.6(4) and Section 713.14].

2. Additional doors must be provided at the hoistway [see Figure 1018.6(5) and Sections 716.5.3 and 3002.6].

3. An elevator shaft door meeting both the smoke and draft protection requirements for corridor doors in Section 716.5.3.1 as well as the appropriate fire protection rating of Table 716.5 for the shaft must be provided.

4. The corridor must be separated from the lobby [see Figure 1018.6(6)].

Option 4 is permitted when one end of a fire-resistance-rated corridor leads directly to an exit. While many elevator hoistway shaft doors are tested and labeled for the 1-hour or 1½-hour fire-resistance rating [see Section 716.5], very few, if any of the doors typically sold in the U.S. will also meet the smoke and draft requirements [see Section 716.5.3.1] that would allow them to open directly into a fire-resistance-rated corridor. Because of this, Items 1, 2 and 4 above will be the general methods for protecting such openings.

For requirements and additional explanation of the elevator lobby requirements for elevator lobbies that are adjacent to rated corridors, see Section 713.14.

For requirements for exit enclosures, see Section 1022. The second means of egress serving the corridor can be an elevator lobby with direct access to an exit.

**SECTION 1019**

**EGRESS BALCONIES**

**1019.1 General.** Balconies used for egress purposes shall conform to the same requirements as corridors for width, headroom, dead ends and projections.

This section regulates balconies that are used as an exit access element. Requirements are the same as exit access corridors, except for the enclosure.

Where exterior egress balconies are used in moderate or severe climates, there may also be a concern to protect the egress balcony from accumulations of snow and ice to provide a safe path of egress travel at all times, including winter. Maintenance of the means of egress in the IFC requires an unobstructed path to allow for full instant use in case of a fire or emergency. Typical methods for protecting these egress elements include roof overhangs or canopies, heated slab and, when approved by the building official, a reliable snow removal maintenance program.

**1019.2 Wall separation.** Exterior egress balconies shall be separated from the interior of the building by walls and openings protective as required for corridors.

**Exception:** Separation is not required where the exterior egress balcony is served by at least two stairs and a dead-
end travel condition does not require travel past an unprotected opening to reach a stair.

- An exterior exit access balcony has a valuable attribute in that the products of combustion may be freely vented to the open air. In the event of a fire in an adjacent space, the products of combustion would not be expected to build up in the balcony area as would commonly occur in an interior corridor. However, there is still a concern for the egress of occupants who must use the balcony for exit access, and consequently, may have to pass the room or space where the fire is located. Therefore, an exterior exit access balcony is required to be separated from interior spaces by fire partitions, as is required for interior corridors. The other provisions of Section 1018 relative to dead ends and opening protective also apply.

If there are no dead-end conditions that require travel past an unprotected opening and the balcony is provided with at least two stairways, then the wall separating the balcony from the interior spaces need not have a fire-resistance rating (see Figure 1019.2). Such an arrangement reduces the probability that occupants will need to pass the area with the fire to gain access to an exit.

**1019.3 Openness.** The long side of an egress balcony shall be at least 50 percent open, and the open area above the guards shall be so distributed as to minimize the accumulation of smoke or toxic gases.

- This section provides an opening requirement that is intended to preclude the rapid buildup of smoke and toxic gases. A minimum of one side of the exterior balcony is required to have a minimum open exterior area of 50 percent of the side area of the balcony. The side openings are to be uniformly distributed along the length of the balcony.

**1019.4 Location.** Exterior egress balconies shall have a minimum fire separation distance of 10 feet (3048 mm) measured from the exterior edge of the egress balcony to adjacent lot lines and from other buildings on the same lot unless the adjacent building exterior walls and openings are protected in accordance with Section 705 based on fire separation distance.

- The location requirements of this section protect the users of the egress balcony from the effects of a fire in another building on the same lot or an adjacent lot. The separation distance reduces the exposure to heat and smoke. If the egress balcony is closer than specified, then the adjacent buildings' exterior walls and openings are to be protected in accordance with Section 705 so that the users of the egress balcony are protected. The reason for the required distance to a lot line is to provide for a future building that could be built on the adjacent lot. While buildings on the same lot can be considered one building for height and area limitations (see Section 503.1.2), they must be separated by a minimum of 10 feet (3048 mm) if there is a path for exit discharge between them. It is not intended that the distance be measured to the imaginary lot line between buildings on the same lot.

Requirements are the same for exterior exit stairways and ramps. For an illustration of how exterior egress balconies and exterior exit stairways work together, see Figure 1026.5.

**SECTION 1020 EXITS**

**1020.1 General.** Exits shall comply with Sections 1020 through 1026 and the applicable requirements of Sections 1003 through 1013. An exit shall not be used for any purpose that interferes with its function as a means of egress. Once a given level of exit protection is achieved, such level of protection shall not be reduced until arrival at the exit discharge.

- This group of sections is applicable to the "exit" portion of the three-part means of egress system. Sections 1003 through 1013 are also applicable to exits. The following sections are covered in this group:
  - Section 1020 are general requirements for exterior exit doorways.
  - Section 1021 talks about the number of exits required from a story and their continuity and arrangement.
• Section 1022 provides criteria for interior exit stairways and ramps.
• Section 1023 covers a horizontal portion of the exit and exit passageways.
• Section 1024 is referenced by the high-rise provisions in Section 403. This section addresses a backup system for means of egress lighting (see Section 1006). "Glow-in-the-dark" stripes identify steps, handrails, obstructions and doorways within the enclosure for interior exit stairways.
• Section 1025 discusses the option of horizontal exits. This type of system is most commonly used for buildings such as hospitals and jails where building evacuation is not always the best option.
• Section 1026 provides criteria for stairways or ramps that are primarily open to the exterior, thus reducing the chance of accumulation of smoke or fumes.

The use of required exterior exit doors, exit stairways, exit passageways and horizontal exits for any purpose other than exiting is prohibited, because it might interfere with use as an exit. This is not intended to prohibit a door or stairway being used as part of normal circulation patterns, such as the exit doors also serving as entrances, or using the stairway to move between floors when there is not an emergency. However, these spaces must not include furniture, storage or work space. For example, the use of an exit stairway landing for storage, vending machines, copy machines, displays or any purpose other than for exiting is not permitted. Such a situation could not only lead to obstruction of the path of exit travel, thereby creating a hazard to life safety, but if the contents consist of combustible materials, then the use of the stairway as a means of egress could be jeopardized by fire or smoke in the exit enclosure.

It is recognized that standpipe risers are provided within the stair enclosure and that vertical electrical conduit may be necessary for power or lighting. However, such risers must be located so as not to interfere with the required clear width of the exit. For example, a standpipe riser located in the corner of a stairway will not reduce the required clear radius of the landing. This also applies true when the stairway landing is used as an area of refuge. The spaces for wheelchairs must not obstruct the general path of egress travel [see Figures 1007.3(1) and 1007.3(2)]. Electrical conduit and mechanical equipment are permitted when necessary to serve the exit enclosure.

In existing buildings, sometimes the only viable option for providing access into the space is a platform lift. These platform lifts can be located within the enclosure for the exit (see Section 1007.3).

Sections 1020 through 1026 apply to all exits but do not apply to elements of the means of egress that are not actually exits, such as access corridors and passageways or elements of the exit discharge. For exit discharge options for the enclosure, other than a door leading directly to the outside, see the requirements for exit passageways in Section 1023 or the options permitting usage of a lobby or vestibule in the exceptions to Section 1027.1.

1020.2 Exterior exit doors. Buildings or structures used for human occupancy shall have at least one exterior door that meets the requirements of Section 1008.1.1.

• The purpose of this section is to specify that at least one exterior exit door is required to meet the door size requirements in Section 1008.1.1. It is not the intent of this section to specify the number of exit doors required, which is addressed in Section 1021.1.

1020.2.1 Detailed requirements. Exterior exit doors shall comply with the applicable requirements of Section 1008.1.

• The purpose of this section is simply to provide a cross reference from the exit section to all of the detailed requirements for doors that are included in Section 1008.1 and all of its subsections. For example, the requirements for door operation on exterior exit doors are controlled by Section 1008.1.9.

1020.2.2 Arrangement. Exterior exit doors shall lead directly to the exit discharge or the public way.

• The exterior exit door is to be the entry point of the exit discharge or lead directly to the public way. When a person reaches the exterior exit door, he or she is directly outside, where smoke and toxic gases are not a health hazard. Additionally, this section will keep exterior doors at other locations, such as to an egress balcony, from being viewed as an exit element.

SECTION 1021
NUMBER OF EXITS AND EXIT CONFIGURATION

1021.1 General. Each story and occupied roof shall have the minimum number of exits, or access to exits, as specified in this section. The required number of exits, or exit access stairways or ramps providing access to exits, from any story shall be maintained until arrival at grade or a public way. Exits or access to exits from any story shall be configured in accordance with this section. Each story above the second story of a building shall have a minimum of one interior or exterior exit stairway, or interior or exterior exit ramp. At each story above the second story that requires a minimum of three or more exits, or access to exits, a minimum of 50 percent of the required exits shall be interior or exterior exit stairways, or interior or exterior exit ramps.

Exceptions:

1. Interior exit stairways and interior exit ramps are not required in open parking garages where the means of egress serves only the open parking garage.
MEANS OF EGRESS

2. Interior exit stairways and interior exit ramps are not required in outdoor facilities where all portions of the means of egress are essentially open to the outside.

- This section starts out saying that every occupant on a story must have access to the required number of means of egress as specified:
  - Per Section 1021.2—At least two means of egress per floor;
  - Per Sections 1021.2.1, 1021.2.2 and 1021.2.3—Limited allowance for a single means of egress from a floor;
  - Per Section 1021.2.4—Three means of egress for floors with greater than 500 occupants and four means of egress for floors with greater than 1,000 occupants;
  - Per Section 1021.2.5—A reference to the unique criteria for high-rise buildings greater than 420 feet in height.

Saying "means of egress" instead of "exits" acknowledges that direct entrances to exits on each story are not always mandatory since access to exits (i.e., exit access stairways or ramps) on some stories is permissible within certain limitations. This allows some freedom of design when, for instance, required exit stairways may not be available without passing through other tenant spaces. The intent is to allow for a balance of security concerns providing adequate safety for emergency evacuation.

The second floor of a building can use two exit access stairways or ramps. Starting at the third floor, and for all upper floors, at least 50 percent, but not less than one means of egress must be provided by direct access to an exit stairway or ramp. The exit stairway and ramp can be interior (see Section 1022) or exterior (see Section 1026). The remaining means of egress could be provided by exit access stairways or ramps if desired (see also Section 1021.2.2 for basements). The same provisions for number of exits used for stories also applies to occupied roofs.

If a designer chooses to use horizontal exits instead of exit stairways or exit ramps, those specific provisions are addressed in Section 1025.4. For buildings built into a hillside, an exit door directly to the outside would also provide the same or better level of protection as an interior exit element. It is not the intent of this provision to prohibit horizontal exits or direct exterior exit doors as an option.

Once the number of means of egress is determined, those paths must remain available until occupants leave the building (see Figure 1021.1). The need for exits to be independent of each other cannot be overstated. Each occupant of each floor must be provided with the required number of exits without having to pass through one exit to gain access to another. Each exit is required to be independent of other exits to prohibit such areas from merging downstream and becoming, in effect, one exit.

The configuration of those exit and exit access elements must not be obstructed (Section 1015.2) and must be placed a certain distance apart (Section 1015.2.1 and 1015.2.2), similar to exit access doorways (Section 1021.3). The appropriate separation is subjective and would be partially dependent on the layout of interior spaces. While an equal distribution of exit capacity among all of the exits is not required,

---

**Figure 1021.1**

NUMBER OF EXITS

- 200 OCCUPANTS
- 450 OCCUPANTS
- 375 OCCUPANTS
- 650 OCCUPANTS

2 EXITS REQUIRED PER FLOOR (≤ 500 THIS FLOOR)

3 EXITS REQUIRED (> 500 THIS FLOOR)
a proper design would not only balance capacity with the occupant load distribution, but also consider a reasoned distribution of capacity to avoid a severe dependence on one exit. Using some other provisions in the code for guidance could be helpful. For instance, Section 1005.5 states that multiple means of egress need to be sized such that the loss of any one will not reduce the egress capacity below 50 percent. This intent is repeated for an assembly space with more than 300 occupants. Sections 1028.2 and 1028.3 can require a Group A space to have a main exit that accommodates one-half of the total occupant load with the balance exits (means of egress), providing capacity for the other half of the occupant load. If there is not a main exit, the exceptions to both Sections 1028.2 and 1028.3 require the means of egress to be "distributed around the perimeter of the building."

Stairways and ramps in open parking garages and outdoor facilities are considered exit access stairways and ramps (Section 1009.3, Exceptions 6 and 7). Exit access travel distance is measured to the top riser of the flight/run (Section 1016.3, Exceptions 1 and 2). The intent of the exceptions in Section 1021.1 is to allow for open parking garages and outdoor facilities to not have to have enclosed exit stairways or ramps from upper levels.

1021.2 Exits from stories. Two exits, or exit access stairways or ramps providing access to exits, from any story or occupied roof shall be provided where one of the following conditions exists:

1. The occupant load or number of dwelling units exceeds one of the values in Table 1021.2(1) or 1021.2(2).

2. The exit access travel distance exceeds that specified in Table 1021.2(1) or 1021.2(2) as determined in accordance with the provisions of Section 1016.1.

3. Helistop landing areas located on buildings or structures shall be provided with two exits, or exit access stairways or ramps providing access to exits.

Exceptions:

1. Rooms, areas and spaces complying with Section 1015.1 with exits that discharge directly to the exterior at the level of exit discharge, are permitted to have one exit.

2. Group R-3 occupancy buildings shall be permitted to have one exit.

3. Parking garages where vehicles are mechanically parked shall be permitted to have one exit.

4. Air traffic control towers shall be provided with the minimum number of exits specified in Section 412.3.

5. Individual dwelling units in compliance with Section 1021.2.3.

6. Group R-3 and R-4 congregate residences shall be permitted to have one exit.

7. Exits serving specific spaces or areas need not be accessed by the remainder of the story when all of the following are met:

7.1. The number of exits from the entire story complies with Section 1021.2.4.

7.2. The access to exits from each individual space in the story complies with Section 1015.1; and

7.3. All spaces within each portion of a story shall have access to the minimum number of approved independent exits based on the occupant load of that portion of the story, but not less than two exits.

The base assumption is that all stories of a building shall have access to at least two separate ways out for emergencies. While this section offers two exits (i.e., exit stairways) or two exit access stairways from each floor, starting at the third floor, Section 1021.1 limits the number of exit access stairways to a maximum of 50 percent. Therefore, the choices for a typical floor (other than a second floor) would be either two exit stairways or one exit stairway and one exit access stairway. Allowing two exit access stairways would not meet the required number of exits. To determine when more than two exits are required due to high occupant load, see Section 1021.2.3.

Items 1, 2 and 3 state what situations require two exits. The reference to Tables 1021.2(1) and 1021.2(2) and Exceptions 1 through 6 basically indicate where occupants in a building or tenant space are only required to have access to one exit. Exception 7 addresses an option where some occupants on a story might not have access to all exits on that story. See the commentary for Tables 1021.2(1) and 1021.2(2) for information on single-exit buildings.

Per Items 1 and 2, if a story can meet the provisions for occupant load, number of units and travel distance in Table 1021.2(1) or 1021.2(2), then that story can have one means of egress. See the commentaries under each table for additional information.

Item 3 allows for helistop landings on the roof of a building to have either two exit stairways or two exit access stairways. While Section 1021.1 is not specific to roofs, it is an upper level and the options would allow two exit stairways or one exit stairway and one exit access stairway.

Exception 1 references Table 1015.1 for single-exit spaces. Table 1015.1 is intended to be applicable to rooms and spaces on a floor, but not to an entire floor level. One of the main concerns has been that vertical travel takes longer than horizontal travel in emergency exiting situations. However, if the single-exit space can exit directly to the exterior rather than egress into an interior corridor, a higher level of safety is provided. While the term "building" limits the area addressed to that bordered by exterior walls or
MEANS OF EGRESS

fire walls, a common application of Exception 1 is on a tenant-by-tenant basis. For example, a single-story strip mall may not meet the provisions for a building with one means of egress but each tenant area meets the provisions for a space with one means of egress in accordance with Section 1015.1. This tenant could exist as either a stand-alone single-exit building or as a single-exit tenant space that exits into an interior corridor. Is it not just as safe to permit this tenant to exist as part of a larger building with the door exiting directly to the exterior?

While not specifically stated in this section, there is a situation where the single means of egress can be used from a multilevel tenant space. When the combined occupant load of the space and a mezzanine meets the occupant load in Table 1015.1 and the common path of travel distance (see Section 1014.3) measured from the most remote point down the exit access stairway and to the exterior exit doorway, the ground floor space and its mezzanine can be considered a space with one means of egress.

Group R-3 is limited to no more than two dwelling units per building. Often these units are townhouse style with direct exits at grade or one unit on top of another. In either configuration, per Exception 2, each unit is required to have only one exit leading from the dwelling. In a multistory unit, any interior stairway would be considered an exit access stairway (Section 1009.3, Exception 2) and would be part of the exit access travel distance in Table 1016.2.

Exception 3 allows for one exit from all stories in a parking garage where the cars are mechanically parked. This is in recognition of the extremely low occupant load in this unique type of building. The single exit would be for maintenance and service personnel that could be on the different levels. Exit access travel would still have to meet Table 1016.2. If this facility is an open parking garage, it could have one exit access stairway compliant with Sections 1016.2, Exception 1, and 1021.2, Exception 1.

Exception 4 is a reference to the requirements specific to traffic control towers in Section 412.3 in recognition of their unique configuration. Only one exit stairway is required when the occupant load per floor is 15 or less.

While Exception 2 addresses Group R-3 buildings, Exception 5 references Section 1021.2.3 for individual dwelling units. This could be single-story or multi-story apartments in a multiple-family building (Group R-2) or it could be a single apartment (Group R-3) over another use, typically business or mercantile. While not specifically a dwelling unit, live/work units are classified as Group R-2; the means of egress is to be designed "for the function served" and vertical openings are permitted without enclosure (Sections 419.2, 419.3 and 419.4). Therefore, it seems reasonable to allow the dwelling portion of the building to have a single exit access stairway as long as it complies with Section 1021.2.3.

Congregate residences in Group R-3 and R-4 are limited to 16 residents that are capable of self-preservation; therefore, they typically operate like a single-family home. With Exception 6, these types of facilities are permitted to have one means of egress leading from the building. Congregate living facilities with more than 16 residents or living facilities where residents are incapable of self-preservation cannot use this exception. Many court cases have been filed under the Fair Housing Act (FHA) requiring that group homes be permitted to operate similar to a single-family home as a point of nondiscrimination. For additional information on the FHA, see the commentary at the beginning of Chapter 11 and under Section 1107.

Exception 7 deals with large multitenant buildings with a floor occupant load of greater than 500. Due to security concerns, tenants do not typically want to allow other tenants to egress through their space, plus there is the requirement that the path to exits shall not be subject to locking (Section 1014.2). This exception would allow for portions of a floor to not have access to all the required exits for the floor, provided they meet three criteria. Per Exception 7.1, the total floor must have the three or four exits required by Section 1021.2.4 based on the occupant load of the entire floor. Per Exception 7.2, each room, space or suite must meet the requirements for the number of exit access doors and the common path of travel requirements. Per Exception 7.3, each portion of the story must have access to the required number of exits if the occupant load of that portion was considered separately. In no case may an occupant have access to less than two exits.

In combination with requirements for distribution of egress capacity (Section 1005.5) and egress through intervening spaces (Section 1014.2), following are two examples of how this exception could or could not work.

In Figure 1021.2(1), the occupant load of the floor requires three stairways (150 + 150 + 200 = 500). The three small tenant spaces do not have access to the stairway in the restaurant. With the restaurant occupant load being 500, it is assumed that with an equal distribution of people exiting from the restaurant, 180 occupants will move towards each of the three required stairways. Adding the portion of the restaurant occupant load to the three tenant spaces (180 + 150 + 150 = 480), the "portion" of the building would still need three stairways. Therefore, this option would not be permitted and the tenant spaces would need access to three stairways.

In Figure 1021.2(2), the occupant load of the floor requires three stairways (300 + 80 + 80 + 80 = 540). Office Suites 1, 2 and 3 do not have access to the stairway in Suite 4. It is assumed that Suite 4, with two stairways required, will have 150 occupants move towards each of the two exit doors in the space. Adding this extra occupant load to the other office suites (150 + 80 + 80 + 80 = 390), this "portion" of the building will need two exit stairways based on occupant loads. Therefore, this option would be permitted.
TABLE 1021.2(1). See page 10-136.

This table addresses when single exits can be provided from stories in Group R-2 occupancies having dwelling units only, such as apartments and condominiums. For Group R-2 occupancies with sleeping units, such as dormitories, sororities, fraternities, convents, monasteries or boarding houses, see Table 1021.2(2). The second row is to clarify that buildings containing Group R-2 single-exit buildings cannot be four stories or taller. In addition to meeting the number of dwelling units per floor and exit access travel distance, these buildings must be equipped throughout with an NFPA13 or 13R sprinkler system and an emergency escape and rescue opening must be provided in every bedroom. The exit access travel distance would be measured from the most remote point in the unit to the exit from the floor. This is different from the travel distance in Sections 1015.1, Exception 1, and 1021.2.3 where the travel distance is measured to the door of the unit. However, in order to be able to use the single-exit building provisions, each unit must also meet the single-exit space requirements, so the occupant load of each apartment is limited. See Figures 1021.2(3) and 1021.2(4) for examples of the differences.

See the commentary under Table 1021.2(2) for additional discussion on single exit building options.

This table is not intended to work in combination

Figure 1021.2(1)

EXAMPLE 2 OF EXCEPTION 7—PERMITTED
MEANS OF EGRESS

with Section 1021.2, Exception 5, and the referenced Section 1021.2.3. Item 2 in that section requires a minimum of two exits from the floor.

**TABLE 1021.2(2). See below.**

- Buildings with one exit are permitted where the configuration and occupancy meet certain characteristics so as not to present an unacceptable fire risk to the occupants. Buildings that are relatively small in size have a shorter travel distance and fewer occupants; thus, having access to a single exit does not significantly compromise the safety of the occupants since they will also be alerted to and get away from the fire more quickly. It is important to note that the provisions in Section 1021.2 apply to individual stories. Multiple single-exit spaces or units may exist in the same building, including those cases where differing occupancies exist. Therefore, Tables 1021.2(1) and 1021.2(2) can address mixed occupancy buildings (see Section 1021.2.1).

Occupants of a story of limited size and configuration may have access to a single exit, provided that the building does not have more than one level below the first story above the grade plane. The limitation on the number of levels above and below the first story is intended to limit the vertical travel an occupant must accomplish to reach the exit discharge in a single-exit building (see Section 1021.2.2).

Only one exit is required from a story where permitted by Table 1021.2(1) or 1021.2(2) regardless of the number of exits required from other stories in the building. For example, a Group B occupancy on the second floor of a two-story building is only required to have one exit from the story, provided its occupant load does not exceed 29 and the maximum exit access travel distance to the exit stairway does not exceed 75 feet (22 860 mm). The number of occupants and travel distances on the first floor do not affect the determination of the second story as a single-exit story. Other stories are also regulated independently as to number of exits. For mixed-occupancy floors or floors where tenant spaces have separate exits, see Section 1021.2.1.

Tables 1021.2(1) and 1021.2(2) list the characteristics a building must have to be of single-exit construction, including occupancy, maximum height of building above grade plane, maximum occupants or dwelling units per floor and exit access travel distance per floor. The occupant load of each floor is determined in accordance with the provisions of Section 1004.1. The exit access travel distance is measured along the natural and unobstructed path to the

<sup>a</sup> Buildings classified as Group R-2 equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2 and provided with emergency escape and rescue openings in accordance with Section 1029.

<sup>b</sup> Group B, F and S occupancies in buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 shall have a maximum travel distance of 100 feet.

<sup>c</sup> This table is used for R-2 occupancies consisting of sleeping units. For R-2 occupancies consisting of dwelling units, use Table 1021.2(1).
exit, as described in Section 1016.3. If the occupant load or number of dwellings is exceeded, two exits are required from each floor in the building. Likewise, if the travel distance is exceeded, two exits are required from each floor of the building.

The enclosure required for the exit in a two- or three-story, single-exit building is identical to any other complying exit (i.e., interior stairs, exterior stairs, etc.). Similarly, the fire-resistance rating required for opening protectives is identical to that required by Section 716. Exit access stairways could be used in two-story buildings, with or without basements, where permitted by Sections 1009.3 and 1021.1.

Table 1021.2(1) address dwelling units in Group R-2 occupancies. For Group R-2 sleeping units, such as congregate residences, fraternities, sororities, dormitories, convents or monasteries, use Table 1021.2(2). Effectively this section allows for small apartment buildings up to three stories in height to have a single-exit stairway when no more than four dwelling units are provided on a floor. The travel distance from the most remote part of a unit to the exit stairway must be less than 125 feet (38.1 m). This is different from the measurement in Sections 1015.1, Exception 1, and 1021.2.3, where the distance is measured to the door of the unit. The apartment building must be sprinklered throughout with an NFPA 13 or 13R system and all bedrooms must have an emergency escape and rescue opening (Section 1029.1).

Table 1021.2(2) allows for two-story business, factory, mercantile and storage facilities to have a single-exit stairway or exit access stairway (see Section 1009.3) from the second floor if the space meets the maximums of 29 occupants and 75-feet (22 860 mm) travel distance. The increased travel distance in Note b is not permitted for the second floor.

Table 1021.2(2) allows for a variety of single-story buildings, with or without basements, that meet the maximum occupant load and exit access travel distance specified. Exit access stairways from the basement would be a viable option where permitted by Section 1009.3. Note a requires a Group R-2 congregate residence with an NFPA 13 or 13R system to also have emergency escape windows provided in all the bedrooms (Section 1029.1). The maximum occupant load would limit the congregate residence to
2,000 square feet (185.81 m²) maximum per floor. Note b allows an additional 25 feet (7.62 m) of travel distance for business, factory and storage facilities in the basement and first floor levels if an NFPA 13 sprinkler system is installed.

Again, these tables are based on a per-floor criteria. These tables would also allow for mixed occupancies, such as four apartments over a restaurant or a business over a day care, as long as occupant loads and travel distances are met. Means of egress could be by a stairway through the floor below or a separate exterior stairway from the upper level. For additional information on a mixed-use floor, see Section 1021.2.1.

1021.2.1 Mixed occupancies. Where one exit, or exit access stairway or ramp providing access to exits at other stories, is permitted to serve individual stories, mixed occupancies shall be permitted to be served by single exits provided each individual occupancy complies with the applicable requirements of Table 1021.2(1) or Table 1021.2(2) for that occupancy. Where applicable, cumulative occupant loads from adjacent occupancies shall be considered in accordance with the provisions of Section 1004.1.

In each story of a mixed occupancy building, the maximum number of occupants served by a single exit shall be such that the sum of the ratios of the calculated number of occupants of the space divided by the allowable number of occupants for each occupancy does not exceed one.

- Where multiple tenants or occupancies are located on a specific story, they are to be regulated by a "unity" formula if they want to use the same exit. If they have separate exits, they will be evaluated separately. This would allow for a second floor of a mixed-use occupancy to be evaluated similarly to Section 1014.2 as when multiple spaces combine. For example, the second story of a building houses two tenants, one business and one mercantile. Each tenant would be permitted a single, but separate, exit, provided each had an occupant load of less than 30 and a travel distance not exceeding 75 feet (22.860 m) (see Figure 1021.2, Option 2). However, if the tenants wanted to share the same single exit, the combined occupant load would have to be less than 30 (see Figure 1021.2.1, Option 3).

The text regarding ratios of occupant loads for mixed-use stories does not address if the mix includes dwelling units. Since four dwelling units are allowed per floor in a single-exit building, perhaps a solution would be to use 0.25 for one unit, 0.50 for two units and 0.75 for three units.

1021.2.2 Basements. A basement provided with one exit shall not be located more than one story below grade plane.

- Tables 1021.2(1) and 1021.2(2) allow for basements with single exits. Even if the multiple levels could meet the provisions for occupant load and exit access travel distance, this section limits a single-exit basement to a single level below grade.

### 1021.2.3 Single-story or multiple-story dwelling units

Individual single-story or multiple-story dwelling units shall be permitted to have a single exit within and from the dwelling unit provided that all of the following criteria are met:

1. The dwelling unit complies with Section 1015.1 as a space with one means of egress and
2. Either the exit from the dwelling unit discharges directly to the exterior at the level of exit discharge, or the exit access outside the dwelling unit’s entrance door provides access to not less than two approved independent exits.

This section is referenced in Section 1021.2, Exception 5, and is based on decades of practice within an individual dwelling. While Section 1021.2, Exception
2, addresses single exits for a Group R-3 building, one or two apartments could be provided in a mixed-use building and still be considered Group R-3. This exception could be used within the unit. Multistory apartments may also be provided within Group R-2 high-rise residential buildings.

In Group R-2 and R-3 facilities with multistory dwelling units, the means of egress from a dwelling or sleeping unit is typically permitted to be from one level only. In a Group R-2 apartment- or townhouse-style building, if the building is sprinklered with an NFPA 13 or 13R system and the common path of travel from the most remote point on any level to the exit door from the unit itself is 125 feet (22,860 mm) maximum (see Table 1014.3), that unit may have only one means of egress. Section 1015.1, Exception 1, provides for an occupant load of 20, rather than the 10 occupants allowed in Table 1015.1. Therefore, this could allow apartments of up to 4,000 square feet (185.81 m²). An exit access stairway would be permitted within the unit as part of the exit access travel distance (Section 1009.3, Exception 2). Once the occupants exit the unit itself; however, they must be outside at grade or the floor level must have access to two or more means of egress for all tenants, depending on the number required for the building as a whole (see Figure 1021.2.3). The common path of egress within the unit would be part of the overall exit access travel distance of 250 feet (45,720 mm) required in Table 1016.2). It is not the intent to allow this exception for apartment-style dwelling units in conjunction with the allowances for a single-exit building. The emergency escape and rescue opening addressed in Section 1029 does not count towards the required number of exits.

1021.2.4 Three or more exits. Three exits, or exit access stairways or ramps providing access to exits at other stories, shall be provided from any story or occupied roof with an occupant load from 501 to and including 1,000. Four exits, or exit access stairways or ramps providing access to exits at other stories, shall be provided from any story or occupied roof with an occupant load greater than 1,000.

Large facilities with high occupant loads are required to have more than two exits leading from each story. This is so that at least one exit will be available in case of a fire emergency and to provide increased assurance that a large number of occupants can be accommodated by the remaining exits when one exit is not available. Section 1005.5 does specify that the loss of one exit must not reduce the available exit capacity by more than 50 percent. This is reiterated in Section 1028.3 for spaces with assembly seating with more than 300 occupants. Exits should be separated in accordance with Section 1015.2.2. While an equal distribution of exit capacity among all the exits is not required, a proper design would consider occupant load distribution as well as reasonable capacity distribution so as to avoid a severe dependence on one exit or bottlenecks in anticipated high-use areas.
1021.2.5 Additional exits. In buildings over 420 feet (128 m) in height, additional exits shall be provided in accordance with Section 403.5.2.

- Super high-rise buildings provide a unique situation for concerns about emergency evacuation and fire department access. Section 403.5.2 requires an additional stairway in these buildings. Since this is in excess of the required exit stairways, this additional stairway is not required to meet remoteness requirements from other exits. If the alternative for evacuation is provided by an occupant evacuation elevator, then the additional stairway is not required (Sections 403.6.2 and 3008.).

1021.3 Exit configuration. Exits, or exit access stairways or ramps providing access to exits at other stories, shall be arranged in accordance with the provisions of Sections 1015.2 through 1015.2.2. Exits shall be continuous from the point of entry into the exit to the exit discharge.

- The entrance to the enclosures for exit stairways or exit access stairways shall meet the same arrangement as exit and exit access doorways (see Sections 1015.2 through 1015.2.2). The need for exits to be independent of each other cannot be overstated. Each occupant of each floor must be provided with the required number of exits without having to pass through one exit to gain access to another. Each exit is required to be independent of other exits to prohibit such areas from merging downstream and becoming, in effect, one exit.

The requirement for exits to be continuous is repeated from Section 1021.1 and is consistent with the exit termination requirements in Section 1022.3 and the exit discharge termination requirements in Section 1023.4. The intent of this section is to provide safety in all portions of the exit by requiring continuity of the fire protection characteristics of the enclosure for the exit stairway or ramp. Exit passageways (see Section 1023) are a continuation of an exit enclosure. This would include, but not be limited to, the fire-resistance rating of the exit enclosure walls and the opening protection rating of the doors.

Section 1027.1, Exceptions 1 and 2, allows for an alternative for direct access to the outside via an intervening lobby or vestibule. Horizontal exits (see Section 1025), while not providing direct access to the outside of the structure, do move occupants to another “building” by moving through a fire wall (see Section 1025 and Section 1027.1, Exception 3) or into a refuge area protected by fire barriers and horizontal assemblies. Horizontal exits are commonly used in hospitals and jails for a defend-in-place type of protection.

1021.3.1 Access to exits at adjacent levels. Access to exits at other levels shall be by stairways or ramps. Where access to exits occurs from adjacent building levels, the horizontal and vertical exit access travel distance to the closest exit shall not exceed that specified in Section 1016.1. Access to exits at other levels shall be from an adjacent story.

Exception: Landing platforms or roof areas for helistops that are less than 60 feet (18 288 mm) long, or less than 2,000 square feet (186 m²) in area, shall be permitted to access the second exit by a fire escape, alternating tread device or ladder leading to the story or level below.

- Emergency evacuation from a multistory building will typically involve stairways or ramps as the vertical element for the means of egress route. These stairways and ramps can be exit access (Section 1009.3) or exits (Section 1022). When exit access stairways or ramps complying with Section 1009.3 are part of that route, the measurement of the exit access travel distance will include travel from the most remote point on the floor, to and down the exit access stairway or ramp and from the bottom of the stairway or ramp to an enclosure for an exit stairway or ramp or exterior exit door (see Section 1016.3). Vertical travel is slower than horizontal travel, so the exit access stairway or ramp should not be used for more than one story before an exit is reached.

It is not the intent of this section to require stairways in open parking structures or outdoor facilities to have enclosed stairways after one story of vertical travel. Due to the open nature of these facilities and the specific exceptions for openness (Section 1009.3, Exception 6 and 7) and measurement of exit access travel to the top of the stair or ramp (Section 1016.3, Exception 1 and 3), the exit access stairway can extend the total height of the building.

The exception is to allow for the second exit from small helistops to be a fire escape, alternating tread device or ladder instead of an exit or exit access stairway or ramp.

1021.4 Vehicular ramps. Vehicular ramps shall not be considered as an exit access ramp unless pedestrian facilities are provided.

- A vehicle-only ramp may be considered as one of the required exit access ramps if pedestrian walkways are provided along the ramp. The low-slope ramps that are lined with parking spaces are not considered vehicle ramps. In open parking garages, according to Section 1009.3, Exception 6, the exit access stairways and ramps are not required to be enclosed since an open parking structure is designed to permit the ready ventilation of the products of combustion to the outside by exterior wall openings (see Section 406.5.2). Also, parking structures are characterized by open floor areas that allow the occupants to observe a fire condition and choose a travel path that would avoid the fire threat.
SECTION 1022
INTERIOR EXIT STAIRWAYS AND RAMPS

1022.1 General. Interior exit stairways and interior exit ramps serving as an exit component in a means of egress system shall comply with the requirements of this section. Interior exit stairways and ramps shall lead directly to the exterior of the building or shall be extended to the exterior of the building with an exit passageway conforming to the requirements of Section 1023, except as permitted in Section 1027.1. An interior exit stairway or ramp shall not be used for any purpose other than as a means of egress.

The first sentence is a general reference to the rest of the section. Sections 1022.2 through 1022.7 deal with the construction of the walls and ceiling that enclose the exit stairway or exit ramp. Sections 1022.8 and 1022.9 deal with information required in the enclosure for safe exiting. Section 1022.10 provides criteria for stairways in high-rise or underground buildings where smokeproof enclosure and pressurization of the stair tower is required (see Sections 403.5.4 and 405.7.2).

Most exit stairways have an exterior door at the level of exit discharge that leads directly to the outside. From this doorway, there must be a path for exit discharge that leads to the public way; however, there are other options. Exit passageways are considered an extension of the exit enclosure. The stairway enclosure discharges into the exit passageway, which in turn leads to the outside of the building. There are limited allowances for the exit enclosure to discharge through a lobby or vestibule (see Section 1027.1, Exceptions 1 and 2). A stairway enclosure could also discharge through a horizontal exit (see Section 1027.1, Exception 3). The termination requirements are the same as stated in Sections 1009.2 and 1022.3.

It is important that an exit stairway or ramp not be used for any purpose other than as a means of egress. For example, there is a tendency to use stairway landings for storage purposes. Such a situation obstructs the path of exit travel and if the stored contents consist of combustible materials, the use of the exit stairway as part of the path for a means of egress may be jeopardized, creating a hazard to life safety. It is not the intent of these provisions to prohibit an exit stairway from being used as part of the normal building circulation system. If the tenants or building owner have security concerns that would wish them to limit stairway access, consult Section 1008.1.9.11.

It is not the intent of this provision to exclude inclined platform lifts in the enclosure for the stairway; however, it is important that when not in operation they do not block access to the exit stairway or handrails. The referenced technical standard, ASME A18.1, basically requires noncombustible elements. Platform lifts are an important option for providing accessibility in a building. Section 1109.7 limits the use of platform lifts in new construction to main areas with minimal occupant loads or where elevators and ramps are impracticable. Platform lifts can be part of an accessible means of egress in limited situations (Section 1007.5). Section 3411.8.3 allows for platform lifts anywhere in existing buildings in order to gain accessibility for persons with mobility impairments. The industry is currently working on different options to address the concern that the lift may be in operation during an event that requires evacuation.

1022.2 Construction. Enclosures for interior exit stairways and ramps shall be constructed as fire barriers in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both. Interior exit stairway and ramp enclosures shall have a fire-resistance rating of not less than 2 hours where connecting four stories or more and not less than 1 hour where connecting less than four stories. The number of stories connected by the interior exit stairways or ramps shall include any basements, but not any mezzanines. Interior exit stairways and ramps shall have a fire-resistance rating not less than the floor assembly penetrated, but need not exceed 2 hours.

Exception: Interior exit stairways and ramps in Group I-3 occupancies in accordance with the provisions of Section 408.3.8.

This section requires that all interior exit stairways or ramps are to be enclosed with rated walls (i.e., fire barriers) and floor/ceiling assemblies (i.e., horizontal assemblies). The fire-resistance rating required depends on the number of connected stories and the required fire-resistance rating of the penetrated floors. The minimum fire-resistance rating of an enclosure for an exit stairway or ramp is at least 1 hour. The fire-resistance rating of the enclosure must be increased to 2 hours if the stairway or ramp connects four or more stories or if it penetrates a floor system with a fire-resistance rating of 2 hours or more (see Table 602 for Type I construction). Note that the criteria are based on the number of stories connected by the stairway or ramp and not the height of the building. Therefore, a building that has three stories located entirely above the grade plane and a basement would require an enclosure with a 2-hour fire-resistance rating if the stairway or ramp connects all four stories. Where the floor construction penetrated by the enclosure has a fire-resistance rating, the enclosure must have the same minimum rating. For example, an enclosure that penetrates a 2-hour floor assembly must have a minimum fire-resistance rating of 2 hours, regardless of the number of stories the enclosure connects. The fire-resistance rating of an enclosure need never exceed 2 hours. If the floor assembly penetrated requires a minimum 3-hour fire-resistance rating, the enclosure rating is only required to be 2-hour fire-resistance rated. All linear voids at joints between fire-resistance-rated wall and floor/ceiling assemblies and where an enclosure would intersect with an exterior wall must be filled so that the integrity of the enclosure is maintained (see Section 715). The fire-resistance-rated requirements for
enclosures for exit stairways and ramps are consistent with those for shaft enclosures and enclosures for exit access stairways and ramps.

The enclosure is needed because an exit stairway or ramp penetrates the floor/ceiling assemblies between the levels, thus creating a vertical opening or shaft. In cases of fire, a vertical opening may act as a chimney, causing smoke, hot gases and light-burning products to flow upward (buoyant force). If an opening is unprotected, these products of combustion will be forced by positive pressure differentials to spread horizontally into the building spaces. There are exceptions for shaft protection around stairways and ramps that are not part of a means of egress in Section 712 or exit access stairways as permitted in Section 1009.3.

The enclosure of interior stairways or ramps with construction having a fire-resistance rating is intended to prevent the spread of fire from floor to floor. Another important purpose is to provide a safe path of travel for the building occupants and to serve as a protected means of access to the fire floor by fire department personnel. For this reason, Sections 1022.4 through 1022.6 limit the penetrations and openings permitted in the enclosure for an exit stairway or ramp.

For travel distance measurements at the exit stairways, see the commentary to Section 1016.3. While not specifically mentioned as an exception, Section 1026 for exterior stairways is considered to provide an equivalent level of protection to enclosed interior stairways.

Per the exception, because of security needs in detention facilities, one of the exit stairs is permitted to be glazed in a manner similar to atrium enclosures. Specific limitations and requirements are discussed in Section 408.3.8. Exit access stairways within housing units are addressed in Sections 408.5.1 and 1009.3, Exception 10.

1022.3 Termination. Interior exit stairways and ramps shall terminate at an exit discharge or a public way.

Exception: Interior exit stairways and ramps shall be permitted to terminate at an exit passageway complying with Section 1023, provided the exit passageway terminates at an exit discharge or a public way.

The intent of this section is to provide safety in all portions of the exit by requiring continuity of the fire protection characteristics of the enclosure for the exit stairway. Exit passageways (see Section 1023) are a continuation of the enclosure for the exit stairway. This would include, but not be limited to, the fire-resistance rating of the exit enclosure walls and the opening protection rating of the doors. Section 1027.1 would allow for an alternative for direct access to the outside via an intervening lobby or vestibule.

Horizontal exits (see Section 1025), while not providing direct access to the outside of the structure, do move occupants to another "building" by moving through a fire wall (see Sections 1025 and 1027.1, Exception 3) into a refuge area protected by fire barriers and horizontal assemblies. Horizontal exits are commonly used in hospitals and jails for a defend-in-place type of protection.

This is consistent with the exit continuity requirements in Section 1021.3 and exit discharge requirements in Section 1023.4. This requirement is repeated in Sections 1003.2 and 1022.1.

1022.3.1 Extension. Where interior exit stairways and ramps are extended to an exit discharge or a public way by an exit passageway, the interior exit stairway and ramp shall be separated from the exit passageway by a fire barrier constructed in accordance with Section 707 or a horizontal assembly constructed in accordance with Section 711, or both. The fire-resistance rating shall be at least equal to that required for the interior exit stairway and ramp. A fire door assembly complying with Section 716.5 shall be installed in the fire barrier to provide a means of egress from the interior exit stairway and ramp to the exit passageway. Openings in the fire barrier other than the fire door assembly are prohibited. Penetrations of the fire barrier are prohibited.

Exception: Penetrations of the fire barrier in accordance with Section 1022.5 shall be permitted.

Once a person enters the enclosure surrounding an exit stairway, that same level of protection should be provided to them until they can leave the building. When an enclosure for an exit stairway connects to an exit passageway, either at the ground level or at an intermediate transition floor, the exit passageway must provide the same level of protection as the enclosure for the exit stairway, including fire-resistance of the walls, floor, ceiling and supporting construction and protection of any openings. At the junction between the enclosure for the exit stairway and the exit passageway, there must be both a rated fire barrier and a fire door. This has the additional benefit of preventing any smoke that may migrate into the exit passageway from also moving up the exit stairway or ramp. Permitted penetrations for the exit passageway are the same as those limitations set for the enclosure for the exit stairway. See Sections 1011.1 and 1024 for egress markings and signage within these types of spaces.

For the situation when an exit stairway is constructed as a smokeproof enclosure or a pressurized stairway, see Section 1022.10.1.

1022.4 Openings. Interior exit stairway and ramp opening protective shall be in accordance with the requirements of Section 716.

Openings in interior exit stairways and ramps other than unprotected exterior openings shall be limited to those necesa-
Elevators shall not open into interior exit stairways and ramps.

- In order for fire doors to be effective, they must be in the closed position; therefore, the preferred arrangement is to install self-closing doors. Recognizing that operational practices often require doors to be open for an extended period of time, automatic-closing doors are permitted as long as this opening will not pose a threat to occupant safety and the doors will be self-latching. Automatic-closing devices enable the opening to be protected during a fire condition. The basic requirement for closing devices and specific requirements for automatic-closing and self-closing devices are given in NFPA 80. Automatic-closing doors that are provided at protected openings in exits are also required to close on the actuation of smoke detectors or loss of power to the smoke detectors (see Section 716.5.9.3).

The only openings that are permitted in fire-resistance-rated enclosures for exit stairways or ramps are doors that lead from normally occupied spaces into the enclosure and doors leading out of the enclosure to the outside. This restriction on openings essentially prohibits the use of windows in an exit enclosure except for those exterior windows that are not exposed to any hazards. This requirement is not intended to prohibit windows or other openings in the exterior walls of the exit enclosure. The verbage "unprotected exterior openings" includes windows or doors not required to be protected by either Section 705.8 or 1022.7. The only exception would be window assemblies that have been tested as wall assemblies in accordance with ASTM E 119 or UL 263. The objective of this provision is to minimize the possibility of fire spreading into an enclosure and endangering the occupants or even preventing the use of the exit at a time when it is most needed. The limitation on openings applies regardless of the fire protection rating of the opening protective. The limitation on openings from normally occupied spaces is intended to reduce the probability of a fire occurring in an unoccupied area, such as a storage closet, which has an opening into the stairway, thereby possibly resulting in fire spread into the stairway. Other spaces that are not normally occupied include, but are not limited to, toilet rooms, electrical/mechanical equipment rooms and janitorial closets. For connection between the vertical exit enclosure and an exit passageway, see Section 1023.5.

Elevators may not open into exit enclosures. The difficulty is to have elevator doors that can meet the opening protective for a fire barrier, but still operate effectively as elevator doors. For additional information on elevator lobbies and doors, see the commentary for Sections 713.14 and 1018.6.

These opening limitations are very similar to those required for an exit passageway (see Section 1023.5).

**1022.5 Penetrations.** Penetrations into and openings through interior exit stairways and ramps are prohibited except for required exit doors, equipment and ductwork necessary for independent ventilation or pressurization, sprinkler piping, standpipes, electrical raceway for fire department communication systems and electrical raceway serving the interior exit stairway and ramp and terminating at a steel box not exceeding 16 square inches (0.010 m²). Such penetrations shall be protected in accordance with Section 714. There shall be no penetrations or communicating openings, whether protected or not, between adjacent interior exit stairways and ramps.

**Exception:** Membrane penetrations shall be permitted on the outside of the interior exit stairway and ramp. Such penetrations shall be protected in accordance with Section 714.3.2.

- This section specifically lists the items that are allowed to penetrate the walls and ceiling of the enclosure for the exit stairway. This is consistent for all types of enclosures for exits, including interior exit stairways or interior exit ramps and exit passageways (see Section 1023.6). In general, only portions of the building service systems that serve the enclosure are allowed to penetrate the enclosure. As indicated in the commentary to Section 1020.1, standpipe systems are commonly located in the exit stair enclosures. If two exit enclosures are adjacent to one another, there must be no penetrations between them, thereby limiting the chances of smoke being in both stairwells.

Section 714 addresses through penetrations and membrane penetrations for fire-resistance-rated wall and floor/ceiling assemblies. The intent is to maintain the integrity of the enclosure for the exit access stairway. This section and Section 1022.6 are meant to work together. Penetrations in exterior walls are addressed in Section 1022.7.

The exception allows for electrical boxes, "Exit" signs or fire alarm pull stations to be installed on the outside of the enclosure, provided that the boxes are installed so that the required fire-resistance rating is not reduced (see Section 714.3.2).

**1022.6 Ventilation.** Equipment and ductwork for interior exit stairway and ramp ventilation as permitted by Section 1022.5 shall comply with one of the following items:

1. Such equipment and ductwork shall be located exterior to the building and shall be directly connected to the interior exit stairway and ramp by ductwork enclosed in construction as required for shafts.

2. Where such equipment and ductwork is located within the interior exit stairway and ramp, the intake air shall be taken directly from the outdoors and the exhaust air shall be discharged directly to the outdoors, or such air shall be conveyed through ducts enclosed in construction as required for shafts.
3. Where located within the building, such equipment and ductwork shall be separated from the remainder of the building, including other mechanical equipment, with construction as required for shafts.

In each case, openings into the fire-resistance-rated construction shall be limited to those needed for maintenance and operation and shall be protected by opening protectives in accordance with Section 716 for shaft enclosures.

The interior exit stairway and ramp ventilation systems shall be independent of other building ventilation systems.

The purpose of the requirements for the ventilation system equipment and ductwork is to maintain the fire resistance of the enclosure for the exit stairway. The ventilation system serving the enclosure is to be independent of other building systems to prevent smoke in the enclosure from traveling to other areas of the building. This section and Section 1022.5 are meant to work together. Where ductwork penetrates the outside wall, if it is not required to be rated by Section 1022.7, then the duct does not require a fire and smoke damper. If the ductwork serving the shaft does penetrate a rated wall or rated floor/ceiling assembly, a fire and smoke damper would be required by Section 717.5.3. Openings required for access to the ventilation system for maintenance and operation shall be protected in accordance with Section 716.

1022.7 Interior exit stairway and ramp exterior walls. Exterior walls of the interior exit stairway and ramp shall comply with the requirements of Section 705 for exterior walls. Where nonrated walls or unprotected openings enclose the exterior of the stairway and the walls or openings are exposed by other parts of the building at an angle of less than 180 degrees (3.14 rad), the building exterior walls within 10 feet (3048 mm) horizontally of a nonrated wall or unprotected opening shall have a fire-resistance rating of not less than 1 hour. Openings within such exterior walls shall be protected by opening protectives having a fire protection rating of not less than 1/3 hour. This construction shall extend vertically from the ground to a point 10 feet (3048 mm) above the topmost landing of the stairway or to the roof line, whichever is lower.

This section does not require exterior walls of an enclosure for an exit stairway to have the same fire-resistance rating as the interior walls. Table 602 and Section 705 establish when exterior walls are required to be rated and openings limited due to adjacent buildings or lot lines. This exposure is different from exterior load-bearing walls that are required to be rated due to the type of construction per Table 601. What is unique to exterior walls at exit stairways is the need to stop fires from burning through an exterior wall adjacent to the enclosure, which may then jeopardize the occupants ability to continue to use that exit stairway. Essentially, there are two alternatives where an exposure hazard exists: either (1) provide protection to the stairway by having a fire-resistance rating on its exterior wall or (2) provide a fire-resistance rating to the walls adjacent to the stairway. The ratings apply for a distance of 10 feet (3048 mm) measured horizontally and vertically from the stairway enclosure where those walls are at an angle of less than 180 degrees (3.14 rad) from the exterior wall portion of the enclosure [see Condition 1 in Figure 1022.7(1)]. When the adjacent exterior wall is protected in lieu of the stairway enclosure wall, the protection is to extend from the ground to a level of 10 feet (3048 mm) above the highest landing of the stairway. However, the protection is not required to extend beyond the normal roof line of the building.

The 180-degree (3.14 rad) angle criteria is based on the scenario where the exterior wall of the stair enclosure is in the same plane and flush with the exterior wall of the building [see Conditions 2 and 3 in Figure 1022.7(1)]. In this scenario, heat or fire would need to travel 180 degrees (3.14 rad) around in order to impinge on the stair. Based on studies of existing buildings, this 180-degree (3.14 rad) spread of fire does not appear to be a problem. This criteria is only applicable when the angle between the walls is 180 degrees (3.14 rad) or less.

As the fire exposure on the exterior is different than can be expected on the interior, the fire-resistance rating of the exterior wall is not required to exceed 1 hour, regardless of whether it is the stairway enclosure wall or the adjacent exterior wall, unless the exterior wall is required by other sections of the code to have a higher fire-resistance rating (see Tables 601 and 602). The fire protection rating on any openings in the exterior wall of a stairway enclosure or adjacent exterior wall within 180 degrees (3.14 rad) is to be a minimum of 1/3 hour [see Figure 1022.7(2)].

In a situation where the upper levels are smaller than lower levels, an interior stairway can end up having an exterior wall when it moves above the roof of the lower levels. In this situation, the question is the rating requirements for the exterior wall of the stairway over the roof. Therefore, the exterior wall of the stairway must meet the vertical opening provisions in Section 705.8.6.

1022.8 Discharge identification. An interior exit stairway and ramp shall not continue below its level of exit discharge unless an approved barrier is provided at the level of exit discharge to prevent persons from unintentionally continuing into levels below. Directional exit signs shall be provided as specified in Section 1011.

So that building occupants using an exit stairway during an emergency situation will be prevented from going past the level of exit discharge, the run of the stairway is to be interrupted by a partition, door, gate or other approved means. These devices help the users of the stairway to recognize when they have reached the point that is the level of exit discharge. Exit signs, including raised letters and Braille, are to be provided for occupant guidance at the door leading to the way out (i.e., directly to the exterior, or via an exit passageway, lobby or vestibule). Further-
more, signs are to be placed at each floor landing in all interior exit stairways connecting more than three floor levels that designate the level or story of the landings in accordance with Section 1022.9.

The code does not specify the type of material or construction of the barrier used to identify the level of exit discharge. The key issues to be considered in the selection and approval of the type of barrier to be used are: (1) will the barrier provide a visible and physical means of alerting occupants who are exiting under emergency conditions that they have reached the level of exit discharge and (2) is the barrier constructed of materials that are permitted by the construction type of the building? In an emergency situation, some occupants are likely to come in contact with the barrier during exiting before realizing that they are at the level of exit discharge. Therefore, the barrier should be constructed in a manner that is substantial enough to withstand the anticipated physical contact, such as pushing or shoving. It would be reasonable, as a minimum, to design the barrier to withstand the structural load requirements of Section

For St: 1 foot = 304.8 mm, 1 degree = 0.01745 rad.

Figure 1022.7(1)
EXAMPLES OF EXTERIOR WALL PROTECTIVES
MEANS OF EGRESS

1607.5 for interior walls and partitions. The barrier could be opaque (such as gypsum wallboard and stud framing) or not (such as a wire grid-type material).

The use of signage only or relatively insubstantial barriers, such as ropes or chains strung across the opening, is typically not sufficient to prevent occupants from attempting to continue past the level of exit discharge during an emergency.

Figure 1022.8 is an example of one method of discharge identification.

**1022.9 Stairway identification signs.** A sign shall be provided at each floor landing in an interior exit stairway and ramp connecting more than three stories designating the floor level, the terminus of the top and bottom of the interior exit stairway and ramp and the identification of the stair or ramp. The signage shall also state the story of, and the direction to, the exit discharge and the availability of roof access from the interior exit stairway and ramp for the fire department. The sign shall be located 5 feet (1524 mm) above the floor landing in a position that is readily visible when the doors are in the open and closed positions. In addition to the stairway identification sign, a floor-level sign in raised characters and Braille complying with ICC A117.1 shall be located at each floor-level landing adjacent to the door leading from the interior exit stairway and ramp into the corridor to identify the floor level.

✓ Signs are to be placed at each floor landing in all exit stairways connecting more than three stories. The signs are to designate the level or story of the land-

![Diagram of building and stairway](image)

**Figure 1022.7(2) EXTERIOR WALL PROTECTION**

For St: 1 foot = 304.8 mm, 1 degree = 0.01745 rad.
ings above or below the level of exit discharge. The purpose is to inform the occupants of their location with respect to the level of exit discharge as they use the stairway to leave the building. More importantly, it allows the fire service to locate and gain quick access to the fire floor. At each level, the direction to the exit discharge is required to be indicated. The identification of the level that is the exit discharge is also to be indicated at each level. The identification of the roof access availability is for the fire department. Roof access is required by Section 1009.16. For visibility, the signs are required to be located approximately 5 feet (1524 mm) above the floor surface and to be visible when the stairway door is open. The need to designate levels remaining to reach the level of exit discharge may mean that the numbering is other than the normal designation used by building management. For example, a designation of P1, P2, P3, etc., would not be acceptable for stairways in the basement parking garage, since in themselves they do not designate the floor level below the level of exit discharge.

To aid people with vision impairments, the floor designation must also be available in both raised letters and Braille at each door. Raised letters and Braille signage indicating the door leading to the exterior is covered in Section 1011.4.

1022.9.1 Signage requirements. Stairway identification signs shall comply with all of the following requirements:

1. The signs shall be a minimum size of 18 inches (457 mm) by 12 inches (305 mm).

2. The letters designating the identification of the interior exit stairway and ramp shall be a minimum of 1 1/2 inches (38 mm) in height.

3. The number designating the floor level shall be a minimum of 5 inches (127 mm) in height and located in the center of the sign.

4. All other lettering and numbers shall be a minimum of 1 inch (25 mm) in height.

5. Characters and their background shall have a nonglare finish. Characters shall contrast with their background, with either light characters on a dark background or dark characters on a light background.

6. When signs required by Section 1022.9 are installed in the interior exit stairways and ramps of buildings subject to Section 1024, the signs shall be made of the same materials as required by Section 1024.4.

* The requirements for stairway identification signage will provide for a consistent approach. The intent is to make signs visible and immediately recognizable to occupants and emergency responders using the stairway. In addition, if the building is a high-rise and luminous egress path markings are required (see Section 1024.1), the stairway identification signage must also be self-luminous or photoluminescent. In order to also meet the contrast requirements in Item 5, typically the sign will be dark letters on a glow-in-the-dark background.

1022.10 Smokeproof enclosures and pressurized stairways and ramps. Where required by Section 403.5.4 or

Figure 1022.8
EXAMPLE OF DISCHARGE IDENTIFICATION
405.7.2. Interior exit stairways and ramps shall be smoke-proof enclosures or pressurized stairways or ramps in accordance with Section 909.20.

While smokeproof enclosures and pressurized stairways for exiting can, at the designer’s option, be used in buildings of any occupancy, height or area, this section specifically requires smokeproof enclosures or pressurized stairway to be provided when either of two conditions occur.

The first condition requires all exit stairways in high-rise buildings [i.e., buildings with floor levels higher than 75 feet (22 860 mm) above the level of exit discharge (see Section 403.5.4)] to be smokeproof enclosures or pressurized stairways. The reason for this provision is that in very tall buildings, often during fire emergencies, total and immediate evacuation of the occupants cannot be readily accomplished. In such situations, exit stairways become places of safety for the occupants and must be adequately protected with smokeproof enclosures or pressurization to provide a safe egress environment. In order to provide this safe environment, the enclosure must be constructed to resist the migration of smoke caused by the “stack effect.” Stack effect occurs in tall enclosures such as chimneys, when a fluid such as smoke, which is less dense than the ambient air, is introduced into the enclosure. The smoke will rise due to the effect of buoyancy and will induce additional flow into the enclosure through openings of any size at the lower levels.

The second condition applies for underground buildings [i.e., when an occupiable floor level is located more than 30 feet (9144 mm) below the level of exit discharge (see Section 405.7.2)]. Stairways serving those levels are also required to be protected by smokeproof enclosures or pressurization because underground portions of a building present unique problems in providing not only for life safety but also access for fire-fighting purposes. The choice of a 30-foot (9144 mm) threshold for this requirement is intended to provide a reasonable limitation on vertical travel distance before the requirement applies.

Detailed system requirements for a smokeproof enclosure or pressurization are in Section 909.20. Note that Sections 403 and 405 each have exceptions for specific building types that are not to be regulated by those sections. Likewise, the requirements of this section do not apply to buildings identified in those exceptions.

1022.10.1 Termination and extension. A smokeproof enclosure or pressurized stairway shall terminate at an exit discharge or a public way. The smokeproof enclosure or pressurized stairway shall be permitted to be extended by an exit passageway in accordance with Section 1022.3. The exit passageway shall be without openings other than the fire door assembly required by Section 1022.3.1 and those necessary for egress from the exit passageway. The exit passageway shall be separated from the remainder of the building by 2-hour fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both.

Exceptions:

1. Openings in the exit passageway serving a smokeproof enclosure are permitted where the exit passageway is protected and pressurized in the same manner as the smokeproof enclosure, and openings are protected as required for access from other floors.

2. Openings in the exit passageway serving a pressurized stairway are permitted where the exit passageway is protected and pressurized in the same manner as the pressurized stairway.

3. The fire barrier separating the smokeproof enclosure or pressurized stairway from the exit passageway is not required, provided the exit passageway is protected and pressurized in the same manner as the smokeproof enclosure or pressurized stairway.

4. A smokeproof enclosure or pressurized stairway shall be permitted to egress through areas on the level of exit discharge or vestibules as permitted by Section 1027.

The walls that comprise the smokeproof enclosure or pressurized stairway, which includes the stairway shaft and the vestibules, must be fire barriers having a fire-resistance rating of at least 2 hours. This level of fire endurance is specified because exit stairways in high-rise buildings serve as principal components of the egress system and as the source of fire service access to the fire floor. This supersedes any allowed reduction of enclosure rating, even if the stair from the level that is more than 30 feet (9144 mm) below exit discharge connects three stories or less.

The first two exceptions apply to openings in the exit passageway that are permitted, provided the exit passageway is protected and pressurized. If the exit stairway enclosure is connected to an exit passageway, Exception 3 allows the elimination of a door between, since this would interfere with the pressurization of the stairway and passageway as a combined exit system. In accordance with Exception 4, 50 percent of the stairways in smokeproof enclosures or pressurized stairways can use the exit discharge exceptions in Section 1027 to egress through a lobby or vestibule.

1022.10.2 Enclosure access. Access to the stairway within a smokeproof enclosure shall be by way of a vestibule or an open exterior balcony.

Exception: Access is not required by way of a vestibule or exterior balcony for stairways using the pressurization alternative complying with Section 909.20.5.

See Figures 1022.10.2(1) and 1022.10.2(2) for illustrations of access to the smokeproof stairway by way of a vestibule or an exterior balcony. The purpose of this requirement is to keep the enclosure clear of smoke. Where a pressurized stairway is used, these elements are not necessary.
SECTION 1023
EXIT PASSAGeways

1023.1 Exit passageway. Exit passageways serving as an exit component in a means of egress system shall comply with the requirements of this section. An exit passageway shall not be used for any purpose other than as a means of egress.

This section provides acceptable methods of continuing the protected path of travel for building occupants. The building designer or owner is given these different options for achieving this protected path of travel. See Figure 1023.1 for an illustration of an exit passageway arrangement. In the case of office buildings or similar types of structures, the exit stairways are often located at the central core or in line with the centrally located exit access corridors. Exit passageways may be used to connect the exit stair to the exterior exit door or to connect enclosures for exit stairways that are not vertically continuous. Such an arrangement provides great flexibility in the design.
use of the building. Without an exit passageway at the grade floor or the level of exit discharge, the occupants of the upper floors or basement levels would have to leave the safety of the exit stairway to travel to the exterior doors. Such a reduction of protection is not acceptable (see Section 1027 for exit discharge alternatives).

Exit passageways may also be used on their own in locations not connected with an enclosure for an exit stairway. The exit passageway is often used as a protected horizontal exit path, such as in a mall or unlimited area building. Sometimes on large floor plans, an exit passageway may be used to extend an exit into areas that would not otherwise be able to meet the travel distance requirements. Like exit stairways, there is no travel distance limitation within an exit passageway.

1023.2 Width. The minimum width of exit passageways shall be determined as specified in Section 1005.1 but such width shall not be less than 44 inches (1118 mm), except that exit passageways serving an occupant load of less than 30 shall not be less than 36 inches (914 mm) in width. The required width of exit passageways shall be unobstructed.

Exception: Encroachments complying with Section 1005.7.

The width of an exit passageway is to be determined in accordance with Section 1005.1, based on the number of occupants served in the same manner as for corridors. The greater of the minimum required width or the width determined based on occupancy is to be used. In situations where the exit passageway also serves as an exit access corridor for the first floor, the corridor width must comply with the stricter requirement.

A cross reference back to Section 1005.7 from the exceptions for encroachments in the required width in corridors (see Section 1018.3), aisles (see Section 1017.1), exit passageways (see Section 1023.2) and exit courts (see Section 1027.4.1) reinforces the fact that the protrusion limits provision is generally applicable for these types of confined routes.

1023.3 Construction. Exit passageway enclosures shall have walls, floors and ceilings of not less than a 1-hour fire-resistance rating, and not less than that required for any connecting interior exit stairway or ramp. Exit passageways shall be constructed as fire barriers in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both.

The entire exit passageway enclosure is to be fire-resistance rated as specified. The floors and ceilings are required to be rated in addition to the walls. When used separately, a minimum 1-hour fire-resistance rating is required. Where extending an enclosure for an exit stairway, the rating must not be less than the enclosure for the exit stairway so that the degree of protection is kept at the same level. Remember that if the exit passageway extends over a lower level, such as a basement, all supporting construction is to have the same fire-resistance rating as the elements supported in accordance with the continuity requirements for fire barriers and horizontal assemblies (see Sections 707.5 and 711.4). The continuity requirements would also be a concern for the rated ceiling of the exit passageway. An alternative for the ceiling of the exit passageway could be a top-of-shaft enclosure (see Section 713.12).

1023.4 Termination. Exit passageways on the level of exit discharge shall terminate at an exit discharge. Exit passageways on other levels shall terminate at an exit.

This is consistent with the exit continuity and enclosure requirements in Sections 1021.3 and 1022.3. The intent of this section is to provide safety in all por-
tions of the exit by requiring continuity of the fire protection characteristics of the enclosure for the exit stairway in combination with an exit passageway. This would include, but not be limited to, the fire-resistance rating of the enclosure walls for the exit stairways and the opening protection rating of the doors. When an exit passageway is supported by the structure, the supporting construction must be fire-resistance rated equal to the walls and floors of the passageway being supported.

Section 1027.1, Exceptions 1 and 2, allow for an alternative for direct access to the outside via an intervening lobby or vestibule.

Horizontal exits, while not providing direct access to the outside of the structure, do move occupants to another "building" by moving through a fire wall (see Sections 1025 and 1027.1, Exception 3) into a refuge area protected by fire barriers and horizontal assemblies. Horizontal exits are commonly used in hospitals and jails for a defend-in-place type of protection.

An exit passageway may be used to move between vertical enclosures for exit stairways. This may occur when a building is shaped like a wedding cake, so the stairway towers move outward as the building gets larger toward grade level. If this situation happens, it is very important to let occupants know how to proceed. See Section 1011.1 for exit signage requirements for within the exit passageways.

1023.5 Openings and penetrations. Exit passageway opening protective shall be in accordance with the requirements of Section 716.

Except as permitted in Section 402.8.7, openings in exit passageways other than exterior openings shall be limited to those necessary for exit access to the exit passageway from normally occupied spaces and for egress from the exit passageway.

Where an interior exit stairway or ramp is extended to an exit discharge or a public way by an exit passageway, the exit passageway shall also comply with Section 1022.3.1.

Elevators shall not open into an exit passageway.

In order for fire doors to be effective, they must be in the closed position; therefore, the preferred arrangement is to install self-closing doors. Recognizing that operational practices often require doors to be open for an extended period of time, automatic-closing doors are permitted as long as this opening will not pose a threat to occupant safety and the doors will be self-latching. Automatic-closing devices enable the opening to be protected during a fire condition. The basic requirement for closing devices and specific requirements for automatic-closing and self-closing devices are given in NFPA 80. Automatic-closing doors that protect openings into exits are also required to close on the actuation of smoke detectors or loss of power to the smoke detectors (see Section 716.5.9.3).

The requirements for exit passageways are very similar to those required for enclosures for interior exit stairways (see Section 1022.4). The only openings that are permitted in fire-resistance-rated exit passageways are doors that lead either from normally occupied spaces, from the enclosure for the exit stairway and doors leading to the outside. This restriction on openings essentially prohibits the use of windows in an exit passageway except for those exterior windows that are not exposed to any hazards. This requirement is not intended to prohibit windows or other openings in the exterior walls of the exit enclosure. The verbiage "unprotected exterior openings" includes windows or doors not required to be protected by either Section 705.8 or 1022.7. The only exception would be window assemblies that have been tested as wall assemblies in accordance with ASTM E 119 and UL 263. The objective of this provision is to minimize the possibility of fire spreading into an exit passageway and endangering the occupants or even preventing the use of the exit at a time when it is most needed. The limitation on openings applies regardless of the fire protection rating of the opening protective. The limitation on openings from normally occupied areas is intended to reduce the probability of a fire occurring in an unoccupied area, such as a storage closet, that has an opening into the exit passageway, thereby resulting in smoke spreading into the exit passageway. Other spaces that are not normally occupied include, but are not limited to, toilet rooms, electrical/mechanical equipment rooms and janitorial closets. Note that exit passageways prohibit elevators from opening directly into the passageway. There are some exceptions for these unoccupied spaces in exit passageways in covered malls (see Section 402.4.6).

The third paragraph addresses when the vertical enclosure for an exit stairway or ramp transitions to the exit passageway. While the exit passageway is an extension of the protection offered by the vertical exit, there must still be a door (i.e., opening protective) between the bottom of the stairway or ramp enclosure and the exit passageway. This is to prevent any smoke that may migrate into the exit passageway from also moving up the exit stairway or ramp. This door is not required if the exit stairway and exit passageway are protected by pressurization (see Section 1022.10.1).

Elevators may not open into exit passageways. The difficulty is to have elevator doors that can meet the opening protective for a fire barrier, but still operate effectively. For additional information on elevator lobbies and doors, see the commentary for Sections 713.14 and 1018.6.

These opening limitations are very similar to those required for an exit enclosure (see Section 1022.3).

1023.6 Penetrations. Penetrations into and openings through an exit passageway are prohibited except for required exit doors, equipment and ductwork necessary for Independent pressurization, sprinkler piping, standpipes, electrical raceway for fire department communication and electrical race-
way serving the exit passageway and terminating at a steel box not exceeding 16 square inches (0.010m²). Such penetrations shall be protected in accordance with Section 714. There shall be no penetrations or communicating openings, whether protected or not, between adjacent exit passageways.

Exception: Membrane penetrations shall be permitted on the outside of the exit passageway. Such penetrations shall be protected in accordance with Section 714.3.2.

- This section specifically lists the items that are allowed to penetrate an exit passageway. This is consistent for all types of exit enclosures, including enclosures for exit stairways or ramps (see Section 1022.5) and exit passageways. In general, only portions of the building service systems that serve the exit passageways are allowed to penetrate the exit passageway. Section 714 addresses through penetrations and membrane penetrations for fire-resistance-rated wall and floor/ceiling assemblies. The intent is to maintain the integrity of the enclosure for the exit access stairway. If the ductwork serving the exit passageway does penetrate a rated wall or floor/ceiling assembly, a fire and smoke damper is required by Section 717.5.3. This requirement is not intended to prohibit windows in the exterior walls of exit passageways that are not required to be rated.

The exception allows for electrical boxes or fire alarm pull stations to be installed on the outside of the enclosure, provided that the boxes are installed so that the required fire-resistance rating is not reduced (see Section 714.3.2).

SECTION 1024
LUMINOUS EGRESS PATH MARKINGS

1024.1 General. Approved luminous egress path markings delineating the exit path shall be provided in high-rise buildings of Group A, B, E, I, M, and R-1 occupancies in accordance with Sections 1024.1 through 1024.5.

Exception: Luminous egress path markings shall not be required on the level of exit discharge in lobbies that serve as part of the exit path in accordance with Section 1027.1, Exception 1.

- Improved safety for individuals negotiating stairs during egress of a high-rise building is provided by improving the visibility of stair treads and handrails under emergency conditions. A second source of emergency power for exit illumination, exit signs and stair shaft pressurization systems in smokeproof enclosures is currently mandated for high-rise buildings. In the event of an emergency that disconnects utility power, the emergency power source should engage, causing the stair shaft to be illuminated and smoke free by the pressurization system. Unfortunately, such systems can fail under demand conditions. The provisions of Section 1024 add an additional level of safety to the egress path by requiring the installation of photoluminescent or self-illuminating marking systems which do not require electrical power and its associated wiring and circuits. An additional means for ensuring that occupants can safely egress a building via exit stairways is now available even if the emergency power supply and system fails to operate. The groups indicated have a high anticipated occupant load or occupants may not be as familiar with the space. Note that the provisions only require these markings within the enclosure for the exit stairway, exit ramp and the exit passageway used for enclosure continuation. The markings are not required before reaching the exit (i.e., exit access) or after leaving the exit (i.e., exit discharge).

The exception indicates that if the exit stairway enclosure discharges through the lobby (see Section 1027.1, Exception 1), the egress markings would not be required outside the stairway enclosure for the portion from the stairway enclosure to the door leading to the outside. If the exit stairway discharges through an exit passageway, the exit path markings must continue to the door leading to the outside. The current text is silent for the options of vestibules and horizontal exits, but since Sections 1024.1 through 1024.5 only address within the enclosure for the exit, and not the exit discharge, exit path markings in the vestibule or after the horizontal exit are not required.

1024.2 Markings within exit components. Egress path markings shall be provided in interior exit stairways, interior exit ramps and exit passageways, in accordance with Sections 1024.2.1 through 1024.2.6.

- Luminous egress path markings are required inside the enclosure for exit stairways or ramps for all floors. If the stairway connects to an exit passageway as part of the travel down to the level of exit discharge or on the level of exit discharge, the path markings must also be continued in the exit passageway.

The subsections include marking the tread nosings, the surrounding edges of landings and any exit passageways, handrails and any protruding objects within the protected enclosure.

All exit path markings are required to be solid and continuous stripes. A key requirement for marking systems is that their design must be uniform. The placement and dimensions of markings must be consistent along the entire exit stairway. By specifying a standard marking dimension, the requirements will ensure that the marking is visible during dark conditions and provides consistent and standard application in the design and enforcement of exit path markings. Markings installed on stair steps, perimeter demarcation lines and handrails must have a minimum width of 1 inch (25 mm). For stair steps and perimeter demarcation lines, their maximum width cannot exceed 2 inches (51 mm). The provisions for stair steps, perimeter demarcation lines and handrails allow the width of the marking to be reduced to less than 1 inch (25 mm) when marking stripes are listed in accordance with UL 1994.
1024.2.1 Steps. A solid and continuous stripe shall be applied to the horizontal leading edge of each step and shall extend for the full length of the step. Outlining stripes shall have a minimum horizontal width of 1 inch (25 mm) and a maximum width of 2 inches (51 mm). The leading edge of the stripe shall be placed at a maximum of $1\frac{1}{2}$ inch (13 mm) from the leading edge of the step and the stripe shall not overlap the leading edge of the step by not more than $1\frac{1}{2}$ inch (13 mm) down the vertical face of the step.

Exception: The minimum width of 1 inch (25 mm) shall not apply to outlining stripes listed in accordance with UL 1994.

- Luminous stripes are required the full width of the stairway on all tread nosings and along the leading edge of stair landings. These demarcation lines serve to identify the transition from the stair steps to the landing, which is important to minimize the risk of a fall inside of a stairway enclosure that is not illuminated. In order to clearly identify the leading edge of the step, the front edge of the stripe must be within $1\frac{1}{2}$ inch (13 mm) plus or minus of the leading edge of the tread (see Figure 1024.2.1).

The code does not specify any minimum slip-resistance requirements for luminous products installed on walking surfaces. However, Section 1003.4 does require all walking surfaces for means of egress to be slip resistant. Persons with vision impairments often rely on high contrast elements to delineate changes in elevation such as that required in Sections 1009.7.4 and 1028.11.2. In medium light conditions, the luminous materials may be hard to discern. Luminous materials installed adjacent to dark contrasting materials may help with both situations.

The provisions for stair steps, perimeter demarcation lines and handrails allow the width of the marking to be reduced to less than 1 inch (25 mm) when marking stripes are listed in accordance with UL 1994.

1024.2.2 Landings. The leading edge of landings shall be marked with a stripe consistent with the dimensional requirements for steps.

- The edge of the landing at the top of the steps must be marked in the same manner as the tread nosing so that a person can tell where the steps start. See the commentary to Section 1024.2.1 and Figure 1024.2.1.

1024.2.3 Handrails. All handrails and handrail extensions shall be marked with a solid and continuous stripe having a minimum width of 1 inch (25 mm). The stripe shall be placed on the top surface of the handrail for the entire length of the handrail, including extensions and newel post caps. Where handrails or handrail extensions bend or turn corners, the stripe shall not have a gap of more than 4 inches (102 mm).

Exception: The minimum width of 1 inch (25 mm) shall not apply to outlining stripes listed in accordance with UL 1994.

The handrail must have a glow-in-the-dark stripe along the entire length. The 1-inch (25 mm) minimum width stripe needs to be on the top of the handrail both so it can charge and so that someone would be best able to see it in the dark. Bends or turns may result in a break in the marking which must not be more than 4 inches (102 mm) maximum (see Figure 1024.2.3).
MEANS OF EGRESS

The provisions for stair steps, perimeter demarcation lines and handrails allow the width of the marking to be reduced to less than 1 inch (25 mm) when marking stripes are listed in accordance with UL 1994.

1024.2.4 Perimeter demarcation lines. Stair landings and other floor areas within interior exit stairways, interior exit ramps and exit passageways, with the exception of the sides of steps, shall be provided with solid and continuous demarcation lines on the floor or on the walls or a combination of both. The stripes shall be 1 to 2 inches (25 mm to 51 mm) wide with interruptions not exceeding 4 inches (102 mm).

Exception: The minimum width of 1 inch (25 mm) shall not apply to outlining stripes listed in accordance with UL 1994.

- In addition to the leading edge of the landing, the landing must have a luminous stripe all the way around the edge. If the enclosure includes any type of exit passageway, that corridor must also have a perimeter stripe. The stripe can be on the floor or on the wall at baseboard height (see Sections 1024.2.4.1 and 1024.2.4.2).

The provisions for stair steps, perimeter demarcation lines and handrails allow the width of the marking to be reduced to less than 1 inch (25 mm) when marking stripes are listed in accordance with UL 1994.

1024.2.4.1 Floor mounted demarcation lines. Perimeter demarcation lines shall be placed within 4 inches (102 mm) of the wall and shall extend to within 2 inches (51 mm) of the markings on the leading edge of landings. The demarcation lines shall continue across the floor in front of all doors.

Exception: Demarcation lines shall not extend in front of exit discharge doors that lead out of an exit and through which occupants must travel to complete the exit path.

- Luminous stripes shall extend all the way around any stair landings. This section specifies the option of stripes on the floor (see Figure 1024.2.4.1). On a typical landing, the stripe will extend across the front of the door, indicating to someone moving down the stairway that they should continue (see Figure 1024.2.4.3). At the level of exit discharge the occupant has a different visual queue. The line should not extend in front of the door leading to the exterior (see Figure 1024.2.6). This should allow people to understand which door they need to move through to get to safety.

1024.2.4.2 Wall mounted demarcation lines. Perimeter demarcation lines shall be placed on the wall with the bottom edge of the stripe no more than 4 inches (102 mm) above the finished floor. At the top or bottom of the stairs, demarcation lines shall drop vertically to the floor within 2 inches (51 mm) of the step or landing edge. Demarcation lines on walls shall transition vertically to the floor and then extend across the floor where a line on the floor is the only practical method of outlining the path. Where the wall line is broken by a door, demarcation lines on walls shall continue across the face of the door or transition to the floor and extend across the floor in front of such door.

Exception: Demarcation lines shall not extend in front of exit discharge doors that lead out of an exit and through which occupants must travel to complete the exit path.

- Luminous stripes that surround the stairway landings can be on the floor or on the wall. This section specifies the option of stripes on the wall (see Figure 1024.2.4.2). See the commentary to Sections 1024.2.4 and 1024.2.4.1.

1024.2.4.3 Transition. Where a wall mounted demarcation line transitions to a floor mounted demarcation line, or vice versa, the wall mounted demarcation line shall drop vertically to the floor to meet a complimentary extension of the floor mounted demarcation line, thus forming a continuous marking.

- While the luminous perimeter stripes on landing can be on either the wall or the floor, when they transition from one to another, the lines should appear continuous. See Section 1024.2.4.2 for special requirements for when the wall perimeter marking transitions to the floor stripe indicating leading edge of the landing.

When perimeter lines cross a door frame, the lines can transition or stay on the same plain (see Figure 1024.2.4.3).
1024.2.5 Obstacles. Obstacles at or below 6 feet 6 inches (1981 mm) in height and projecting more than 4 inches (102 mm) into the egress path shall be outlined with markings no less than 1 inch (25 mm) in width comprised of a pattern of alternating equal bands, of luminescent luminous material and black, with the alternating bands no more than 2 inches (51 mm) thick and angled at 45 degrees. Obstacles shall include, but are not limited to, standpipes, hose cabinets, wall projections, and restricted height areas. However, such markings shall not conceal any required information or indicators including but not limited to instructions to occupants for the use of standpipes.

- Any obstacles within the stairway must be marked with a dashed line of diagonal slashes (see Figure 1024.2.5). The markings of obstacles are consistent with the intent of protruding object provisions in Section 1003.3. However, there is a difference in the height of 6 feet, 6 inches (1981 mm) instead of 6 feet, 8 inches (2032 mm). Items permitted within the enclosures for exit stairways are limited by Sections 1022.2 and 1022.5.

1024.2.6 Doors within the exit path. Doors through which occupants must pass in order to complete the exit path shall be provided with markings complying with Sections 1024.2.6.1 through 1024.2.6.3.

- Doors within an enclosure for an exit stairway can lead directly to the exterior, pass through a horizontal exit (Section 1027.1, Exception 3) or lead to an exit passageway on the level of exit discharge, to a lobby or vestibule at the level of exit discharge (Section 1027.1, Exceptions 2 and 3) or to an exit passageway on a transition level. Doors at these locations should be marked as indicated in the following three subsections. Combined with the landing markings not extending across the bottom of this door, this will provide several visual cues to indicate that this is the door to continue through to get out of the building (see Figure 1024.2.6).

The NIST egress study of the World Trade Center indicated that transition floors can cause delays in egress because people hesitate when it is unclear about which way they should continue. Effectively marking these doors in four different ways will decrease that hazard. Which doors to mark is consistent with the exit sign requirements within exit enclosures in Section 1011.1.

1024.2.6.1 Emergency exit symbol. The doors shall be identified by a low-location luminous emergency exit symbol complying with NFPA 170. The exit symbol shall be a minimum of 4 inches (102 mm) in height and shall be mounted on the door, centered horizontally, with the top of the symbol no higher than 18 inches (457 mm) above the finished floor.

- The door shall include a low luminous level exit symbol within 18 inches (457 mm) of the floor. For an example of the emergency exit symbol, see Figure 1024.2.6.1. The sign on the door can be just this symbol or it can also contain additional information such as a directional arrow or "EXIT."
1024.2.6.2 Door hardware markings. Door hardware shall be marked with no less than 16 square inches (406 mm²) of luminous material. This marking shall be located behind, immediately adjacent to, or on the door handle or escutcheon. Where a panic bar is installed, such material shall be no less than 1 inch (25 mm) wide for the entire length of the actuating bar or touchpad.

- Door hardware locations must be clearly visible. If a panic bar is used, a luminous stripe with a minimum width of 1 inch (25 mm) should be provided down the entire length of the activation bar/paddle [see Figure 1024.2.6, Example 1]. If lever hardware is used, a donut, square or rectangle with a minimum area of 16 square inches (10 322 mm²) should be provided behind the hardware [see Figure 1024.2.6, Example 2]. There is also the option of marking the door handle itself, but it would be difficult to get 16 square inches (10 322 mm²) of visible surface area. Plus, over time, a finish on the hardware has a greater chance of wearing off with normal use. The language does allow freedom for the designer to decide with wear and hardware options which configuration would give the best results.

1024.2.6.3 Door frame markings. The top and sides of the door frame shall be marked with a solid and continuous 1-inch- to 2-inch-wide (25 mm to 51 mm) stripe. Where the door molding does not provide sufficient flat surface on which to locate the stripe, the stripe shall be permitted to be located on the wall surrounding the frame.

- Doors must be marked along the sides and top with stripes similar to those provided on the stair nosing. Door frames come in a variety of shapes. If there is not space on the door for the marking stripe, the stripe can be around the perimeter of the door [see Figure 1024.2.6, Examples 1 and 2].

EXAMPLES OF EXIT DOOR TO EXTERIOR OPTIONS
MEANS OF EGRESS

1024.3 Uniformity. Placement and dimensions of markings shall be consistent and uniform throughout the same enclosure.

- All exit path markings are required to be solid and continuous stripes. A key requirement for marking systems is that their design must be uniform. The placement and dimensions of markings must be consistent for the path of travel along the exit stairway. By specifying a standard marking dimension, the requirements will ensure that the marking is visible during dark conditions and provides consistent and standard application in the design and enforcement of exit path markings. Markings installed on stair steps, perimeter demarcation lines and handrails must have a minimum width of 1 inch (25 mm). For stair steps and perimeter demarcation lines, their maximum width cannot exceed 2 inches (51 mm). The provisions for stair steps, perimeter demarcation lines and handrails allow the width of the marking to be reduced to less than 1 inch (25 mm) when marking stripes are listed in accordance with UL 1994.

1024.4 Self-luminous and photoluminescent. Luminous egress path markings shall be permitted to be made of any material, including paint, provided that an electrical charge is not required to maintain the required luminance. Such materials shall include, but not be limited to, self-luminous materials and photoluminescent materials. Materials shall comply with either:

1. UL 1994; or
2. ASTM E 2072, except that the charging source shall be 1 footcandle (11 lux) of fluorescent illumination for 60 minutes, and the minimum luminance shall be 30 millicandela per square meter at 10 minutes and 5 milliandela per square meter after 90 minutes.

- Products utilized to meet the requirements for luminous egress path markings in high-rise buildings (see Sections 411.7 and 1024) or exit signs (see Section 1011.5) may be photoluminescent or self-luminous (see definitions in Chapter 2). An example of photoluminescent material is paint or tape that is charged by exposure to light. When the lights are turned off, the product will "glow" in the dark. Self-luminous products do not need an outside light source to charge them like photoluminescent materials do.

A variety of materials can comply with the referenced standards for egress path markings—UL 1994, and ASTM E 2072 and for signs—UL 924.

ASTM E 2072 allows the use of paints and coatings, which can be useful because it avoids a potential tripping hazard, especially in locations where the surface substrate may not be even. The luminescence of the selected marking system must provide an illumination of 1 foot-candle (11 lux) for 60 minutes, which is consistent with the requirement in Section 1006.2 for the illumination of walking surfaces. Section 1006.3 does require the emergency lighting system to have power for 90 minutes, however, due to normal battery considerations. The IFC only requires a 60-minute duration in existing buildings.

1024.5 Illumination. Where photoluminescent exit path markings are installed, they shall be provided with the minimum means of egress illumination required by Section 1006 for at least 60 minutes prior to periods when the building is occupied.

- Analogous to rechargeable batteries, many photoluminescent egress path markings require exposure to light to perform properly. Thus, photoluminescent egress path markings must be exposed to a minimum 1 foot-candle (11 lux) of light energy at the walking surface for at least 60 minutes prior to the building being occupied. The charging rate for photoluminescent egress path markings is based on the wattage of lamps used to provide egress path illumination. Therefore it is important to verify that the specified lamps have sufficient wattage to meet the specified time period. This requirement may be a concern for buildings developed with the International Energy Conservation Code® (IECC®) or trying for LEED certification.

Note that this requirement does not apply to self-luminous materials since these materials operate independently of the external power source. See the definitions for "Photoluminescent" and "Self-luminous" in Chapter 2.

SECTION 1025
HORIZONTAL EXITS

1025.1 Horizontal exits. Horizontal exits serving as an exit in a means of egress system shall comply with the requirements of this section. A horizontal exit shall not serve as the only exit from a portion of a building, and where two or more exits are required, not more than one-half of the total number of exits or total exit width shall be horizontal exits.

Exceptions:

1. Horizontal exits are permitted to comprise two-thirds of the required exits from any building or floor area for occupancies in Group I-2.

2. Horizontal exits are permitted to comprise 100 percent of the exits required for occupancies in Group I-3. At least 6 square feet (0.6 m²) of accessible space per occupant shall be provided on each side of the horizontal exit for the total number of people in adjoining compartments.

- Horizontal exits can provide up to 50 percent of the exits from a given area of a building. The percentage is higher for Group I-2 and I-3 occupancies where the evacuation strategy is defined in place rather than direct egress (see Figure 1025.1 for a typical horizontal exit arrangement). However, a horizontal exit cannot serve as the only exit from a single exit space. Section 1025.4 allows for some areas to have all the exits from a space to be horizontal exits under specific conditions. A horizontal exit can be designed for either one-way or two-way operation, depending on the exiting needs of each side of the wall providing the horizontal exit.
A horizontal exit may be an element of a means of egress when in compliance with the requirements of this section. The actual horizontal exit is the protected door opening in a wall, or the open-air balcony or bridge that separates two areas of a building. A horizontal exit is often used in hospitals and in prisons where it is not feasible or desirable that all occupants exit the facility (see Chapter 2 for the definition of a "Horizontal exit").

Horizontal exits and their associated "refuge areas" are considered to provide the same or higher level of protection as an "area of refuge" for people who cannot use the egress system. Sections 1007.3 and 1007.4 allow for a horizontal exit or an area of refuge as alternatives. See these sections for exceptions for buildings with sprinkler systems and/or where the path of travel has protection from the accumulation of smoke (i.e., open parking garages, open air assembly seating, smoke-protected assembly seating).

![Diagram of horizontal exits](image)

**Figure 1025.1**
**TYPICAL HORIZONTAL EXITS**

1025.2 Separation. The separation between buildings or refuge areas connected by a horizontal exit shall be provided by a fire wall complying with Section 706; or it shall be provided by a fire barrier complying with Section 707 or a horizontal assembly complying with Section 711, or both. The minimum fire-resistance rating of the separation shall be 2 hours. Opening protective in horizontal exits shall also comply with Section 716. Duct and air transfer openings in a fire wall or fire barrier that serves as a horizontal exit shall also comply with Section 717. The horizontal exit separation shall extend vertically through all levels of the building unless floor assemblies have a fire-resistance rating of not less than 2 hours with no unprotected openings.

**Exception:** A fire-resistance rating is not required at horizontal exits between a building area and an above-grade pedestrian walkway constructed in accordance with Section 3104, provided that the distance between connected buildings is more than 20 feet (6096 mm).

**Horizontal exits** constructed as fire barriers shall be continuous from exterior wall to exterior wall so as to divide completely the floor served by the horizontal exit.

- The basic concept of a horizontal exit is that during a fire emergency, the occupants of a floor will transfer from one fire area to another. Separation between areas of a building can be accomplished by either a fire wall (see Section 706) a fire barrier (see Section 707) horizontal assemblies (see Section 711), or a combination thereof, with a fire-resistance rating not less than 2 hours. Any fire shutters or fire doors must have an opening protective of not less than 1 1/2 hours (see Table 716.5). Ducts and air transfer openings must comply with Section 717.

In buildings of Groups I-2 and I-3, it may also be desirable (while not mandatory) for the horizontal exit to serve as a smoke barrier. In such cases, the wall containing the horizontal exit must also comply with the requirements for a smoke barrier (see Section 709).

In order to decrease the amount of smoke able to migrate around the edges of a horizontal exit, the horizontal exit must extend from at least the floor to the deck above (i.e., fire barrier), as well as across the floor level from one side of the building to another. Moving up from floor to floor, there are two choices. One option is that the horizontal exit can extend vertically through all levels of the building (i.e., fire wall or fire barriers). The second option is to utilize fire barriers that are not aligned vertically (i.e., a combination of fire barriers and horizontal assemblies), but then the floor must have a 2-hour fire-resistance rating and no unprotected openings are permitted between any two refuge areas. The supporting construction would also have to be a minimum of 2 hours.

The exception is permitting a pedestrian walkway or sky bridge to act as a horizontal exit when buildings are at least 20 feet (6096 mm) apart.

1025.3 Opening protective. Fire doors in horizontal exits shall be self-closing or automatic-closing when activated by a smoke detector in accordance with Section 716.5.9.3. Doors, where located in a cross-corridor condition, shall be automatic-closing by activation of a smoke detector installed in accordance with Section 716.5.9.3.

- For the safety of occupants using a horizontal exit, it is important that the doors be fire doors that are self-
closing or automatic closing by activation of a smoke detector. Smoke detectors that initiate automatic closing should be located at both sides of the doors (see the commentary to Section 907.3 for an additional explanation of the installation requirements). Any openings in the fire barriers or fire walls used as horizontal exits must be protected in coordination with the rating of the wall. There is a reference to Section 716 for opening protectives.

1025.4 Capacity of refuge area. The refuge area of a horizontal exit shall be a space occupied by the same tenant or a public area and each such refuge area shall be adequate to accommodate the original occupant load of the refuge area plus the occupant load anticipated from the adjoining compartment. The anticipated occupant load from the adjoining compartment shall be based on the capacity of the horizontal exit doors entering the refuge area. The capacity of the refuge area shall be computed based on a net floor area allowance of 3 square feet (0.2787 m²) for each occupant to be accommodated therein.

Exception: The net floor area allowable per occupant shall be as follows for the indicated occupancies:

1. Six square feet (0.6 m²) per occupant for occupancies in Group I-3.
2. Fifteen square feet (1.4 m²) per occupant for ambulatory occupancies in Group I-2.
3. Thirty square feet (2.8 m²) per occupant for nonambulatory occupancies in Group I-2.

The refuge area into which a horizontal exit leads shall be provided with exits adequate to meet the occupant requirements of this chapter, but not including the added occupant load imposed by persons entering it through horizontal exits from other areas. At least one refuge area exit shall lead directly to the exterior or to an interior exit stairway or ramp.

Exception: The adjoining compartment shall not be required to have a stairway or door leading directly outside, provided the refuge area into which a horizontal exit leads has stairways or doors leading directly outside and are so arranged that egress shall not require the occupants to return through the compartment from which egress originates.

The building area on the discharge side of a horizontal exit must serve as a refuge area for the occupants of both sides of the floor areas connected by the horizontal exit. Therefore, adequate space must be available on each side of the wall to hold the full occupant load of that side, plus the number of occupants from the other side that may be required to use the horizontal exit. Explaining the anticipated occupant load is easiest with an example. If one side of the horizontal exit contained an assembly space with 750 occupants, three exits would be required. If one of the exits through the horizontal exit was a double door, that double exit door would have a capacity of 320 (64 inches/0.2 = 320 occupants). Therefore, the refuge area must be sized for the occupant load in the space, plus the 320 people that might come through the horizontal exit. This is a higher number than would be anticipated if the occupant load of the assembly space was divided equally between the three exits, but it is also not the entire occupant load of the assembly space.

These refuge areas are meant to hold the occupants temporarily in a safe place until they can evacuate the premises in an orderly manner or, in the case of hospitals and like facilities, to hold bedridden patients and other nonambulatory occupants in a protected area until the fire emergency has ended. The size of the refuge area is based on the nature of the expected occupants. In the case of Group I-3, the area will be used to hold the occupants until deliberate egress can be accomplished with staff assistance or supervision. In other cases, it is assumed that the occupants simply wait in line to egress through the required exit facilities provided on the discharge side. Although similar language is used in describing the "area of refuge" for an accessible means of egress, Section 1007.6 specifies area requirements that are insufficient for use as a "refuge area" for a horizontal exit. Care must be taken when applying both principles to the same horizontal exit.

The 3-square-feet (0.28 m²) per occupant requirement is based on the maximum permitted occupant density at which orderly movement to the exits is reasonable. The 30-square-feet (2.8 m²) per hospital or nursing home patient requirement is based on the space necessary for a bed or litter. It should be noted that 30 square feet (2.8 m²) is not based on the total occupant load, as would be determined in accordance with Section 1004.1, but rather on the number of nonambulatory patients. The 15-square-feet (1.4 m²) requirement for occupancies in Group I-2 facilities is based on each ambulatory patient having a staff attendant.

In a single-tenant facility, any of the spaces that are constantly available (e.g., not lockable) can be used as places of refuge. However, in spaces housing more than one tenant, public refuge areas, such as corridors or passageways, must be provided and be accessible at all times. This requirement is necessary because if a horizontal exit connected two areas occupied by different tenants, the tenants could (for privacy and security purposes) render the necessary free access through the horizontal exit ineffective. When the horizontal exit discharges into a public or common space, such as a corridor leading to an exit, each tenant can obtain the desired security.

Note that the capacity of the exit (such as an exit stairway) from the refuge area to which the horizontal exit leads is required to be sufficient for the design occupant load in the area, and does not include those who come into the space from other areas via the horizontal exit. This is because the adjacent refuge area is of sufficient safety to house occupants during a fire or until the egress system is available.

The door through the horizontal exit and the second exit must meet the separation requirements in
Means of Egress

Section 1015.2.1. Measurement of the travel distance stops at the doorway that serves as the horizontal exit. There are not travel distance requirements for the distance from the horizontal exit to the exit (i.e., exterior exit doorway, exit stairway or exit ramp) on the other side; however, the areas on each side need to be evaluated for all means of egress requirements individually.

When there is one horizontal exit and two fire compartments, at least one exit from each side of the horizontal exit must go directly to the outside of an exit stairway or ramp enclosure (see Figure 1025.1). The exception allows for a central building/fire area with access to two horizontal exits and no direct exterior exit door or exit stairway/ramp enclosure as long as the piece on each side has access to exterior exits or exit stairways/ramps (see Figure 1025.4).

SECTION 1026
EXTERIOR EXIT STAIRWAYS AND RAMPS

1026.1 Exterior exit stairways and ramps. Exterior exit stairways and ramps serving as an element of a required means of egress shall comply with this section.

- Stairways and ramps can be exit access, exit or exit discharge elements. Exterior exit access and exit discharge stairs and ramps typically involve a change of elevation of less than a story. Exterior exit access stairways or ramps between stories must comply with Section 1009.3, and where permitted as part of the required means of egress are limited by Section 1021. Exit stairways and ramps traverse a full story or more. Interior exit stairways and ramps must be enclosed in accordance with Section 1022. This section addresses exterior stairways and ramps that function as exit elements.

- Exterior exit stairways and ramps are an important element of the means of egress system and must be designed and constructed so that they will serve as a safe path of travel. The general requirements in Section 1009 also apply to exterior stairways (for ramp provisions, see Section 1010).

Outdoor stadiums and open parking garages are examples of buildings that may appear to have exterior exit stairways, but are only actually required to have exit access stairways (Section 1021.1, Exceptions 1 and 2).

1026.2 Use in a means of egress. Exterior exit stairways shall not be used as an element of a required means of egress for Group I-2 Occupancies. For occupancies in other than Group I-2, exterior exit stairways and ramps shall be permitted as an element of a required means of egress for buildings not exceeding six stories above grade plane or which are not high-rise buildings.

This section specifies the conditions where exterior exit ramps or stairways can be used as required exits. Exterior exit stairways are not permitted for Group I-2 since quick evacuation of nonambulatory patients from buildings using exterior stairways is impractical. Some patients may not be capable of self-preservation and, therefore, may require assistance from staff. The period of evacuation of nonambulatory patients could become lengthy, especially in bad weather conditions.

Exterior stairways or ramps are not allowed to be required exits in buildings that exceed six stories in height due to the hazard of using such a stairway or ramp in poor weather. Some persons may not be willing to use such a stair due to vertigo. When confronted with a view from a great height, vertigo sufferers can become confused, disoriented and dizzy. They could injure themselves, become disoriented or refuse to move (freeze). In a fire situation, they could become an obstruction in the path of
MEANS OF EGRESS

travel, possibly causing panic and injuries to other users of the exit.

1026.3 Open side. Exterior exit stairways and ramps serving as an element of a required means of egress shall be open on at least one side. An open side shall have a minimum of 35 square feet (3.3 m²) of aggregate open area adjacent to each floor level and the level of each intermediate landing. The required open area shall be located not less than 42 inches (1067 mm) above the adjacent floor or landing level.

An important factor in exterior exit stairways or ramps is natural ventilation. Sufficient natural ventilation is necessary so that smoke will not be trapped above the stairway or ramp walking surfaces, thereby compromising safe egress.

The exterior exit stairway or ramp must have at least one of its sides directly facing an outer court, yard or public way. This will allow the products of combustion escaping from the interior of the building to quickly vent to the outdoor atmosphere and let the building occupants egress down the exterior exit stairway or ramp. Since exterior exit stairways or ramps are partially bounded by exterior walls, a minimum amount of exterior openness is specified by the code.

The openings on each and every floor level and landing must total 35 square feet (3.3 m²) or greater. The openings for which credit is given must occur higher than 42 inches (1067 mm) above each floor and intermediate landing levels. [The bottom edge of the opening is consistent with the height requirements for guards (see Section 1013.3)]. With a standard 8-foot (2438 mm) ceiling height minus the 42 inch (1067 mm) high guard and a typical 8-foot-wide (2438 mm) opening, the result would be 4.5 feet x 8 feet = 36 square feet (3.34 m²). Openings of this height and area readily dissipate the smoke buildup from the exterior exit stairway or ramp (see Figure 1026.3).

1026.4 Side yards. The open areas adjoining exterior exit stairways or ramps shall be either yards, courts or public areas.

![Diagram of exterior stairway and landing](image)

**Figure 1026.3**

EXTERIOR STAIRWAY

For SI:

1 inch = 25.4 mm;

1 square foot = 0.0929 m².
ways; the remaining sides are permitted to be enclosed by the exterior walls of the building.

- This section simply specifies the type of areas that the exterior opening of the exterior exit stairway or ramp is to adjoin. These open spaces will enable the smoke to dissipate from the exterior exit stairway or ramp so it will be usable as a required exit. See Section 1026.3 for a discussion of the opening requirements. See Sections 1027.4 and 1206 for the minimum sizes of yards and courts.

1026.5 Location. Exterior exit stairways and ramps shall have a minimum fire separation distance of 10 feet (3048 mm) measured from the exterior edge of the stairway or ramp, including landings, to adjacent lot lines and from other buildings on the same lot unless the adjacent building exterior walls and openings are protected in accordance with Section 705 based on fire separation distance.

- The location requirements of this section protect the users of the exterior exit stairway or ramp from the effects of a fire in another building on the same lot or an adjacent lot. The separation distance reduces the exposure to heat and smoke. If the exterior exit stairway or ramp is closer than specified, then adjacent buildings' exterior walls and openings are to be protected in accordance with Section 705 so that the users of the exterior exit stairway or ramp are protected. The reason for a minimum required distance to a lot line is to provide for a future building that could be built on an adjacent lot. While buildings on the same lot can be considered one building for height and area limitations (see Section 503.1.2), they must be separated by a minimum of 10 feet (3048 mm) if there is a path for exit discharge between them. It is not intended that the distance be measured to an imaginary lot line between buildings on the same lot.

Requirements are the same for exterior egress balconies (Section 1019.4). For an illustration of exterior egress balconies and exterior exit stairways working together, see Figure 1026.5.

1026.6 Exterior stairway and ramp protection. Exterior exit stairways and ramps shall be separated from the interior of the building as required in Section 1022.2. Openings shall be limited to those necessary for egress from normally occupied spaces.

Exceptions:

1. Separation from the interior of the building is not required for occupancies, other than those in Group R-1 or R-2, in buildings that are no more than two stories above grade plane where a level of exit discharge serving such occupancies is the first story above grade plane.

2. Separation from the interior of the building is not required where the exterior stairway or ramp is served by an exterior ramp or balcony that connects two remote exterior stairways or other approved exits with a perimeter that is not less than 50 percent open. To be considered open, the opening shall be a minimum of 50 percent of the height of the enclosing wall, with the top of the openings no less than 7 feet (2134 mm) above the top of the balcony.

3. Separation from the interior of the building is not required for an exterior stairway or ramp located in a building or structure that is permitted to have unenclosed exit access stairways in accordance with Section 1009.3.
4. Separation from the interior of the building is not required for exterior stairways or ramps connected to open-ended corridors, provided that Items 4.1 through 4.5 are met:

4.1. The building, including corridors, stairways or ramps, shall be equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2.

4.2. The open-ended corridors comply with Section 1018.

4.3. The open-ended corridors are connected on each end to an exterior exit stairway or ramp complying with Section 1026.

4.4. The exterior walls and openings adjacent to the exterior exit stairway or ramp comply with Section 1022.7.

4.5. At any location in an open-ended corridor where a change of direction exceeding 45 degrees (0.79 rad) occurs, a clear opening of not less than 35 square feet (3.3 m²) or an exterior stairway or ramp shall be provided. Where clear openings are provided, they shall be located so as to minimize the accumulation of smoke or toxic gases.

- Exterior exit stairways or ramps must be protected from interior fires that may project through windows or other openings adjacent to the exit stairway or ramp, possibly endangering the occupants using this means of egress to reach grade. The protection of an exterior exit stairway or ramp is to be obtained by separating the exterior exit from the interior of the building using exterior walls having a fire-resistance rating of at least 1 hour opening protective. Consistent with the protection required in Sections 1022.2 and 1022.7 for interior exit stairways, the fire-resistance rating must be provided for a distance of 10 feet (3048 mm) horizontally and vertically from the ramp or stairway edges, and from the ground to a level of 10 feet (3048 mm) above the highest landing.

   All window and door openings falling inside the 10-foot (3048 mm) horizontal separation distance as well as all window and door openings 10 feet (3048 mm) above the topmost landing and below the stairway must be protected with minimum 1/2-hour fire protection-rated opening protective [see Figure 1026.6(1)].

   Openings within the width of the stairway must only be from normally occupied spaces. This is consistent with the requirements for vertical exit enclosures (see Sections 1022.4 and 1022.5).

   Exception 1 indicates that opening protective are not required for occupancies (other than Groups R-1 and R-2) that are two stories or less above grade when the level of exit discharge is at the lower story. The reason for this exception is that in cases of fire in low buildings, the occupants are usually able to evacuate the premises before the fire can emerge through exterior wall openings and endanger the exit ramp or stairways. In hotels and apartments, however, the occupants' response to a fire emergency could be significantly reduced because they may be either unfamiliar with the surroundings or sleeping.

   Exception 2 allows the opening protective to be omitted when an exterior exit access balcony is served by two exits and when the exits are remote from each other. Remoteness is regulated by Section 1015.2. This exception is applicable to all groups. In such instances, it is unlikely that the users of the exterior stairway or ramp will become trapped by fire, since they have the option of using the balcony to gain access to either of the two available exits, and the products of combustion will be vented directly to the outside (see Section 1019.1 regarding exterior balconies). At least one-half of the total perimeters of the exterior balcony must be permanently open to the outside. The requirement for at least one-half of the height of that level to be open allows for columns, solid guards and architectural or decorative elements, such as arches. With the top of the opening at least 7 feet (2134 mm) above the walking surface, products of combustion can vent and allow occupant passage below the smoke layer [see Figure 1026.6(2)].

   Exception 3 exempts exterior stairways or ramps from protection when Section 1009.3 permits unenclosed interior exit access stairways. This would be areas such as open parking garages, individual dwelling units in Groups R-2 and R-3, etc.

   Exception 4 deletes the requirement for a separation between the interior of the building and the exterior wall area immediately adjacent to the exit stairway where an open-ended corridor (breezeway) interfaces with an exterior stairway or ramp. The separation is not needed due to the NFPA 13 or 13R sprinkler system required in all areas of the building, including the open-ended corridor. The other characteristics of the open-ended corridor described in this exception are needed so that it is safe to be used in the event of a fire. The requirements for an exterior stairway or ramp at each end, and the additional openings or exterior stairways or ramps where the open-ended corridor has a change of direction of greater than 45 degrees (0.79 rad) are for adequate ventilation of the open-ended corridor. The corridor may be required to be rated per Table 1018.1. The reference back to Section 1022.7 results in any exterior walls that form an angle less than 180 degrees (3.14 rad) from the side of the exterior exit stairway to be protected for a distance of 10 feet (3048 mm) [see Figure 1026.6(3)]. Exit access travel distance on an open-ended corridor is measured to the first riser of an exterior stair or the beginning slope of an exterior ramp.

   Similar separation language is used in describing the exterior wall requirements for an exterior area for assisted rescue that is provided at an exit located above grade level. Where there are steps, they are merely part of the exit discharge, not exterior exit stairways as addressed in this section.

SECTION 1027
EXIT DISCHARGE

1027.1 General. Exits shall discharge directly to the exterior of the building. The exit discharge shall be at grade or shall provide direct access to grade. The exit discharge shall not reenter a building. The combined use of Exceptions 1 and 2 shall not exceed 50 percent of the number and capacity of the required exits.

Exceptions:

3. Horizontal exits complying with Section 1025 shall not be required to discharge directly to the exterior of the building.

◆ The exit discharge is the third piece of the means of egress system, which includes exit access, exit, and exit discharge. The general provisions for means of egress in Sections 1003 through 1013 are applicable to the exit discharge. The basic provision is that exits must discharge directly to the outside of the building. The exit discharge is the path from the termination of the exit to the public way. When it is not practical to discharge directly to the outside, there are four alternatives: an exit passageway (see Section 1023), an exit discharge lobby (see Sections 1027.1, Exception 1), an exit discharge vestibule (see Section 1027.1, Exception 2) or a horizontal exit (see Sections 1025 and 1027.1, Exception 3).

While Exceptions 1 and 2 could be applicable for exit passageways and exit ramps, most of the real-life application of the exceptions is for exit stairways. This commentary for Section 1027 will be limited to interior exit stairways that are enclosed in accordance with Section 1022 (see Sections 1003.3 and 1021 for exit access stairway requirements). Up to 50 percent of the interior exit stairways in a building may use either Exception 1 or 2; therefore, neither exception is viable for a single-exit building. In a two- or three-exit building, either a lobby or a vestibule can be used for exit discharge for one of the exit stairways. In a four-exit building, two of the exit stairways can use either a lobby or a vestibule for exit discharge.

An interior exit discharge lobby is permitted to receive the discharge from an exit stairway in lieu of the stairway discharging directly to the exterior. A fire door must be provided at the point where the exit stairway discharges into the lobby. Without an opening protective between the stairway and a lobby, it would be possible for the stairway to be directly exposed to smoke movement from a fire in the lobby. The opening protective provides for full continuity of the vertical component of the exit arrangement. Additionally, in buildings where stair towers must be pressurized, pressurization would not be possible without a door at the lobby level.

An exit discharge lobby is the sole location recognized in the code where an exit element can be used for purposes other than pedestrian travel for means of egress. The lobby may contain furniture or decoration and nonoccupiable spaces may open directly into the lobby. The lobby, and all other areas on the same level that are not separated from the lobby by fire barriers consistent with the rating of the stair enclosure, must be sprinklered in accordance with an NFPA 13 or NFPA 13R system [see Figure 1027.1(1)]. If the entire level is sprinklered, no separation is required. In this case, the automatic sprinkler system is antici-
MEANS OF EGRESS

A path of travel through the lobby must be continually clear and available. The exit door leading out of the building must be visible and identifiable immediately when a person leaves the exit. This does not mean the exterior exit door must be directly in front of the door at the bottom of the stairway, but the intent is that it should be within the general range of vision. It should not be required that a person must turn completely around or go around a corner to be able to see the way out.

An exit is also allowed to discharge through a vestibule, provided it complies with the specified requirements of Exception 2. Vestibules utilizing this provision are not to be used for other purposes, such as access to closets, furniture/seating, drinking fountains, vending machines, etc. The vestibule floor and any supporting construction must be rated the same as the stairway enclosure. If the vestibule is slab on grade, this requirement is not applicable. The interior walls of the vestibule must be constructed with materials no less substantial than wired glass in steel frames. Doors are typically opening protectives with a fire protection rating of at least 20 minutes. The size of the vestibule is limited so that it cannot be used for other activities, and the travel distance from the exit stairway to the exterior exit doorway is limited (see Figures 1027.1(2) and 1027.1(3)).

Exception 3 acknowledges that horizontal exits utilize refuge areas and are not required to exit to the exterior. Many hospitals and correctional facilities use horizontal exits to "defend in place" rather than require an immediate building evacuation. There are exit stairways or exits available from the refuge areas, so occupants can move to the outside if they need to (see Section 1025 for additional information).

1027.2 Exit discharge capacity. The capacity of the exit discharge shall be not less than the required discharge capacity of the exits being served.

- This section specifies the exit discharge capacity. The exit discharge is required to be designed for the required capacity of all the exits it serves. If the exit discharge serves two exits, it is to be designed for the sum of the occupants served by both exits. Note that the capacity of the exit discharge is not required to match the capacity of both exits, which is typically higher than the sum of the occupants served by both exits.

SEPARATION DETAILS FOR VESTIBULE WITH EXIT DISCHARGE

For SI: 1 inch = 25.4 mm.
1027.3 Exit discharge components. Exit discharge components shall be sufficiently open to the exterior so as to minimize the accumulation of smoke and toxic gases.

- An exit discharge component could be a large open space where people could discharge in a number of different directions or it could be limited to a narrower path by landscaping or walls (i.e., egress court). In all cases, the space must be open enough to the outside that smoke and fumes will vent upward and away from people evacuating the building.

1027.4 Egress courts. Egress courts serving as a portion of the exit discharge in the means of egress system shall comply with the requirements of Section 1027.

- A portion of the exit discharge that is partially confined by exterior walls or other elements that confine the discharge path to a single narrow route is regulated as an egress court.

This section and the following subsections address the detailed requirements for egress courts. It is essential that exterior egress courts that serve occupants from an exit to a public way be sufficiently open to prevent the accumulation of smoke and toxic gases in the event of a fire as well as wide enough to accommodate the number of occupants leaving in that direction.

See Section 1206 for additional minimum width and openness requirements when yards and courts are needed for natural light or ventilation.

1027.4.1 Width. The minimum width of egress courts shall be determined as specified in Section 1005.1, but such width shall not be less than 44 inches (1118 mm), except as specified herein. Egress courts serving Group R-3 and U occupancies shall not be less than 36 inches (914 mm) in width. The required width of egress courts shall be unobstructed to a height of 7 feet (2134 mm).

Exception: Encroachments complying with Section 1005.7.

Where an egress court exceeds the minimum required width and the width of such egress court is then reduced along the path of exit travel, the reduction in width shall be gradual. The transition in width shall be affected by a guard not less than 36 inches (914 mm) in height and shall not create an angle of more than 30 degrees (0.52 rad) with respect to the axis of the egress court along the path of egress travel. In no case shall the width of the egress court be less than the required minimum.

The width of an exterior court is to be determined in the same fashion as for an interior corridor. The width is not to be less than required to serve the number of occupants from the exit or exits and not less than the minimum specified in this section (see also Section 1206). A cross reference back to Section 1005.7 from the exceptions for width in corridors (see Section 1018.3), aisles (see Section 1017.1), exit passageways (see Section 1023.2) and exit courts (see Section 1027.4.1) reinforces the fact that the protrusion limit provision is generally applicable for these types of confined routes.

Many egress courts are significantly larger than required. Thus, the code allows such an egress court to decrease in width along the path of travel to the public way. The gradual transition requirement is so the flow of the occupants will be uniform without pockets of congestion. The transition requirements should be applied to egress courts where a reduction results in a width that is near the minimum based on the number of occupants served. It is this condition where the uniform flow of occupants is essential.

1027.4.2 Construction and openings. Where an egress court serving a building or portion thereof is less than 10 feet (3048 mm) in width, the egress court walls shall not have less than 1-hour fire-resistance-rated construction for a distance of 10 feet (3048 mm) above the floor of the court. Openings within such walls shall be protected by opening protectives having a fire protection rating of not less than 1/4 hour.

Exceptions:

1. Egress courts serving an occupant load of less than 10.
2. Egress courts serving Group R-3.

- The purpose of this section is to protect the occupants served by the egress court from the building that they are exiting from. If occupants must walk closely by the exterior walls of the court, the walls are required to have the specified fire-resistance rating and the openings are required to be protected as specified. This requirement is only for the first 10 feet (3048 mm) above the level of the egress court since the exposure hazard from walls and openings above 10 feet (3048 mm) is reduced. The two exceptions provide for egress courts that serve a very low number of occupants and the specified residential occupancy where the protection requirement would be located.

1027.5 Access to a public way. The exit discharge shall provide a direct and unobstructed access to a public way.

Exception: Where access to a public way cannot be provided, a safe dispersal area shall be provided where all of the following are met:

1. The area shall be of a size to accommodate at least 5 square feet (0.46 m²) for each person.
2. The area shall be located on the same lot at least 50 feet (15 240 mm) away from the building requiring egress.
3. The area shall be permanently maintained and identified as a safe dispersal area.
4. The area shall be provided with a safe and unobstructed path of travel from the building.

- There are instances where the path of travel to the public way is not safe or not achievable due to site constraints or security concerns. The provisions in this section specify what would constitute a safe area to allow occupants of a building to assemble in an emergency. The 5 square feet (0.28 m²) would allow adequate space for standing persons as well as
some space for persons in wheelchairs or on stretchers. Everyone who is expected to wait in this dispersal area for fire department assistance must be a minimum of 50 feet (15 240 mm) away from the building. This refuge must always remain open and not be used for parking, storage or temporary structures. A safe dispersal area is commonly found at schools or jails. Stadiums are more specifically addressed in Section 1008.2.1. Walls or fences may surround the building and part of the site due to other safety concerns. These walls and fences could stop occupants from reaching the public way.

SECTION 1028
ASSEMBLY

1028.1 General. A room or space used for assembly purposes which contains seats, tables, displays, equipment or other material shall comply with this section.

- Although most of the provisions in Section 1028 focus on fixed seating auditoriums or theaters, this section also addresses loose seats, tables, displays, equipment, etc. Assembly spaces that contain elements that would affect the path of travel for the means of egress must comply with this section. Assembly spaces require special consideration due to the large occupant loads and possible low lighting (e.g., nightclubs, theaters). Spaces used for assembly seating may appear in buildings of other occupancy types; for example a library in a school, or a meeting room in office building. For evaluation of the occupant load and the means of egress in these spaces, they should be regulated based on their function, rather than their occupancy group.

1028.1.1 Bleachers. Bleachers, grandstands and folding and telescopic seating, that are not building elements, shall comply with ICC 300.

- On February 24, 1999, the Bleacher Safety Act of 1999 was introduced in the House of Representatives. The bill, which cites the ICC and the code, authorizes the Consumer Product Safety Commission (CPSC) to issue a standard for bleacher safety. This was in response to concerns relative to accidents on bleacher-type structures. As a result, the CPSC developed and revised the Guidelines for Retrofitting Bleachers. The ICC Board of Directors decided that a comprehensive standard dealing with all aspects of both new and existing bleachers was warranted and authorized the formation of the ICC Consensus Committee on Bleacher Safety. The committee is comprised of 12 members, including the requisite balance of general, user interest and producer interest.

ICC 300 was completed in December 2001, and submitted to ANSI on January 1, 2002. ICC 300 was reissued with some revisions in 2007 and 2012. While the term “bleachers” is generic, the standard addresses all aspects of tiered seating associated with bleachers, grandstands and folding and telescopic seating. These types of seating are supported on dedicated structural systems, which in turn may sit on the ground or on a building floor system. Single seats or bench seats bolted down to a stepped floor are not considered a bleacher or grandstand and should comply with Section 1028. See the definitions in Chapter 2 for “Building element,” “Bleachers,” “Grandstands” and “Folding and telescopic seating.” While ICC 300 is consistent and also relies on Chapter 10 of the code for some provisions, the standard addresses items specific to these types of seating arrangement. For example, the minimum number of exits from a bleacher is addressed in ICC 300, Section 404.1; however, to determine the minimum number of exits from the room the bleacher is located in Section 1021 is applicable. The bleacher standard references Chapter 11 of the code and ICC A117.1 for accessibility requirements.

1028.1.1.1 Spaces under grandstands and bleachers. When spaces under grandstands or bleachers are used for purposes other than ticket booths less than 100 square feet (9.29 m²) and toilet rooms, such spaces shall be separated by fire barriers complying with Section 707 and horizontal assemblies complying with Section 711 with not less than 1-hour fire-resistance-rated construction.

- Sometimes spaces under grandstands are used for other purposes such as bathrooms, concession stands, storage, etc. If that space caught on fire, it could jeopardize the safe evacuation options for persons on the bleachers. For safety, the spaces below must be separated from the bleachers by fire-resistance-rated construction. This is typically the roof and back walls of the concession stand or storage room. If the space below is either a small ticket booth or bathrooms of any size, the potential fire load is low enough that these spaces are not required to be separated.

Note that Section 903.2.1.5 requires enclosed spaces with an area of over 1,000 square feet (93 m²) and under an outdoor bleacher system to be sprinklered.

While the path for means of egress passing under the bleachers (i.e., vomitory) is not specifically addressed in this section, when a bleacher system is outside, the capacity factors for determining minimum egress width [Table 404.5(3) of ICC 300] are based on the assumption that the egress route is essentially open to the outside and, therefore, has a limited chance for the accumulation of smoke along that route. Two of the three legacy codes specifically exempted open means of egress routes under bleachers from separation requirements.

1028.2 Assembly main exit. In a building, room or space used for assembly purposes that has an occupant load of greater than 300 and is provided with a main exit, the main exit shall be of sufficient width to accommodate not less than one-half of the occupant load, but such width shall not be less than the total required width of all means of egress leading to the exit. Where the building is classified as a Group A occu-
MEANS OF EGRESS

panic, the main exit shall front on at least one street or an unoccupied space of not less than 10 feet (3048 mm) in width that adjoins a street or public way. In a building, room or space used for assembly purposes where there is no well-defined main exit or where multiple main exits are provided, exits shall be permitted to be distributed around the perimeter of the building provided that the total width of egress is not less than 100 percent of the required width.

- Assembly buildings as well as other buildings that include spaces that function as assembly spaces (i.e., the band classroom in a school, the training room in an office, the cafeteria in a large factory) present an unusual life safety problem that includes frequent high occupant densities and therefore large occupant loads and the opportunity for irrational mass response to a perceived emergency, i.e., panic. For this reason, the code requires a specific arrangement of the exits. Studies have indicated that in any emergency, occupants will tend to egress via the same path of travel used to enter the room and building. Therefore, a main entrance to the building must also be designed as the main exit to accommodate this behavior, even if the required exit capacity might be more easily accommodated elsewhere. The main entrance (and exit) must be sized to accommodate at least 50 percent of the total occupant load of the structure and must front on a large, open space, such as a street, for rapid dispersal of the occupants outside the building. The remaining exits must also accommodate at least 50 percent of the total occupant load from each level (see Figure 1028.2). The total occupant load includes those within the theater seating area, the foyer and any other space (e.g., ticket booth, concession stand, offices, storage and the like). When the assembly space is within a mixed use building, the intent is that the main exits from the space comply with these provisions for one-half the capacity, but not necessarily that they lead directly to the outside. Egress requirements from the building would depend on how it was anticipated for the assembly space occupants to disperse. For example, an office building may have a large training/conference room where the path of exit access travel from the room goes out a main exit from the space and then disseminates into the general floor egress system. The room exit access doors may need to meet the 50-percent criteria, but once the occupants leave the room and enter the general floor egress system, exit capacity can be dispersed.

The required width of the means of egress in places of assembly is more often determined by the occupant load than in most other occupancies. In other occupancies, the minimum required widths and the travel distances will often determine the required widths of the exits.

This section only requires the main exit to accommodate 50 percent of the occupant load when there is a single main entrance. Therefore, a large stadium or civic center, in which there are numerous entrances (and exits), need not comply with the main entrance criteria.

Figure 1028.2
GROUP A-1 WITH WAITING SPACE
1028.3 Assembly other exits. In addition to having access to a main exit, each level of a building used for assembly purposes having an occupant load greater than 500 and provided with a main exit, shall be provided with additional means of egress that shall provide an egress capacity for at least one-half of the total occupant load served by that level and shall comply with Section 1015.2. In a building used for assembly purposes where there is no well-defined main exit or where multiple main exits are provided, exits for each level shall be permitted to be distributed around the perimeter of the building, provided that the total width of egress is not less than 100 percent of the required width.

- This section provides for the egress of one-half of the total occupant load by way of exits other than the main exit that is described in Section 1028.2. Assembly buildings as well as other buildings that include spaces that function as assembly spaces that are provided with multiple entrances but no single main entrance do not provide a well-defined main exit; therefore, the total required exit width needs to be distributed around the perimeter of the space or building. Examples of these assemblies would be a school gymnasium or a large stadium or civic center in which there are numerous entrances (and exits).

1028.4 Foyers and lobbies. In Group A-1 occupancies, where persons are admitted to the building at times when seats are not available, such persons shall be allowed to wait in a lobby or similar space, provided such lobby or similar space shall not encroach upon the required clear width of the means of egress. Such foyers, if not directly connected to a public street by all the main entrances or exits, shall have a straight and unobstructed corridor or path of travel to every such main entrance or exit.

- In theaters, people may be arriving and waiting for the next show while another group has yet to exit. This is extremely common in multiplex theater complexes. In every case, the main entrance (exit) and all other exits are to be constantly available for the entire building occupant load.

   For example, because of the queuing of large crowds, particularly in theaters where a performance may be in progress and people must wait to attend the next one, standing space is often provided. For reasons of safety, such spaces cannot be located in or interfere with established paths of egress from the assembly areas. While a facility may choose to separate the route for means of egress using partitions or railings from the general lobby space to allow for easy traffic flow through the lobby to the street, it is not required to designate these areas (see Figure 1028.2).

1028.5 Interior balcony and gallery means of egress. For balconies, galleries or press boxes having a seating capacity of 50 or more located in a building, room or space used for assembly purposes, at least two means of egress shall be provided, with one from each side of every balcony, gallery or press box and at least one leading directly to an exit.

- This section states the threshold where two means of egress are required based on the occupant load of the interior balcony, gallery or press box. Note that one of the means of egress must lead directly to an exit. While Section 1009.3, Exception 9, does not require the exit access stairways serving the balcony to be enclosed in an exit enclosure, requiring direct access to an exit would be either an exit stairway surrounded by a protected enclosure (see Section 1022) or a door leading directly to the exterior. These requirements will ensure that at least one path of travel is always available and occupants face a minimum number of hazards.

   For balconies, galleries or press boxes with 50 or fewer occupants, see Section 1028.8. When balconies, galleries or press boxes contain wheelchair spaces, the area must also meet the accessible means of egress requirements (Sections 1007.1, Exception 3, and 1028.8).

1028.6 Width of means of egress for assembly. The clear width of aisles and other means of egress shall comply with Section 1028.6.1 where smoke-protected seating is not provided and with Section 1028.6.2 or 1028.6.3 where smoke-protected seating is provided. The clear width shall be measured to walls, edges of seating and tread edges except for permitted projections.

- The means of egress width for spaces used for assembly is to be in accordance with this section and the referenced sections instead of the criteria specified in Section 1005 when dealing with the means of egress within the seating area. The width factors in Section 1028.6 and its subsections apply to those doorways, passageways, aisle steps, ramped aisles and level aisles that serve the assembly seating areas.

   The Board for the Coordination of Model Codes (BMC) issued a report on means of egress dated June 10, 1985. The provisions in Section 1028 are based on this report. This report limits the application of these provisions to aisles and aisle accessways that provide exit access within the room or space with the assembly seating. This would include aisle accessways, level aisles, aisle steps and ramped aisles. The primary concern for occupant safety would be that where the different provisions for the capacity requirements in Sections 1028 and 1005 were utilized, there would not be a bottleneck in the path of travel for means of egress. For example, a common configuration at football fields is to have the seating area raised several feet above grade. Where a step or series of steps leading to grade from a raised seating area are a continuation of the aisle steps, the width of the aisle steps between seats and
MEANS OF EGRESS

the steps without adjacent seats should be the same. In theaters, commonly the occupants leave the seating area for a concourse or lobby area that leads to exit stairways between floor levels. In this situation the capacity requirement in Section 1005.3 would be applicable for the exit stairway. For the many situations between these two scenarios, the decision would be based on the configuration of the seating and exit stairways between levels.

For example, in a facility without smoke protection and an occupant load of 800, doorways would need to be calculated based on 0.20 inches (5.1 mm) per occupant (see Item 4 of Section 1028.6.1). An occupant load of 800 x 0.2 inches (4064 mm) = 160 inches (4064 mm) of egress width capacity, which translates into not less than five doors [assuming each with a minimum 32-inch (813 mm) clear opening]. This facility needs to have not less than three distinct means of egress (Section 1021.2.4). A main exit must accommodate not less than one-half of the occupant load (Section 1028.2). Therefore, the result would be not less than six doors: three located at the main exit and three others distributed to at least two other locations (Section 1028.3).

Different means of egress width criteria are also specified for assembly seating where smoke protection is provided versus areas it is not provided. The egress width for smoke-protected seating is allowed to be less than for areas where smoke protection is not provided, since the smoke level is required to be maintained at least 6 feet (1829 mm) above the floor of the means of egress, according to Section 1028.6.2.1.

1028.6.1 Without smoke protection. The clear width of the means of egress shall provide sufficient capacity in accordance with all of the following, as applicable:

1. At least 0.3 inch (7.6 mm) of width for each occupant served shall be provided on stairs having riser heights 7 inches (178 mm) or less and tread depths 11 inches (279 mm) or greater, measured horizontally between tread nosings.

2. At least 0.005 inch (0.127 mm) of additional stair width for each occupant shall be provided for each 0.10 inch (2.5 mm) of riser height above 7 inches (178 mm).

3. Where egress requires stair descent, at least 0.075 inch (1.9 mm) of additional width for each occupant shall be provided on those portions of stair width having no handrail within a horizontal distance of 30 inches (762 mm).

4. Ramped means of egress, where slopes are steeper than one unit vertical in 12 units horizontal (8-percent slope), shall have at least 0.22 inch (5.6 mm) of clear width for each occupant served. Level or ramped means of egress, where slopes are not steeper than one unit vertical in 12 units horizontal (8-percent slope), shall have at least 0.20 inch (5.1 mm) of clear width for each occupant served.

This section prescribes the criteria needed to calculate the clear widths of aisles and aisle accessways in order to provide sufficient capacity to handle the occupant loads established by the "catchment areas" described in Section 1028.9.2. Clear width is to be measured to walls, edges of seating and tread edges.

The criteria for determining the required widths are based on analytical studies and field tests that used people to model egress situations [see Figures 1028.6.1(1) and 1028.6.1(2)].

Criterion 1 addresses the method for determining the required egress width for aisles and aisle accessways that are stepped. This method corresponds with the requirements of Section 1005.3.1 for egress width per occupant of stairways in an unsprinklered building.

Criterion 2 addresses the method for determining the additional stair width required for aisle and aisle accessway stairs with risers greater than 7 inches (178 mm).

\[ \text{Figure 1028.6.1(1)} \]
COMPUTATION OF WIDTH FOR STEPPED AISLES

For SI: 1 inch = 25.4 mm.
Criterion 3 addresses the method for determining the additional stair width where a handrail is not located within 30 inches (762 mm). Due to the increased chance of falling and not being within reach of a handrail, the capacity per occupant is increased by 25 percent for the entire stairway. For example, to calculate the capacity of a 72-inch-wide (1829 mm) stepped aisle, the answer would be 72 inches / 0.375 inch = 192 occupants.

Criterion 4 addresses the method for determining the required widths for level or ramped and level means of egress. Where slopes are less than 1:12 (see definition for "Ramp"), the capacity requirements are also less. Level floors are quicker to negotiate than ramped surfaces for persons with limited mobility.

Figure 1028.6.1(2)  
COMPUTATION OF WIDTH FOR LEVEL, SLOPED OR RAMPS AISLES

9 ROWS PER SIDE  
292 PEOPLE PER CATCHMENT AREA  
292 x 0.2 PER PERSON = 58.4" REQ'D AISLE WIDTH

For SI: 1 inch = 25.4 mm.

1028.6.2 Smoke-protected seating. The clear width of the means of egress for smoke-protected assembly seating shall not be less than the occupant load served by the egress element multiplied by the appropriate factor in Table 1028.6.2. The total number of seats specified shall be those within the space exposed to the same smoke-protected environment. Interpolation is permitted between the specific values shown. A life safety evaluation, complying with NFPA 101, shall be done for a facility utilizing the reduced width requirements of Table 1028.6.2 for smoke-protected assembly seating.

Exception: For an outdoor smoke-protected assembly seating with an occupant load not greater than 18,000, the clear width shall be determined using the factors in Section 1028.6.3.

- Special consideration is given to facilities with features that will prevent the means of egress from being blocked by smoke. Facilities to be considered smoke protected by Sections 1028.6.2.1 through 1028.6.2.3 are permitted increases in travel distance, egress capacity, longer dead-end aisles and increased row lengths. Smoke control increases allowable egress time. Typically, model codes based on research by Dr. John Fruin and others recognize the need for occupants exposed to the fire environment to evacuate to a safe area within 90 seconds of notification and to reach a refuge area within 5 minutes. With the increases permitted for smoke-protected facilities, these times are effectively doubled since the time available for safe egress also increases.

The exception is a pointer to the specific criteria for outdoor seating areas. For outdoor stadiums with 18,000 seats or greater, use Table 1028.6.2.

TABLE 1028.6.2. See page 10-176.

- This section requires the egress component to be of adequate size to accommodate the occupant load. For smoke-protected seating, the egress width per occupant is based on Table 1028.6.2. Typically, the larger the facility, the higher the ceiling; therefore, more space for smoke containment is associated with more time for egress. The egress width per occupant for nonsmoke-protected seating is to be based on Section 1028.6.1 and is similar to the provisions in Table 1005.1.

1028.6.2.1 Smoke control. Means of egress serving a smoke-protected assembly seating area shall be provided with a smoke control system complying with Section 909 or natural ventilation designed to maintain the smoke level at least 6 feet (1829 mm) above the floor of the means of egress.

- The means of egress and the assembly seating area are required to have some type of smoke control system that will prevent smoke buildup from encroaching on the egress path. This may be a mechanical smoke control system, designed in accordance with Section 909, or natural ventilation as in open-air stadiums.

In either type of system, the major consideration is that a smoke-free environment be maintained at least 6 feet (1829 mm) above the floor of the means of egress for a period of at least 20 minutes.

1028.6.2.2 Roof height. A smoke-protected assembly seating area with a roof shall have the lowest portion of the roof deck not less than 15 feet (4572 mm) above the highest aisle or aisle accessway.

Exception: A roof canopy in an outdoor stadium shall be permitted to be less than 15 feet (4572 mm) above the highest aisle or aisle accessway provided that there are no
MEANS OF EGRESS

objects less than 80 inches (2032 mm) above the highest aisle or aisle accessway.

- One element of a smoke-protected assembly seating facility is that the lowest portion of the roof is required to be at least 15 feet (4572 mm) above the highest aisle or aisle accessway. The objective of this provision is to have a minimum 6-foot (1829 mm) smoke-free height to accommodate safe egress through the area. The additional 9 feet (2743 mm) of height is to provide a volume of space that will act to dissipate smoke. The measurement of the height is shown in Figures 1028.6.2.2(1) and 1028.6.2.2(2).

**1028.6.2.3 Automatic sprinklers.** Enclosed areas with walls and ceilings in buildings or structures containing smoke-protected assembly seating shall be protected with an approved automatic sprinkler system in accordance with Section 903.3.1.1.

**Exceptions:**

1. The floor area used for contests, performances or entertainment provided the roof construction is more than 50 feet (15 240 mm) above the floor level and the use is restricted to low fire hazard uses.

2. Press boxes and storage facilities less than 1,000 square feet (93 m²) in area.

3. Outdoor seating facilities where seating and the means of egress in the seating area are essentially open to the outside.

- If there are areas in the smoke-protected assembly seating structure enclosed by walls and ceilings, the entire structure is to be provided with an automatic sprinkler system to meet the requirements of NFPA 13.

Exception 1 indicates that the area over the playing field or performance area is not required to be sprinklered if the use of the floor area is restricted. If the facility is used for conventions, trade shows, displays or similar purposes, sprinklers are required throughout, since the occupancy would no longer be a low fire-hazard use. A characteristic of a low fire-hazard occupancy is that the fuel load due to combustibles is

For SI: 1 inch = 25.4 mm.

**Figure 1028.6.2.2(1)**

ROOF HEIGHT (CONVEX DOME ROOF)

For SI: 1 foot = 304.8 mm.
approximately 2 pounds per square foot (9.8 kg/m²) or less.

In order for the contest, performance or entertainment area to be nonsprinklered, the roof over that area must be at least 50 feet (15 240 mm) above the floor in addition to the floor area meeting the low fire-hazard criteria. The 50-foot (15 240 mm) criterion was selected because the response time for sprinklers at this height is extremely slow. It is estimated that the response time for standard sprinklers [50 feet (15 240 mm) above a floor with a fire having a heat release rate of 5 British thermal units (Btu) per square foot per second] exceeds 15 minutes. Therefore, it is not reasonable to install sprinklers at that height with little expectation of timely activation [see Figure 1028.6.2.3(1)]. Note that if this exception is utilized, the tradeoffs for a fully sprinklered building, such as increased height and area limitations or decreased corridor ratings, are no longer permitted.

Exception 2 indicates that automatic sprinklers are not required in small spaces in buildings. Sprinklers are required in press box and storage areas of outdoor facilities when the area exceeds 1,000 square feet (93 m²). The primary reason for sprinklers in these areas is that both are anticipated to have a relatively large combustible load when compared to the main seating and participant areas. Additionally, in the case of storage areas, there is an increased potential for an undetected fire condition to occur [see Figure 1028.6.2.3(2)].

Exception 3 provides for outdoor seating facilities where smoke entrapment is not a safety concern.

1028.6.3 Width of means of egress for outdoor smoke-protected assembly seating. The clear width in inches (mm) of aisles and other means of egress shall not be less than the total occupant load served by the egress element multiplied by 0.08 (2.0 mm) where egress is by aisles and stairs and multiplied by 0.06 (1.52 mm) where egress is by ramps, corridors, tunnels or vomitories.

Exception: The clear width in inches (mm) of aisles and other means of egress shall be permitted to comply with Section 1028.6.2 for the number of seats in the outdoor smoke-protected assembly seating where Section 1028.6.2 permits less width.

This section has the coefficients for the determination of the width of egress required for outdoor smoke-protected assembly areas. Note that the coefficients are significantly less when compared to the values in Section 1028.6.1 for assembly areas without smoke protection. The coefficients are also less than those for smoke-protected assembly seating in Table 1028.6.2 except for very large assembly areas. The exception in this section would apply where the coefficients in Table 1028.6.2 are less than those in this section.

Low coefficients are a result of the very low hazards for outdoor smoke-protected assembly areas and increased egress time.

Generally, an outdoor assembly area meets the smoke control requirements of Section 1028.6.2 by natural ventilation and does not require an automatic sprinkler system according to Section 1028.6.2.3, Exception 3.
MEANS OF EGRESS

Figure 1028.6.2.3(1)
INDOOR SEATING SPRINKLERED AREAS (CONVEX DOME ROOF)

Figure 1028.6.2.3(2)
INDOOR SEATING SPRINKLERED AREAS (CONCAVE SUSPENDED ROOF)

For SI: 1 foot = 304.8 mm.
1 square foot = 0.0929 m².
1028.7 Travel distance. Exits and aisles shall be so located that the travel distance to an exit door shall not be greater than 200 feet (60 960 mm) measured along the line of travel in nonsprinklered buildings. Travel distance shall not be more than 250 feet (76 200 mm) in sprinklered buildings. Where aisles are provided for seating, the distance shall be measured along the aisles and aisle accessway without travel over or on the seats.

Exceptions:

1. Smoke-protected assembly seating: The travel distance from each seat to the nearest entrance to a vomitory or concourse shall not exceed 200 feet (60 960 mm). The travel distance from the entrance to the vomitory or concourse to a stair, ramp or walk on the exterior of the building shall not exceed 200 feet (60 960 mm).

2. Open-air seating: The travel distance from each seat to the building exterior shall not exceed 400 feet (122 m). The travel distance shall not be limited in facilities of Type I or II construction.

This section includes the travel distance limits for an assembly occupancy, which are the same as those in Table 1016.2 for Group A. The travel distance is to be measured along the same path as the occupants would normally take to exit the facility.

Exception 1 provides an extended travel distance for smoke-protected assembly seating that meets the requirements of Sections 1028.6.2 through 1028.6.2.3. Exception 2 applies to outdoor open-air seating areas where the smoke and fire hazard is very low. The Type I and II construction referenced to in this exception is described in Section 602.

1028.8 Common path of egress travel. The common path of egress travel shall not exceed 30 feet (9144 mm) from any seat to a point where an occupant has a choice of two paths of egress travel to two exits.

Exceptions:

1. For areas serving less than 50 occupants, the common path of egress travel shall not exceed 75 feet (22 860 mm).

2. For smoke-protected assembly seating, the common path of egress travel shall not exceed 50 feet (15 240 mm).

The maximum travel distance down a single access row of seating to a location where a patron would have two choices for a way out of the space is 30 feet (9144 mm). In smoke-protected seating, the common path of travel can be up to 50 feet (15 240 mm).

If the room or space (e.g., box, gallery or balcony) has 50 or fewer occupants, the travel distance can be increased to 75 feet (22 860 mm). For example, this allows for a path of travel from a box seat, out of the box and to a main aisle or even a corridor located outside the assembly room itself.

When this section is referenced for accessible means of egress (see Section 1007.1, Exception 3), the utilization of Exception 1 would include the entire occupant load of the box, gallery or balcony, not just the number of wheelchair spaces and/or companion seats. Wheelchair spaces that are integrated into the general seating would have the same common path of travel distance of 30 feet (9144 mm) before the person needing the accessible route could choose two different paths for accessible means of egress. This provides the same level of protection for the persons in the accessible seating as provided for others within the space.

Both Sections 1014.3 and 1028.8 must be considered when determining the common path of travel requirements for a building. Section 1014.3 regulates the means of egress from a room or space. Section 1028.8, however, regulates the distance to a decision point within a room or space used for assembly seating where a single access row of seating is provided to a location where a patron would have two choices for a way out of the space.

1028.8.1 Path through adjacent row. Where one of the two paths of travel is across the aisle through a row of seats to another aisle, there shall be not more than 24 seats between the two aisles, and the minimum clear width between rows for the row between the two aisles shall be 12 inches (305 mm) plus 0.6 inch (15.2 mm) for each additional seat above seven in the row between aisles.

Exception: For smoke-protected assembly seating there shall not be more than 40 seats between the two aisles and the minimum clear width shall be 12 inches (305 mm) plus 0.3 inch (7.6 mm) for each additional seat.

In establishing the point where the occupants of a row served by a single access aisle have two distinct paths of travel, the code allows one of those paths to be through the rows of an adjacent seating area or section. This requirement increases the row widths for the single-access seating section and the adjacent dual-access seating section. This allows the occupants to either travel down the single access aisle or readily traverse the oversized row widths to gain access to a second means of egress (see Figure 1028.8.1). This exception allows a greater number of seats spaced with a minimum clearance of 12 inches (305 mm) for smoke-protected assembly seating that complies with Sections 1028.6.2 through 1028.6.2.3 or Section 1028.6.3. For the base width requirements for single- and dual-access rows, see the commentary to Sections 1028.10.2 through 1028.10.2.2.

1028.9 Assembly aisles are required. Every occupied portion of any building, room or space used for assembly purposes that contains seats, tables, displays, similar fixtures or equipment shall be provided with aisles leading to exits or exit access doorways in accordance with this section. Aisle accessways for tables and seating shall comply with Section 1028.10.1.

This section requires that each assembly space have designated aisles. For aisle accessway requirements, see Section 1028.10. For aisles in other occupancies, see Section 1017.
1028.9.1 Minimum aisle width. The minimum clear width for aisles shall be as shown:

1. Forty-eight inches (1219 mm) for aisle stairs having seating on each side.
   **Exception:** Thirty-six inches (914 mm) where the aisle serves less than 50 seats.

2. Thirty-six inches (914 mm) for aisle stairs having seating on only one side.
   **Exception:** Twenty-three inches (584 mm) between an aisle stair handrail and seating where an aisle does not serve more than five rows on one side.

3. Twenty-three inches (584 mm) between an aisle stair handrail or guard and seating where the aisle is subdivided by a handrail.

4. Forty-two inches (1067 mm) for level or ramped aisles having seating on both sides.

   **Exceptions:**

   1. Thirty-six inches (914 mm) where the aisle serves less than 50 seats.
   2. Thirty inches (762 mm) where the aisle does not serve more than 14 seats.

5. Thirty-six inches (914 mm) for level or ramped aisles having seating on only one side.
   **Exception:** Thirty inches (762 mm) where the aisle does not serve more than 14 seats.

The clear widths of aisles and other means of egress established by the formulas given in Section 1028.6 must not be less than the minimum width requirements of this section. The development of minimum width requirements is based on the association of aisle capacity with the path of exit travel as influenced by the different features of aisle construction. The purpose is to create an aisle system that would provide an even flow of occupant egress. The minimum width of the aisles is also based on an anticipated movement of people in two directions. Note that each exception is only applicable to the item directly above.

1028.9.2 Aisle width. The aisle width shall provide sufficient egress capacity for the number of persons accommodated by the catchment area served by the aisle. The catchment area served by an aisle is that portion of the total space that is served by that section of the aisle. In establishing catchment areas, the assumption shall be made that there is a balanced
use of all means of egress, with the number of persons in proportion to egress capacity.

- The determination of required aisle and aisle accessway width is a function of the occupant load. In calculating the required widths, the assumption is that in a system or network of aisles and aisle accessways serving an occupied area, people will normally exit the area in a way that will distribute the occupant load throughout the system in proportion to the egress capacity of the aisles and aisle accessways. Each aisle and aisle accessway would take its tributary share (catchment area) of the total occupant load (see Figure 1028.9.2).

In addition to the provisions in this section, the requirement for the capacity of the main exit and other exits must also be considered (see Sections 1028.2 and 1028.3). While this section assumes an equal distribution, Section 1028.2 requires that where the facility has a main exit, the main exit and the access thereto must be capable of handling 50 percent of the occupant load.

### 1028.9.3 Converging aisles

Where aisles converge to form a single path of egress travel, the required egress capacity of that path shall not be less than the combined required capacity of the converging aisles.

- Where one or more aisles or aisle accessways meet to form a single path of egress travel, that path must be sized to handle the combined occupant capacity of the converging aisles and aisle accessways (see Figure 1028.9.3). The reason for this requirement is to maintain the natural pace of travel all the way through the aisle accessways or aisles to the exits and to minimize the queuing of occupants.

This section requires combining the required occupant capacity of converging aisles and aisle accessways, but not necessarily the required widths. For example, if two 48-inch (1219 mm) aisles converge, the result need not be a 96-inch (2438 mm) aisle unless the 48-inch (1219 mm) width of the aisles is required based on the requirements of Section 1028.6 for the actual occupant load served. However, if the 48-inch (1219 mm) width is not based on the

---

**Figure 1028.9.2**

**Typical Aisle Catchments**
MEANS OF EGRESS

occupant load but is required to comply with the minimum aisle width requirements of Section 1028.9.1, the resulting aisle width must be sized for the total occupant load served by the converging aisles, as determined by Section 1028.6, but not less than the minimum widths of Section 1028.9.1.

1028.9.4 Uniform width. Those portions of aisles, where egress is possible in either of two directions, shall be uniform in required width.

- Aisles that connect or lead to opposite exits must be of uniform width throughout their entire length to allow for exit travel in two directions without creating a traffic bottleneck (see Figure 1028.9.4).

1028.9.5 Assembly aisle termination. Each end of an aisle shall terminate at cross aisle, foyer, doorway, vomitory or concourse having access to an exit.

Exceptions:

1. Dead-end aisles shall not be greater than 20 feet (6096 mm) in length.

2. Dead-end aisles longer than 20 feet (6096 mm) are permitted where seats beyond the 20-foot (6096 mm) dead-end aisle are no more than 24 seats from another aisle, measured along a row of seats having a minimum clear width of 12 inches (305 mm) plus 0.6 inch (15.2 mm) for each additional seat above seven in the row.

3. For smoke-protected assembly seating, the dead-end aisle length of vertical aisles shall not exceed a distance of 21 rows.

4. For smoke-protected assembly seating, a longer dead-end aisle is permitted where seats beyond the 21-row dead-end aisle are not more than 40 seats from another aisle, measured along a row of seats having an aisle accessway with a minimum clear width of 12 inches (305 mm) plus 0.3 inch (7.6 mm) for each additional seat above seven in the row.

- Both ends of a cross aisle must terminate at either an intersecting aisle, a foyer, a doorway or a vomitory (lane) that gives access to an exit(s). Each exception allows an aisle to have a dead-end of limited length. Exceptions 1 and 2 address dead-end aisles in assembly spaces with or without smoke protection. Exceptions 3 and 4 address dead-end aisles only in smoke-protected assembly seating. In accordance with Exception 1, dead-end aisles (similar to corridors and passageways) that terminate at one end of a cross aisle or a foyer, doorway or vomitory must not be more than 20 feet (6096 mm) in length. The intent of the row width requirements in the exceptions is to provide sufficient clear width between rows of seating to allow the occupants in times of emergency to pass quickly from a dead-end aisle to the aisle at the opposite end. In Exception 2, the 0.6-inch (15

For SI: 1 inch = 25.4 mm.

Figure 1028.9.3
COMPUTATION OF EXIT PASSAGE FOR CONVERGING AISLES

10-182
2012 INTERNATIONAL BUILDING CODE® COMMENTARY
mm) increase beyond seven seats is consistent with the minimum width determined in accordance with Section 1028.10.2 for single access rows. The code recognizes that one dead-end aisle may not be usable, thus creating a single access row condition. Exceptions 3 and 4 allow longer dead-end aisles for smoke-protected assembly seating that complies with Sections 1028.6.2 through 1028.6.2.3 or Section 1028.6.3 (see Figure 1025.9.5).

The overall purpose of this section is to provide aisle/seating arrangements that would allow the occupants to seek safe and rapid passage to exits in case of fire or other emergency.

1028.9.6 Assembly aisle obstructions. There shall be no obstructions in the required width of aisles except for handrails as provided in Section 1028.13.

 Except for handrails, aisles are required to be clear of any obstructions so that the full width is available for egress purposes. Handrails are allowed to project into the required aisle width in the same manner as handrail projections in stairways.

1028.10 Aisle accessways. Aisle accessways for seating at tables shall comply with Section 1028.10.1. Aisle accessways for seating in rows shall comply with Section 1028.10.2.

 Aisle accessways are paths for means of egress between rows of seats or between tables. The aisle accessway leads to aisles, which in turn lead towards exits from the space. This is the same idea as moving through a room full of furniture to a corridor to reach an exit. In both situations, the path for means of egress is confined. For aisle accessway requirements in other occupancies, see Section 1017.

1028.10.1 Seating at tables. Where seating is located at a table or counter and is adjacent to an aisle or aisle accessway, the measurement of required clear width of the aisle or aisle accessway shall be made to a line 19 inches (483 mm) away from and parallel to the edge of the table or counter. The 19-inch (483 mm) distance shall be measured perpendicular to the side of the table or counter. In the case of other side boundaries for aisle or aisle accessways, the clear width shall be measured to walls, edges of seating and tread edges, except that handrail projections are permitted.

Exception: Where tables or counters are served by fixed seats, the width of the aisle accessway shall be measured from the back of the seat.

 Most seating at tables should be adjacent to aisles or aisle accessways. In measuring the width of an aisle or aisle accessway for movable seating, the measurement is taken at a distance of 19 inches (483 mm) perpendicular to the side of the table or counter. This 19-inch (483 mm) space from the edge of the table or counter to the line where the aisle or aisle accessway measurement begins is intended to represent the space occupied by a typical seated occupant. This dimension is also considered to be
Means of Egress

adequate to accommodate seats with armrests that are too high to fit under the table where fixed seats are used. The aisle width is permitted to be measured from the back of the seat based upon the exception. As indicated in Figure 1028.10.1, where seating abuts an aisle or aisle accessway, 19 inches (483 mm) must be added to the required aisle or aisle accessway width for seating on only one side and 38 inches (965 mm) for seating on both sides. When seating will not be adjacent to the aisles or aisle passageways, as is the case when tables are at an angle to the aisle or aisle accessway, the measurement may be taken to the edge of the seating, table, counter or tread. Sections 1028.10.1.1 and 1028.10.1.2 address width and travel along aisle accessways. For aisles between tables, see Section 1028.9.

1028.10.1.1 Aisle accessway width for seating at tables. Aisle accessways serving arrangements of seating at tables or counters shall have sufficient clear width to conform to the capacity requirements of Section 1005.1 but shall not have less than a minimum of 12 inches (305 mm) of width plus $\frac{1}{4}$ inch (12.7 mm) of width for each additional 1 foot (305 mm), or fraction thereof, beyond 12 feet (3658 mm) of aisle accessway length measured from the center of the seat farthest from an aisle.

Exception: Portions of an aisle accessway having a length not exceeding 6 feet (1829 mm) and used by a total of not more than four persons.

This section specifies two criteria for the determination of the required width of aisle accessways at tables: the requirements of Section 1005.1 for capacity based on the number of occupants and the option described in this section. The aisle accessway width is to be the wider of the two requirements. The aisle accessway width between tables is determined similarly to the aisle accessway between rows of seats that view an event.

The relationship of tables and seating sometimes results in a situation in which it is difficult to determine which chairs are served by which aisle accessway; therefore, the width of the aisle accessway is a function of the distance from the aisle. The same minimum 12 inches (305 mm) is used and is increased $\frac{1}{4}$ inch (12.7 mm) for each additional foot of travel beyond 12 feet (3658 mm).

Recognizing that the normal use of table and chair seating will require some clearance for access and service, the exception eliminates the minimum width criteria if the distance to the aisle (or an aisle accessway of at least 12 inches (305 mm)) is less than 6 feet (1829 mm) and the number of people served is not more than four. Therefore, the first 6 feet (1829 mm) are not required to meet any minimum width criteria. After the first 6 feet (1829 mm), the requirements for an aisle accessway will apply. The length of the aisle accessway is then restricted by Section 1028.10.1.2. When the maximum length of the aisle accessway is reached, either an aisle, corridor or exit access door must be provided (see Figure 1028.10.1.1).
MEANS OF EGRESS

**Figure 1028.10.1**
AISLE AND AISLE ACCESSWAY MEASUREMENT WITH SEATING AND TABLES

For SI: 1 inch = 25.4 mm.

**Figure 1028.10.1.1**
ACCESS FOR TABLES AND SEATING

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.
MEANS OF EGRESS

1028.10.2 Seating at table aisle accessway length. The length of travel along the aisle accessway shall not exceed 30 feet (9144 mm) from any seat to the point where a person has a choice of two or more paths of egress travel to separate exits.

At some point in the exit access travel, it is necessary to reach an aisle complying with the minimum widths of Section 1028.9.1. Aisle accessway travel distance for seating at tables is not to exceed 30 feet (9144 mm), which may represent a dead-end condition (see Figure 1028.10.1.1).

1028.10.2 Clear width of aisle accessways serving seating in rows. Where seating rows have 14 or fewer seats, the minimum clear aisle accessway width shall not be less than 12 inches (305 mm) measured as the clear horizontal distance from the back of the row ahead and the nearest projection of the row behind. Where chairs have automatic or self-rising seats, the measurement shall be made with seats in the raised position. Where any chair in the row does not have an automatic or self-rising seat, the measurements shall be made with the seat in the down position. For seats with folding tablet arms, row spacing shall be determined with the tablet arm in the used position.

Exception: For seats with folding tablet arms, row spacing is permitted to be determined with the tablet arm in the stored position where the tablet arm when raised manually to vertical position in one motion automatically returns to the stored position by force of gravity.

The requirements of this section are applicable to theater-type seating arrangements. This includes both "continental" and "traditional" seating arrangements. Theater-type seating is characterized by a number of seats arranged side by side and in rows. In this type of seating arrangement, the potential exists for a large number of occupants to be present in a confined environment where the ability of the occupants to move quickly is limited. In order to egress, people are required to move single file within a narrow row (i.e., aisle accessway) before reaching an aisle; both the aisle or aisle accessway limit movement toward an exit. To provide adequate passage between rows of seats, this section requires that the clear width between the back of a row to the nearest projection of the seating immediately behind must be at least 12 inches (305 mm) (see Figure 1028.10.2). Where chairs are manufactured with automatic or self-lifting seats, the minimum width requirement may be measured with the seats in a raised position. Commonly used in college lecture halls, seats with built in tablet arms are provided so that students can take notes.

When tablet arm chairs are used, the required width is to be determined with the tablet arm in its usable position. The exception allows for folding tablet arms that fall back into the stored position when a person rises out of the seat. With seats occupied and tablets raised, students egressing en-masse down the row would at most encounter one tablet to move out of the way. With these types of arms, the aisle accessway can be measured for the seat or arm as indicated in Figure 1028.10.2.

With respect to self-rising seats, ASTM F 851 provides one method of determining acceptability.

1028.10.2.1 Dual access. For rows of seating served by aisles or doorways at both ends, there shall not be more than 100 seats per row. The minimum clear width of 12 inches (305 mm) between rows shall be increased by 0.3 inch (7.6 mm) for every additional seat beyond 14 seats, but the minimum clear width is not required to exceed 22 inches (559 mm).

Exception: For smoke-protected assembly seating, the row length limits for a 12-inch-wide (305 mm) aisle accessway, beyond which the aisle accessway minimum clear width shall be increased, are in Table 1028.10.2.1.

Where rows of seating are served by aisles or doorways located at both ends of the path of row travel, the number of seats that may be used in a row may be up to, but not more than, 100 (continental seating) and the minimum required clear width aisle accessway of 12 inches (305 mm) between rows of seats must be increased by 0.3 inch (8 mm) for every addi-
tional seat beyond 14, but not more than a total of 22 inches (559 mm) (see Figure 1028.10.2.1). For example, in a row of 24 seats, the minimum clear width would compute to 15 inches (381 mm) [12 + (0.3 x 10)]. For a row of 34 seats, a clear width of 18 inches (457 mm) would be required. Increases in the clear width between rows of seats would occur up to a row of 46 seats. From 47 to 100 seats, a maximum clear width between rows of 22 inches (559 mm) would apply.

Since the row is to provide access to an aisle in both directions, the minimum width applies to the entire length of the row aisle accessway.

The exception allows more seats in a row with the minimum 12-inch (305 mm) seat spacing since safe egress time is extended for this condition.

When a second means of egress for occupants of a single access row is possible through an adjacent dual access row, see Section 1028.8.1.

</table>

For SI: 1 inch = 25.4 mm.

Table 1028.10.1 recognizes the increased egress time available in smoke-protected assembly seating areas. Therefore, the table permits greater lengths of rows that have the minimum 12 inches (305 mm) of clear width. When a row exceeds the lengths identified in the table, the row width is to be increased in accordance with Section 1028.10.2.2 [0.3 inch (8 mm) per additional seat for dual access rows and Section 1028.10.2.2 [0.6 inch (15 mm) per additional seat for single access rows. Column one in this table is based on the total number of seats contained within the assembly space, not the seats per level.

**1028.10.2.2 Single access.** For rows of seating served by an aisle or doorway at only one end of the row, the minimum clear width of 12 inches (305 mm) between rows shall be increased by 0.6 inch (15.2 mm) for every additional seat beyond seven seats, but the minimum clear width is not required to exceed 22 inches (559 mm).

**Exception:** For smoke-protected assembly seating, the row length limits for a 12-inch-wide (305 mm) aisle accessway, beyond which the aisle accessway minimum clear width shall be increased, are in Table 1028.10.2.1.

- Where rows of seating are served by an aisle or doorway at only one end of a row, the minimum clear width of 12 inches (305 mm) between rows of seats must be increased by 0.6 inch (15 mm) for every additional seat beyond seven, but not more than a total of 22 inches (559 mm) (see Figure 1028.10.2.2). While this section does not specify the maximum number of seats permitted in a row, the 30-foot (9144 mm) common path of travel limitation (see Section 1028.8) essentially restricts the single access row to approximately 20 seats, based on an 18-inch (457 mm) width per seat. A row of 12 seats would compute to a required minimum width of 15 inches [12 + (0.5 x 5)]. Similarly, a row of 17 seats would require a clear width of 18 inches (457 mm) and so on. Since dual access is not provided, incremental increases would be permitted in the aisle accessway width as shown in Figure 1028.10.2.2. Incremental increases in the...
MEANS OF EGRESS

required width would occur up to the maximum number of seats, which is determined by the 30-foot (9144 mm) dead-end limitation.

The reason for increasing the row accessway widths incrementally with increases in the number of seats per row is to provide more efficient passage for the occupants who are using the aisle accessway. As a practical matter, where dual-access (see Section 1028.10.2.1) and single-access seating arrangements are used together, the largest computed clear width dimension would normally be applied by the designer to both arrangements so that the rows of seats will be in alignment. When a second means of egress for occupants of a single access row is possible through an adjacent dual access row, see Section 1028.8.1.

1028.11 Assembly aisle walking surfaces. Aisles with a slope not exceeding one unit vertical in eight units horizontal (12.5-percent slope) shall consist of a ramp having a slip-resistant walking surface. Aisles with a slope exceeding one unit vertical in eight units horizontal (12.5-percent slope) shall consist of a series of risers and treads that extends across the full width of aisles and complies with Sections 1028.11.1 through 1028.11.3.

Assembly facilities such as theaters and auditoriums often require sloping or stepped floors to provide seated occupants with preferred sightlines for viewing presentations (for sightlines for wheelchair spaces, see Section 1108.2). Aisles must, therefore, be designed to accommodate the changing elevations of the floor in such a manner that the path of travel will allow occupants to leave the area at a rapid pace with minimal possibilities for stumbling or falling during times of emergency.

This section requires that aisles with a gradient of one unit vertical and eight units horizontal (12.5 percent slope) or less must consist of a ramp with a slip-resistant surface. Aisles with a gradient exceeding one unit vertical and eight units horizontal (12.5-percent slope) must consist of a series of treads and risers that comply with the requirements of Sections 1028.11.1 through 1028.11.3. Note that ramps that serve as part of an accessible route to and from accessible wheelchair spaces must comply with the more restrictive requirements for ramps in Section 1010 (see Section 1010.1, Exception 1).

While not specifically indicated for stepped aisles, such floor surfaces must also be slip resistant in accordance with Section 1003.4. Field testing and uniform enforcement of the concept of slip resistance is not practical. One method used to establish slip resistance is that the static coefficient of friction between leather [Type 1 (Vegetable Tanned) of Federal Specification KK-L-165C] and the floor surface is greater than 0.5. Laboratory test procedures can determine the static coefficient of resistance.

What must be recognized here is that stepped aisles are part of the floor construction and are intended to provide horizontal egress. Tread and riser construction for this purpose should not be compared to the requirements for treads and risers in conventional stairways that serve as means of vertical egress. Sometimes, because of design considerations, the gradient of an aisle is required to change from a level floor to a ramp and then to steps. In cases where there is no uniformity in the path of travel, occupants tend to be considerably more cautious, particularly in the use of stepped aisles, than they would normally be in the use of conventional stairways.

1028.11.1 Treads. Tread depths shall be a minimum of 11 inches (279 mm) and shall have dimensional uniformity.

Exception: The tolerance between adjacent treads shall not exceed $\frac{3}{16}$ inch (4.8 mm).

 Depths of treads are not to be less than 11 inches (279 mm) and uniform throughout each flight, except that a variance of not more than $\frac{3}{16}$ inch (4.8 mm) is permitted between adjacent treads to accommodate variations in construction. While the minimum tread depth provision is the same as the limiting dimension for treads in interior stairways (see Section 1009.7.2),

![Figure 1028.10.2.2](image)

Typical Single Access Row—Minimum Aisle Accessway Width

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.
it rarely applies in the construction of stepped aisles. A more common form of stepped aisle construction is to provide a tread depth equal to the back-to-back distance between rows of seats. This way the treads can be extended across the full length of the row and serve as a supporting platform for the seats. Other arrangements might require two treads between rows of seats.

In theaters, for example, the back-to-back distance between rows of fixed seats usually ranges somewhere between 3 and 4 feet (914 and 1219 mm), depending on seat style and seat dimensions as well as the ease of passage between the rows (see Figure 1028.11.1). The selection of single-tread or two-tread construction between rows of seats depends on the gradient and suitable riser height (see Section 1028.11.2), as needed for sightlines.

In comparing this section with Section 1028.11.2, it is significant to note the emphasis placed on the tread depth. While not desirable, the code permits riser heights to deviate; however, tread dimensions must not vary beyond the 3/16-inch (4.8 mm) tolerance.

1028.11.2 Risers. Where the gradient of aisle stairs is to be the same as the gradient of adjoining seating areas, the riser height shall not be less than 4 inches (102 mm) nor more than 8 inches (203 mm) and shall be uniform within each flight.

Exceptions:

1. Riser height nonuniformity shall be limited to the extent necessitated by changes in the gradient of the adjoining seating area to maintain adequate sightlines. Where nonuniformities exceed 3/16 inch (4.8 mm) between adjacent risers, the exact location of such nonuniformities shall be indicated with a distinctive marking stripe on each tread at the nosing or leading edge adjacent to the nonuniform risers. Such stripe shall be a minimum of 1 inch (25 mm), and a maximum of 2 inches (51 mm), wide. The edge marking stripe shall be distinctively different from the contrasting marking stripe.

2. Riser heights not exceeding 9 inches (229 mm) shall be permitted where they are necessitated by the slope of the adjacent seating areas to maintain sightlines.

In stepped aisles where the gradient of the aisle is the same as the gradient of the adjoining seating area, riser heights are not to be less than 4 inches (102 mm) nor more than 8 inches (203 mm) (see Figure 1028.11.2). For the safety of the occupants, risers should have uniform heights, where possible, throughout each flight of steps. However, nonuniformity of riser heights is permitted in cases where changes to the gradient in the adjoining seating area are required because of sightlines and other seating layout considerations.

Where variations in height exceed 3/16 inch (4.8 mm) between adjacent risers, a distinctive marking stripe between 1 and 2 inches (25 and 51 mm) wide is to be located on the nosings of each tread as a visual warning to the occupants to be cautious. Frequently, this is done with "runway" lights. Note that this stripe must be different from the tread contrast marking stripes required in Section 1028.11.3. These stripes must be visible in lighted conditions; therefore, they are not required to comply with the provisions for luminous tread markings in Section 1024.

In comparing this section with Section 1028.11.1, it is significant to note the emphasis placed on the tread depth. While not desirable, the code permits riser heights to deviate; however, Section 1028.11.1 does not permit tread dimensions to vary beyond the 3/16-inch (4.8 mm) tolerance.

1028.11.3 Tread contrasting marking stripe. A contrasting marking stripe shall be provided on each tread at the nosing or leading edge such that the location of each tread is readily apparent when viewed in descent. Such stripe shall be a mini-
MEANS OF EGRESS

Minimum of 1 inch (25 mm), and a maximum of 2 inches (51 mm), wide.

Exception: The contrasting marking stripe is permitted to be omitted where tread surfaces are such that the location of each tread is readily apparent when viewed in descent.

The exception provides for the omission of the contrasting marking stripe where the tread is readily apparent such as when aisle stair treads are provided with a roughened metal nosing strip or where lighted nosings occur. In this situation, the user is aware of the treads without the marking stripe. This stripe must be different from the marking stripe required for non-uniform risers in Section 1028.11.2, Exception 1.

These stripes must be visible in lighted conditions; therefore, these stripes are not required to comply with the provisions for luminous tread markings in Section 1024.

1028.12 Seat stability. In a building, room or space used for assembly purposes, the seats shall be securely fastened to the floor.

Exceptions:

1. In a building, room or space used for assembly purposes or portions thereof without ramped or tiered floors for seating and with 200 or fewer seats, the seats shall not be required to be fastened to the floor.

2. In a building, room or space used for assembly purposes or portions thereof without ramped or tiered floors for seating, the seats shall not be required to be fastened to the floor.

3. In a building, room or space used for assembly purposes or portions thereof without ramped or tiered floors for seating and with greater than 200 seats, the seats shall be fastened together in groups of not less than three or the seats shall be securely fastened to the floor.

4. In a building, room or space used for assembly purposes where flexibility of the seating arrangement is an integral part of the design and function of the space and seating is on tiered levels, a maximum of 200 seats shall not be required to be fastened to the floor. Plans showing seating, tiers and aisles shall be submitted for approval.

5. Groups of seats within a building, room or space used for assembly purposes separated from other seating by railings, guards, partial height walls or similar barriers with level floors and having no more than 14 seats per group shall not be required to be fastened to the floor.

6. Seats intended for musicians or other performers and separated by railings, guards, partial height walls or similar barriers shall not be required to be fastened to the floor.

The purpose of this section is to require that assembly seating be fastened to the floor where it would be a significant hazard if loose and subject to tipping over. The exceptions allow loose assembly seating for situations where the hazard is lower, such as where ramped or tiered seating is not used, where no more than 200 seats are used and for box seating arrangements where a limited number of seats are within railings, guards or partial height walls.

1028.13 Handrails. Ramped aisles having a slope exceeding one unit vertical in 15 units horizontal (6.7-percent slope) and aisle stairs shall be provided with handrails in compliance with Section 1012 located either at one or both sides of the aisle or within the aisle width.

Exceptions:

1. Handrails are not required for ramped aisles having a gradient no greater than one unit vertical in eight
units horizontal (12.5-percent slope) and seating on both sides.

2. Handrails are not required if, at the side of the aisle, there is a guard that complies with the graspability requirements of handrails.

3. Handrail extensions are not required at the top and bottom of aisle stair and aisle ramp runs to permit crossovers within the aisles.

For the safety of occupants, handrails must be provided in aisles where ramps exceed a gradient of one unit vertical in 15 units horizontal (6.67-percent slope) (see Figure 1028.13). Handrails can be on one side, both sides or in the center of the aisle. Typically, handrails are in the center of the aisle when there is seating on both sides or on one side when the aisle is adjacent to the side walls of the room or a guard. Sections 1009.12 and 1010.8 specify that handrails are required on both sides of stairways or ramps. The exceptions to these sections allow for Section 1028.13 to be utilized for handrail location when dealing with steps and ramps within assembly seating areas. This would include handrails being within 30 inches (762 mm) (Section 1012.9) of the stairway width. Safety for aisles with center handrails wider than 60 inches (1524 mm) and side aisles wider than 30 inches (762 mm) is specifically addressed with the capacity increases in Sections 1028.6.1 and 1028.6.2. What the reference to Section 1012 will require are the provisions for handrail height, graspability and fittings. Continuity, extensions, clearance and projections are more specifically addressed in Section 1028.9.1, this section and subsequent sub-sections. Section 102.1 states that when a specific requirement conflicts with a general requirement, the specific requirement is applicable.

Exception 1 omits the handrail requirements where ramped aisles are steeper, but the seats on both sides of the aisle effectively reduce the fall hazard.

Exception 2 allows handrails to be omitted where there is a guard at the side of the aisle with a top rail that complies with the requirements for handrail graspability (see Section 1012.3). Note that the guard must meet the height and opening requirements specified in Section 1013 or 1028.14, as applicable.

While Section 1028.13.1 does allow for discontinuous handrails, and Exception 3 (as well as Section 1012.6, Exception 2) exempts handrail extensions, the handrail must extend the full run of the aisle stair. Stopping the handrail short of the bottom riser flight would be considered a code violation.

1028.13.1 Discontinuous handrails. Where there is seating on both sides of the aisle, the handrails shall be discontinuous with gaps or breaks at intervals not exceeding five rows to facilitate access to seating and to permit crossing from one side of the aisle to the other. These gaps or breaks shall have a clear width of at least 22 inches (559 mm) and not greater than 36 inches (914 mm), measured horizontally, and the handrail shall have rounded terminations or bends.

Where aisles have seating on both sides, handrails may be located at the sides of the aisles, but are typically located in the center of the aisle. The width of each section of the subdivided aisle between the handrail and the edge of seating is not to be less than 23 inches (584 mm) measured to the handrail centerline (see Section 1028.9.1, Item 3). For reasons of life safety in fire situations and also as a practical matter in the efficient use of the facility, a handrail down the middle of an aisle should not be continuous along its entire length. Crossovers must be provided by means of gaps or breaks in the handrail installation. Such openings must not be less than 22 inches (559 mm) nor more than 36 inches (914 mm) wide, and must be provided at intervals not exceeding the distance of five rows of seats (see Figure 1028.13.1). All handrail terminations should be designed to have rounded ends or bends to avoid possible injury to the occupants (see Figure 1028.13).

Figure 1028.13.1
DISCONTINUOUS AISLE HANDRAILS

1028.13.2 Intermediate handrails. Where handrails are provided in the middle of aisle stairs, there shall be an additional intermediate handrail located approximately 12 inches (305 mm) below the main handrail.

Handrail installations down the middle of an aisle must be constructed with intermediate rails located 12 inches (305 mm) below and parallel to main handrails. This provides handholds for children and prevents them from ducking under the rail or using the rail like a gym apparatus (see Figure 1028.13).

1028.14 Assembly guards. Guards adjacent to seating in a building, room or space used for assembly purposes shall comply with Sections 1028.14.1 through 1028.14.3.

This section establishes the scope of the guard provisions within assembly seating. Depending on the event, the sightline constraints can be for a wide viewing angle. For example, to see the entire football field, a person may have to look right and left. Good design will establish a balance between safety and sight issues that will need to be evaluated on a case-by-case basis.

The purpose of Section 1028.4.1 is to provide for occupant safety with guards along elevated cross aisles, typically in aisles that occupants use to move side to side across the seating bowl. If there is only an aisle accessway between the seats and the guard, then Section 1028.14.2 is applicable. If the aisle is moving down through the seating towards a dropout, then Section 1028.14.3 is applicable.

1028.14.1 Cross aisles. Cross aisles located more than 30 inches (762 mm) above the floor or grade below shall have guards in accordance with Section 1013.

Where an elevation change of 30 inches (762 mm) or less occurs between a cross aisle and the adjacent floor or grade below, guards not less than 26 inches (660 mm) above the aisle floor shall be provided.

Exception: Where the backs of seats on the front of the cross aisle project 24 inches (610 mm) or more above the adjacent floor of the aisle, a guard need not be provided.

The purpose of this section is to provide for occupant safety with guards along elevated cross aisles. The minimum height of the guard is a function of the cross-aisle elevation above the adjacent floor or grade below (i.e., 42 inches (1067 mm) high with more than a 30-inch (762 mm) drop-off and 26 inches (660 mm) high with a 30-inch (762 mm) or less drop-off). When the seatbacks adjacent to cross aisles are a minimum of 24 inches (610 mm) above the floor level of the cross aisle, they will serve as the guard (see Figure 1028.14.2 for an illustration of the requirements in this section).

1028.14.2 Sightline-constrained guard heights. Unless subject to the requirements of Section 1028.14.3, a fascia or railing system in accordance with the guard requirements of Section 1013 and having a minimum height of 26 inches (660 mm) shall be provided where the floor or footboard elevation is more than 30 inches (762 mm) above the floor or grade below and the fascia or railing would otherwise interfere with the sightlines of immediately adjacent seating. At bleachers, a guard must be provided where required by ICC 300.

Exception: The height of the guard in front of seating shall be measured from the adjacent walking surface.

The purpose of this section is to provide for occupant safety with guards along elevated seating for areas other than cross aisles, like at the front of a raised area or balcony level. The seats would only have an access aisle between the seat and the dropout.

This section specifies a height of 26 inches (660 mm) for guards along facias. This is to provide a reasonable degree of safety while improving sightlines for persons seated immediately behind a fascia or balcony edge. The guard opening configuration must comply with Section 1013.3 (see Figure 1028.14.2 for an illustration of the requirements in this section).

The exception was added to clarify that the height for the guard is measured from the floor, not from the top of the seat board as required in ICC 300 (Section 10-192).
408.1, Item 1, of ICC 300). Since bleachers do not typically have backs or arms, people often walk down the seating rows when exiting rather than moving to the aisle steps, thus requiring an additional level of safety at dropoffs.

1028.14.3 Guards at the end of aisles. A fascia or railing system complying with the guard requirements of Section 1013 shall be provided for the full width of the aisle where the foot of the aisle is more than 30 inches (762 mm) above the floor or grade below. The fascia or railing shall be a minimum of 36 inches (914 mm) high and shall provide a minimum 42 inches (1067 mm) measured diagonally between the top of the rail and the nosing of the nearest tread.

This section applies only where the foot end of aisles (the lower end) is greater than 30 inches (762 mm) above the adjacent floor or grade below. This typically occurs where aisles move down through rows of seating to the front edge of a balcony or raised seating area. The guard must satisfy both of the specified height requirements to provide safety for persons at the end of the aisle in case someone trips moving down the ramp or aisle steps. The 36-inch (914 mm) minimum height is measured from the floor vertically to the top of the guard. The minimum 42-inch (1067 mm) diagonal dimension from the nosing of the nearest stair tread to the top of the fascia or guard provides sufficient height to arrest a fall from the nearest aisle riser (see Figure 1028.14.2 for an illustration of the requirements in this section). The end result could be a guard with a vertical height of more than 36 inches (914 mm).

SECTION 1029
EMERGENCY ESCAPE AND RESCUE

1029.1 General. In addition to the means of egress required by this chapter, provisions shall be made for emergency escape and rescue openings in Group R-2 occupancies in accordance with Tables 1021.2(1) and 1021.2(2) and Group R-3 occupancies. Basements and sleeping rooms below the fourth story above grade plane shall have at least one exterior emergency escape and rescue opening in accordance with this section. Where basements contain one or more sleeping rooms, emergency escape and rescue openings shall be required in each sleeping room, but shall not be required in adjoining areas of the basement. Such openings shall open directly into a public way or to a yard or court that opens to a public way.

Exceptions:

1. Basements with a ceiling height of less than 80 inches (2032 mm) shall not be required to have emergency escape and rescue openings.

2. Emergency escape and rescue openings are not required from basements or sleeping rooms that have an exit door or exit access door that opens directly into a public way or to a yard, court or exterior exit balcony that opens to a public way.

3. Basements without habitable spaces and having no more than 200 square feet (18.6 m²) in floor area shall not be required to have emergency escape and rescue openings.

This section requires emergency escape and rescue provisions in residential buildings where occupants
may be sleeping during a potential fire buildup, but are capable of self-preservation (Groups R-2, R-3 and R-4). Group R-2 apartment buildings permitted to have a single exit are also required to have emergency escape openings by Table 1021.2(1), Note a. Group R-2 congregate residences permitted to have a single exit are also required to have an emergency escape and rescue opening by Table 1021.2(2), Note a. All Group R-4 congregate residences would also be required to have emergency and escape rescue openings because Group R-4 follows Group R-3 provisions unless specifically mentioned otherwise (Section 310.6).

All basements and each bedroom/sleeping room are to be provided with an exterior window or door that meets the minimum size requirements and is operable for emergency escape by methods that are obvious and clearly understood by all users. Sleeping rooms four stories or more above grade are not required to be so equipped, since fire service access at that height, as well as escape through such an opening, may not be practical or reliable. Since single-exit apartment buildings are limited to three stories and most Group R-3 and R-4 buildings are two or three stories, this limit is not applicable very often. The provision for basements is in recognition that they typically have only a single means of egress without alternative routes.

It is important to note that this window is only an element of escape and does not comprise any part of the means of egress unless it is a door conforming with normal egress requirements.

Exceptions 1 and 3 are intended to exempt basements that would not be likely to be finished as living space, and thus have sleeping rooms in them.

The intent of Exception 2 is to permit sleeping rooms with a direct access to an exterior-type environment, such as a street or exit balcony, to not have an emergency escape window. The open atmosphere of the escape route would increase the likelihood that the means of egress be available even with the delayed response time for sleeping residents. This would also exempt walk-out basements.

1029.2 Minimum size. Emergency escape and rescue openings shall have a minimum net clear opening of 5.7 square feet (0.53 m²).

Exception: The minimum net clear opening for grade-floor emergency escape and rescue openings shall be 5 square feet (0.46 m²).

- The dimensional criteria of the openings are intended to permit fire service personnel (in full protective clothing with a breathing apparatus) to enter from a ladder, as well as permit occupants to escape. The net clear opening area and minimum dimensions are intended to provide a clear opening through which an occupant can pass to escape the building or a fire fighter can pass to enter the building for rescue or fire suppression activities. Since the emergency escape windows must be usable to all occupants, including children and guests, the required opening dimensions must be achieved by the normal operation of the window from the inside (e.g., sliding, swinging or lifting the sash). It is impractical to assume that all occupants can operate a window that requires a special sequence of operations to achieve the required opening size. While most occupants are familiar with the normal operation by which to open the window, children and guests are frequently unfamiliar with any special procedures that may be necessary to remove or tilt the sashes. The time spent in comprehending the special operation unnecessarily delays egress from the bedroom and could lead to panic and further confusion. Thus, windows that achieve the required opening dimensions only through operations such as the removal of sashes or Mullions are not permitted. It should be noted that the minimum area cannot be achieved by using both the minimum height and minimum width specified in Section 1029.2.1 (see Figure 1029.2).

For SI: 1 inch = 25.4 mm, 1 square foot = 0.0929 m².

Figure 1029.2

EMERGENCY ESCAPE WINDOW

1029.2.1 Minimum dimensions. The minimum net clear opening height dimension shall be 24 inches (610 mm). The minimum net clear opening width dimension shall be 20 inches (508 mm). The net clear opening dimensions shall be the result of normal operation of the opening.

- Note that the minimum dimensions in this section and the minimum area requirements in Section 1029.2
both apply. Thus, a grade-floor window that is only 24 inches (610 mm) in height must be 30 inches (762 mm) wide to meet the 5-square-foot (0.46 m²) area requirement of Section 1029.2 for grade-floor window (see Figure 1029.2).

1029.3 Maximum height from floor. Emergency escape and rescue openings shall have the bottom of the clear opening not greater than 44 inches (1118 mm) measured from the floor.

- This section limits the height of the bottom of the clear opening to 44 inches (1118 mm) or less such that it can be used effectively as an emergency escape (see Figure 1029.2). For a minimum sill height that may affect the emergency escape window, see Section 1013.8.

1029.4 Operational constraints. Emergency escape and rescue openings shall be operational from the inside of the room without the use of keys or tools. Bars, grilles, grates or similar devices are permitted to be placed over emergency escape and rescue openings provided the minimum net clear opening size complies with Section 1029.2 and such devices shall be releasable or removable from the inside without the use of a key, tool or force greater than that which is required for normal operation of the escape and rescue opening. Where such bars, grilles, grates or similar devices are installed in existing buildings, smoke alarms shall be installed in accordance with Section 907.2.11 regardless of the valuation of the alteration.

- If security grilles, decorations or similar devices are installed on escape windows, such items must be readily removable to permit occupant escape without the use of any tools, keys or a force greater than that required for the normal operation of the window. This would include any window fall prevention devices and window opening control devices required by Section 1013.8.

Where bars, grilles, grates or other devices that prevent full operation of the window are placed over the emergency escape and rescue opening, it is important that they are easily removable. Thus, the requirements for ease of operation are the same as required for windows.

Where smoke alarms are not already provided and when items that could possibly slow the opening of emergency escape and rescue windows are installed in existing buildings, smoke alarms must also be installed. Smoke alarms are necessary to provide advance warning of a fire for safety purposes.

1029.5 Window wells. An emergency escape and rescue opening with a finished sill height below the adjacent ground level shall be provided with a window well in accordance with Sections 1029.5.1 and 1029.5.2.

- Emergency escape and rescue openings that are partially or completely below grade need to have window wells so that they can be used effectively (see Figure 1029.5).

1029.5.1 Minimum size. The minimum horizontal area of the window well shall be 9 square feet (0.84 m²), with a minimum dimension of 36 inches (914 mm). The area of the window well shall allow the emergency escape and rescue opening to be fully opened.

- This section specifies the size of the window well that is needed for a rescue person in full protective clothing and breathing apparatus to use the rescue opening. The required 9 square feet (0.84 m²) is the size of the window well. Thus, the window well must project away from the plane of the window at least 3 feet (914 mm), and the required dimension in the plane of the window along the wall is also 3 feet (914 mm) (see Figure 1029.5).

1029.5.2 Ladders or steps. Window wells with a vertical depth of more than 44 inches (1118 mm) shall be equipped with an approved permanently affixed ladder or steps. Ladders or rungs shall have an inside width of at least 12 inches (305 mm), shall project at least 3 inches (76 mm) from the wall and shall be spaced not more than 18 inches (457 mm) on center (o.c.) vertically for the full height of the window wall. The ladder or steps shall not encroach into the required dimensions of the window well by more than 6 inches (152 mm). The ladder or steps shall not be obstructed by the emergency escape and rescue opening. Ladders or steps required by this section are exempt from the stairway requirements of Section 1009.

- This section specifies that a ladder or steps be provided for ease of getting into and out of window wells that are more than 44 inches (1118 mm) deep.

Usually ladder rungs are embedded in the wall of the window well. The 44-inch (1118 mm) dimension is the depth of the window wall, not the distance from the bottom of the window well to grade. Thus, if the floor of a window well is 40 inches (1016 mm) below grade, but the wall of the window well projects above grade by 6 inches (152 mm), steps or a ladder are required since the vertical depth is 46 inches (1168 mm).

It is important that the ladder not obstruct the operation of the emergency escape window (see Figure 1029.5).

Chapter 11: Accessibility

General Comments

Chapter 11 contains provisions that set forth requirements for accessibility of buildings and their associated sites and facilities for people with physical disabilities. Existing building criteria is addressed in Section 3411. Appendix E is included in the code to address accessibility for items in the new Americans with Disabilities Act Accessibility Guidelines (ADAAG) that were not typically enforceable through the standard traditional building code enforcement approach system (e.g., beds, room signage).

In July 2004, the United States Architectural and Transportation Barriers Compliance Board (Access Board) published new design guidelines under the name Americans with Disabilities Act and Architectural Barriers Act Accessibility Guidelines, otherwise known as the "ADA/ABA Guidelines." On September 15, 2010 the U.S. Department of Justice (DOJ) published/adopted the 2004 ADA/ABA Guidelines, officially renaming them the 2010 Standards for Accessible Design. For purposes of the following discussion, the 2010 document will be referred to as the "2010 Standard." In this commentary while the original guidelines of 1991 are referred to as just "ADAAG." For additional technical assistance and information on the 2010 Standard, visit the Access Board website at www.access-board.gov.

The International Residential Code® (IRC®) references Chapter 11 for accessibility provisions; therefore, this chapter may be applicable to housing covered under the IRC (see commentary, Sections 1107.6 and 1107.6.3). Structures referenced to Chapter 11 from the IRC would be considered Group R-3.

Section 1101 contains the broad scope statement of the chapter and identifies the baseline criteria for accessibility as being in compliance with this chapter and 2009 ICC A117.1. ICC A117.1 Accessible and Useable Buildings and Facilities is the consensus national standard that sets forth the technical details, dimensions and construction specifications for accessibility.

Section 1102 contains a list of terms that are associated with accessibility. For the complete definitions and their commentary, see Chapter 2 of this code.

Section 1103 describes the applicability of the provisions of this chapter. Accessibility is broadly required in all buildings, structures, sites and facilities. Those specific circumstances in which accessibility is not required (or is limited) are set forth as exceptions.

Section 1104 contains the requirements for interior and exterior accessible routes. An accessible route is a key component of the built environment that provides a person with a disability access to spaces, elements, facilities and buildings. Note that ramps are addressed in Section 1010.

Section 1105 contains requirements for accessible entrances to buildings and structures. Note that requirements for accessible means of egress are addressed in Section 1007.

Section 1106 sets forth the requirements for accessible parking facilities and passenger loading zones.

Section 1107 contains various accessibility requirements that are unique to occupancies that contain dwelling units and sleeping units and are applicable in addition to other general requirements of this chapter. Specific provisions unique to Group I and R occupancies are included. The Type B dwelling- and sleeping-unit requirements in this section are coordinated with the requirements found in the Fair Housing Accessibility Guidelines (FHAG). Requirements for institutional and transient lodging are also consistent with the 2010 Standard. When federal funding is provided for the project, there may be a higher level of accessibility required.

Section 1108 contains various accessibility requirements that are unique to specific occupancies, other than Groups I and R, and are applicable in addition to all other general requirements of Chapter 11. Specific provisions unique to assembly seating, performance areas, self-storage and judicial facilities are included.

Section 1109 contains various requirements that are applicable to features and facilities that are not occupancy related, including requirements for toilet and bathing facilities; sinks; kitchens; drinking fountains; sauna/steam rooms; elevators; lifts; storage facilities; detectable warnings; seating at tables, counters and work surfaces; service facilities; controls and operating mechanisms; fuel dispensing systems; and recreational facilities.

Section 1110 sets forth requirements for signage identifying certain required accessible elements.

History—Building Codes and Federal Laws

Access to buildings and structures for people with physical disabilities has been a subject that building codes have regulated since the early 1970s. They have consistently relied on a consensus national standard, CABO/ANSI A117.1, as the technical basis for accessibility. The title of CABO/ANSI A117.1 is now ICC/ANSI A117.1 to reflect that the International Code Council® (ICC®) is the secretariat for this standard. Accessibility is not a new subject to the construction regulatory community. There has been a great deal of emphasis and awareness placed on the subject of accessibility through the passage of two federal laws. The Americans with Disabilities Act (ADA) and the Fair Housing Amendment Act (FHA) are federal regulations that
accessibility as it relates to accessibility. ADA, signed into law in July 1990, is a very broad civil
crights law designed to protect persons with disabilities. There are five sections of the ADA that address different
aspects of civil rights for people with disabilities. Title I deals with employment and generally prohibits discrimi
nation against disabled people in employment. Title II deals with public services, including access to all services and
facilities receiving federal funding, and access to public transportation, including buses, rail lines and
passenger transit facilities. Title III requires access to a large category of buildings and structures in a manner
that is equal or comparable to that available to the general public. Note that FHA is a companion document to
ADA. FHA deals with residential and institutional living arrangements that, for the most part, are not covered
under ADA. Title IV deals with accessible telecommunication facilities and Title V further defines miscellaneous
issues dealing with ADA compliance.

Titles II and III of the ADA overlap numerous require
ments customarily regulated by building codes. When
ADA was originally written, Title II had the option to follow either the FED-STD-795-88, Uniform
Federal Accessibility Standards (UFAS) or ADAAG for compliance with accessibility requirements. Title II facilities
include those receiving federal funding for the build
ing or for programs offered in the building, i.e., colleges,
schools, park districts, local and state governments,
hospitals, etc. Implementation of Title III of the ADA was
based on the requirements of ADAAG. Both UFAS and
ADAAG set forth scoping and technical requirements for
building design and construction. The federal govern
ment is interested in bringing more uniformity to federal
accessibility standards and is continuously looking at
ways in which harmonization of all federal and private
sector standards can be accomplished. In many ways,
UFAS and ADAAG are similar to a building code and in
case cover many of the same matters that are dealt with
in such codes. With this in mind, the Access Board
developed new and additional requirements within the
past decade. The new requirements are organized in a
building code format. The ICC and Access Board both
worked toward coordination between the federal and
building code requirements. The 2010 Standard will
replace UFAS (1984) and ADAAG (1991) as the stan
dard referenced for compliance with ADA and another
federal law, the Architectural Barriers Act (ABA, 1968).
From September 15, 2010 to March 15, 2012, com
pliance with either the 1991 ADAAG or the 2010 Standard
will be an option. Beginning March 15, 2012, com
pliance with the 2010 Standard will be required for all new
construction and as well as for alterations to existing
facilities.

It is important to emphasize, however, that the ADA
(a law) is written as civil rights legislation and not as a
building code. The enforcement mechanism for civil
rights laws is significantly different than that for tra
ditional building regulation. The ADA does not preempt
the adoption or enforcement of accessibility-related
codes by state and local governments. All buildings con
structed within a jurisdiction must comply with locally
adopted building codes and any applicable state codes,
as well as the 2010 Standard; however, as a federal
law, state and local governments have neither the
authority nor the responsibility to enforce ADA. Enforce
ment of ADA is the responsibility of the U.S. DOJ. As
previously described, ADA covers a large range of
issues dealing with disabilities. Under Titles II and III,
the scoping and technical requirements of the 2010
Standard deal directly with accessibility of buildings.
Typically, enforcement of these regulations takes place
after the construction process. Any differences between
the regulations and proposed design must be ultimately
reconciled by the building owner or designer. Building
code compliance is typically evaluated during the plan
review and construction process. This is a less costly
time to make required changes to a facility that are nec
essary for compliance. Again, the building official is
expected to enforce the code adopted by the state or
local jurisdiction, and any applicable state laws. The
building official is not responsible for interpretation or
enforcement of ADA unless the state or local jurisdiction
has referenced ADAAG or the 2010 Standard in a
state's accessibility laws. No attempt should be made to
represent that the 2010 Standard is being interpreted or
enforced by the building official or the jurisdiction when
the 2010 Standard has not been specifically adopted by
the jurisdiction.

The concept of two completely separate and independ
ent, broad-based sets of regulations that affect build
ing design and construction may sound onerous, but the
situation may not be quite as bad as it appears. The
reason is that the code has a high level of consistency
with the 2010 Standard. Since the early 1990s, code
change activity has incorporated the recommendations
of the Council of American Building Officials' (CABO)
Board for the Coordination of the Model Codes (BCCM)
succeeded in 1995 by the ICC Board for the Develop
ment of the Model Codes (BDMC). The BDMC under
took the effort to review comprehensively all facets of
the accessibility issue. This effort included a compari
son of ADAAG with the provisions of the model codes in
use at that time. The BDMC's recommendations were
ultimately reflected in codes. This work has continued to
evolve as the industry learns and new technologies
become readily available. There are still differences
between the code and the 2010 Standard, but they are
minimal and will become less in future code editions.

Efforts for coordination with the federal accessibility
requirements are ongoing. Representatives from inter
ested accessibility groups, Department of Housing and
Urban Development (HUD) and the Access Board have
been attending and participating in the code change
process for the code and ICC A117.1. Additionally, the
ICC has participated in the public comment process on
the development of federal regulations. The ICC has
worked toward, and will continue to strive for, accessibil
ity regulations that reflect the highest possible degree of
consistency with federal regulations and, more importantly, reasonable and appropriate provisions to meet the needs of people with disabilities.

The FHA is federal legislation promulgated by HUD that extends fair housing protection against discrimination on the basis of family status or persons with disabilities. The standard for FHA is the FHA, which sets forth accessibility scoping and technical requirements for a broad category of residential construction. The scope of ADAAG generally excludes occupancies that are covered by FHA; however, FHA is being interpreted to overlap the scope of the coverage of ADA in some respects (e.g., dorms, nursing homes). Residential buildings that are covered by FHA must also comply with the locally adopted building code. The same circumstances with respect to differences in the requirements and responsibility for enforcement described for ADA also exist with FHA.

Again, as a federal law, building officials have neither the responsibility nor the authority to enforce the requirements of FHA. Inquiries regarding those laws should be referred to the DOJ or HUD. Until such time that their laws are coordinated with and consider traditional code enforcement mechanisms and methods, building officials are advised not to attempt to interpret or enforce these laws. Permit applicants should be advised that the work they propose has not been reviewed for compliance with FHA.

Due to concerns about residential construction complying with all applicable codes and laws, the National Association of Home Builders (NAHB), along with others, approached the model code groups about incorporating the FHA requirements into the model code requirements. Since the FHA is a civil rights law rather than a building code, careful study was needed to interpret them into enforceable language that could be utilized in model codes. Through the efforts of the BDNC, recommendations to the model codes were proposed in 1994. The "adaptable" dwelling unit requirements were carried forward as a Type A unit, with the FHA requirements reflected in the Type B units.

In 2000, HUD reviewed the 2000 edition of the IBC and the referenced accessibility standard ICC/ANSI A117.1-1998 for compliance with FHA. Based on HUD's report, a series of modifications were proposed as part of the 2000 code change cycle. The proposed modifications were accepted by the voting members and were incorporated into the 2001 Supplement to the IBC and eventually into the 2003, 2006 and 2009 editions of the code. As a result of the earlier code changes, HUD eventually issued press releases stating that the 2000 code with the 2001 Supplement and 2003 code (with the ICC/ANSI A117.1-1998 accessibility standard) and the 2006 IBC (with the ICC/ANSI A117.1-2003 accessibility standard) could be considered "safe harbor" for anyone wanting to comply with FHA scoping and technical requirements. The original safe harbor status that was bestowed on the 2000 IBC and its accessory documents was identified in the preamble of HUD's Fair Housing Act Design Manual.

With the 2003 and the 2006 editions of the code being safe harbor documents, architects and developers could design and be reviewed for compliance with the code through the typical building code review process. At the same time, they would also be in compliance with the building requirements for the FHA. At the time this commentary was written, HUD had not completed its review of the 2009 and 2012 editions of the code for safe-harbor status. Since the code is developed through a code change/public comment process, there have been changes to items in Chapter 11. This is typically a good way for new concepts, concepts or procedures to be incorporated into the requirements. It is the ICC's opinion that none of these changes have jeopardized the safe-harbor status between FHA and the code requirements in this edition.

**Philosophy**

The fundamental philosophy of the code on the subject of accessibility is that everything is required to be accessible. This is reflected in the basic applicability requirement (see Section 1103.1). The code's scoping requirements then address the conditions under which accessibility is not required in terms of exceptions to this general mandate. In the early 1990s, building codes tended to describe where accessibility was required in each occupancy, and any circumstance not specifically identified was excluded. The more recent codes represent a fundamental change in approach. Now one must think of accessibility in terms of "if it is not specifically exempted, it must be accessible."

Another important concept is that of "mainstreaming." There are many accessibility issues that not only benefit people with disabilities, but also provide a tangible benefit to people without disabilities. This type of requirement can be set forth in the code as generally applicable without necessarily identifying it specifically as an accessibility-related issue. Such a requirement would then be considered as having been mainstreamed. For example, the limitation on objects protruding into corridors, aisles and passageways (see Section 1003.3) is intended to aid people with a vision impairment by reducing the potential for unintended contact that may cause injury. Clearly, this has an additional benefit to people without a vision impairment. A protruding object can be encountered by a sighted person who is simply not paying close attention. The concept of mainstreaming is responsive to the desire of people with disabilities to not be singled out and categorized separately from the remainder of society. It is therefore important to recognize that, while the provisions of Chapter 11 are specifically grouped and identified as accessibility related, they do not represent all of the issues that must be taken into consideration when evaluating accessibility in buildings.

There are many items that have some basis in accessibility requirements, but actually result in more "user-friendly" buildings for all of us. Physical disabilities can be permanent or temporary; can affect all age groups; can involve all levels of abilities and can range from per-
sons with minor visual, hearing or mobility impairments to persons who are blind, deaf or confined to a wheelchair. Everyone will benefit from accessible features in buildings, either directly or indirectly through those they care for. With some foresight in designing our built environment, access into and throughout buildings can be better for everyone throughout their lifetimes.

Purpose
The purpose of this chapter is to set forth requirements for accessibility applicable to those elements of the built environment that are included within the scope of the code. There are two categories or types of requirements that must be addressed in order to accomplish accessibility: scoping and technical. Scoping requirements describe what and where accessibility is required, or how many accessible features or elements must be provided. For example, a requirement that at least one of the first 25 sleeping units in a hotel must be accessible is referred to as a scoping requirement because it describes what and how many accessible features are required. Another example of scoping is the exception for detached one- and two-family dwellings from accessibility requirements because it defines what is not required to be accessible. A technical requirement is intended to refer to a statement indicating how accessibility is to be accomplished. For example, a requirement indicating that in order for a parking space to be accessible, it must have a width of 96 inches (2438 mm) with an adjacent 60-inch (1524 mm) access aisle is considered a technical requirement. The provisions of Chapter 11 are scoping requirements in that they all address what and where accessibility is required or how many accessible elements are required. ICC A117.1 indicates how to make something accessible and is the consensus national standard that is referenced for establishing technical requirements. In addition to the provisions of Chapter 11, there are accessibility-related technical requirements elsewhere in the code. These are subject-matter-specific provisions that have been mainstreamed into the chapter or section of the code that deals with those subjects. As such, the code and its references regulate accessibility comprehensively by setting forth the scoping and technical requirements that establish the minimum level of accessibility required in the built environment.

SECTION 1101
GENERAL

1101.1 Scope. The provisions of this chapter shall control the design and construction of facilities for accessibility to physically disabled persons.

This section establishes the scope of the chapter as providing for design and construction of facilities for accessibility to disabled persons. The scope is broadly inclusive of all aspects of construction that affect the ability of people with disabilities to approach, enter and utilize a facility. The term “facility,” as defined in Chapter 2, includes not only buildings and structures, but also the site on which they are located. Features of a site, such as parking areas and paths of travel from a public way to a structure, affect accessibility and are, therefore, within the scope of Chapter 11. Chapter 11, in conjunction with mainstreamed provisions throughout the code, sets forth scoping requirements.

1101.2 Design. Buildings and facilities shall be designed and constructed to be accessible in accordance with this code and ICC A117.1.

This section establishes the primary and fundamental relationship of ICC A117.1 to the code. The code text is intended to “scope” or provide thresholds for application of required accessibility features. The referenced standard contains technical provisions indicating how compliance with the code is achieved. In short, Chapter 11 specifies what, when and how many accessible features are required; the referenced standard indicates how to make that feature accessible. Compliance with both the code and the standard is required.

In accordance with Section 102.4, standards are utilized only to the extent that they are referenced. Note that ICC A117.1 includes technical criteria for several items that are not actually scoped in the code. Such items are not required to comply with ICC A117.1 criteria unless specifically scoped by the authority having jurisdiction. Some examples of items in ICC A117.1 that are not referenced by the code are:

- Section 403.6 – Corridor handrails
- Section 504 – Stairways
- Section 704 – Telephones (scoped in IBC Appendix E)
- Section 707 – Automatic Teller Machines (scoped in IBC Appendix E)

SECTION 1102
DEFINITIONS

1102.1 Definitions. The following terms are defined in Chapter 2:

This section lists terms that are specifically associated with the subject matter of this chapter. It is important to emphasize that these terms are not exclusively related to this chapter but may or may not also be applicable where the term is used elsewhere in the code. For example, the defined term “Accessible” is applicable to where a space or element is required...
to be designed to address the needs of persons with mobility, hearing or vision impairments; however, when other chapters provide criteria for equipment or construction elements to be accessible for maintenance or inspections (i.e., Section 110.1), the intent is for an inspector or maintenance person to have physical and visual access to that element—not wheelchair access.

Definitions of terms can help in the understanding and application of the code requirements. The purpose for including a list within this chapter is to provide more convenient access to terms that may have a specific or limited application within this chapter. For the complete definition and associated commentary, refer back to Chapter 2. Terms that are italicized provide a visual identification throughout the code that a definition exists for that term. The use and application of all defined terms are set forth in Section 201.

ACCESSIBLE.
ACCESSIBLE ROUTE.
ACCESSIBLE UNIT.
CIRCULATION PATH.
COMMON USE.
DETECTABLE WARNING.
EMPLOYEE WORK AREA.
FACILITY.
INTENDED TO BE OCCUPIED AS A RESIDENCE.
MULTILEVEL ASSEMBLY SEATING.
MULTISTORY UNIT.
PUBLIC ENTRANCE.
PUBLIC-USE AREAS
RESTRICTED ENTRANCE.
SELF-SERVICE STORAGE FACILITY.
SERVICE ENTRANCE.
SITE.
TYPE A UNIT.
TYPE B UNIT.
WHEELCHAIR SPACE.

SECTION 1103
SCOPING REQUIREMENTS

1103.1 Where required. Sites, buildings, structures, facilities, elements and spaces, temporary or permanent, shall be accessible to persons with physical disabilities.

This section establishes the broad principle that all buildings, structures and their associated sites and facilities are required to be accessible to persons with physical disabilities. This would include anyone who utilizes a space, including occupants, employees, students, spectators, participants and visitors. The approach taken by the code on the subject of accessibility is to require all construction to be accessible and then provide for the acceptable level of inaccessibility that is reasonable and logical. In codes created before the early 1990s, the approach was to list the conditions and occupancies to which the accessibility requirements applied; however, this is no longer practical, since the exceptions are far fewer than the circumstances to which accessibility applies. The 15 exceptions to this section, Sections 1103.2.1 to 1103.2.15, reflect the extent to which accessibility in construction is either exempt or reduced in scope.

1103.2 General exceptions. Sites, buildings, structures, facilities, elements and spaces shall be exempt from this chapter to the extent specified in this section.

- Accessibility is generally applicable to all building sites and all spaces and elements within the constructed facilities except as specifically exempted in the subsections of Section 1103.2.

1103.2.1 Specific requirements. Accessibility is not required in buildings and facilities, or portions thereof, to the extent permitted by Sections 1104 through 1110.

- This section provides a correlative reference to the various sections in Chapter 11 that identify when the intended number of accessible elements in various occupancies is less than 100 percent. The number of accessible fixtures and elements required by the referenced sections are deemed to provide adequate accessibility for those circumstances. For example, Section 1106 does not require all parking spaces in a parking facility to be accessible, Section 1107.6.1 does not require all sleeping units in Group R-1 to be fully accessible and Section 1109.9 does not require all storage to be accessible.

1103.2.2 Existing buildings. Existing buildings shall comply with Section 3411.

- The second section is a reference to the existing building criteria in Section 3411 for accessibility concerns in existing buildings. In accordance with Section 3401.5, the International Existing Building Code® (IEBC®) could also be used (see commentary, Section 3411).

1103.2.3 Employee work areas. Spaces and elements within employee work areas shall only be required to comply with Sections 907.9.1.2, 1007 and 1104.3.1 and shall be designed and constructed so that individuals with disabilities can approach, enter and exit the work area. Work areas, or portions of work areas, that are less than 300 square feet (30 m²) in area and located 7 inches (178 mm) or more above or below the ground or finish floor where the change in elevation is essential to the function of the space shall be exempt from all requirements.

- This section states that elements within individual work areas are not required to be accessible, with the exception of visible alarms (see Section 907.5.2.3), accessible means of egress (see Section 1007) and circulation paths (see Section 1104.3.1).
assumption is that the employment nondiscrimination requirements of the ADA will provide for "reasonable accommodations" to the disability of the employee and the area in which they work. In other words, employers will modify individual work areas for the specific requirements of the individual utilizing the space. An accessible route will be required to each work area. An example of this is an individual work station in a laboratory. Installing sinks and built-in counters at accessible levels (see commentary, Sections 1109.3 and 1109.11) could make the station impractical for use by a person who is standing. Ergonomic researchers used to recommend a standing counter at a minimum of 36 inches (914 mm), but are now advising even higher counters to reduce fatigue. When a station is required to be adapted for an individual, it would be revised based on the individual's needs and abilities. An accessible route to each work station in the laboratory would be required so that access to and from that station would be available. Note that the 36-inch (914 mm) clear width for the accessible route is the same as the minimum required width of an exit access aisle. For exceptions to the route to work areas, see Section 1104.3.1.

There is an additional exception for work areas that need to be raised or lowered 7 inches (178 mm) or more above the floor and have an area of less than 300 square feet (14 m²). Examples of raised work areas would include an area around a metal stamping machine, a safety manager's observation station on a production line or the pulpit area in a church. Raised courtroom areas are specifically addressed in Section 1108.4.1. An example of a lowered work area might be a pit under a car in a car-repair station.

An employee's work area can be something as simple as an office or cubicle, or it can extend over a much wider area. For example, an office space might include copy rooms, file rooms, mail rooms, etc., or a nurse or doctor in a clinic would have part of their work area in each exam room as well as at a central station area. In addition, not all employee-only spaces are considered work areas. Areas used by employees not for work (i.e., break rooms, bathrooms, corridors) would not fall under this exception (see the definition for "Employee work area").

1103.2.4 Detached dwellings. Detached one- and two-family dwellings and accessory structures, and their associated sites and facilities, are not required to be accessible.

- This section exempts detached one- and two-family dwellings from accessibility requirements. The key word here is "detached." For example, a structure containing four or more dwelling units, even if the dwelling units are separated by fire walls, would still be required to be accessible as indicated in Section 1107.

Although one- and two-family detached dwellings are typically regulated by the IRC, this exception in the code is still necessary. Single-family dwellings or duplexes that are four stories or higher would be designed and constructed under Group R-3 requirements of the code. The IRC references Chapter 11 of the code for accessibility requirements in Section R320. Those multiple-family structures with four or more dwelling units that qualify as townhouses or congregate residences with four or more sleeping units under the IRC are required to comply with the requirements for Group R-3 in Section 1107.(616,380),(992,762)

1103.2.5 Utility buildings. Occupancies in Group U are exempt from the requirements of this chapter other than the following:

1. In agricultural buildings, access is required to paved work areas and areas open to the general public.

2. Private garages or carparks that contain required accessible parking.

- This section exempts Group U from accessibility requirements except as indicated, on the basis that such structures are a low priority when considering the need for accessibility. Areas in utility buildings that are required to be accessible would be paved work areas or areas open to the general public, such as if a farmer included a farmstand within his or her barn or buildings in which accessible parking spaces are located.

1103.2.6 Construction sites. Structures, sites and equipment directly associated with the actual processes of construction including, but not limited to, scaffolding, bridging, materials holists, materials storage or construction trailers are not required to be accessible.

- This section exempts structures directly associated with the construction process because the need for accessibility on a continuous or regular basis in those circumstances is unlikely to arise. Portable toilets that are for the construction workers would be exempted. Note that all structures that may be involved during a construction project are not exempt—only those specifically involved in the actual process of construction. For example, if mobile units are brought into house classrooms during a school addition, these classrooms must be accessible. A construction trailer that also serves as a sales office would also be required to be accessible.

1103.2.7 Raised areas. Raised areas used primarily for purposes of security, life safety or fire safety including, but not limited to, observation galleries, prison guard towers, fire towers or lifeguard stands, are not required to be accessible or to be served by an accessible route.

- If there is a reason to elevate an area for concerns about security or safety, these areas are not required to be accessible (see Figure 1103.2.7).

1103.2.8 Limited access spaces. Nonoccupiable spaces accessed only by ladders, catwalks, crawl spaces, freight ele-
vators or very narrow passageways are not required to be accessible.

- Nonoccupiable, limited access spaces are considered areas where work could not reasonably be performed by a person using a wheelchair due to the physical requirements of the job activity. These areas are not required to be accessible.

**1103.2.9 Equipment spaces.** Spaces frequented only by personnel for maintenance, repair or monitoring of equipment are not required to be accessible. Such spaces include, but are not limited to, elevator pits, elevator penthouses, mechanical, electrical or communications equipment rooms, piping or equipment catwalks, water or sewage treatment pump rooms and stations, electric substations and transformer vaults, and highway and tunnel utility facilities.

- Spaces that only contain heating, ventilation and air conditioning (HVAC), electrical, elevator, communication and similar types of equipment are considered areas where work could not reasonably be performed by a person utilizing a wheelchair due to the physical requirements of the job activity. These areas are not required to be accessible.

**1103.2.10 Single-occupant structures.** Single-occupant structures accessed only by passageways below grade or elevated above grade including, but not limited to, toll booths that are accessed only by underground tunnels, are not required to be accessible.

- This section addresses facilities such as toll booths, which are raised to facilitate access to higher vehicles as well as to provide protection from being struck by vehicles. Access to these spaces are often lanes by tunnel or bridge. Some of these types of facilities could also be covered by Section 1103.2.3.

**1103.2.11 Residential Group R-1.** Buildings of Group R-1 containing not more than five sleeping units for rent or hire that are also occupied as the residence of the proprietor are not required to be accessible.

- This section exempts small bed-and-breakfast or transient boarding house facilities that are also the home of the owner.

**1103.2.12 Day care facilities.** Where a day care facility is part of a dwelling unit, only the portion of the structure utilized for the day care facility is required to be accessible.

- When an adult day care or child day care facility is part of a person's home, the accessibility requirements are only applicable to the portion of the home that constitutes the day care facility, not the home itself. For other home-based businesses, see the discussion on live/work units in Sections 419 and 1103.2.13.

**1103.2.13 Live/work units.** In live/work units constructed in accordance with Section 419, the portion of the unit utilized for nonresidential use is required to be accessible. The residential portion of the live/work unit is required to be evaluated separately in accordance with Sections 1107.6.2 and 1107.7.

- Live/work units are dwelling units in which a significant portion of the space includes a nonresidential use operated by the tenant/owner. Although the entire unit is classified as a Group R-2 occupancy for construction purposes, for accessibility purposes it is viewed more as a mixed-use condition. The residential portion of the unit is regulated differently for accessibility purposes than the nonresidential portion.

The floor area of the dwelling unit that is intended for residential use is regulated under the provisions of Section 1107.6.2 for Group R-2 occupancies. The requirements for an Accessible unit, Type A unit or Type B unit would be applied based upon the specific residential use of the unit and the number of units in the structure. The exceptions for Type A and Type B units set forth in Section 1107.7 would also exempt such units where applicable. For example, a two-story dwelling unit above the work unit in a nonelevator building would not be subject to Type B requirements due to the exemption in Section 1107.7.2. The code does not clarify if a two-story live/work unit with the business on the entire first floor and the residence on the entire second floor would be considered a multi-story dwelling unit for purposes of the exception in Section 1107.7.2. Just as a reminder, Type B units are applied per structure, not per building, so legal property lines may not be relevant when evaluating accessibility requirements (see Section 1107).

In the nonresidential portion of the unit, full accessibility would be required based upon the intended use. For example, if the nonresidential area of the unit is utilized for hair care services, all elements related to the service activity must be accessible. This would include site parking where provided, site and building accessible routes, the public entrance, and applicable patron services. In essence, the work portion of the
live/work unit would be regulated in the same manner as a stand-alone commercial occupancy.

1103.2.14 Detention and correctional facilities. In detention and correctional facilities, common use areas that are used only by inmates or detainees and security personnel, and that do not serve holding cells or housing cells required to be accessible, are not required to be accessible or to be served by an accessible route.

- Section 1107.5.5 addresses when sleeping units, special holding or housing cells and medical care units in detention and correctional facilities are required to be accessible. If the purpose of any common or shared space is to serve only the associated cells that are not required to be accessible (e.g., shared bathrooms or living space serving a specific group of cells), then those common or shared spaces are not required to be accessible.

1103.2.15 Walk-in coolers and freezers. Walk-in coolers and freezers intended for employee use only are not required to be accessible.

- Walk-in coolers and freezers usually have features that make accessibility difficult. For thermal efficiency they may have raised floors, special door seals, unconventional door-operating hardware, tight internal storage, wheeled racking systems, etc. For these and other reasons they are not required to have an accessible entry or to be accessible within. Walk-in coolers and freezers may also be considered exempted under Section 1103.2.3. Coolers that are accessed from the front by customers would need to comply with operable parts and display criteria on the public side (see Sections 1109.9.2 and 1109.13).

SECTION 1104
ACCESSIBLE ROUTE

1104.1 Site arrival points. Accessible routes within the site shall be provided from public transportation stops; accessible parking; accessible passenger loading zones; and public streets or sidewalks to the accessible building entrance served.

Exception: Other than in buildings or facilities containing or serving Type B units, an accessible route shall not be required between site arrival points and the building or facility entrance if the only means of access between them is a vehicular way not providing for pedestrian access.

The intent of this section is to require an accessible route from the point at which one enters the site to any buildings or facilities that are required to be accessible on that site. It is presumed that people with disabilities are capable of gaining access to the site from such locations as accessible parking, public transportation stops, loading zones, public streets or sidewalks.

The exception addresses vehicular routes that provide the only route between an arrival point and an accessible entrance. An accessible route for pedestrian access is not required except in buildings or structures having or serving Type B units. For example, if there is a bus stop at the front of an industrial complex, but the only route to the building entrance is via a long driveway, an accessible pedestrian route to that entrance from the bus stop is not required. For special considerations in residential developments, see the commentary to Sections 1107.4, 1107.7.4, 1107.7.5, 1109.15.1 and 1109.15.2.

1104.2 Within a site. At least one accessible route shall connect accessible buildings, accessible facilities, accessible elements and accessible spaces that are on the same site.

Exception: An accessible route is not required between accessible buildings, accessible facilities, accessible elements and accessible spaces that have, as the only means of access between them, a vehicular way not providing for pedestrian access.

- Developments may include several buildings on the same site. The intent of this section is to require an accessible route to all facilities offered on a site. Often sites are designed such that the only way to reach a building or facility is by automobile. If there are multiple, separated parking areas serving one or more buildings on a site, an accessible route is required between all such parking facilities and the buildings they serve. If there is an exterior feature, such as a swimming pool, located on a site containing multiple buildings, an accessible route is required from each building to the swimming pool. The exception clarifies that an accessible route is not required where no pedestrian access is otherwise intended or provided to a particular building or feature on the site. For special considerations in residential developments with recreational facilities, see the commentary to Sections 1107.3 and 1109.15.

1104.3 Connected spaces. When a building or portion of a building is required to be accessible, an accessible route shall be provided to each portion of the building, to accessible building entrances connecting accessible pedestrian walkways and the public way.

Exceptions:

1. In a building, room or space used for assembly purposes with fixed seating, an accessible route shall not be required to serve levels where wheelchair spaces are not provided.

2. In Group I-2 facilities, doors to sleeping units shall be exempted from the requirements for maneuvering clearance at the room side provided the door is a minimum of 44 inches (1118 mm) in width.

- This section requires that there be at least one route from an accessible entrance to all required accessible features within a building. If an area is addressed with a specific exception, then an accessible route is not required. For example, mechanical penthouses are exempt under Section 1103.2.9; therefore, an accessible route would not be required to this area. Once someone gets into a space, they must also be able to evacuate in an emergency situation. This
may or may not be via the same route. For accessible means of egress requirements, see Section 1007.

Exception 1 reemphasizes that levels in assembly seating that do not contain wheelchair seating locations are not required to be accessed by an accessible route; however, the types of services available in the facility must be considered when determining what services must be available to accessible seats. A route is required to services from accessible seats in accordance with Section 1108.2.1.

Exception 2 recognizes the practical implications of door maneuvering clearances on the room side at in-swinging doors in smaller sized patient sleeping rooms in hospitals and nursing homes. The maneuvering clearance is still required on the outside of the Accessible patient sleeping room door. Since the maneuvering clearance in ICC A117.1 is based on the size of the door, there is no credit provided for the wider 44-inch (1118 mm) door width (required in Section 1008.1.1 in Group I-2 for movement of bed) versus the standard 36-inch (914 mm) wide door. Without this exception a patient room would likely require extra width when a toilet room is located on the same wall as the door. Due to operational procedures and observation needs, the door position is normally open, therefore, the need for door maneuvering clearance on the interior side is reduced. At hospitals, nursing homes and rehabilitation centers, the patient room door is usually closed only when privacy is needed during procedures.

The percentage of Accessible units and Type B units in hospitals, nursing homes and rehabilitation centers is addressed in Sections 1107.5.2, 1107.5.3 and 1107.5.4. Maneuvering clearances are part of an accessible route, and accessible routes connect accessible elements; therefore, maneuvering clearances at patient sleeping rooms that are not Accessible or Type B units are not required since an accessible route is not required. For additional information on when Type B units are required in institutional facilities, see the commentary to Section 1107.

1104.3.1 Employee work areas. Common use circulation paths within employee work areas shall be accessible routes.

Exceptions:

1. Common use circulation paths, located within employee work areas that are less than 1,000 square feet (93 m²) in size and defined by permanently installed partitions, counters, casework or furnishings, shall not be required to be accessible routes.

2. Common use circulation paths, located within employee work areas, that are an integral component of equipment, shall not be required to be accessible routes.

3. Common use circulation paths, located within exterior employee work areas that are fully exposed to the weather, shall not be required to be accessible routes.

◆ This requirement for common use circulation paths within employee work areas is consistent with the exception in Section 1103.2.3. An accessible route is required to each employee work area. When employees share work areas, an accessible route must be available throughout that area. Note that the accessible route minimum width of 36 inches (914 mm) clear is consistent with the minimum means of egress pathways.

Exception 1 addresses the accessible route within small employee work areas. Shared work areas that are less than 1,000 square feet (93 m²) and confined by walls, partitions, permanently installed equipment, cabinets and counters are not required to have an accessible route through that particular area. The square footage limitation does not always pertain to a room, but also to part of a room. The intent was to allow such areas as the last two work stations down an aisle, two or three work stations in a small office, the employee side of a beverage bar, portions of commercial kitchens, etc. An accessible route is required to these areas, but not necessarily throughout the area. There can be multiple exceptions within the same area, such as in a commercial kitchen. Again, modifications would be performed at a later date based on employee needs.

Exception 2 permits nonaccessible areas around and through pieces of equipment. An example would be the shared work areas around a piece of assembly equipment in a factory where one or more persons are required to monitor and operate the machine and incoming or outgoing product.

Exception 3 is an exception for outdoor work areas. This would be applicable to landscapers, sewer workers, gravel pit crews, etc.

1104.3.2 Press boxes. Press boxes in a building, room or space used for assembly purposes shall be on an accessible route.

Exceptions:

1. An accessible route shall not be required to press boxes in bleachers that have points of entry at only one level, provided that the aggregate area of all press boxes is 500 square feet (46 m²) maximum.

2. An accessible route shall not be required to freestanding press boxes that are elevated above grade 12 feet (3660 mm) minimum provided that the aggregate area of all press boxes is 500 square feet (46 m²) maximum.

◆ Press boxes are required to be served by an accessible route. If the occupant load is five or less, this could be provided by a platform lift (see Section 1109.8, Item 3).

Exception 1 is mainly applicable to press boxes located at the back of the bleacher seating in an out-
door sports facility. The "point of entry at only one level" refers to access to the press box directly from the bleacher seating (see Figure 1104.3.2).

Exception 2 is mainly applicable to the free-standing press box. If that press box is either less than 12 feet (3677 mm) above the ground or more than 500 square feet (46 m²) in area, it must be served by an accessible route. Historically, the 12-foot (3677 mm) height limit was chosen because that was the maximum rise for a platform lift in previous editions of ASME A18.1.

For both exceptions, if one press box is provided, the total area of the press box must be less than 500 square feet (46 m²). If more than one press box overlooks the same playing field, the aggregate area of both press boxes must be less than 500 square feet (46 m²). The aggregate area is not intended to be applicable to press boxes that happen to be on the same multiple-facility site. For example, if a high school has a football field with two press boxes, the area of those two press boxes must be added together; however, if the same high school also has a press box for the baseball field, the area of the press box in the baseball field would not be included with the area of the press boxes in the football field.

![Figure 1104.3.2](image)

**Figure 1104.3.2**
**EXAMPLE OF PRESS BOX ACCESSED FROM BLEACHER SEATING**

1104.4 Multilevel buildings and facilities. At least one accessible route shall connect each accessible level, including mezzanines, in multilevel buildings and facilities.

**Exceptions:**

1. An accessible route is not required to stories and mezzanines that have an aggregate area of not more than 3,000 square feet (278.7 m²) and are located above and below accessible levels. This exception shall not apply to:

   1.1. Multiple tenant facilities of Group M occupancies containing five or more tenant spaces;

   1.2. Levels containing offices of health care providers (Group B or I); or

   1.3. Passenger transportation facilities and airports (Group A-3 or B).

2. Levels that do not contain accessible elements or other spaces as determined by Section 1107 or 1108 are not required to be served by an accessible route from an accessible level.

3. In air traffic control towers, an accessible route is not required to serve the cab and the floor immediately below the cab.

4. Where a two-story building or facility has one story with an occupant load of five or fewer persons that does not contain public use space, that story shall not be required to be connected by an accessible route to the story above or below.

5. Vertical access to elevated employee work stations within a courtroom is not required at the time of initial construction, provided a ramp, lift or elevator can be installed without requiring reconfiguration or extension of the courtroom or extension of the electrical system.

- At least one accessible route is required between levels in a facility. This requirement does not mandate an elevator. The accessible route between levels can be via ramps, platform lifts (where permitted), limited use/limited access (LULA) elevators, passenger elevators, etc. The intent of the exceptions is to allow limited areas to be inaccessible without restricting access to services available to the general public.

   Exception 1 addresses conditions under which it may not be practical or economical to provide an accessible route in multilevel buildings. The primary economic consideration is that, in the vast majority of circumstances, the means of providing an accessible route to floor levels above or below the entrance level of the building will be by an elevator. This exception applies to levels above and below the entrance level that have an aggregate area of 3,000 square feet (279 m²) or less and does not include the area of the accessible level. For example, if a building had a second floor that is 2,000 square feet (186 m²) and a basement that is 2,000 square feet (186 m²), since the aggregate area of the basement and second floor is 4,000 square feet (372 m²), at least one of the two floor areas would be required to be connected to the entrance level by an accessible route. There are certain facilities that, despite being relatively small in size, are not exempt from the requirement for an accessible route. Due to the critical nature of the services provided, offices of health care providers, passenger transportation facilities and airports are not included in this exception. Multitenant mercantile occupancies (i.e., five or more tenants in the facility), which include facilities such as shopping malls, are not included in the exception because individual retail stores have limited types of commodities (i.e., shoes, eyeglasses, sporting goods, etc.), and the exception

---

2012 INTERNATIONAL BUILDING CODE® COMMENTARY
would mean that people with disabilities would not have access to the same range of goods that are available to the general public. In these cases, access must be provided such that people with disabilities may patronize all the establishments within the facility. The 3,000-square-foot (279 m²) exception can be applied to a mercantile facility with fewer than five tenants.

A mezzanine is required by Section 505.2 to have a clear height below of at least 7 feet (2134 mm), therefore, Exception 1 cannot be applied to platforms or raised floor areas.

Exception 2 is a direct reference to the specific items addressed in Sections 1107 and 1108. It is not a general exception for Groups A, I, R and S. The purpose of Exception 2 is to address areas within specific occupancies where a single element would be repeated multiple times on a level. Where Sections 1107 and 1108 would allow construction of a floor level with no accessible features, this section is not intended to trigger an accessible route to that otherwise inaccessible level. For example, an accessible route would not be required to upper levels in a hotel with all public spaces and all required accessible sleeping units located on the ground floor. If an elevator is to be provided in a building that qualifies for this exception, and the elevator is not part of an accessible route, signage must be provided in accordance with Section 1110.2.

Exception 3 is specific to the unique situations found in air traffic control towers.

Exception 4 permits small nonpublic second floors to not require access. An example would be the second floor in a doctor's office that is used only for storage. The occupant load table in Section 1004.1.1 would limit this storage area to 1,500 square feet (139 m²) [i.e., 300 square feet (28 m²) per occupant x 5 occupants maximum = 1,500 square feet (28 m²)]. If the second floor also contained a mechanical room, that area would be exempt under Section 1103.2.9; however, if the doctor chose later to expand exam rooms into this second floor, he or she would have to provide an accessible route. Another example would be a second level in an airport that included only operational offices. In this case, the area would be limited by the occupant load table in Section 1004.1.1 to 500 square feet (46 m²) [i.e., 100 square feet (9 m²) per occupant x 5 occupants maximum = 500 square feet (46 m²)]. While the exception is specifically stated as applicable only to second-story buildings, it could be interpreted to apply to a one-story building with a basement level or a one-story building with a mezzanine.

Exception 5 is specific to raised platform areas used for employee work stations (judge, clerk, court reporter) in courtrooms. These areas are permitted to be constructed as adaptable for a future accessible route if and when a route is necessary for a mobility impaired employee. This exception does not apply to raised public areas in courtrooms such as witness stands or jury boxes. See Section 1108.4.1 for specific criteria for seating areas in a courtroom that are not employee areas, such as the gallery, the witness stand and the jury box.

1104.5 Location. Accessible routes shall coincide with or be located in the same area as a general circulation path. Where the circulation path is interior, the accessible route shall also be interior. Where only one accessible route is provided, the accessible route shall not pass through kitchens, storage rooms, restrooms, closets or similar spaces.

Exceptions:

1. Accessible routes from parking garages contained within and serving Type B units are not required to be interior.

2. A single accessible route is permitted to pass through a kitchen or storage room in an Accessible unit. Type A unit or Type B unit.

One of the objectives of accessibility requirements is to normalize, to the extent possible, the facilities provided for disabled persons and those comparable facilities that exist for people without disabilities. In addition, the intent of this section is to avoid the circumstance where an interior path between facilities is provided but the only accessible route between those same facilities is an exterior path.

When only one accessible route is provided, this section puts limits on the types of spaces through which that accessible route may pass so that it is readily available. Spaces, such as storage rooms, restrooms, closets and kitchens, can be subject to being locked or their availability may be restricted to authorized personnel; therefore, they would not serve as reliable accessible routes for all building occupants.

Exception 1 addresses individual dwelling units that include their own garages and residential facilities with shared garage levels. This exception is limited to accessible parking for Type B units. It is intended to allow a person to exit the garage and enter through the front door, instead of requiring access from the garage into the unit directly. Section 1106.2 requires that when parking is provided within a building, accessible parking must also be located within the building. If this exception is utilized in accordance with Sections 1104.1 and 1107.4, an accessible route must be provided from the accessible parking spaces to the front door.

Exception 2 allows a single accessible route to pass through a kitchen or storage room within a unit that is required to be an Accessible, Type A or Type B dwelling or sleeping unit. Given the space limitations and typical arrangements of dwelling units, it is not unreasonable to allow access, for example, through a kitchen, to reach an eating area or an exterior patio as the only means of access.

1104.6 Security barriers. Security barriers including, but not limited to, security bollards and security check points shall
not obstruct a required accessible route or accessible means of egress.

Exception: Where security barriers incorporate elements that cannot comply with these requirements, such as certain metal detectors, fluoroscopes or other similar devices, the accessible route shall be permitted to be provided adjacent to security screening devices. The accessible route shall permit persons with disabilities passing around security barriers to maintain visual contact with their personal items to the same extent provided others passing through the security barrier.

This requirement provides guidance for when a security feature is required along an accessible route. An example would be the security checkpoints in airports. The intent is that the route for a person with mobility impairments should move through security checkpoints as close to the typical route as possible. It is recognized that some people using wheelchairs or with braces could not move through standard security barriers, such as metal detectors.

SECTION 1105
ACCESSIBLE ENTRANCES

1105.1 Public entrances. In addition to accessible entrances required by Sections 1105.1.1 through 1105.1.6, at least 60 percent of all public entrances shall be accessible.

Exceptions:

1. An accessible entrance is not required to areas not required to be accessible.

2. Loading and service entrances that are not the only entrance to a tenant space.

A facility is not inaccessible if the entrances into it are inaccessible. This section establishes a reasonable criteria for providing accessible entrances. A facility is not required to have all of its entrances accessible in order to provide reasonable accommodation to disabled persons. If a facility has multiple public entrances, as a minimum, it is not considered unreasonable to require at least 60 percent of the entrances to be accessible. In addition to the 60-percent accessible public entrances, entrances that have a specific function or provide access to only certain portions of the facility must be addressed (see commentary, Sections 1105.1.1 through 1105.1.6). Sections 1110.1 and 1110.2 require signage at all entrances if all entrances are not accessible. "Public entrance," "Restricted entrance" and "Service entrance" are defined in Chapter 2.

Doors that are only for means of egress are not considered when determining the number of entrances required to be accessible. However, these doors may need to be on an accessible route for accessible means of egress requirements (see Section 1007). Depending on the arrangement, sometimes the entrance requirements are more restrictive, and sometimes the means of egress requirements are more restrictive. For example, take a small tenant space with two exterior doors—the front door is the public entrance and the back door is the service entrance. Section 1105.1 along with Exception 2 would require only the front door to be on an accessible route for ingress into the building. However, when a space has two means of egress required, Section 1007.1 would require both doors to be on an accessible route for means of egress purposes.

Exception 1 is self-evident in that if a facility or portion of a facility is not required to be accessible, then the entrances to such facilities or spaces are not required to be accessible. An example would be an exterior entrance to the sprinkler room (see Section 1103.2.9).

Exception 2 exempts loading and service entrances from the accessibility requirement on the basis that such entrances are unlikely to be used on a regular basis and may be raised to allow truck unloading. Loading and service entrances are required to be accessible if they are the only means of access into a facility or tenant space. This is consistent with Section 1105.1.5.

The intent of the reference to Sections 1105.1.1 through 1105.1.6 is to provide reasonable and convenient availability of an accessible entrance from the accessible facilities provided on the site. All entrances that serve distinct arrival points on the site are required to be accessible. For example, a public entrance from a public parking structure must be accessible (see Section 1105.1.1), as well as the employees-only entrance adjacent to separate employee parking (see Section 1105.1.3). This should deter the formerly common practice of designating an entrance as "the handicapped entrance" (which is inappropriate) without regard to its location relative to such arrival points as accessible parking facilities, transportation facilities, passenger loading zones, taxi stands, public streets or sidewalks and tunnels or elevated walkways. In conjunction with Section 1104.5, this section also is intended to provide reasonable and convenient availability of an accessible entrance to the building's accessible vertical movement elements, such as the elevators. This would allow a person with disabilities to move readily throughout all levels of the building.

1105.1.1 Parking garage entrances. Where provided, direct access for pedestrians from parking structures to buildings or facility entrances shall be accessible.

Occasionally, a parking garage is attached to an office building or mall. An accessible route must be provided from the accessible parking spaces in that parking garage to an accessible entrance into the office or mall portion of the building.

1105.1.2 Entrances from tunnels or elevated walkways. Where direct access is provided for pedestrians from a pedestrian tunnel or elevated walkway to a building or facility, at
least one entrance to the building or facility from each tunnel or walkway shall be accessible.

- Elevated walkways are sometimes provided between adjacent buildings for easy access or protection from the weather for people who must commonly move between certain buildings. Tunnels may serve the same purpose. Washington, DC, has tunnels between many of its congressional buildings. Chicago has a "pedway" system connecting the commuter train stations with the basement level of many buildings in the downtown area. Minneapolis deals with the extreme winter weather conditions in that city by having a system of elevated walkways that connect many of the downtown buildings (see Figure 1105.1.2). When these types of walkways or tunnels are provided, at least one of the building entrances off of these walkways or tunnels must be an accessible entrance.

![Figure 1105.1.2](image)

**EXAMPLE OF ELEVATED WALKWAY ENTRANCE**

1105.1.3 Restricted entrances. Where restricted entrances are provided to a building or facility, at least one restricted entrance to the building or facility shall be accessible.

- Where access into a specific entrance is controlled (see the definition for "Restricted entrance" in Chapter 2), at least one of that type of entrance must be accessible. An entrance that is locked is not necessarily a restricted entrance. For example, an apartment building may have multiple entrances for tenants where they enter with their key; however, there may be only one entrance for visitors if they need to access a tenant intercom system to gain entrance. The one visitor entrance is considered to be the restricted entrance and is required to be accessible.

1105.1.4 Entrances for inmates or detainees. Where entrances used only by inmates or detainees and security personnel are provided at judicial facilities, detention facilities or correctional facilities, at least one such entrance shall be accessible.

- Where access to a specific entrance is limited for security reasons to inmates or detainees and the staff supervising them, that entrance must be accessible. This type of situation could occur at courthouses, jails and police stations (see also Sections 1103.2.14, 1107.5.5 and 1108.4.2).

1105.1.5 Service entrances. If a service entrance is the only entrance to a building or a tenant space in a facility, that entrance shall be accessible.

- Loading and service entrances are required to be accessible if they are the only means of access into a facility or tenant space. Typically, loading and service entrances are exempted from the accessibility requirement on the basis that such entrances are unlikely to be used on a regular basis and may be raised to allow for truck unloading (see the definition for "Service entrance" in Chapter 2). This is consistent with Section 1105.1, Exception 2.

1105.1.6 Tenant spaces, dwelling units and sleeping units. At least one accessible entrance shall be provided to each tenant, dwelling unit and sleeping unit in a facility.

**Exceptions:**

1. An accessible entrance is not required to tenants that are not required to be accessible.

2. An accessible entrance is not required to dwelling units and sleeping units that are not required to be Accessible units, Type A units or Type B units.

- Each tenant space must have at least one accessible entrance. Dwelling and sleeping units that are Accessible, Type A or Type B units must have at least one accessible entrance. For multitenant buildings with shared entrances, the 60-percent entrance requirement in Section 1105.1 is also applicable. If a space, whether a tenant, dwelling unit or sleeping unit, does not have accessibility requirements, then an accessible entrance is not required.

SECTION 1106

PARKING AND PASSENGER LOADING FACILITIES

1106.1 Required. Where parking is provided, accessible parking spaces shall be provided in compliance with Table 1106.1, except as required by Sections 1106.2 through 1106.4. Where more than one parking facility is provided on a site, the number of parking spaces required to be accessible shall be calculated separately for each parking facility.

**Exception:** This section does not apply to parking spaces used exclusively for buses, trucks, other delivery vehicles,
law enforcement vehicles or vehicular impound and motor pools where lots accessed by the public are provided with an accessible passenger loading zone.

Accessible parking facilities are an important component of building and site accessibility. This section addresses the number of parking spaces required. The location of such parking spaces in relation to accessible building entrances is addressed in Section 1106.6. Parking facility requirements are primarily intended to facilitate accessibility for people with a mobility impairment, not just persons that use wheelchairs.

This section is not intended to require that parking facilities be provided; rather, when parking is provided, the minimum number of accessible parking spaces specified herein must be provided. ICC A117.1 contains detailed requirements on the size and configuration of accessible parking spaces, including the required access aisle adjacent to the space, as well as the dimensional requirements for van-accessible parking spaces required by Section 1106.5.

Multitenant facilities, such as a shopping mall, or large facilities, such as hospitals or assembly occupancies, may have multiple parking lots or parking garages. If multiple parking lots, or a combination of parking garages and parking lots are provided for a facility, the number of spaces in each separate parking facility is utilized to determine the number of accessible spaces required. Accessible car and van parking would then be provided in each parking facility accordingly, except as otherwise permitted by Section 1106.6. What constitutes a multiple facility is somewhat subjective. Putting a line of trees or landscaping along the side of the parking spaces does not always constitute a separate facility. From a practical viewpoint, the separate facilities would serve specific groups of people (i.e., employee-only parking), provide different types of parking (i.e., surface lots, garage parking, covered parking) or serve distinct areas of the building (i.e., upper and lower levels as you move around a large mall).

In certain types of lots it is not logical to require accessible parking spaces. The exception helps to clarify these situations. Parking lots that contain only parking for buses, trucks and delivery vehicles would not need accessible parking spaces. Lots where the parked cars are limited to vehicles used by law enforcement, impound lots or motor pools are also not required to provide accessible spaces. An accessible passenger drop-off is required to be provided on the site, so that when a person with a mobility impairment comes to that site, he or she has a place to exit the arrival vehicle safely and enter a vehicle coming from the lot.

1106.2 Groups R-2 and R-3. At least 2 percent, but not less than one, of each type of parking space provided for occupancies in Groups R-2 and R-3, which are required to have Accessible, Type A or Type B dwelling or sleeping units, shall be accessible. Where parking is provided within or beneath a building, accessible parking spaces shall also be provided within or beneath the building.

This section provides a separate criterion for the required number of accessible parking spaces for occupancies in Groups R-2 and R-3 that include Accessible, Type A or Type B units. The 2-percent requirement is based on HUD's FHAG. Section 1107.7 identifies buildings where accessible units may not be required.

Where parking is provided within or beneath a building, accessible parking spaces also are to be provided within or beneath the building. If a combination of surface and covered parking is provided, accessible parking may be provided in both locations. This is intended to establish consistency in the type and location of parking spaces available to all people.
If parking is provided in individual private parking garages, 2 percent of the parking garages would have to contain accessible parking spaces (see the exception to Section 1106.5). Note that parking provided for visitors should comply with the numbers indicated in Table 1106.1.

In a development, typically parking for dwelling units is considered on a site basis rather than a building by building basis. Accessible parking should be dispersed throughout the development so as to provide the best access possible. It is not the intent to require accessible parking spaces at the entrance to every building, or within every strip of parking garages. For example, it would not be logical to ask for a surface space and a garage space for each building in developments with multiple four-unit buildings. See Section 1106.5 for a discussion of the distribution of van-accessible spaces.

1106.3 Hospital outpatient facilities. At least 10 percent, but not less than one, of care recipient and visitor parking spaces provided to serve hospital outpatient facilities shall be accessible.

- Certain facilities can be expected to have a higher demand for accessible parking spaces than that reflected in Table 1106.1. Medical outpatient facilities are one such facility. This section requires that at least 10 percent of the parking provided for patients and visitors of these types of facilities be accessible. Parking provided for the employees of these facilities should comply with Table 1106.1. If a hospital contains multiple clinics or types of facilities, the amount of parking dedicated to the outpatient facility is interpretive. Options for determining the number of accessible spaces could be based on the area percentage of the outpatient facilities to other facilities or the anticipated number of patients and visitors to these facilities in relation to other facilities.

1106.4 Rehabilitation facilities and outpatient physical therapy facilities. At least 20 percent, but not less than one, of the portion of care recipient and visitor parking spaces serving rehabilitation facilities specializing in treating conditions that affect mobility and outpatient physical therapy facilities shall be accessible.

- Medical facilities that specialize in treatment or other services for people with mobility impairments can be expected to have a higher demand for accessible parking spaces. In these cases, at least 20 percent of the parking spaces provided for visitors and care recipients are required to be accessible. Parking provided for the employees of these facilities should comply with Table 1106.1. If a hospital contains multiple types of facilities, the amount of parking dedicated to the rehabilitation and physical therapy facility is interpretive. Options for determining the number of accessible spaces could be based on the area percentage of the rehabilitation and physical therapy facilities to other facilities or the anticipated number of care recipients and visitors to these facilities in relation to other facilities.

1106.5 Van spaces. For every six or fraction of six accessible parking spaces, at least one shall be a van-accessible parking space.

Exception: In Group R-2 and R-3 occupancies, van-accessible spaces located within private garages shall be permitted to have vehicular routes, entrances, parking spaces and access aisles with a minimum vertical clearance of 7 feet (2134 mm).

- Vans that are specially equipped to accommodate a person using a wheelchair require wider parking spaces than the typical accessible parking space. This is because vans are usually equipped with a mechanized loading/unloading platform that extends outward from the passenger side of the vehicle. ICC A117.1 contains the dimensional requirements for van-accessible spaces. In order to accommodate the growing usage of these specially equipped vans, this section requires that one in every six accessible parking spaces, or a fraction thereof, be of a size to accommodate these vans. The requirement for van-accessible spaces is not intended to require a greater number of accessible spaces than required by Table 1106.1. For example, if Table 1106.1 requires six accessible parking spaces, one of those six must be van accessible. If seven accessible spaces are required by Table 1106.1, two of those seven are required to be van accessible. On the other hand, if only one accessible parking space is required by Table 1106.1, that space would be a van-accessible space.

The exception modifies the height criteria for van-accessible spaces in ICC A117.1 for private garages serving dwelling units. This is a reduction from the 98-inch (2489 mm) height requirement in ICC A117.1. Since many vans are now converted by lowering the floor rather than raising the roof, the 82-inch (2083 mm) height should accommodate most private passenger vans with lifts.

Note that the determination of the number of van-accessible spaces is not tied to separate facilities as the number of spaces is in Sections 1106.1 and 1106.2. However, distribution of van-accessible spaces throughout the accessible parking space in large facilities is good design practice. Van-accessible spaces can be used by cars with accessible placards. It is just common courtesy to leave the van-accessible space for vans when there are other accessible spaces available.

1106.6 Location. Accessible parking spaces shall be located on the shortest accessible route of travel from adjacent parking to an accessible building entrance. In parking facilities that do not serve a particular building, accessible parking spaces shall be located on the shortest route to an accessible pedestrian entrance to the parking facility. Where buildings have multiple accessible entrances with adjacent parking,
accessible parking spaces shall be dispersed and located near the accessible entrances.

Exceptions:

1. In multilevel parking structures, van-accessible parking spaces are permitted on one level.

2. Accessible parking spaces shall be permitted to be located in different parking facilities if substantially equivalent or greater accessibility is provided in terms of distance from an accessible entrance or entrances, parking fees and user convenience.

As previously stated, the majority of disabled parking permits and license plate holders in most states are ambulatory, mobility-impaired persons. Travel distance, as well as severe weather conditions encountered when traversing from the parking lot to the building entrance, are more difficult for persons with mobility impairments to deal with than the general population. The intent of this section is to locate the parking so that the people utilizing the accessible parking spaces have to travel a minimum distance to an accessible entrance (see Figure 1106.6). This requirement is stated in performance terms and requires a degree of subjective judgment on the part of both the designer and the building official in determining the appropriate location for accessible spaces that meets the intent of this section. If a facility has multiple accessible entrances, accessible parking spaces are to be dispersed consistent with the location of these entrances.

Exception 1 is intended to acknowledge a practical difficulty associated with multilevel parking structures. In many cases, a multilevel parking structure will serve accessible building entrances on more than one or all of its parking levels. Specially equipped vans for persons using wheelchairs may be modified by raising the roof of the vehicle in order to provide greater interior headroom. Consequently, such vans require greater vertical clearances. Typical parking structure design may not easily accommodate the necessary vertical clearance for accessible vans due to their low floor-to-ceiling heights. It would be impractical and economically unjustified to require parking structures to be designed solely for the purpose of enabling van-accessible spaces to be located on upper levels. Accordingly, the exception allows the required van-accessible parking spaces to be located on only one level of a multilevel parking structure. The route to and from the space, as well as at the van space and associated access aisle, must meet the minimum clear height of 98 inches (2489 mm) as specified in Section 502.6 of ICC A117.1. This will usually be the entry level of the parking facility.

Exception 2 addresses sites where multiple parking facilities are provided to serve a single destination or facility. Since one or more of the parking lots or parking garages may be more attractive to users for various reasons, it is acceptable to locate the required accessible parking based on perceived user convenience and preferences, including distance, parking fees and amenities.

1106.7 Passenger loading zones. Passenger loading zones shall be accessible.

This section does not require passenger loading zones to be provided; however, where provided, they must be accessible in accordance with Section 503 of ICC A117.1. For locations where passenger loading zones are required, see Sections 1106.7.1 through 1106.7.4.

1106.7.1 Continuous loading zones. Where passenger loading zones are provided, one passenger loading zone in every continuous 100 linear feet (30.4 m) maximum of loading zone space shall be accessible.

The intent of this section is to address the continuous loading zones found at most larger airports as well as some other types of transportation facilities, such as commuter train "kiss-n-ride" drop-off areas. At least one 20-foot (6096-mm) section for every 100 feet (30 480 mm) of passenger loading zone must meet the accessibility provisions in Section 503 of ICC A117.1.

1106.7.2 Medical facilities. A passenger loading zone shall be provided at an accessible entrance to licensed medical and long-term care facilities where people receive physical or medical treatment or care and where the period of stay exceeds 24 hours.

The requirement for accessible passenger loading zones is applicable to both medical and long-term care facilities. The most common examples are hospitals and nursing homes; however, this could also be applicable to some rehabilitation and assisted living facilities (typically Group I-2). Medical and long-term care facilities typically have a higher percentage of people with mobility impairments living in the facility or visiting on a regular basis. Due to their mobility impairment, such people will be frequently driven by a friend or family member, and it is desirable and convenient to drop them off at the entrance rather than parking and requiring them to travel from the parking.
lot to the facility’s entrance. As such, this section requires that a passenger loading zone be provided at no less than one accessible entrance to the facility.

1106.7.3 Valet parking. A passenger loading zone shall be provided at valet parking services.

- Valet parking is typically the public access point to a facility. When valet parking is provided, the passenger loading zone must be accessible so that it may be utilized by persons requiring wheelchairs. This would include the access aisle and an accessible route from the access aisle to the front entrance. Note that providing valet parking services does not eliminate the need for accessible parking spaces where parking is provided. Some vehicles that are modified for persons with disabilities may not be drivable by a valet attendant. In addition, valet parking may only be provided during certain periods of time, such as during dinner hours at a restaurant.

1106.7.4 Mechanical access parking garages. Mechanical access parking garages shall provide at least one passenger loading zone at vehicle drop-off and vehicle pick-up areas.

- Mechanical parking garages allow a much higher density of vehicles in a given footprint due to the elimination of ramps and drive lanes. With respect to the customer interface, mechanical garages are similar to valet parking and, therefore, require similar scoping for accessibility.

SECTION 1107
DWELLING UNITS AND SLEEPING UNITS

- The development of this section was part of the coordination effort with the FHA and the FHAG. For further explanation, see the general comments for this chapter.

One of the phrases developed as part of this coordination was the defined phrase "intended to be occupied as a residence." This defines a type of dwelling or sleeping unit that is a person’s home or place of abode. The intent of this language is to clarify that, consistent with the FHA, all dwelling units or sleeping units that can or will be used as a place of abode—even for a short period of stay—must meet the requirements for Type B dwellings. There is a presumption in the IBC that if a building is nontransient (i.e., occupants stay more than 30 days), it is covered by the requirements in this section. In addition, in coordination with the FHA, occupancies that allow stays of fewer than 30 days may be required to meet Type B design and construction requirements.

Accordingly, this commentary will provide guidance for determining when short-term occupancies that might not typically be viewed as housing are covered by this section. Such short-term Group R occupancies may include residential hotels and motels; corporate housing; seasonal vacation units; timeshares; boarding houses; dormitories and migrant-farm worker housing. Also included are some occupancies in Group I, such as nursing homes, assisted living facilities, hospices and homeless shelters.

The key factor in determining whether any of these occupancies are subject to Type B requirements is whether the occupant will have the right to return to the property and whether he or she would have anywhere else in which to return to. If it is intended that an occupant will have a right to return to the property and will not have anywhere else to return, the unit is "intended to be occupied as a residence" and must meet the Type B requirements regardless of the length of stay. Thus, for example, homeless shelters where occupants have a right to return nightly must comply with Type B unit criteria even if the occupants stay only a few nights. Additionally, nursing homes in which a resident moves after vacating his or her primary residence are subject to Type B requirements.

If the occupants have a right to return to the property but also have another place in which to return to, the unit may still be subject to Type B criteria. Additional factors must be considered to determine whether the property is a short-term dwelling or sleeping unit that must meet Type B criteria, or a transient property that is not required to comply with Type B criteria. These factors must be considered by owners, builders, developers, architects and other designers to determine whether or not a building must be designed and constructed in accordance with Type B unit requirements.

For additional discussion on the elements related to hotels, motels, corporate housing and seasonal vacation units and timeshares, see the commentary to Section 1107.6.1 (Group R-I). With respect to most other occupancies, the following factors are also relevant to determine whether the units are subject to Type B requirements:

1. Whether the property is to be marketed as short-term housing;
2. Whether the terms and length of occupancy will be established through a written agreement;
3. How payment will be calculated (e.g., on a daily, weekly, monthly or yearly basis); and
4. What types of amenities and services are offered with the occupancy.

For example, an assisted living facility that provides sleeping units and medical services to its occupants, and bills them on a monthly basis is subject to Type B design and construction requirements. In addition, housing for migrant farm workers that is provided in conjunction with the worker’s employment (whether or not rent is paid) and contains amenities for cooking and sleeping would be subject to Type B criteria.
1107.1 General. In addition to the other requirements of this chapter, occupancies having dwelling units or sleeping units shall be provided with accessible features in accordance with this section.

There are two basic types of facilities that this section covers: dwelling units and sleeping units. A "dwelling unit" is defined in Chapter 2 as a single unit that contains permanent provisions for "living, sleeping, eating, cooking and sanitation." A "sleeping unit" is defined in Chapter 2 as a room in which people sleep, which can include some of the provisions found in a dwelling unit but not all. Occupancy of dwelling units or sleeping units can be transient or nontransient. Dwelling units are typically apartments, condominiums, detached homes or townhouses. Dwelling units can be located in hotels that offer cabins, suites or rooms with kitchen facilities. Bedrooms within dwelling units are not considered sleeping units.

A sleeping unit could be a typical hotel guestroom; a bedroom in a congregate residence, such as a dorm, sorority house, fraternity house, convent, monastery or boarding house; a nursing home room or a jail cell.

1107.2 Design. Dwelling units and sleeping units that are required to be Accessible units, Type A units and Type B units shall comply with the applicable portions of Chapter 10 of ICC A117.1. Units required to be Type A units are permitted to be designed and constructed as Accessible units. Units required to be Type B units are permitted to be designed and constructed as Accessible units or as Type A units.

There are three levels of accessibility that can be required in a dwelling unit or sleeping unit: Accessible units, Type A units and Type B units. All three types are defined in Chapter 2.

An Accessible unit is constructed for full accessibility in accordance with Section 1002 of ICC A117.1. For example, grab bars are in place in the bathrooms, a clear floor space is provided for front approach at the kitchen sink and bathroom lavatories, 32-inch (813 mm) clear width doors with maneuvering clearances and lever hardware are provided, etc. None of the elements in the unit are constructed for adaptability. The requirements for an Accessible unit provide a higher level of accessibility than either a Type A unit or a Type B unit.

A Type A unit has some elements that are constructed accessible [e.g., 32-inch (813 mm) clear width doors with maneuvering clearances and lever hardware] and some elements designed to be added or altered when needed (e.g., grab bars can be easily added in bathrooms since blocking in the walls is in place). Type A units follow the technical criteria in Section 1003 of ICC A117.1. This type of unit is less accessible than an Accessible unit and more accessible than a Type B unit.

The scoping or technical requirements for Type B units are consistent with the requirements for units required by the FHAG (see the definition for "Type B units" in Chapter 2). A Type B unit is constructed to a lower level of accessibility than either an Accessible unit or a Type A unit. While a person who uses a wheelchair could maneuver in a Type B unit, the technical requirements are geared more towards persons with lesser mobility impairments. Type B units follow the technical requirements in Section 1004 of ICC A117.1. Areas of a Type B unit are allowed to be totally nonaccessible (e.g., sunken living room, extra bedrooms on a mezzanine level). Side approach is permitted to sinks in the kitchen and lavatories in the bathroom rather than planning for a front approach. Some elements are constructed with a minimal level of accessibility [e.g., doors within the unit have a 31 1/4-inch (806 mm) clear width but do not require maneuvering clearances], while some elements are designed to be altered when needed (e.g., blocking in the walls of the bathroom for future installation of grab bars).

This section also takes into consideration the fact that Accessible unit requirements provide a higher level of accessibility than Type A requirements, and Type A requirements provide a higher level of accessibility than Type B requirements. Units are permitted to be constructed to a higher level of accessibility than required. In other words, Accessible units are constructed wheelchair ready. Type A units are constructed wheelchair friendly and Type B units are constructed wheelchair usable.

The technical criteria for each type of unit in ICC A117.1 is organized in the same order and section number for each element, so make comparisons between types easier. For example, looking at the door provisions in Sections 1002.5, 1003.5 and 1004.5 of ICC A117.1 would clarify that the maneuvering clearances are required at all doors that are part of the accessible route through an Accessible unit or a Type A unit, but for the Type B unit, the maneuvering clearance is only required at the front door to the unit, not within the unit. Another example would be the requirements for operable parts: Sections 1002.9 and 1003.9 address requirements for plumbing fixture and appliance controls, while in accordance with Section 1004.9, Type B units do not require plumbing fixture and appliance controls to meet operable parts requirements.

1107.3 Accessible spaces. Rooms and spaces available to the general public or available for use by residents and serving Accessible units, Type A units or Type B units shall be accessible. Accessible spaces shall include toilet and bathing rooms, kitchen, living and dining areas and any exterior spaces, including patios, terraces and balconies.

Exceptions:

1. Recreational facilities in accordance with Section 1109.15.
2. In Group I-2 facilities, doors to sleeping units shall be exempted from the requirements for maneuvering.
clearance at the room side provided the door is a minimum of 44 inches (1118 mm) in width.

Spaces available for use by residents or the general public that are associated with Accessible units, Type A units or Type B units are required to be accessible. This would include spaces within the unit and outside the unit in the same building, as well as facilities that may be outside the building somewhere else on the site. The intent is that a person with a disability could take full advantage of the amenities associated with his or her dwelling or sleeping unit. While it is fairly clear which elements within a unit must be accessible, the associated facilities outside the unit vary depending on the type of building and facilities provided. Public use spaces within a building would include lobby areas while spaces for residents could include shared storage areas or refuse rooms. Shared spaces in nursing homes or assisted living facilities might be dining rooms, therapy rooms and recreational rooms. In dormitories, residents may share study rooms, laundry rooms or mail rooms and facilities located remotely, such as cafeterias. Examples of shared spaces in congregate residences could include community kitchens, living rooms and shared bathrooms. Examples in apartment complexes could include grouped mailboxes, rental offices, exercise rooms and exterior spaces, such as community buildings and swimming pools.

Exception 1 allows for limited access to exterior recreational facilities when multiples of the same type of facility are provided. An example would be multiple tennis courts on the same site for use by residents in a complex (see Section 1109.15 for additional information). The net result is that a person with a disability, either a resident or guest, can access all Accessible, Type A and Type B units, as well as any associated facilities and public areas on the site.

Exception 2 recognizes the practical implications of door maneuvering clearances on the room side at in-swinging doors in smaller sized patient sleeping rooms in hospitals and nursing homes. The maneuvering clearance is still required on the outside of the Accessible patient sleeping room door. Since the maneuvering clearance in ICC A117.1 is based on the size of the door, there is no credit provided for the wider 44-inch (1118 mm) door width (required in Section 1008.1.1 in Group I-2 for movement of bed) versus the standard 36-inch (914 mm) door. Without this exception a patient room would likely require extra width when a toilet room is located on the same wall as the door. Due to operational procedures and observation needs, the door position is normally open, therefore, the need for door maneuvering clearance on the interior side is reduced. At hospitals, nursing homes and rehabilitation centers, the patient room door is usually closed only when visitors or caregivers are present.

The percentage of Accessible units and Type B units in hospitals, nursing homes and rehabilitation centers is addressed in Sections 1107.5.2, 1107.5.3 and 1107.5.4. Maneuvering clearances are part of an accessible route, and accessible routes connect accessible elements; therefore, maneuvering clearances at patient sleeping rooms that are not Accessible or Type B units are not required since an accessible route is not required. For additional information on when Type B units are required in institutional facilities, see the commentary to Section 1107. This is consistent with Section 1104.3, Exception 2.

1107.4 Accessible route. At least one accessible route shall connect accessible building or facility entrances with the primary entrance of each Accessible unit, Type A unit and Type B unit within the building or facility and with those exterior and interior spaces and facilities that serve the units.

Exceptions:

1. If due to circumstances outside the control of the owner, either the slope of the finished ground level between accessible facilities and buildings exceeds one unit vertical in 12 units horizontal (1:12), or where physical barriers or legal restrictions prevent the installation of an accessible route, a vehicular route with parking that complies with Section 1106 at each public or common use facility or building is permitted in place of the accessible route.

2. Exterior decks, patios or balconies that are part of Type B units and have impervious surfaces, and that are not more than 4 inches (102 mm) below the finished floor level of the adjacent interior space of the unit.

Section 1107.3 indicates which spaces associated with accessible dwelling and sleeping units (i.e., Accessible, Type A and Type B units) are required to be accessible. Section 1105 indicates which building entrances are required to be accessible. The intent of this section is twofold: that there will be at least one accessible route that connects required accessible building entrances with the entrance of all accessible dwelling and sleeping units, and that there also must be accessible routes connecting accessible unit entrances with all interior and exterior common and public use spaces and facilities that serve the accessible dwelling or sleeping unit. Some additional facilities that serve units that are not really considered spaces would be accessible parking (see Section 1106.1), passenger loading zones (see Section 1106.7) and public transportation stops located either on site or adjacent to the perimeter. In determining the site arrival points that serve an accessible unit, the designer should make a reasonable determination of how pedestrians and vehicles would arrive at the site.

HUD's review of the 2003 and 2006 editions of the code found that they meet or exceed the seven design and construction requirements of the FHA and are "safe harbor" documents for complying with the FHA. To read the final report of the HUD review, go to http://www.hud.gov/offices/fheo/disabilities/model-codes/. HUD stated, "Having a more recent edition of
the IBC recognized by HUD as a safe harbor will ensure that covered dwelling units will be built with the accessible features required by the Act. For additional information, see the commentary at the beginning of this chapter.

The following commentary concerning the accessible route serving dwelling units and sleeping units has been provided by HUD:

The five examples serve to illustrate a variety of conditions that may be encountered on nonlevel building sites where Exception 1 is applicable. These examples pertain to the accessible route between facilities on a site. In addition to the on-site accessible routes, the accessible route(s) between the site arrival point(s) and facilities on the site must be considered. Note that the exception in Section 1104.1 does not apply to facilities containing or serving Type B units.

The intent of this section is to ensure that there will be at least one accessible route that connects all accessible building and facility entrances with the entrance of all Accessible, Type A and Type B units. To qualify as an accessible route, that route must serve pedestrians (i.e., sidewalk or other walkway). People with disabilities who need the features of an Accessible, Type A or Type B dwelling or sleeping unit cannot use them if accessible routes are not provided from the entrances to buildings or facilities to the primary entrance of their dwelling or sleeping unit. There also must be accessible routes connecting accessible building or facility entrances with all interior and exterior spaces and facilities that serve such dwelling or sleeping units. For example, if a development has a recreational facility, such as a community center, persons with disabilities who need the features of an Accessible, Type A or Type B unit need an accessible route from their dwelling unit to that community center.

Exception 1 is intended to provide consistency with the federal FHA, which recognizes that, in very rare circumstances, an accessible pedestrian route between an accessible entrance to an accessible unit or an accessible entrance to a building containing accessible units and an exterior public use or common use facility may be impractical because of factors outside the control of the owner. Section 1107.4 requires an accessible pedestrian route between covered dwelling units and public use or common use areas and facilities that are required to be accessible, except in rare circumstances that are outside the control of the owner where extreme terrain or impractical site characteristics result in a finished grade exceeding 8.33 percent or physical barriers or legal restrictions prevent the installation of an accessible pedestrian route. In these cases, Exception 1 allows access to be provided by means of a vehicular route leading from the accessible parking serving the accessible unit to the accessible parking serving the public use or common use facility. Accessible parking complying with Section 1106 must be provided in each parking area. If a building containing accessible units also contains accessible features that are required by other code provisions or federal, state or local laws, then Exception 1 may not apply at all.

It is important to understand that compliance with the accessible design and construction requirements of the FHA is a legal obligation applicable to all architects, engineers, builders, developers and others involved in the design and construction of housing. HUD’s regulations implementing the FHA make it clear that the burden of showing the applicability of exceptions is the responsibility of those individuals and entities involved in the design and construction of such housing. In order to ensure compliance with FHA, architects, engineers, developers, builders and others who use the code must make accessibility a priority at the planning and design phase of Group I and R developments, including the siting of housing and public use or common use areas. To do this, at the initial stage of site planning and design for all sites, before considering whether Exception 1 applies, persons and entities involved in the design of covered residential occupancies must determine whether and how the exceptions of Sections 1107.7.4 and 1107.7.5 apply.

After careful site planning and design has been completed, the following factors may then be considered to determine whether it is outside the control of the owner to provide an accessible pedestrian route between a building/Type B dwelling unit entrance and a given public use or common use facility. Each such route must be analyzed individually. Exception 1 will only apply when at least one of the following factors is present:

1. Legal restrictions outside the control of the owner. These include setback requirements, tree-save ordinances, easements, environmental restrictions and other limitations that prevent installation of an accessible pedestrian route without violating the law.

2. Physical barriers outside the control of the owner. These include physical characteristics of the site, which are outside the control of the owner that prevent the installation of an accessible pedestrian route.

3. On sites that qualify for the exceptions of Sections 1107.7.4 and 1107.7.5, the presence of extreme terrain or other unusual site characteristics (e.g., flood plain, wetlands) outside the control of the owner that would require substantial additional grading to achieve a slope that will allow for an accessible pedestrian route.

In considering whether the additional grading is substantial enough to qualify for Exception 1, the extent to which the builder has elected to grade the site for other purposes unassociated with accessibility must be considered. If grading for those other purposes is extensive, then substantial additional grad-
ing would be necessary to provide the required accessible pedestrian route. If grading for other purposes is not extensive, and substantial additional grading is necessary to provide an accessible pedestrian route, then reliance on Exception 1 would be appropriate. Note that when determining whether the additional grading is substantial, one may not consider the grading that the builder must perform to provide accessible pedestrian routes from site arrival points to the accessible entrances of accessible dwelling or sleeping units. If none of the factors above are present, Exception 1 does not apply. If one or more of these factors is present, then the next step in determining whether Exception 1 applies (i.e., the vehicular route is the only feasible option) is to consider alternative locations and designs for buildings, facilities and accessible pedestrian routes connecting each accessible building and accessible dwelling unit entrance and each public use or common use area required to be accessible to ensure that there is no other way to provide the required accessible pedestrian routes. It is important to recognize that if a road sloping 8.33 percent or less can be provided, then an accessible pedestrian route would also be feasible and must be provided.

Following are some examples to illustrate the proper application of Exception 1:

Example 1: An undisturbed site has slopes of 8.33 percent or less between required accessible entrances to Type B dwelling units and public use or common use areas and there are no legal restrictions or other unique characteristics preventing the construction of accessible routes. For aesthetic reasons, the developer would like to create some hills or decorative berms on the site. Because there are no extreme site conditions (severe terrain or unusual site characteristics such as flood plains), and no legal barriers that prevent installation of an accessible pedestrian route between the buildings/Type B dwelling units and any planned public use or common use facilities, the developer will still be obligated to provide accessible pedestrian routes. Exception 1 to Section 1107.4 is inapplicable in this circumstance.

Example 2: A developer plans to construct several buildings with Type B units clustered in a level area of a site that has some slopes of 10 percent. A swimming pool and tennis court will be added on the two opposing sides of the site. The builder plans grading that will result in a finished grade exceeding a slope of 8.33 percent along the route between the Type B units and the swimming pool and tennis court. There are no physical barriers or legal restrictions outside the control of the owner or builder that prevent him or her from reducing the existing grade to provide an accessible pedestrian route between the Type B units and the pool and tennis court. Therefore, the builder’s building plan would not be approved under the code because it is within the owner’s control to have the final grading fall below 8.33 percent and meet the slope and other requirements for an accessible pedestrian route. Accessible pedestrian routes between the Type B units, pool and tennis court must be provided.

Example 3: A multiple-family housing complex is built on two sections of a large piece of property, which is divided by a wide stream running through protected wetlands. Both sections of the property are at the same relative elevation and have dwelling units with accessible routes from site arrival points; however, a combination clubhouse and swimming pool is located on one section of the property. Access to each section is provided by an existing public road outside the boundary of the site, which includes a bridge over the stream. Environmental restrictions prevent construction of any type of paved surface between the two sections within the boundary of the site. If environmental restrictions do not prevent the construction of an accessible pedestrian route, such as a boardwalk, through the wetlands connecting the two sections, then the accessible pedestrian route must be provided even if a road cannot be provided. If construction of any type of pedestrian route is prohibited, then a vehicular route that utilizes the public road and bridge is permitted with parking complying with Section 1106 located at the clubhouse/swimming pool, even though the vehicular route relies on a public road instead of a road through the development.

Example 4: A narrow and deep site has a level section in the front taking up most of the site and another level section at the back that is located up a steep incline. The developer chooses to place all of the buildings/Type B dwelling units on the front section to provide for accessible routes from site arrival points to building entrances. After considering all options for situating buildings and facilities in different locations, including the priority of accessibility, the most feasible location for a planned swimming pool is at the top of the higher section to the rear of the property. Because of the narrowness of the site and the relative elevation of the upper level at the rear of the property, it is impracticable to construct an accessible pedestrian route to the pool; however, a road that slopes more than 8.33 percent can be provided. Under these circumstances, Exception 1 is applicable and access to the swimming pool on the upper level of the site may be provided by means of a vehicular route with parking complying with Section 1106 provided at the Type B dwelling units and the pool.

Example 5: A developer plans to build a multiple-family housing complex with one elevator buildings on a site with hilly terrain. All of these buildings will have some Type B dwelling units. The developer plans to locate a tennis court on the site. There are gentle slopes exceeding 8.33 percent with existing trees between the entrances to the Type B units and the tennis court. There is also a tree-save ordinance in place. If the builder can grade the site to allow for an accessible pedestrian route to the tennis court with-
out disturbing the trees in violation of the tree-save ordinance, then an accessible pedestrian route between the Type B units and the planned location of the tennis court must be provided. If, however, the grading necessary to reduce the slope of the site near the trees to provide an accessible route would cause tree loss or damage in violation of the ordinance, then the developer cannot grade without violating the tree-save ordinance. The developer must then consider whether the tennis court can be relocated so it is served by an accessible pedestrian route, and if so, the tennis court must be relocated. If the tennis court cannot be relocated so it can be served by an accessible pedestrian route, then the developer may provide a vehicular route from the Type B dwelling units to the tennis court with parking complying with Section 1106 at the Type B dwelling units and the tennis court. Note, however, that if the developer can provide an accessible pedestrian route from some of the buildings without violating the ordinance, the developer must do so, even if it is necessary to provide a vehicular route from other buildings. Additionally, if the grading and construction of the proposed vehicular route can be limited to 8.33 percent by design and would not violate the tree-save ordinance, it is likely that an additional accessible walkway adjacent to the vehicular route would also fall under the scope of work that would not violate the tree-save ordinance and, therefore, must be provided, eliminating the use of Exception 1.

This completes the guidance on this topic provided by HUD for inclusion in this commentary.

Exception 2 is intended for application to Type B units with either a private deck, patio or balcony within an individual unit or to a shared deck, patio or balcony in a "residents only" area of a congregate residence. Decks, patios or balconies located in areas such as the community building or swimming pool should be constructed accessible. When the outside walking surface is impervious to water, such as concrete, there may be a 4-inch (102 mm) step-down between the inside finished floor surface and the outside floor surface. The step-down is permitted to address the concern of water infiltration under the doors at such locations. With a maximum 4-inch (102 mm) difference in elevation, adaptation for accessibility is achievable with raised sleepers and decking.

Normal door threshold criteria apply.

1107.5 Group I. Accessible units and Type B units shall be provided in Group I occupancies in accordance with Sections 1107.5.1 through 1107.5.5.

This section introduces five subsections that set forth the threshold for accessibility in institutional occupancies.

Note that among the various categories of institutional facilities, only Accessible units and Type B units are scoped. There are no requirements for Type A units in institutional occupancies. The criteria for Accessible units and Type B units are specified in Chapter 10 of ICC A117.1.

1107.5.1 Group I-1. Accessible units and Type B units shall be provided in Group I-1 occupancies in accordance with Sections 1107.5.1.1 and 1107.5.1.2.

- Group I-1 is comparable in many respects to Group R-2 in that it is a residential setting. The difference is that Group I-1 is a supervised environment because of the reduced abilities of the occupants; physical, mental or both (see Section 308.3).

1107.5.1.1 Accessible units. At least 4 percent, but not less than one, of the dwelling units and sleeping units shall be Accessible units.

- The threshold for accessibility in apartments (Group R-2), in accordance with Section 1107.6.2.1.1, is that 2 percent of the units are required to be Type A units. It is anticipated that Group I-1 will experience a greater demand for accessible facilities because of the nature of the occupants and the frequency of occupant turnover. As such, this section requires that 4 percent of the sleeping units and their associated facilities (e.g., bathing and toilet facilities) must meet the criteria for Accessible units.

1107.5.1.2 Type B units. In structures with four or more dwelling units or sleeping units intended to be occupied as a residence, every dwelling unit and sleeping unit intended to be occupied as a residence shall be a Type B unit.

Exception: The number of Type B units is permitted to be reduced in accordance with Section 1107.7.

- As discussed in the general comments to this section, most Group I-1 assisted living facilities are intended to serve as a person's place of residence. Since a Group I-1 starts at an occupant load of 16 residents, the Type B criteria for any units that are not Accessible units are almost always required. The exception is a general reference to Section 1107.7, which addresses situations where it is logical to back off on the requirements for Type B units within a structure.

1107.5.2 Group I-2 nursing homes. Accessible units and Type B units shall be provided in nursing homes of Group I-2 occupancies in accordance with Sections 1107.5.2.1 and 1107.5.2.2.

- The requirements for accessibility in Group I-2 are based on the anticipated frequency of usage by disabled persons. There are different thresholds established for different types of health care occupancies, based on the nature of their activity (see Section 308.4). A nursing home is anticipated to have a high percentage of residents who use wheelchairs or some type of mobility aid.

1107.5.2.1 Accessible units. At least 50 percent but not less than one of each type of the dwelling units and sleeping units shall be Accessible units.

- Nursing homes, which generally provide long-term care, are more likely to have patients with physical disabilities. As such, 50 percent of the patient sleeping rooms and their associated facilities (e.g., bathing and toilet facilities) must meet the criteria for Accessi-
ble units. Sections 1104.3, Exception 2, and 1107.3, Exception 2, exempt any 44-inch (1118 mm) doors from the maneuvering clearance on the inside of the patient sleeping room. Wider doors are required in Section 1008.1.1 for Group I-2 facilities where residents are moved while in their beds.

Housing the elderly should not automatically be classified as a “nursing home.” Some residential care/assisted living facilities provide quarters for residents that more closely represent a residential setting (i.e., sleeping, eating, cooking and sanitation within the individual living accommodations) and the residents are more ambulatory than in a nursing home. Based on the anticipated frequency of residents needing wheelchairs, these facilities might be more appropriately classified within the 4- or 10-percent requirement for Accessible units (see Sections 1107.5.1.1 and 1107.5.3.1).

1107.5.2.2 Type B units. In structures with four or more dwelling units or sleeping units intended to be occupied as a residence, every dwelling unit and sleeping unit intended to be occupied as a residence shall be a Type B unit.

Exception: The number of Type B units is permitted to be reduced in accordance with Section 1107.7.

fat discussed in the general comments to this section, most Group I-2 nursing homes are intended to serve as a person’s place of residence. The Type B criteria for any units that are not Accessible units are almost always required. The exception is a general reference to Section 1107.7, which addresses situations where it is logical to back off on the requirements for Type B units within a structure.

1107.5.3 Group I-2 hospitals. Accessible units and Type B units shall be provided in general-purpose hospitals, psychiatric facilities and detoxification facilities of Group I-2 occupancies in accordance with Sections 1107.5.3.1 and 1107.5.3.2.

fat the requirements for accessibility in Group I-2 are based on the anticipated disabled occupants. There are different thresholds established for different types of health care occupancies based on the nature of their services and level of care provided. The anticipated need in hospitals is partially based on patients needing varying levels of assistance due to temporary disabilities resulting from illness or operations.

1107.5.3.1 Accessible units. At least 10 percent, but not less than one, of the dwelling units and sleeping units shall be Accessible units.

fat the anticipated percentage of patients in general-purpose hospitals is typically higher than 10 percent, there is also an anticipation that many of the patients will be routinely assisted by staff. Section 1109.2, Exception 5, exempts the bathrooms associated with critical care or intensive care. Sections 1104.3, Exception 2 and 1107.3, Exception 2, exempt any 44-inch (1118 mm) doors from the maneuvering clearance on the inside of the Accessible patient sleeping room. Wider doors are required in Section 1008.1.1 for Group I-2 facilities where there is movement of patients in their beds. In the case of psychiatric facilities, detoxification facilities or residential care/assisted facilities, it is less likely that the typical patient will be physically disabled.

1107.5.3.2 Type B units. In structures with four or more dwelling units or sleeping units intended to be occupied as a residence, every dwelling unit and sleeping unit intended to be occupied as a residence shall be a Type B unit.

Exception: The number of Type B units is permitted to be reduced in accordance with Section 1107.7.

fat discussed in the general comments to this section, most Group I-2 hospitals are not intended to serve as a person’s place of residence, therefore, Type B units are not required in most hospitals. However, whether or not a Group I-2 psychiatric or detoxification facility is a person’s place of abode is subject for interpretation. Please see the general discussion to this section for additional information. The exception is a general reference to Section 1107.7, which addresses situations where it is logical to back off on the requirements for Type B units within a structure.

1107.5.4 Group I-2 rehabilitation facilities. In hospitals and rehabilitation facilities of Group I-2 occupancies which specialize in treating conditions that affect mobility, or units within either which specialize in treating conditions that affect mobility, 100 percent of the dwelling units and sleeping units shall be Accessible units.

fat the requirements for accessibility in Group I-2 are based on the anticipated frequency of usage by disabled persons. There are different thresholds established for different types of health care occupancies based on the nature of their activity. In rehabilitation facilities that specialize in treating conditions that affect mobility, the anticipated need is very high compared to other Group I-2 facilities. In such cases, it is realistic to presume that the majority, if not all, of the patients will have some degree of mobility impairment and will, thus, require accessible features. Accordingly, all patient rooms and their associated bathing and toilet facilities are required to be Accessible units. Section 1104.3, Exception 2, and Section 1107.3, Exception 2, exempt any 44-inch (1118 mm) doors from the maneuvering clearance on the inside of the patient sleeping room. Wider doors are required in Section 1008.1.1 for Group I-2 facilities where there is movement of patients in their beds. While this facility may also be intended to be occupied as a residence, Accessible unit requirements are more restrictive than Type B requirements, so those needs are already addressed.

1107.5.5 Group I-3. Accessible units shall be provided in Group I-3 occupancies in accordance with Sections 1107.5.5.1 through 1107.5.5.3.

fat the requirement for accessibility in Group I-3 facilities was taken from the 2010 Standard (see Section
308.5 for Group I-3). Section 1107.5.5.1 contains requirements for general housing cells. Sections 1107.5.5.2 and 1107.5.5.3 are additional requirements for special types of cells or holding areas. While jail cells may be considered a detainee's residence, since the FHA does not cover detention and correctional facilities, Type B units are not required in Group I-3 occupancies.

1107.5.5.1 Group I-3 sleeping units. In Group I-3 occupancies, at least 2 percent, but not less than one, of the dwelling units and sleeping units shall be Accessible units.

- The requirement for sleeping units or cells in Group I-3 is for 2 percent of the general housing cells and their associated facilities to be Accessible units. The current trend in jail design is to group housing cells into "pods." Since the administration of the correctional facility will determine where detainees will reside, there are no requirements for distribution of the Accessible units. A correctional facility may decide to locate all its Accessible cells in one pod due to suicide prevention and other safety concerns. Sections 1103.2.14 and 1109.11 have exceptions for spaces shared by detainees for areas within the jail where Accessible units are not provided.

1107.5.5.2 Special holding cells and special housing cells or rooms. In addition to the Accessible units required by Section 1107.5.5.1, where special holding cells or special housing cells or rooms are provided, at least one serving each purpose shall be an Accessible unit. Cells or rooms subject to this requirement include, but are not limited to, those used for purposes of orientation, protective custody, administrative or disciplinary detention or segregation, detoxification and medical isolation.

Exception: Cells or rooms specially designed without protrusions and that are used solely for purposes of suicide prevention shall not be required to include grab bars.

- If special types of holding or housing cells are provided within a facility (e.g., orientation, protective custody, disciplinary detention, segregation, detoxification, medical isolation), at least one of each type must be an Accessible unit. A cell that is designed specifically for a suicide watch is required to meet Accessible unit criteria, but if a toilet is provided, grab bars are not required.

1107.5.5.3 Medical care facilities. Patient sleeping units or cells required to be Accessible units in medical care facilities shall be provided in addition to any medical isolation cells required to comply with Section 1107.5.5.2.

- When medical care facilities are provided within a detention or correctional facility, 10 percent of the units are required to be Accessible units. The intent is to be consistent with the hospital requirements found in Section 1107.5.3.1.

1107.6 Group R. Accessible units. Type A units and Type B units shall be provided in Group R occupancies in accordance with Sections 1107.6.1 through 1107.6.4.

- This section introduces four subsections that address accessibility requirements for occupancies in Group R. Criteria for Accessible units, Type A units and Type B units are specified in Chapter 10 of ICC A117.1.

The IRC references this chapter for accessibility provisions; therefore, this chapter may be applicable to housing covered under the IRC (see commentary, Section 1107.6.3). Structures referenced to Chapter 11 from the IRC would be considered Group R-3 for purposes of accessibility only.

1107.6.1 Group R-1. Accessible units and Type B units shall be provided in Group R-1 occupancies in accordance with Sections 1107.6.1.1 and 1107.6.1.2.

- The terms "dwelling unit" and "sleeping unit" are utilized instead of "guestrooms" so that the amenities in the units themselves are reflected. An exception applicable to small bed-and-breakfast style hotels is provided in Section 1103.2.11.

Hotels, motels, boarding houses and other short-term housing types are required to provide Accessible units. Where such facilities are also intended to be occupied as a residence, Type B unit criteria is applicable. For additional discussion, please see the general comments at the beginning of this chapter.

The following factors should be considered where persons can stay more or less than 30 days, including hotels, motels, corporate housing and seasonal vacation units, in determining the applicability of Type B unit criteria:

1. Amenities included inside the units, including kitchen facilities;
2. Whether the property is to be marketed to the public as short-term housing;
3. Whether the terms and length of the occupancy will be established through a lease or other written agreement; and
4. How payment is calculated (e.g., on a daily, weekly, monthly or yearly basis).

If the amenities and operation of the units are closer to those of apartments than of hotels, they are subject to Type B requirements. For example, if a hotel is marketed as short-term housing, payment is made monthly, and if the units contain kitchens, the hotel would be subject to Type B unit criteria. For additional information see the commentary at the beginning of this chapter and Section 1107.

1107.6.1.1 Accessible units. Accessible dwelling units and sleeping units shall be provided in accordance with Table 1107.6.1.1. All dwelling units and sleeping units on a site shall be considered to determine the total number of Accessi-
Accessible units shall be dispersed among the various classes of units. Roll-In showers provided in Accessible units shall include a permanently mounted folding shower seat.

The required number of Accessible dwelling or sleeping units in Group R-1 is indicated in Table 1107.6.1.1. The table requires Accessible units to include a variety of bathing options. Where roll-in-type showers are provided, this section requires that they must include folding shower seats mounted on the shower wall. These showers can then serve the dual purpose of roll-in and transfer showers, which is a requirement in ICC A117.1. ICC A117.1 also provides for a fixed-seat option in roll-in showers. That alternative would be considered to provide an equivalent level of accessibility.

For sites where the hotel rooms are provided in multiple buildings, all the units on the site should be considered to determine the number of Accessible units. For example, if a hotel consists of several small buildings on a site, the same number of Accessible units would be required as if the hotel was constructed as a single structure.

Accessible units must be dispersed among the different types of units. This is not an automatic requirement to disperse the Accessible units to different floor levels. When different classes of dwelling or sleeping units are available, special amenities must also be made available in the Accessible units, including suites or larger rooms, kitchenettes, executive levels, etc. For example, if sleeping units with three options of single room, suit or kitchenettes are provided, and two Accessible units are required, the Accessible units must be provided in two of the three options. If no other types of amenities are provided on other levels, the hotel could provide the Accessible units on the main level. Some hotels chose to provide all Accessible units on the main level due to concerns for disabled guests' ease of escape from the building during an emergency, such as a fire. Keep in mind that services available to guests (i.e., pools, exercise rooms, laundry rooms) must also be on an accessible route for guests in the Accessible units.

**ACCESSIBILITY**

1107.6.1.1 Accessible unit facilities. All interior and exterior spaces provided as part of or serving an Accessible dwelling unit or sleeping unit shall be accessible and be located on an accessible route.

**Exceptions:**

1. Where multiple bathrooms are provided within an Accessible unit, at least one full bathroom shall be accessible.

2. Where multiple-family or assisted bathrooms serve an Accessible unit, at least 50 percent but not less...
3. Five percent, but not less than one bed shall be accessible.

- This section reinforces the provision in Section 1107.3, which requires that spaces that serve an accessible unit are required to be accessible. Exception 1 addresses when an accessible unit is a suite where multiple bathrooms are provided. Revisions in the 2009 edition of ICC A117.1 for Accessible units also allow this exception. Exception 2 would be utilized in a hotel with a group of bathrooms in a central location. This is consistent with Section 1109.2, Exception 3, which requires the bedrooms to be large enough to allow for the bed to be accessible. In a multiple-bedroom or a dormitory-type setup, such as in a scout camp, at least one bed would be accessible. ICC A117.1 requires beds to have an adjacent clear floor space and to be on a bed frame (instead of a platform) to allow for the use of a Hoyer lift for transfer.

1107.6.1.2 Type B units. In structures with four or more dwelling units or sleeping units intended to be occupied as a residence, every dwelling unit and sleeping unit intended to be occupied as a residence shall be a Type B unit.

- Most hotels and motels are not intended to be occupied as a residence; therefore, the criteria for Type B units would not be applicable. However, in certain situations, extended-stay hotels or similar corporate housing arrangements are required to meet Type B unit criteria. For additional information on how to determine if this section is applicable, see the comments at the beginning of this chapter and Sections 1107 and 1107.6.1. The Accessible sleeping units required by Section 1107.6.1.1 exceed Type B unit requirements. The exception is a general reference to Section 1107.7, which addresses situations where it is logical to back off on the requirements for Type B units within a structure.

1107.6.2 Group R-2. Accessible units, Type A units and Type B units shall be provided in Group R-2 occupancies in accordance with Sections 1107.6.2.1 and 1107.6.2.2.

- The terms "dwelling unit" and "sleeping unit" are utilized instead of "apartment," "dorm room," "sleeping accommodations," "suites," etc., so that the amenities in the units themselves are reflected and for consistent application within all Group R-2 facilities. Since these types of facilities are intended to be occupied as a residence, Type B unit criteria would be applicable. For a complete discussion, please see the comments to this chapter and this section.

Timeshare properties require a different analysis. Timeshare owners have an interest in the property, yet they typically stay less than 30 days. For a time-share property to be subject to Type B requirements, the owners must have an ownership interest in the property itself, rather than in just coming to the area for a vacation without ties to a particular property. The following additional factors must be considered to determine whether timeshare units must meet Type B design and construction requirements:

1. Whether traditional rights of ownership are to be unrestricted (e.g., whether the timeshare owner has the right to occupy, alter or exercise control over a particular unit over a period of time);

2. The nature of the ownership interest conveyed (e.g., fee simple); and

3. The extent to which operations resemble those of a hotel, motel or inn (e.g., reservation, central registration, meals, laundry service).

If an owner's rights regarding the units are subject to few restrictions and the operation of the units is closer to that of condominiums/apartments rather than hotels, the units are subject to Type B requirements.

1107.6.2.1 Apartment houses, monasteries and convents. Type A units and Type B units shall be provided in apartment houses, monasteries and convents in accordance with Sections 1107.6.2.1.1 and 1107.6.2.1.2.

- Unless they receive some type of federal funding, apartments and condominiums are not covered by the 2010 Standard. Note that the code deals with apartments and condominiums in the same manner when dealing with accessibility requirements. However, owners of Type A units do have some options under the provisions for alterations in Section 3411.6.

Convents and monasteries are associated with religious organizations, so they are not covered by ADA requirements. Since all these facilities may serve as a person's residence, they are covered by FHA. A convent or monastery cannot be sued under FHA for selectively limiting its residents; however, it must comply with the FHA construction requirements for the residential units that it provides. The scope for Type B units is consistent with FHA requirements.

1107.6.2.1.1 Type A units. In Group R-2 occupancies containing more than 20 dwelling units or sleeping units, at least 2 percent but not less than one of the units shall be a Type A unit. All Group R-2 units on a site shall be considered to determine the total number of units and the required number of Type A units. Type A units shall be dispersed among the various classes of units.

Exceptions:

1. The number of Type A units is permitted to be reduced in accordance with Section 1107.7.

2. Existing structures on a site shall not contribute to the total number of units on a site.

- To be able to better accommodate a person who uses a wheelchair, 2 percent of apartments and condominiums are required to provide Type A units
within the development. Congregate residences, such as convents and monasteries, must also provide Type A units. (Other types of congregate living arrangements are addressed in Section 1107.6.2.2.) The housing industry has been concerned that dwelling units equipped with the full range of features to accomplish accessibility will not be marketable to people without disabilities. The Type A requirements are intended to accomplish a middle ground that will satisfy both needs. Allowances made during the construction process for future conversion for accessibility, such as reinforcement in bathroom walls for future installation of grab bars, will allow a unit to be altered later at a considerably lesser cost.

Type A units are required when the site contains more than 20 dwelling units or sleeping units. So that there is a consistent number of Type A units in multiunit buildings sites based on the size of a development as a whole, all the buildings are added together to determine the number required. For example, a 300-unit building would require six Type A units, and a development with 75 buildings with four units per building would also require six Type A units. Exception 2 is in recognition that a development may be built in stages. Only the units that are being constructed as part of that development phase are considered in determining the number of Type A units.

The Type A units must be dispersed among the classes of units provided. For example, if one-, two- and three-bedroom units are available with the development and two Type A units are required, it is the designer's choice as to which two of the options to provide as Type A units. The designer, however, cannot choose to only provide the one-bedroom option with both Type A units. This is not intended to require Type A units to be provided in different buildings in a multiple-building site. Many times in a multiple-building developments, there are shared facilities such as clubhouses or pools. The designer may choose to locate the Type A units in the building closest to those amenities for ease of access for the residents. This is acceptable as long as the dispersion by type requirement is met.

In limited circumstances, townhouse-style units can be Group R-2 facilities (see Section 310.4). If multistory units are provided for the Type A units, ICC A117.1 would require an accessible route between levels. Within the dwelling, this can be provided by a passenger elevator, a LULA, a private residence elevator (see Section 1109.7) or a platform lift (see Section 1109.8, Item 4). A possible alternative would be to provide some single-story units within the development to meet Type A-unit requirements. If the amenities and size are the same, they could be considered the same type as a multilevel unit. The multistory exception in Section 1107.7.2 is not applicable to Type A units.

Exception 1 allows the number of Type A units to be reduced in accordance with Section 1107.7.5 when the building's first-floor elevation is required to be raised due to flood-plain regulations. This is the only exception that allows for a reduction in the number of Type A units required.

1107.6.2.1.2 Type B units. Where there are four or more dwelling units or sleeping units intended to be occupied as a residence in a single structure, every dwelling unit and sleeping unit intended to be occupied as a residence shall be a Type B unit.

Exception: The number of Type B units is permitted to be reduced in accordance with Section 1107.7.

When four or more dwelling or sleeping units are provided in a single structure, those units must meet Type B criteria (note the use of the term "structure" instead of "building"). The criteria is applicable if four dwelling units are built together, regardless of fire walls [see Figures 1107.6.2.1.2(1) and 1107.6.2.1.2(2)]. The exception is a general reference to Section 1107.7, which addresses situations where it is logical to back off on the requirements for Type B units within a structure.

Type A units provided in accordance with Section 1107.6.2.1.1 exceed Type B unit requirements.

1107.6.2.2 Group R-2 other than apartment houses, monasteries and convents. In Group R-2 occupancies, other than
apartment houses, monasteries and convents, Accessible units and Type B units shall be provided in accordance with Sections 1107.6.2.2.1 and 1107.6.2.2.2.

- This would include congregate housing types, such as dormitories, boarding houses, fraternities and sororities. Nontransient hotels and motels would typically be grouped with these requirements since they may also be operating as transient and nontransient. A building used for two purposes must be designed for the most restrictive provisions (see Section 302.1). Time shares should comply with Section 1107.6.2.1 or 1107.6.2.2, based on whichever it most closely represents (see also commentary, Section 1107.6.2).

  Dormitories are typically located in universities. Universities are required to make all programs accessible; therefore, dormitories are covered by ADA requirements. Boarding houses, fraternity houses and sorority houses have similar types of living arrangements; therefore, it seems logical that the same anticipated need should result in the same level of required Accessible units. Since all these facilities typically serve as a person's residence, they are covered by FHA. The scope for Accessible units is consistent with ADA requirements for dormitories. The scope for Type B units is consistent with FHA requirements.

1107.6.2.2.1 Accessible units. Accessible dwelling units and sleeping units shall be provided in accordance with Table 1107.6.1.1.

- The number of Accessible units required in these Group R-2 facilities is the same as that required in hotels and motels. All associated and shared areas (e.g., bathrooms, kitchens, study rooms) must also be accessible in accordance with Section 1002 of ICC A117.1. A certain number of the Accessible units must have associated bathrooms equipped with a roll-in shower.

1107.6.2.2 Type B units. Where there are four or more dwelling units or sleeping units intended to be occupied as a residence in a single structure, every dwelling unit and every sleeping unit intended to be occupied as a residence shall be a Type B unit.

  Exception: The number of Type B units is permitted to be reduced in accordance with Section 1107.7.

- The FHA specifically considers dormitories as places where students live, even if it is just for the school year. Therefore, when four or more sleeping units are provided in a single structure, those units must meet Type B criteria. The Accessible sleeping units required by Section 1107.6.2.2.1 exceed Type B unit requirements. The exception is a general reference to Section 1107.7, which addresses situations where it is logical to back off on the requirements for Type B units within a structure.

1107.6.3 Group R-3. In Group R-3 occupancies where there are four or more dwelling units or sleeping units intended to be occupied as a residence in a single structure, every dwelling unit and sleeping unit intended to be occupied as a residence shall be a Type B unit.

  Exception: The number of Type B units is permitted to be reduced in accordance with Section 1107.7.

- When four or more dwelling or sleeping units are provided in a single structure, those units must meet Type B criteria (note the use of the term "structure" instead of "building"). Since Group R-3 structures can be a series of one or two dwellings per building separated by fire walls (see Section 310.5), the provisions for Type B units would apply to groups of R-3 units. Transient congregate residences with 10 or fewer occupants and nontransient congregate residences with 16 or fewer occupants are permitted to comply with Group R-3 construction requirements (see Section 310.5). Small bed-and-breakfast-type hotels are exempted from accessibility under Section 1103.2.11. These congregate residences may be

Figure 1107.6.2.1.2(2)
TWO STRUCTURALLY JOINED BUILDINGS ARE TREATED AS A SINGLE STRUCTURE
covered by ADAAG, so a designer/owner may want to consider providing Accessible units (see Sections 1107.6.1.1 and 1107.6.2.2.1) in facilities such as hotels, dormitories, sororities and fraternities. The criteria is applicable if four dwelling units are built together, regardless of fire walls. The exception is a general reference to Section 1107.7, which addresses situations where it is logical to back off on the requirements for Type B units within a structure.

Section 101.2, Exception 1 states that detached one- and two-family dwellings and townhouses that are both three stories or less and have an independent means of egress must comply with the IRC. Section 1103.2.4 exempts detached single-family homes and duplexes from accessibility requirements, but not townhouses. In the IRC, townhouses are further defined as extending from foundation to roof and open on at least two sides; therefore, the typical side-by-side townhouse is constructed using the IRC. Any configuration of townhouses that does not meet all four criteria has to be constructed under the IBC as Group R-2 or possibly Group R-3. If the structure is divided into one- or two-dwelling units per building with fire walls, the structure is a Group R-3 (see commentary, Sections 310.4 and 310.5). Group I-1 and I-2 institutional-type facilities with five or fewer residents and Group R-4 facilities have the option of complying with the code or the IRC, since they often operate similar to a single-family home (see Sections 308.3.1, 308.3.2, 308.4.1 and 310.6). Day care facilities within single-family homes are specifically addressed under Section 1103.2.12. Live/work units are specifically addressed under Section 1003.2.13.

Section 320.1 of the IRC refers any structure with four or more sleeping units or dwelling units back to the code as Group R-3 buildings for accessibility requirements. Since these types of facilities typically serve as a person’s permanent residence, the units must meet Type B criteria. The exception is a general reference to Section 1107.7, which addresses situations where it is logical to back off on the requirements for Type B units within a structure.

1107.6.4 Group R-4. Accessible units and Type B units shall be provided in Group R-4 occupancies in accordance with Sections 1107.6.4.1 and 1107.6.4.2.

- Group R-4 facilities are limited to between six and 16 residents. A Group R-4 is basically a small Group I-1 facility (see Sections 308.3.2 and 310.6). The Group R-4 occupancy was originally developed in response to some lawsuits filed under FHA concerning homes for mentally disabled adults. Under the past legacy codes, a structure where persons live in a supervised environment is a Group I occupancy. In neighborhoods zoned residential only, a variance is required if a group of mentally disabled adults wants to move into a single-family-style dwelling. Additionally, Group I facilities are typically required to be sprinklered throughout with an NFPA 13 system. This type of sprinkler system is not what is typically used in a single-family home. The 16-resident criteria is based on two things: (1) In the last census, 98 percent of the households in the United States that identified themselves as single family had 16 or fewer residents; and (2) in facilities where residents are capable of self-preservation, the number 16 also happens to be the limit of residents permitted in a building where an NFPA 13D sprinkler system can be utilized. Establishing these types of facilities as part of Group R eliminates potential conflict with the zoning issue. The limit on the number of residents and allowing the alternative sprinkler system addresses the discrimination in housing concerns and provides a reasonable level of sprinkler protection for the residents.

1107.6.4.1 Accessible units. At least one of the dwelling or sleeping units shall be an Accessible unit.

- The requirement for one sleeping unit and its associated facilities (e.g., bathing room) to meet Accessible unit criteria is consistent with Group I-1 requirements.

Section 1002 of ICC A117.1 provides the technical criteria for Accessible sleeping units.

1107.6.4.2 Type B units. In structures with four or more dwelling units or sleeping units intended to be occupied as a residence, every dwelling unit and sleeping unit intended to be occupied as a residence shall be a Type B unit.

Exception: The number of Type B units is permitted to be reduced in accordance with Section 1107.7.

- Since these types of facilities typically serve as a person’s permanent residence, the sleeping unit must meet Type B criteria. The Accessible sleeping unit required by Section 1107.6.4.1 exceeds Type B unit requirements. The exception is a general reference to Section 1107.7, which addresses situations where it is logical to back off on the requirements for Type B units within a structure. Since Group R-4 is a congregate residence, this section would be applicable when four or more sleeping units are provided.

1107.7 General exceptions. Where specifically permitted by Section 1107.5 or 1107.6, the required number of Type A units and Type B units is permitted to be reduced in accordance with Sections 1107.7.1 through 1107.7.5.

- Section 1107.5 or 1107.6 establish when Accessible, Type A or Type B units are expected to be provided. Section 1107.7 covers the general exceptions where it is reasonable and logical to not provide accessibility for some of the units. This would be consistent with the general provisions of Section 1103.2.1. Code users should start out with the assumption that everything, in this case Group I and R dwelling and sleeping units, is required to be accessible, and then back off from that level of accessibility when specific exceptions are indicated. Note that there are no exceptions for Accessible units. While Type A units are mentioned in Section 1107.7.1, the only exception for Type A units is found in Section 1107.7.5.

Sections 1107.7.1 through 1107.7.4 primarily deal with nonelevator buildings. If elevators are provided, except as addressed in Section 1107.7.3, all units in
the building are required to meet Type B criteria or better. Providing access to the upper floors in these cases would require either an elevator or a ramp system (or multiple elevators or ramps), both of which would be unreasonable. These exceptions are intended to be consistent with the scope of FHAG. It should be noted that these are only exceptions to the requirements for Type B dwelling units.

In accordance with Section 1107.2, Accessible and Type A units provide a higher level of accessibility than Type B units. Therefore, if Accessible or Type A units are provided on the accessible levels, this would exceed Type B-unit requirements. For clarity in the commentary for the exceptions, only Type B units will be mentioned.

1107.7.1 Structures without elevator service. Where no elevator service is provided in a structure, only the dwelling units and sleeping units that are located on stories indicated in Sections 1107.7.1.1 and 1107.7.1.2 are required to be Type A units and Type B units, respectively. The number of Type A units shall be determined in accordance with Section 1107.6.2.1.1.

- Only the units located on the floor levels defined in Sections 1107.7.1.1 and 1107.7.1.2 are required to contain Type A or Type B units when no elevator service is provided in the building. Floor levels that do not meet the criteria are not required to have an accessible route to that level, nor do the dwelling units or sleeping units on those levels have to meet Type A or Type B unit criteria. The building must still have the minimum number of Type A units required on the first floor.

1107.7.1.1 One story with Type B units required. At least one story containing dwelling units or sleeping units intended to be occupied as a residence shall be provided with an accessible entrance from the exterior of the structure and all units intended to be occupied as a residence on that story shall be Type B units.

- This section basically states that Type B units must be provided on at least one level of a building that is not equipped with elevator service. For example, on a flat site, a two-story structure with Type B dwelling units or sleeping units on the first floor would not require an accessible route to, or Type B units on, the second floor (see Figure 1107.7.1.1).

1107.7.1.2 Additional stories with Type B units. On all other stories that have a building entrance in proximity to arrival points intended to serve units on that story, as indicated in Items 1 and 2, all dwelling units and sleeping units intended to be occupied as a residence served by that entrance on that story shall be Type B units.

1. Where the slopes of the undisturbed site measured between the planned entrance and all vehicular or pedestrian arrival points within 50 feet (15 240 mm) of the planned entrance are 10 percent or less, and

2. Where the slopes of the planned finished grade measured between the entrance and all vehicular or pedestrian arrival points within 50 feet (15 240 mm) of the planned entrance are 10 percent or less.

Where no such arrival points are within 50 feet (15 240 mm) of the entrance, the closest arrival point shall be used unless that arrival point serves the story required by Section 1107.7.1.1.

- This section addresses the idea that a building could have two levels that would be provided with accessible routes. This could be a structure built into a hill or a building with the first level a few feet down and the second level a few feet up from grade level [see Figure 1107.7.1.2(1)].

The basic test for multiple accessible levels is to check for the slope between the building entrance and any arrival points within a 50-foot (15 240 mm) arc. If no arrival points (e.g., sidewalk, parking) are within that 50-foot (15 240 mm) arc, the closest arrival point should be used as a reference. If the slope between these two points is 10 percent or less both before and after grading of the site, than an accessible route is required to that level [see Figures 1107.7.1.2(2) and 1107.7.1.2(3)].

In the case of sidewalks, the closest point to the

---

Figure 1107.7.1.1
DWELLING UNITS ON ONE STORY
entrance will be where a public sidewalk entering the site intersects with the sidewalk to the entrance. In the case of resident parking areas, the closest point to the planned entrance will be measured from the entry point to the parking area that is located closest to the planned entrance. The measurement for elevation should be taken from the center of the entrance door to the top of the pavement at the arrival point.

Figure 1107.7.1.2(1)
BUILDING HAS TWO ACCESSIBLE LEVELS, EACH WITH AN ACCESSIBLE ENTRANCE ON AN ACCESSIBLE ROUTE

For SI: 1 foot = 304.8 mm.

Figure 1107.7.1.2(2)
SINGLE BUILDING WITH MULTIPLE COMMON ENTRANCES—LOWER GROUND FLOOR UNITS MAY BE COVERED
1107.7.2 Multistory units. A multistory dwelling or sleeping unit which is not provided with elevator service is not required to be a Type B unit. Where a multistory unit is provided with external elevator service to only one floor, the floor provided with elevator service shall be the primary entry to the unit, shall comply with the requirements for a Type B unit and a toilet facility shall be provided on that floor.

- Section 1107.7.2 addresses multistory dwelling units (see the definition in Chapter 2). For example, the typical townhouse scenario, where there is a series of two-story units adjacent to each other in a single structure, would not require Type B units. If multistory units are provided in a building containing elevators and access is provided at only one floor level, that level must be accessible and contain a toilet facility [see Figures 1107.7.2(1) and 1107.7.2(2)].

1107.7.3 Elevator service to the lowest story with units. Where elevator service in the building provides an accessible route only to the lowest story containing dwelling or sleeping units intended to be occupied as a residence, only the units on that story which are intended to be occupied as a residence are required to be Type B units.

- Section 1107.7.3 exempts dwelling units located on upper floors as long as the dwelling units on the first floor containing dwelling units are at least Type B units. For example, a three-story structure has a business on the first floor with apartments on the second and third levels. An accessible route is required to the second level, and all dwelling units on that level are required to be Type B units; however, an accessible route and Type B units are not required to the third level. (Note: If an elevator is utilized to provide access to only the lowest level containing dwelling or sleeping units, this building would not be considered an "elevator" building) [see Figures 1107.7.3(1) and 1107.7.3(2)].

1107.7.4 Site impracticality. On a site with multiple nonelevaor buildings, the number of units required by Section 1107.7.1 to be Type B units is permitted to be reduced to a percentage which is equal to the percentage of the entire site having grades, prior to development, which are less than 10 percent, provided that all of the following conditions are met:

1. Not less than 20 percent of the units required by Section 1107.7.1 on the site are Type B units;
2. Units required by Section 1107.7.1, where the slope between the building entrance serving the units on that story and a pedestrian or vehicular arrival point is no greater than 8.33 percent, are Type B units;
3. Units required by Section 1107.7.1, where an elevated walkway is planned between a building entrance serv-
ing the units on that story and a pedestrian or vehicular arrival point and the slope between them is 10 percent or less are Type B units; and

4. Units served by an elevator in accordance with Section 1107.7.3 are Type B units.

Section 1107.7.4 addresses multiple buildings on a sloping site. For example, if an apartment complex was built on a steep or hilly site, the number of Type B dwelling units required on the ground floor could be reduced due to the difficulty of providing accessible routes. A minimum of 20 percent of the total ground floor units on the site must be Type B units, regardless of site complications (see Figure 1107.7.4).

2012 INTERNATIONAL BUILDING CODE® COMMENTARY  11-35
For Si: 1 inch = 25.4 mm, 1 foot = 304.8 mm.
1107.7.5 Design flood elevation. The required number of Type A units and Type B units shall not apply to a site where the required elevation of the lowest floor or the lowest horizontal structural building members of nonelevator buildings are at or above the design flood elevation resulting in:

1. A difference in elevation between the minimum required floor elevation at the primary entrances and vehicular and pedestrian arrival points within 50 feet (15,240 mm) exceeding 30 inches (762 mm), and

2. A slope exceeding 10 percent between the minimum required floor elevation at the primary entrances and vehicular and pedestrian arrival points within 50 feet (15,240 mm).

Where no such arrival points are within 50 feet (15,240 mm) of the primary entrances, the closest arrival points shall be used.

- Residential structures in flood hazard areas must be elevated (see Section 1612). If, based on the required floor elevation, the criteria in either Item 1 or 2 are met, it is considered that an accessible route to the units is not feasible. This section applies to both Type A and Type B dwelling units [see Figures 1107.7.5(1) and 1107.7.5(2)].

- Flood-resistant requirements, in part, address concerns about public safety. The code provides for reductions in the level of accessibility in residential facilities without elevators that are elevated to comply with Section 1612. Note that the exception is based on the required design-flood elevation. If the first-floor elevation is higher than the design-flood elevation by choice, the measurement would still be from the design-flood elevation rather than the actual floor elevation.

SECTION 1108
SPECIAL OCCUPANCIES

1108.1 General. In addition to the other requirements of this chapter, the requirements of Sections 1108.2 through 1108.4 shall apply to specific occupancies.

- The criteria provided herein are occupancy specific, and are intended to result in a reasonable level of accessibility in areas with assembly seating, self-service storage facilities and judicial facilities.

1108.2 Assembly area seating. A building, room or space used for assembly purposes with fixed seating shall comply with Sections 1108.2.1 through 1108.2.5. Lawn seating shall comply with Section 1108.2.6. Assistive listening systems shall comply with Section 1108.2.7. Performance areas viewed from assembly seating areas shall comply with Section 1108.2.8. Dining areas shall comply with Section 1108.2.9.

- Sections 1108.2.1 through 1108.2.8 specifically address facilities with fixed seating utilized for purposes of viewing an event, typically facilities and spaces of occupancies of Groups A-1, A-3, A-4 and A-5. These criteria would also be applicable in assembly-type spaces with fixed seats that are located in buildings of other occupancies. The requirement for access to services; number and dispersion of wheelchair spaces and their associated companion seats; designated aisle seats; lawn seating; assistive listening systems and performance areas are addressed. The requirements for seating in areas for eating or drinking, typically Group A-2 spaces or facilities, and the dispersion of this seating are addressed in Section 1108.2.9.

1108.2.1 Services. If a service or facility is provided in an area that is not accessible, the same service or facility shall be provided on an accessible level and shall be accessible.

- This section establishes an important concept. The intent is that all types of services provided by a facility must be accessible. For example, a stadium may have a particular section of seating that is not accessible (assuming that the required number and dispersion of spaces is in compliance with the code). This section establishes that if a souvenir stand is located in or near that section, one of three circumstances would apply: an additional souvenir stand must be provided in the facility on an accessible level; the souvenir stand would have to be relocated to an accessible level or the section where the souvenir stand is located must be made accessible. This section also emphasizes that not only must that service or facility be located on an accessible level, the service itself must also be accessible. Obviously, it would be inappropriate to locate a souvenir stand on an accessible level if the approach or entrance to that area is inaccessible.

1108.2.2 Wheelchair spaces. In theaters, bleachers, grandstands, stadiums, arenas and other fixed seating assembly areas, accessible wheelchair spaces shall be provided in accordance with Sections 1108.2.2.1 through 1108.2.2.4.

- The intent of this section is to provide a reasonable number of spaces in an assembly occupancy with fixed seating to accommodate persons who use wheelchairs. Demographic statistics from the National Center for Health Statistics on the number of noninstitutionalized Americans who use wheelchairs indicate that these requirements are realistic. These required wheelchair spaces consist of an open, available floor space in which the wheelchair takes the place of the fixed seat that would otherwise occupy that space. Section 1108.2.3 is consistent with ICC A117.1 in requiring companion seating adjacent to each wheelchair space.

1108.2.2.1 General seating. Wheelchair spaces shall be provided in accordance with Table 1108.2.2.1.

- The number of required wheelchair spaces is indicated in Table 1108.2.2.1 and is based on the total number of fixed seats set up to view the same event, with the exception of box seats covered in Sections 1108.2.2.2 and 1108.2.2.3. For example, the fixed seating on all levels and all types provided in a sports stadium, excluding box seats, is used to calculate the
number of required wheelchair spaces for the general seating. The requirements for box- or suite-type seating are calculated separately. Seating provided in different rooms, such as in a series of lecture halls in a university, must be calculated separately. Note that the percentage of wheelchair spaces is less for facilities with a capacity of more than 5,000. The industry has been able to provide statistics to show that the higher percentage of wheelchair spaces is not typically utilized in large facilities.

<tr>
<td>5,001 and over</td>
<td>36 plus 1 for each 200, or fraction thereof, over 5,000</td>
</tr>
</tbody>
</table>

This table sets forth the required number of wheelchair spaces based on the capacity of seating in the space containing the fixed seating. Any fixed seating with less than four seats is not required to provide wheelchair spaces. There is special criteria for wheelchair spaces in facilities with a seating capacity of over 500 and over 5,000. For example, six wheelchair spaces would be required for an assembly space with a seating capacity of 500. Seven wheelchair spaces would be required for a seating capacity of 501 through 650. Both of the last two rows use the term "or fraction thereof" to designate the next step up.

1108.2.2.2 Luxury boxes, club boxes and suites. In each luxury box, club box, and suite within arenas, stadiums and grandstands, wheelchair spaces shall be provided in accordance with Table 1108.2.2.1.

When luxury boxes, club boxes or suites are provided, each luxury box, club box or suite must have an accessible route to that box and at least one wheelchair space and associated companion space. If the luxury box, club box or suite has more than 25 seats, the number of required wheelchair spaces is increased in accordance with Table 1108.2.2.1. For example, if a stadium has three luxury boxes with 51 seats in each, at least four wheelchair spaces and their associated companion seats must be provided in each box. While the total of all three luxury boxes (i.e., 153 occupants) would only require five total wheelchair spaces, these specific types of boxes must be calculated individually.

Luxury boxes are most commonly found in larger facilities, thus the reference to arenas, stadiums and grandstands. Boxes that are portions of balconies, such as in an opera house, or boxes separated by rails in general seating areas, such as behind home plate in baseball stadiums, are addressed in Section 1108.2.2.3.

1108.2.2.3 Other boxes. In boxes other than those required to comply with Section 1108.2.2.2, the total number of wheelchair spaces provided shall be determined in accordance with Table 1108.2.2.1. Wheelchair spaces shall be located in not less than 20 percent of all boxes provided.

- Examples of the boxes covered in this section are the seats separated by railings or low walls behind home plate in a baseball stadium (see Figure 1108.2.2.3(1)), or side balconies in opera houses (see Figure 1108.2.2.3(2)). Luxury boxes are typically located in a separate level, and are often attached to
some type of party room behind a group of seats. When boxes other than luxury boxes, club boxes or suites are provided, at least 20 percent of the boxes must have an accessible route to that box and at least one wheelchair space and associated companion space in that box. The total number of box seats is utilized to calculate the total number of required wheelchair spaces in accordance with Table 1108.2.2.1. For example, if a stadium has five boxes with 51 seats in each, the total of all five boxes (i.e., 255 occupants) would require five total wheelchair spaces. The wheelchair spaces could be located in one box (i.e., 20 percent minimum) or dispersed to all five boxes. Note that there is additional dispersion criteria for assembly seating based on lines of sight in Section 802.8 of ICC A117.1, as well as dispersion by level in Section 1108.2.4.

1108.2.4 Team or player seating. At least one wheelchair space shall be provided in team or player seating areas serving areas of sport activity.

Exception: Wheelchair spaces shall not be required in team or player seating areas serving bowling lanes that are not required to be located on an accessible route in accordance with Section 1109.15.4.1.

Accessible seating for sports teams and players is a logical code requirement that allows players to maintain team participation when injured. This requirement coordinates with the new 2010 Standard.

The exception acknowledges that only 5 percent of lanes in bowling facilities are required to be provided with an accessible route. Since teams sit at their lanes while playing, this provides a balance between player seating and access to the playing field (see Section 1109.15.4.1).

1108.2.3 Companion seats. At least one companion seat shall be provided for each wheelchair space required by Sections 1108.2.2.1 through 1108.2.2.3.

A companion seat allows a friend, relative, associate, etc., to accompany a person using a wheelchair at an event and to share in the experience with the same level of companionship as others attending the event. The ICC A117.1 standard permits two wheelchair spaces to be located next to each other; however, each wheelchair space must also be adjacent to at least one companion seat. Accessible seating areas are sometimes provided with nonfixed companion chairs allowing the users to adjust the adjacency of seats and wheelchair spaces to their liking. If fixed seats are provided, the companion seat must have shoulder alignment with the person using the wheelchair space.

1108.2.4 Dispersion of wheelchair spaces in multilevel assembly seating areas. In multilevel assembly seating areas, wheelchair spaces shall be provided on the main floor level and on one of each two additional floors or mezzanine levels. Wheelchair spaces shall be provided in each luxury box, club box and suite within assembly facilities.

Exceptions:
1. In multilevel assembly seating areas utilized for worship services where the second floor or mezzanine level contains 25 percent or less of the total seating capacity, wheelchair spaces shall be permitted to all be located on the main level.
2. In multilevel assembly seating areas where the second floor or mezzanine level provides 25 percent or less of the total seating capacity and 300 or fewer seats, all wheelchair spaces shall be permitted to be located on the main level.
3. Wheelchair spaces in team or player seating serving areas of sport activity are not required to be dispersed.

When facilities provide seating on multiple levels, wheelchair spaces must also be provided on multiple levels. For example, if a theater has a main level and a balcony level, wheelchair spaces must be provided on both. If a theater has a main level and two balcony levels, wheelchair spaces must be provided on the main level and at least one of the two balcony levels. While the term "level" is difficult to define in some assembly arrangements, the intent is to provide the wheelchair user with a choice of seating similar to what is available to all persons in the space. A "level" is not each time that there is a step-down to another row of seating. Subjective judgment on the part of both the designer and the building official is required for each individual facility.

There are three specific exceptions to this multi-level dispersion requirement.

Exception 1 is applicable to assembly spaces utilized for worship services. There is typically not a cost or line-of-sight issue in this type of facility, as there is in other assembly seating areas. The balcony is not required to contain accessible seating or have an accessible route, as long as accessible seating is provided on the main level and the balcony does not contain more than 25 percent of the seating.

Exception 2 is applicable to balconies in assembly facilities with a limited number of seats in the upper level. If accessible seating is provided on the main level and the balcony contains less than 25 percent of the seating and less than 300 seats, then the balcony is not required to contain accessible seating or have an accessible route.

Exception 3 relieves the requirement for wheelchair space dispersion among the various team or player seating options that may be provided in a facility. However, there must be at least one wheelchair space for each team.

The dispersion requirements in the code must be combined with the additional wheelchair dispersion requirements in ICC A117.1, including side to side (horizontally) across a venue, front to back (vari-.
ACCESSIBILITY

ety of distances) within the seating, and by type (distinct service or amenities) of seating. The standard also looks at requirements for line of sight or seated or standing spectators. Wheelchair spaces and their associated companion seats may be grouped, but must, at a minimum, be distributed into the number of locations indicated in Table 802.10 of ICC A117.1.

For requirements for accessible means of egress from these wheelchair spaces, please see Sections 1007.1, Exception 3, 1028.5.1 and 1028.8.

1108.2.5 Designated aisle seats. At least 5 percent, but not less than one, of the total number of aisle seats provided shall be designated aisle seats and shall be the aisle seats located closest to accessible routes.

Exception: Designated aisle seats are not required in team or player seating serving areas of sport activity.

- Designated aisle seats allow some persons with mobility impairments to be able to easily access certain seats along aisles. Due to an impairment, it may be difficult or impossible for some to move further into the narrow space between rows. It is not the intent of the designated aisle seats to be transfer locations. The person using this space can be someone using a walker, crutches or cane or anyone who may have difficulty with steps; hence, the requirement that the designated aisle seats be close to accessible routes. When seats have armrests, ICC A117.1 requires each designated aisle seat to have a folding or retractable armrest allowing easier access or better fit.

1108.2.6 Lawn seating. Lawn seating areas and exterior overflow seating areas, where fixed seats are not provided, shall connect to an accessible route.

- Lawn seating on both flat and sloped sites is fairly common at less formal venues. It may be the only type of seating provided or one of several options. Sometimes lawns are overflow areas, with or without movable chairs, located beyond the fixed seating areas. In any case, these lawn areas must be located on an accessible route. Access onto the lawn seating depends on the ability of the person and/or assistance from companions (see Figure 1108.2.6).

1108.2.7 Assistive listening systems. Each building, room or space used for assembly purposes where audible communications are integral to the use of the space shall have an assistive listening system.

Exception: Other than in courtrooms, an assistive listening system is not required where there is no audio amplification system.

- This section is intended to accommodate people with a hearing impairment. Assembly seating areas, such as stadiums, theaters, auditoriums, lecture halls and similar spaces, are required to make provisions for the use of assistive listening devices in accordance with Section 1108.2.7.1 and Table 1108.2.7.1. In these assembly areas, audible communication is often integral to the use and full enjoyment of the space. This requirement offers the possibility for individuals with hearing impairments to attend functions in these facilities without having to give advance notice and without disrupting the event in order to have a portable assistive listening system set up and made ready for use.

There are three primary types of listening systems available: induction loop, AM/FM and infrared. Each type of system has certain advantages and disadvantages that the designer should take into consideration when choosing the type of system that is most appropriate for the intended application. Signage notifying the general public of the availability of these systems must be provided in accordance with Section 1110.3.

If an audio amplification system is not provided within a facility, an assistive listening system is not required. Given the essential nature of the proceedings, this exception is not applicable to courtrooms. All courtrooms must have an assistive listening system.

1108.2.7.1 Receivers. Receivers shall be provided for assistive listening systems in accordance with Table 1108.2.7.1.

Exceptions:

1. Where a building contains more than one room or space used for assembly purposes, the total number of required receivers shall be permitted to be calculated according to the total number of seats in the building, provided that all receivers are usable with all systems and if the rooms or spaces used for assembly purposes required to provide assistive listening are under one management.

2. Where all seats in a building, room or space used for assembly purposes are served by an induction loop assistive listening system, the minimum number of
receivers required by Table 1108.2.7.1 to be hearing-aid compatible shall not be required.

- Table 1108.2.7.1 specifies the number of required receivers in an assembly area. Exception 1 states that if a facility has more than one assembly space with an audio amplification system, such as a multiplex theater, then the total seating for all the spaces may be used to determine the number of receivers required.

Exception 2 states that since induction loop technology renders an entire space accessible to the assistive listening system, the hearing-aid compatible receivers are not necessary.

**TABLE 1108.2.7.1.** See below.

- Table 1108.2.7.1 specifies the number of required receivers in an assembly occupancy. At least 25 percent of the receivers provided (but not less than two receivers) must be hearing-aid compatible, as persons with hearing aids typically cannot use earpieces or headphone-equipped receivers. When determining the general number of receivers required, the table is to be applied as though it reads "2 plus 1 for each additional 25 over 50, or a fraction thereof." For example, where 51 to 75 total seats are provided, three assistive listening devices are required. Where 76 to 100 total seats are provided, four assistive listening devices are required.

The number of required receivers is based on the capacity of the assembly areas. Note that as the size of the assembly area increases, the number of required receivers also increases; however, the percentage of receivers to seats decreases. This is based on the actual usage in large assembly areas.

**1108.2.7.2 Ticket windows.** Where ticket windows are provided in stadiums and arenas, at least one window at each location shall have an assistive listening system.

- An assistive-listening system is required at one window in each location where tickets are sold. Note that this is limited to stadiums and arenas where it is assumed that the technology is already provided for inside the space (see Section 1108.2.7). This will allow a person with a hearing impairment to be able to communicate with the ticket salesperson regarding date, cost and location of tickets being purchased. The New York Yankees and Minnesota Twin stadiums are currently using an induction-loop system at their ticket windows.

**1108.2.7.3 Public address systems.** Where stadiums, arenas and grandstands have 15,000 fixed seats or more and provide audible public announcements, they shall also provide pre-recorded or real-time captions of those audible public announcements.

- If stadiums, arenas or grandstands provide public announcements, the same information should be displayed on some type of electronic signage. With seating of 15,000 or more, most stadiums, arenas and grandstands have electronic scoreboards that are capable of displaying text messages. This is especially important when dealing with emergency evacuation situations. Prerecorded messages related to emergencies should be worked out with the fire department as part of the fire and safety evacuation plans [see Section 404 of the International Fire Code® (IFC®)]. Fire alarm systems for assembly occupancies (Section 907.2.1) with an occupant load of 1,000 or more must include an emergency voice/alarm communication system. Where captioned audible public announcements are required for stadiums by this section, the emergency voice/alarm communication system must also be captioned (see Section 907.2.1.2). Specific criteria is provided in Section 907.5.2.2.4.

ICC A117.1 has new provisions for variable message signs (VMS), which provides guidance for appropriate case, style, size, spacing, contrast and rate of change. There are special allowances that address large assembly occupancies and the distance from the viewer to the sign.

**1108.2.8 Performance areas.** An accessible route shall directly connect the performance area to the assembly seating area where a circulation path directly connects a performance area to an assembly seating area. An accessible route shall be provided from performance areas to ancillary areas or facilities used by performers.

- Performance areas, such as stages, orchestra pits, band platforms, choir lofts and similar spaces, must be accessible. If there is a direct route from the seating to the performance area, there must also be an accessible route. For example, if steps are provided from the assembly seating area to the stage within

* = or fraction thereof
the theater, then an accessible route (e.g., ramp or platform lift) to the stage must also be provided within the theater. An accessible route must also be provided to any ancillary areas, such as greenrooms or practice/warm-up rooms. The intent is that a person with mobility impairments could participate in the event. This could include high school graduation with students coming from the audience up onto the stage to receive their diplomas; participating with the community band; playing in the orchestra for a performance; acting in a production or giving a speech.

Technical production areas for the stage are exempted under Section 1103.2.8.

**1108.2.9 Dining and drinking areas.** In dining and drinking areas, all interior and exterior floor areas shall be accessible.

**Exceptions:**

1. An accessible route between accessible levels and stories above or below is not required where permitted by Section 1104.4, Exception 1.

2. In buildings or facilities not required to provide an accessible route between stories, an accessible route to a mezzanine is not required, provided that the mezzanine contains less than 25 percent of the total area and the same services, decor and amenities are provided in the accessible area.

3. In sports facilities, tiered dining areas providing seating required to be accessible shall be required to have accessible routes serving at least 25 percent of the dining area, provided that accessible routes serve accessible seating and where each tier is provided with the same services.

4. Employee-only work areas shall comply with Sections 1103.2.3 and 1104.3.1.

- Dining and drinking areas most frequently occur in Group A-2 buildings (restaurants, cafeterias, nightclubs, dinner theaters, etc.). The provisions of this section are intended to govern such areas, rather than the criteria specified in Sections 1108.2.2 through 1108.2.5. This section requires the total floor area allotted for dining and drinking to be accessible, including areas with tables and chairs, bar seating, standing spaces, gaming areas, outdoor decks, etc. An accessible route would be required to dining areas that are raised or lowered by one or more risers. The intent is that a person with a disability may not be able to get to every seat, but they will still have a choice of tables. The four exceptions specifically address tiered dining areas in sports facilities and dining on mezzanine levels.

Exception 1, with a reference back to Exception 1 in Section 1104.4 exempts a basement, mezzanine or second floor from being served by an accessible route, provided the aggregate area of the nonaccessible levels is 3,000 square feet (278.7 m²) or less. Keep in mind that a mezzanine is required by Section 505.2 to have a clear height below of at least 7 feet (2134 mm). Therefore, Exception 1 cannot be applied to platforms or raised floor areas.

Exception 2 is intended to acknowledge a practical and reasonable limitation in buildings with a mezzanine level that provides less than 25 percent of the total area for dining and drinking. In addition, all services and amenities provided in the mezzanine must also be available in an accessible area. Any mezzanine condition that does not meet the criteria of this exception does not qualify for the exception and must be served by an accessible route. Nonqualifying examples are as follows: a dining mezzanine that contains 25 percent or more of the total dining area; a raised or depressed dining area that is not actually a mezzanine; and a mezzanine level that contains the only area where a specific service or amenity is provided, like a bar or private party room. The area of the mezzanine is not limited by this exception to 3,000 square feet (278.7 m²); it could be a larger area or a smaller area.

Exception 3 is for sports facilities. Some sports facilities also have accommodations for dining or picnicking while watching the event. For line-of-sight issues, the dining terraces are tiered. If the same services are available on the accessible level as any other level, only 25 percent of the dining area is required to be on an accessible route. Section 1109.8 allows platform lifts to provide access to these levels when the sporting event and dining facilities are outdoors, such as at a baseball park.

At this time the code does not contain specific information on tiered dining facilities that also have issue of line of sight for viewing an event, such as a dinner theater or dinner seating during a sport event such as at a racetrack. These types of spaces may want to look at the provisions for both dining (see Section 1108.2.9) and seating for viewing an event (see Section 1108.2.2) and develop a reasonable compromise.

Exception 4 is simply a reference to employee work area exceptions. Employee work areas may be within the mezzanine levels, such as the area behind a bar.

**1108.2.9.1 Dining surfaces.** Where dining surfaces for the consumption of food or drink are provided, at least 5 percent, but not less than one, of the dining surfaces for the seating and standing spaces shall be accessible and be distributed throughout the facility and located on a level accessed by an accessible route.

- Section 1108.2.9.1 establishes the criteria for the percentage of spaces at tables, booths, bars and counters that will be used for eating or drinking that must be accessible. This criteria is consistent with Section 1109.11 for the required percentage of accessible built-in surfaces in all other occupancies. The accessible surfaces are also required to be distributed throughout the facility such that a comparable choice of locations and types (i.e., tables, booths, counters, etc.) is available (see Figure 1108.2.9.1). This requirement, in conjunction with Section 1108.2.9, provides a reasonable and appropriate degree of accessibility throughout dining areas. The result is that a person with a mobility impairment will be able
to approach, enter and move about in the dining area. In addition, 5 percent of the total spaces at dining surfaces provided must be accessible. Each seating location at a table or seat section of a bar is considered a dining surface. The issue of whether a portion of a bar or dining counter in a restaurant is required to be accessible is subjective. The assumption is that if other types of seating are provided adjacent to the counter, then services provided at the counter will also be available at the adjacent seating; therefore, if adequate accessible seating is available adjacent to the bar area, the bar is not required to be lowered. If the bar is the only eating or dining surface in a restaurant or in a separate room in the restaurant, then a portion of the bar must be made accessible.

1108.3 Self-service storage facilities. Self-service storage facilities shall provide accessible individual self-storage spaces in accordance with Table 1108.3.

- This section addresses facilities that provide self-storage units or spaces. These types of facilities are often storage garages located in long rows. Some facilities also provide climate-controlled storage within large multistory warehouses. The key is that the storage is moved in and out and accessed by the renter of the space. The intent is to provide access for persons with disabilities to this service without requiring the entire facility to be accessible.

<table>
<thead>
<tr>
<th>TOTAL SPACES IN FACILITY</th>
<th>MINIMUM NUMBER OF REQUIRED ACCESSIBLE SPACES</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 to 200</td>
<td>5%, but not less than 1</td>
</tr>
<tr>
<td>Over 200</td>
<td>10. plus 2% of total number of units over 200</td>
</tr>
</tbody>
</table>

- The minimum number of accessible spaces is based on the number of self-storage spaces available in a facility.

1108.3.1 Dispersion. Accessible individual self-service storage spaces shall be dispersed throughout the various classes of spaces provided. Where more classes of spaces are provided than the number of required accessible spaces, the number of accessible spaces shall not be required to exceed that required by Table 1108.3. Accessible spaces are permitted to be dispersed in a single building of a multibuilding facility.

- Self-storage facilities may offer a variety of spaces, such as heated/nonheated, different sizes, etc. If the variety offered is greater than the number of accessible spaces required, the accessible spaces should be dispersed as much as possible. For example, if a facility offers the choice of a 10-foot by 10-foot (3048 mm by 3048 mm) unit and a 10-foot by 20-foot (3048 mm by 6096 mm) unit, but only one accessible space is required, then only one unit is required to be accessible. The choice of which unit is made accessible is up to the building owner or designer. When a facility has multiple buildings, accessible spaces are permitted to be located in a single building.

At this time, ICC A117.1 does not provide specific information on how to make a self-service storage unit accessible. Since overhead doors are not typically considered accessible, alternatives to be discussed between the owner/designer and code official are the possibility of man doors on the side of the unit or electric garage door openers.

1108.4 Judicial facilities. Judicial facilities shall comply with Sections 1108.4.1 through 1108.4.3.

- Accessibility in judicial facilities (e.g., courthouses) includes access to all public areas as well as special requirements for the courtrooms, holding cells and visitation areas. This section was added for coordination with new requirements for judicial facilities from the DOJ.

1108.4.1 Courtrooms. Each courtroom shall be accessible and comply with Sections 1108.4.1.1 through 1108.4.1.5.

- All courtrooms are required to be accessible for participants at every level. This would include participation as a employee of the court, counselor, litigant, juror, witness or observer. All courtrooms must be on an accessible route from both the public side and courtroom staff side. The waiting areas, lawyer meeting rooms and vestibule that are sometimes located immediately adjacent to the courtroom entrance must be accessible. Access must be readily available to the gallery, as well as the witness stand and jury box. Members of the jury must have an accessible route to the jury deliberation room. The witness box in a courtroom is often raised to have a line of sight between the judge and witness. It is not acceptable to ask someone to testify from an area outside the box; therefore, the witness box must always be accessible. Elements would include an accessible route to all portions of the courtroom unless limited by the following subsections which identify areas and features of courtrooms that have specific accessibility requirements.
An accessible route must also be available to the holding cells addressed in Section 1108.4.2.

The ICC was very proud to participate in a special Courthouse Access Advisory Committee that assisted the Access Board in developing recommendations for accessibility to courtrooms and courthouses. This report includes information on both requirements and recommended design practices. The committee was able to construct actual mock-ups to verify design configurations. The committee report can be located at http://www.access-board.gov/caac/.

1108.4.1.1 Jury box. A wheelchair space shall be provided within the jury box.

Exception: Adjacent companion seating is not required.

- Jury boxes may be configured in numerous ways, including with multiple tiers. At least one wheelchair space within the "box" is required. A wheelchair space adjacent to (or outside of) the jury box could not be used to satisfy the requirement. Since only jury members are seated in the jury box, companion seating is not required.

1108.4.1.2 Gallery seating. Wheelchair spaces shall be provided in accordance with Table 1108.2.2.1. Designated aisle seats shall be provided in accordance with Section 1108.2.5.

- Gallery seating in a courtroom is regulated similarly to other assembly seating areas with respect to wheelchair spaces, associated companion seating and designated aisle seats (see Figure 1108.4.1.2).

Every courtroom must have an assistive listening system. Unlike other assembly occupancies, the requirement is not dependent upon an audio amplification system being provided. The assumption is that any person in a courtroom with a hearing impairment should be provided with an enhanced ability to hear the proceedings when desired. Issues of privacy may dictate the type of system provided within the courtrooms.

1108.4.1.4 Employee work stations. The judge’s bench, clerk’s station, bailiff’s station, deputy clerk’s station and court reporter’s station shall be located on an accessible route. The vertical access to elevated employee work stations within a courtroom is not required at the time of initial construction, provided a ramp, lift or elevator can be installed without requiring reconfiguration or extension of the courtroom or extension of the electrical system.

- Employee work stations in courtrooms are permitted to be constructed as adaptable for a future accessible route if and when a route is necessary for a mobility impaired employee. Depending on the type of courtroom (i.e., panel, trial, jury, traffic), employee work stations will vary. The judge is typically raised to establish a level of authority over the courtroom and to have his or her eyes approximately level with those of the standing lawyers. Associated clerk stations are raised to ease interaction with the judge. The vertical portion of the accessible route (ramp, platform lift, elevator) can be an adapting element and is expected to be pre-designed and readily incorporated into the courtroom when needed. This option is consistent with the modification for employees based on the need of the employee expressed in Section 1103.2.3. This option does not apply to the raised public areas in courtrooms, namely, witness stands, jury boxes and galleries, which are required to be constructed accessible.

1108.4.1.5 Other work stations. The litigant’s and counsel stations, including the lectern, shall be accessible.

- The well of the court typically contains the area for the litigant’s and counselor’s tables and a lectern for lawyers to address the judge and/or jury. Depending on the courtroom, this configuration may vary. The tables should be constructed appropriately for a front approach for work stations (see Figure 1108.4.1.5). The lectern can be adjustable so that it can work for lawyers seated in wheelchairs as well as those standing.

1108.4.2 Holding cells. Central holding cells and court-floor holding cells shall comply with Sections 1108.4.2.1 and 1108.4.2.2.

- If holding cells are provided, Sections 1108.4.2.1 and 1108.4.2.2 indicate which cells shall be accessible.
1108.4.2.1 Central holding cells. Where separate central holding cells are provided for adult males, juvenile males, adult females or juvenile females, one of each type shall be accessible. Where central holding cells are provided and are not separated by age or sex, at least one accessible cell shall be provided.

- Some courthouse facilities have a central holding area for detainees that are in the courthouse for judicial proceedings. At least one central holding cell is required to be accessible. If separate holding cells are provided for males and females or to separate juvenile offenders from the adult offenders, at least one of each type is required to be accessible.

1108.4.2.2 Court-floor holding cells. Where separate court-floor holding cells are provided for adult males, juvenile males, adult females or juvenile females, each courtroom shall be served by one accessible cell of each type. Where court-floor holding cells are provided and are not separated by age or sex, courtrooms shall be served by at least one accessible cell. Accessible cells shall be permitted to serve more than one courtroom.

- Some courthouse facilities have a holding cell located in the area of the courtroom for detainees who are in the courthouse for judicial proceedings. For security reasons, these holding cells may be provided on each floor of the facility in order to have the detainees as close to the courtrooms they are to appear in as possible. At least one holding cell per floor is required to be accessible. One accessible holding cell could serve all the courtrooms on one floor. If separate holding cells are provided for males and females or to separate juvenile offenders from the adult offenders, at least one of each type is required to be accessible.

1108.4.3 Visiting areas. Visiting areas shall comply with Sections 1108.4.3.1 and 1108.4.3.2.

- Persons appearing in court proceedings may need to talk with their lawyer, social worker, parole officer, etc. Typically, these visitation areas include cubicles or counters in supervised areas.

1108.4.3.1 Cubicles and counters. At least 5 percent but no fewer than one of the cubicles shall be accessible on both the visitor and detainee sides. Where counters are provided, at least one shall be accessible on both the visitor and detainee sides.

Exception: This requirement shall not apply to the detainee side of cubicles or counters at noncontact visiting areas not serving accessible holding cells.

- If detainee/visitor counters or cubicles are provided, at least 5 percent must be accessible. Since it is not known if the person needing the accessible counter is on the visitor side or the detainee side, at least one counter location shall be accessible on both sides. In accordance with the exception, visiting areas that do not serve accessible holding cells would still require 5 percent of the counters or cubicles to be accessible on the visitor's side (see Figure 1108.4.3.1). This is consistent with the exception to certain areas of jails in accordance with Section 1103.2.14.

1108.4.3.2 Partitions. Where solid partitions or security glazing separate visitors from detainees, at least one of each type of cubicle or counter partition shall be accessible.

- Section 1108.4.3.1 requires 5 percent of cubicles or counters in courthouse visiting areas to be accessible in accordance with the built-in counter/work surface requirements. This section deals with the visiting situ-
SECTION 1109
OTHER FEATURES AND FACILITIES

1109.1 General. Accessible building features and facilities shall be provided in accordance with Sections 1109.2 through 1109.15.

Exception: Accessible units, Type A units and Type B units shall comply with Chapter 10 of ICC A117.1.

This section clarifies that the provisions of Section 1109 are applicable in addition to all other requirements of Chapter 11. For example, although Section 1109.2 sets forth accessibility requirements for toilet rooms and bathing facilities within a store, it is not intended to mean that these are the only accessibility requirements that are applicable to stores. The building features and facilities covered by this section are required to be accessible to the extent set forth herein. The exception is a reminder that Accessible Type A and Type B dwelling and sleeping units should comply with Chapter 10 of ICC A117.1 within the individual dwelling units. Common and public areas associated with Group R-2 and R-3 occupancies should comply with Section 1109.

1109.2 Toilet and bathing facilities. Each toilet room and bathing room shall be accessible. Where a floor level is not required to be connected by an accessible route, the only toilet rooms or bathing rooms provided within the facility shall not be located on the inaccessible floor. At least one of each type of fixture, element, control or dispenser in each accessible toilet room and bathing room shall be accessible.

Exceptions:

1. In toilet rooms or bathing rooms accessed only through a private office, not for common or public use and intended for use by a single occupant, any of the following alternatives are allowed:

   1.1. Doors are permitted to swing into the clear floor space, provided the door swing can be reversed to meet the requirements in ICC A117.1;
   1.2. The height requirements for the water closet in ICC A117.1 are not applicable;
   1.3. Grab bars are not required to be installed in a toilet room, provided that reinforcement has been installed in the walls and located so as to permit the installation of such grab bars; and

2. The requirement for height, knee and toe clearance shall not apply to a lavatory.

3. This section is not applicable to toilet and bathing rooms that serve dwelling units or sleeping units that are not required to be accessible by Section 1107.

4. Where no more than one urinal is provided in a toilet room or bathing room, the urinal is not required to be accessible.

5. Toilet rooms that are part of critical care or intensive care patient sleeping rooms are not required to be accessible.

6. Where toilet facilities are primarily for children's use, required accessible water closets, toilet compartments and lavatories shall be permitted to comply with the children's provisions of ICC A117.1.

This section generally requires toilet rooms and bathing rooms to be accessible. A person using a wheel- chair must be able to approach and enter the room. Within the toilet room and/or bathing room, a minimum of one of each element or fixture provided is required to be accessible. Elements and fixtures include such things as water closets, lavatories, mirrors, towel dispensers, hand dryers and any other device that is installed and intended for use by the occupants of the room. Showers and bathtubs are both considered bathing fixtures, but not as different types of bathing fixtures. If a shower and a bathtub are both provided in the same bathing room, only one is required to be accessible. The designer or owner can choose which one. Requirements for the total number of bathing and toilet rooms are in Chapter 29 of the code (which is duplicated from Section 403 of the International Plumbing Code® (IPC®)). Large assembly and mercantile occupancies must also include a family or assisted use toilet room in addition to their other toilet facilities (see commentary, Section 1109.2.1).

Provisions for accessible bathrooms are required even on levels that are not accessed by an accessible route. Many people benefit from the accessibility provisions in accessible bathrooms. For example, a person who is arthritic can use the grab bars to stand up and sit down, as well as finding the level handles on the lavatory easier to use. In addition, Title I of the ADA might require that level to be made accessible as part of an employee modification. If the bathroom is already accessible, it does not need to be modified, thus reducing the changes that need to be made to the building.

ICC A117.1 is the document referenced for all accessible toilet room requirements. The technical requirements in ICC A117.1 are based on allowing a
person in a wheelchair to perform a side transfer [see Figure 1109.2(1)]. Maintaining a clear floor space at each fixture is important [see Figure 1109.2(2) for possible configurations]. The single-occupant bathroom requirements in the 2010 Standard are now consistent with the provisions in ICC A117.1.

Exception 1 addresses a condition in which a toilet room or bathing room is permitted to be adaptable rather than fully accessible. The intent is that if a toilet room is part of an individual office and serves only the occupant of that office, the adaptable toilet room can be readily modified to be fully accessible based on that individual's needs. Preplanning during construction and design, such as installing blocking for grab bars and arranging plumbing fixtures to have adequate clear floor space, will facilitate future alterations.

Exception 2 is intended to correlate with the provisions of Section 1107, which establish the minimum number of facilities required to be Accessible, Type A or Type B units. Without this exception, the code would literally be requiring accessible fixtures in inaccessible dwelling and sleeping units. It is important to note that the bathrooms associated with required Accessible, Type A and Type B dwelling and sleeping units must comply with the requirements in Chapter 10 of ICC A117.1.

Exception 3 specifies that all toilet rooms that are clustered together need not be accessible. In such configurations, typically found in a doctor's office or drug test center, the requirement is reduced to a 50 percent minimum. If these toilet rooms are clustered in separate locations, such as in a multiclinic facility, the 50 percent minimum would be applied to each cluster. A single-occupant women's bathroom adjacent to a single-occupant men's bathroom is not considered a cluster since they each serve a different sex.

The IPC permits urinals to be substituted for water closets to a maximum of 67 percent in each toilet room (see Section 419.2 of the IPC). Exception 4 states that if only one urinal is provided within a toilet room, that urinal is not required to be accessible. This situation would typically only occur in toilet rooms with one water closet compartment.

While Exception 2 would exempt all the nonaccessible patient rooms in a hospital from accessible bathroom requirements, the intent of Exception 5 is also to exempt the Accessible units that may be provided within the critical-care or intensive-care units from requiring accessible bathrooms. In critical-care or intensive-care units the patients are often too ill to use the bathroom without assistance; therefore, assistance is offered and expected in these areas to all patients. In addition, critical-care and intensive-care rooms often must be designed to maximize free space for equipment and personnel in case of emergency care situations.

Exception 6 acknowledges the allowances in the ICC A117.1 for a toilet room and water closet compartment specifically designed for children's use. This may be appropriate in areas such as day care facilities and certain areas of elementary schools.

**1109.2.1 Family or assisted-use toilet and bathing rooms.** In assembly and mercantile occupancies, an accessible family or assisted-use toilet room shall be provided where an aggregate of six or more male and female water closets is required. In buildings of mixed occupancy, only those water closets required for the assembly or mercantile occupancy shall be used to determine the family or assisted-use toilet room requirement. In recreational facilities where separate-sex bathing rooms are provided, an accessible family or assisted-
ACCESSIBILITY

Use bathing room shall be provided. Fixtures located within family or assisted-use toilet and bathing rooms shall be included in determining the number of fixtures provided in an occupancy.

Exception: Where each separate-sex bathing room has only one shower or bathtub fixture, a family or assisted-use bathing room is not required.

The requirements for family or assisted-use (referred to as "family" in the following commentary) toilet and bathing rooms were recommended for adoption into the codes by the BCMA, in conjunction with representatives of the Access Board. The primary issue relative to family toilet/bathing facilities is that some people with disabilities require assistance to utilize them. If that attendant is of the opposite sex, a toilet or bathing facility that can accommodate both persons is required. It is important to note that these provisions will typically not result in a substantial cost burden to the building owners, since the fixtures provided also count towards the minimum number required (see Section 2902.1.2 or Section 403.1.2 of the IPC).

The family or assisted-use bathing room requirements, although beneficial to all occupancies and building sizes, have been limited to those structures that typically have large transient occupant loads, namely assembly and mercantile. The section also identifies how mixed-occupancy buildings are to be addressed relative to the calculation. The fixtures provided in family toilet and bathing rooms count towards the number of required fixtures for the occupancy. The number of fixtures to be located in such rooms is limited, based on the premise that these rooms are securable (see commentary, Section 1109.2.1.2). The provision for bathing facilities is primarily geared towards recreational facilities. It is only required where the designer has chosen to provide separate-sex facilities for bathing and has provided more than one tub or shower for each sex. The exception acknowledges that smaller bathing rooms such as those described can be utilized by a disabled person.

For SI: 1 inch = 25.4 mm.

Figure 1109.2(2)
EXAMPLES OF TOILET ROOM PLANS WITH OVERLAP
person with assistance without much hardship to a nondisabled person.

Many facilities have been installing family bathrooms as part of their standard bathroom layouts prior to the code requirement, viewing them as "customer friendly." For example, a person requiring assistance can also be a small child or an elderly adult. A parent shopping or attending an event with a child of the opposite sex can utilize this facility as well as an adult who may need assistance from a spouse.

Note that the requirement for family bathrooms does not exempt separate-sex bathrooms from providing accessible or ambulatory stalls. For a discussion of family bathrooms in existing buildings, see Section 3411.8.11.

1109.2.1.1 Standard. Family or assisted-use toilet and bathing rooms shall comply with Sections 1109.2.1.2 through 1109.2.1.7.

- The facilities are required to comply with the accessible technical provisions for toilet rooms in ICC A117.1 as well as the additional criteria established in the following subsections. In smaller tenant spaces, the IPC now permits two family or assisted-use toilet rooms in place of two single-occupant separate-sex bathrooms (Section 2902.2.2 and Section 403.2.1 of the IPC).

1109.2.1.2 Family or assisted-use toilet rooms. Family or assisted-use toilet rooms shall include only one water closet and only one lavatory. A family or assisted-use bathing room in accordance with Section 1109.2.1.3 shall be considered a family or assisted-use toilet room.

Exception: A urinal is permitted to be provided in addition to the water closet in a family or assisted-use toilet room.

- A family toilet room must include a lavatory and a water closet. The exception permits a urinal to also be installed in the family toilet room if desired. If a family bathing room is provided within a facility, it can serve as the required family toilet room.

1109.2.1.3 Family or assisted-use bathing rooms. Family or assisted-use bathing rooms shall include only one shower or bathtub fixture. Family or assisted-use bathing rooms shall also include one water closet and one lavatory. Where storage facilities are provided for separate-sex bathing rooms, accessible storage facilities shall be provided for family or assisted-use bathing rooms.

- A family bathing facility is required to have one shower or tub, one water closet and one lavatory. The shower can be a transfer type, a roll-in type or a combination of the two. Accessible storage facilities, such as lockers, are also required if storage facilities are provided in the separate-sex bathing facilities. A family bathing room can also serve a dual purpose (bathing and toilet) as the required family toilet room (see commentary, Section 1109.2.1.2).

1109.2.1.4 Location. Family or assisted-use toilet and bathing rooms shall be located on an accessible route. Family or assisted-use toilet rooms shall be located not more than one story above or below separate-sex toilet rooms. The accessible route from any separate-sex toilet room to a family or assisted-use toilet room shall not exceed 300 feet (152 m).

- A one-story, 500-foot (1524 mm) limitation for access to customer toilet facilities is currently in Section 2902.3.2 (which is duplicated from Section 403.3.3 of the IPC). The distance to the customer toilet facilities is measured from the main entrance of a store or space to the toilet facility. The distance in this section is measured from the separate-sex facility to the family facility. The general travel distance requirement, in combination with this section, could result in a total travel distance for a family toilet room of two stories or 1,000 feet (3048 mm) maximum. The travel distance limitation is why there is more than one family bathroom in large facilities. An accessible route is required to provide access to the family facilities. Signage is required at both the separate-sex and family facilities in accordance with Sections 1110.1 and 1110.2.

1109.2.1.5 Prohibited location. In passenger transportation facilities and airports, the accessible route from separate-sex toilet rooms to a family or assisted-use toilet room shall not pass through security checkpoints.

- Security checkpoints in airports and similar facilities represent a potential delay, which may cause missed flights or connections. Due to security concerns, more and more facilities are adding security checkpoints. For example, many large sports facilities, courthouses and government buildings have checkpoints where the public move into certain portions of the facilities. While not required, due to the delay in moving through a security system, a designer might want to follow this same guidance for location of the family bathrooms in other types of facilities.

1109.2.1.6 Clear floor space. Where doors swing into a family or assisted-use toilet or bathing room, a clear floor space not less than 30 inches by 48 inches (762 mm by 1219 mm) shall be provided, within the room, beyond the area of the door swing.

- The clear floor space provisions are intended to provide a room that is large enough to allow a person in a wheelchair to enter and close the door before utilizing the fixtures. This requirement is also in ICC A117.1 [see Figure 1109.2.1.6].

1109.2.1.7 Privacy. Doors to family or assisted-use toilet and bathing rooms shall be securable from within the room.

- Since privacy while utilizing bathing and toilet facilities is an issue, the door to the facility must be securable from the inside. The securing mechanism must be within reach and not require any tight pinching, grasping or sharp turning of the wrist to operate. While it is not prohibited to lock bathrooms, this bathroom should be as easily accessed as the separate men's and women's bathroom. A person who needed this facility should not have to find someone with a key for the family bathroom if the men's and
women's bathrooms are readily available. This bathroom does count towards the required fixture count (see Section 2902.1.2) and as such must be available.

1109.2.2 Water closet compartment. Where water closet compartments are provided in a toilet room or bathing room, at least one wheelchair-accessible compartment shall be provided. Where the combined total water closet compartments and urinals provided in a toilet room or bathing room is six or more, at least one ambulatory-accessible water closet compartment shall be provided in addition to the wheelchair-accessible compartment.

- There are different configurations of water closet compartments that facilitate different degrees of physical disability. The provisions of ICC A117.1 establish the configuration and dimensional requirements for various types of water closet compartments. A wheelchair-accessible compartment is one in which sufficient space is provided for the wheelchair to enter completely the water closet compartment [see Figures 1109.2.2(2) and 1109.2.2(3)]. The wheelchair user then transfers from the wheelchair to the water closet in order to utilize the fixture. It is important that the required clear floor space be maintained. The configuration did not intend for a lavatory to be provided within the minimum-sized compartment. If a lavatory is located within a compartment, it must meet the same provisions as a single-occupant toilet room.

An ambulatory-accessible compartment is intended to facilitate use by a person with a mobility impairment that necessitates the use of a walking aid, such as a cane or walker [see Figure 1109.2.2(1)]. An ambulatory-accessible water closet compartment is not intended to be utilized by a person in a wheelchair. The 36-inch (914 mm) width is intended to allow standing persons to support themselves utilizing the grab bars on both sides. A wider compartment would not allow adequate bearing. Since these provisions are intended to address, within reason, the needs of both ranges of mobility impairment, this section requires a wheelchair-accessible compartment in all cases. In larger toilet rooms (i.e., those with a total of six or more water closet compartments and urinals), one ambulatory-accessible compartment is required in addition to the wheelchair-accessible compartment.

This section is not intended to increase the required number of fixtures beyond that required by the IPC. For example, if a toilet room contains 10 water closets, eight water closet compartments may be of conventional design, one water closet compartment must be wheelchair accessible and one must be ambulatory accessible.

1109.2.3 Lavatories. Where lavatories are provided, at least 5 percent, but not less than one, shall be accessible. Where the total lavatories provided in a toilet room or bathing facility is six or more, at least one lavatory with enhanced reach ranges shall be provided.

- A lavatory is a type of sink for which the primary purpose is hand washing. This section provides scoping requirements for lavatories located in spaces not specifically addressed or exempted by Section 1109.2. If a lavatory is provided in toilet and bathing rooms specifically exempted by Section 1109.2, it is not required to be accessible. Lavatories are not as commonly part of an employee work station as sinks are, however, if they are they are exempted under Section 1103.2.3. An example of a lavatory that was part of an employee’s work area would be the lavatories found in the exam rooms. The lavatories are there for the nurses and doctors to wash their hands before examining a patient.

When lavatories are provided in other areas, a minimum of 5 percent, but not less than one, is required to be accessible via a front approach with appropriate knee and toe clearances.

![Figure 1109.2.2(1) AMBULATORY-ACCESSIBLE COMPARTMENT](image)
In large facilities, where the designer has located six or more lavatories within one toilet facility (similar to the ambulatory stall), one of the lavatories must also be provided with enhanced reach range for the faucet controls in accordance with Section 606.5 of ICC A117.1. This would require the faucets to be located on the side of the lavatory, or provide access to the side of one of the lavatories, or to have automatic controls. This is to address the needs of persons who may have a limited reach over the lavatory where they may have difficulty reaching the controls. The lavatory with enhanced reach range could be the

WHEELCHAIR-ACCESSIBLE COMPARTMENT; OUT-SWINGING DOOR

---

**Figure 1109.2.2(3)**
WHEELCHAIR-ACCESSIBLE COMPARTMENT; IN-SWINGING DOOR
same lavatory as the accessible lavatory, or it could be another lavatory.

There are allowances in ICC A117.1 for lavatories specifically designed for children's use. This may be appropriate in areas such as day care facilities and certain areas of elementary schools.

1109.3 Sinks. Where sinks are provided, at least 5 percent but not less than one provided in accessible spaces shall be accessible.

Exception: Mop or service sinks are not required to be accessible.

❖ A sink may have numerous functions, unlike a lavatory which is primarily provided for hand washing. Sinks in kitchens, kitchenettes and classrooms are examples that may have scoping and accessibility requirements different from those for lavatories. When sinks are provided, a minimum of 5 percent, but not less than one, is required to be accessible via a front approach with knee and toe clearances. There is a specific exception here for mop or service-type sinks. Service sinks include a wide variety of specialized sinks manufactured for multiple or specific functions. Service sinks are sized and positioned for their function which usually renders them incapable of being accessible. Also, when a sink is part of an individual work station, that sink is not required to be accessible in accordance with Section 1103.2.3.

A forward approach to sinks, as required for a lavatory within a toilet room, is not always required (see commentary, Section 1109.4).

There are allowances in A117.1 for sinks specifically designed for children's use. This may be appropriate in areas such as day care facilities and certain areas of elementary schools.

1109.4 Kitchens and kitchenettes. Where kitchens and kitchenettes are provided in accessible spaces or rooms, they shall be accessible.

❖ Kitchens, kitchenettes and wet bars in accessible spaces, other than within Type A and Type B dwelling units, must be accessible. An accessible kitchen would include clear floor spaces at all appliances, a sink with a front approach and a work surface with a front approach (see Section 804 of ICC A117.1 for specific details). Kitchenettes (where a cooktop or conventional range is not provided) allow a side approach to the sink (Section 606 of ICC A117.1) and do not require an accessible work surface. A common mistake is to forget that the sink must be set at a maximum height of 34 inches (864 mm) to allow for reach to the faucets (see Figure 1109.4).

1109.5 Drinking fountains. Where drinking fountains are provided on an exterior site, on a floor or within a secured area, the drinking fountains shall be provided in accordance with Sections 1109.5.1 and 1109.5.2.

❖ This section establishes a reasonable threshold for the required number of accessible drinking fountains. It should be noted that this section does not require the installation of drinking fountains where none are required or provided. Chapter 29 (which is duplicated from Section 403 of the IPC) contains criteria indicating the number of drinking fountains that are required based on occupancy. There are spaces that are not required to have drinking fountains. Examples are spaces with fewer than 15 occupants and spaces that serve water, like a restaurant.

Current requirements for plumbing fixtures (see Table 2902 and Table 403 of the IPC) stipulate only one drinking fountain per number of occupants for many facilities or tenant spaces. Through Note e, the provisions in Section 1109.5.1 and Section 410.2 of the IPC stipulate a minimum of two drinking fountains for these facilities and spaces in order to meet the high/flow criteria. Additionally, the plumbing requirements would allow for 50 percent of the drinking fountains to be substituted with bottled water coolers (see Section 410.3 of the IPC). While the provisions in Sections 1109.5.1 and 1109.5.2 and Section 410.2 of the IPC would not prohibit the substitution, the requirement for two drinking fountains would effectively negate this substitution unless there were at least three drinking fountains required for a floor.

The IPC now includes provisions for travel distance to a drinking fountain (see Section 403.5 of the IPC), which is 500 feet (152 400 mm) and one-story maximum travel. In malls, the travel is reduced to 300 feet (91 440 mm).

1109.5.1 Minimum number. No fewer than two drinking fountains shall be provided. One drinking fountain shall comply with the requirements for people who use a wheelchair and one drinking fountain shall comply with the requirements for standing persons.

Exceptions:

1. A single drinking fountain that complies with the requirements for people who use a wheelchair and
standing persons shall be permitted to be substituted for two separate drinking fountains.

2. Where drinking fountains are primarily for children’s use, drinking fountains for people using wheelchairs shall be permitted to comply with the children’s provisions in ICC A117.1 and drinking fountains for standing children shall be permitted to provide the spout at 30 inches (762 mm) minimum above the floor.

*Where a single drinking fountain is provided, this section mandates a minimum of two fixtures be provided: one for seated persons and one for standing persons. The seated and standing drinking fountains that serve a facility need not be provided at the same location in the facility. The exception allows the use of a single fixture that accommodates both seated and standing persons. Technical criteria for both wheelchair accessible fountains and standing person fountains are located in Section 602 of ICC A117.1 (see Figure 1109.5.1). The drinking fountains must be located so that they are not protruding objects (see Section 1003.3).

Exception 1 allows for a single drinking fountain to meet the requirements for both high and low heights; however, at this time, drinking fountains that can meet the two spout heights are very limited.

Exception 2 allows for both the high and low drinking fountains to be designed for children. There are technical criteria in A117.1 for wheelchair drinking fountains specifically designed for children who are age 12 and younger. This may be appropriate for facilities such as day care facilities and certain areas of elementary schools.

1109.5.2 More than the minimum number. Where more than the minimum number of drinking fountains specified in Section 1109.5.1 are provided, 50 percent of the total number of drinking fountains provided shall comply with the requirements for persons who use a wheelchair and 50 percent of the total number of drinking fountains provided shall comply with the requirements for standing persons.

**Exceptions:**

1. Where 50 percent of the drinking fountains yields a fraction, 50 percent shall be permitted to be rounded up or down, provided that the total number of drinking fountains complying with this section equals 100 percent of the drinking fountains.

2. Where drinking fountains are primarily for children’s use, drinking fountains for people using wheelchairs shall be permitted to comply with the children’s provisions in ICC A117.1 and drinking fountains for standing children shall be permitted to provide the spout at 30 inches (762 mm) minimum above the floor.

*When an even number of drinking fountains is provided, half must accommodate seated persons and half must accommodate standing persons. Exception 1 addresses when an odd number of drinking fountains is provided.*

An example:

- Two drinking fountains are required by Section 1109.5.1 and Section 410.2 of the IPC.
- Seven drinking fountains are provided.
- Fifty percent of seven is three and one-half.
- Rounding up yields four; rounding down yields three.
- Therefore, there are two choices:
  - Provide four sitting and three standing fountains; or
  - Provide three sitting and four standing fountains.
- Both choices comply since the complying fixtures total 100 percent.

This logic applies whenever an odd number of three or more drinking fountains is provided, regardless of the total quantity. This is based on the number provided—not the number required. In accordance with Section 410.3 of the IPC, a designer/owner could switch out some of the required drinking fountains for bottled water.

Exception 2 is consistent with the same exception in Section 1109.5.2, allowing for both standing and seating drinking fountains to be designed for children. There are technical criteria in ICC A117.1 for wheelchair drinking fountains specifically designed for children who are age 12 and younger. This may be appropriate for day care facilities and certain areas of elementary schools.
1109.6 Saunas and steam rooms. Where provided, saunas and steam rooms shall be accessible.

Exception: Where saunas or steam rooms are clustered at a single location, at least 5 percent of the saunas and steam rooms, but not less than one, of each type in each cluster shall be accessible.

The 2009 edition of the ICC A117.1 standard has included technical requirements for saunas and steam rooms. The scoping in the IBC is consistent with bathrooms and coordinates with the 2010 Standard. What constitutes a "cluster" is subjective; however, typically the rooms would have to have the entrances immediately adjacent or across the hall from one another to be considered "clustered."

The requirements within the standard provide for entering the room, closing the door and then transferring to the bench in the room. Removing the wheelchair from the space is not addressed, so perhaps a special chair might be utilized. Section 914 of the International Mechanical Code® (IMC®) addresses safety requirements for sauna rooms.

1109.7 Elevators. Passenger elevators on an accessible route shall be accessible and comply with Chapter 30.

This section requires all passenger elevators on an accessible route to be accessible. The reference to Chapter 30 requires all passenger elevators to conform to general elevator safety standards as well as accessibility standards. It is not the intent of this section to prohibit service elevators, LULA elevators, private residence elevators or platform lifts (as permitted by Section 1109.7). Service, LULA and private residence elevators are recognized as types of passenger lifts by ASME A17.1/CSA B44.

Elevators are defined in ASME A17.1 as "a hoisting and lowering mechanism, equipped with a car, that moves within guides and serves two or more landings..." The limitations of use for the different types of elevators are controlled by the standard.

ASME limits the occupants in "freight elevators" to just the operator and the people needed to load and unload the freight. Also "construction elevators" are limited to construction purposes only. Only passenger-type elevators can serve as part of an accessible route; therefore, freight and construction types of elevators are not required to be accessible.

The term "service elevator" is not defined in ASME A17.1. This is a slang term used by building owners to separate the "back of the house" passenger elevator used by staff (and typically designed to accommodate a heavier load) from the passenger elevators used by the general public for circulation. As part of an accessible route to employee work areas, a service elevator is required to be accessible.

LULA elevators have a maximum vertical travel distance of 25 feet (7620 mm). Private residence elevators are limited to within or serving individual dwelling units.

It should also be noted that unlike plumbing fixtures, this section does not establish that a certain number of passenger elevators are required to be accessible while other passenger elevators may be of a design that is not fully accessible. All passenger elevators that are on an accessible route are required to be accessible. If a bank of passenger elevators is provided as part of an accessible route, all elevators in that bank must be accessible. See Section 3411.8.2 for existing elevators being altered.

The reference to an accessible route (see Sections 1104.3.1, 1004.4 and 1109.6) is important because some areas in certain buildings may not be required to be accessible (see Sections 1103.2 and 1104.4). For example, since an elevator penthouse is not required to be accessible (see Section 1103.2.9), the passenger elevator is not required to serve that level. Keep in mind that the penthouse must be accessible by a stairway (see Section 1009.17). In addition, certain types of elevators (e.g., freight elevators) may not be part of an accessible route.

Note that there are additional requirements for elevators depending on the building height:

- In buildings four stories and higher, at least one elevator must be sized in order to accommodate stretchers (see Section 3002.4).
- In buildings five stories and higher, an elevator must be available for serving as part of an accessible means of egress (see Section 1007.2.1).
- Buildings 120 feet (36 576 mm) or taller shall have fire service access elevators (see Sections 403 and 3007).
- Occupant evacuation elevators are also an option (see Section 3008).

1109.8 Lifts. Platform (wheelchair) lifts are permitted to be a part of a required accessible route in new construction where indicated in Items 1 through 10. Platform (wheelchair) lifts shall be installed in accordance with ASME A18.1.

1. An accessible route to a performing area and speaker platforms in Group A occupancies.
2. An accessible route to wheelchair spaces required to comply with the wheelchair space dispersion requirements of Sections 1108.2.2 through 1108.2.6.
3. An accessible route to spaces that are not open to the general public with an occupant load of not more than five.
4. An accessible route within a dwelling or sleeping unit.
5. An accessible route to wheelchair seating spaces located in outdoor dining terraces in Group A-5 occupancies where the means of egress from the dining terraces to a public way are open to the outdoors.
6. An accessible route to jury boxes and witness stands; raised courtroom stations including judges' benches,
